The 24th International AIDS Conference

aids2022.org

AIDS 2022 Organizing Committee

Co-Chairs

Adeeba Kamarulzaman, Malaysia
Jean-Pierre Routy, Canada

Members

Sharon Lewin, Australia
Birgit Poniatowski, Switzerland
Kenneth Ngure, Kenya
Jessica Whitbread, Bulgaria
Glory Alexander, India
Erika Castellanos, The Netherlands
Ken Monteith, Canada
R. Brad Jones, USA
Brenda Crabtree Ramirez, Mexico
Ayesha Kharsany, South Africa
Margaret Kisikaw Piyesis, Canada
Nittaya Phanuphak, Thailand
Matthew Weait, United Kingdom
Morten Ussing, Switzerland
Geoff Garnett, USA
Howard Njoo, Canada
Tanaka Chirombo, Malawi

Track Committees

Track A: Basic and translational science

Lead: R. Brad Jones

Jonathan Li, USA
Jori Symons, Netherlands
Lenine Julie Phillips Liebenberg, South Africa
Nicolas Chomont, Canada
Rachel Rutishauser, USA
Walter Jaoko, Kenya

Track B: Clinical science

Lead: Brenda Crabtree Ramirez

Alexandra Calmy, Switzerland
Claudia Cortes, Chile
Francois Venter, South Africa
Rajesh Gandhi, USA
Sandra Wagner Cardoso, Brazil
Thanyawee Puthanakit, Thailand

Track C: Epidemiology and prevention science

Lead: Ayesha Kharsany

Adamson Muula, Malawi
Damilola Walker, USA
Darrell Tan, Canada
Jason Ong, Australia
Joseph Cox, Canada
Keri Althoff, USA
Monica Ciupagea, Austria

Track D: Social and behavioural science

Lead: Margaret Kisikaw Piyesis

Dinah de Riquets-Bon, Netherlands
Dominique Gomis, Senegal
Ines Dourado, Brazil
Lorraine Sherr, United Kingdom
Morten Skovdal, Denmark
Nompumelelo Zungu, South Africa
Renata Arrington-Sanders, USA

Track E: Implementation science

Lead: Nittaya Phanuphak

Carlos Caceres, Peru
Catherine Hankins, Canada
Giten Khwairakpam, Thailand
Jeffrey Lazarus, Spain
Kimberly Green, Vietnam
Ruanne Barnabas, USA

Track F: Political science, laws, ethics, policies and human rights

Lead: Matthew Weait

Alexander McClelland, Canada
Gnilane Turpin, US
Happy Assan, Tanzania
Lillian Mworeko, Uganda
Max Appenroth, Germany
Renata Tallarico, South Africa

Abstract submission

Over 6,000 abstracts were submitted to the 24th International AIDS Conference.

The Organizing Committee (OC) is very grateful for all the abstract submissions received. While the OC found many very high-quality abstracts among the submissions, due to limitations in the conference programme, more abstracts were rejected than accepted – with an overall acceptance rate of 40%.

All abstracts went through a blind peer-review process completed by over 700 abstract reviewers. These reviewers are international experts in the field of HIV, including members of the OC and track committees. Each abstract was reviewed by three to four reviewers. The abstracts were reviewed for the quality and originality of the work. Late-breaking abstract reviews included an additional assessment of the late-breaking nature of the research.

All reviewers were instructed to abstain from scoring any abstract on which they were an author or co-author, had a financial or personal conflict of interest, or did not have the appropriate expertise to evaluate. Each abstract was scored numerically against five pre-determined criteria, which were equally weighted to get a final score. The final score ranged from one (the lowest) to six (the highest). Any abstracts that received less than two reviews or where there was a scoring discrepancy between reviewers were additionally reviewed by the track committees.

Statistics for abstracts

6248 Regular abstracts submitted

2515 Regular abstracts accepted

120 Oral abstracts

300 Poster exhibition abstracts

2095 E-poster abstracts

652 Late-breaking abstracts submitted

101 Late-breaking abstracts accepted

29 Late-breaking oral abstracts

12 Late-breaking poster exhibition abstracts

60 Late-breaking e-poster abstracts

6900 Total abstracts submitted

2616 **Total abstracts accepted**

Abstract Mentor Programme

The Abstract Mentor Programme (AMP) was introduced at the 15th International AIDS Conference (AIDS 2004), with the objective to help young or less experienced researchers improve their abstracts before submitting them, in order to increase the chance of their work being presented at conferences.

Over the years, the AMP has proven to increase the motivation of early career researchers, as well as the number of abstract submissions received from resource-limited countries. In total this year, 174 mentors were enlisted and 162 abstracts from 135 people were reviewed by mentors. 78% of the reviewed abstracts were submitted to AIDS 2022 and the following were selected (32%):

- 2 in an oral abstract session (one as back up)
- 2 in Posters Exhibition
- 40 in E-Posters

We would like to thank all volunteer abstract mentors, listed below, who supported early-career HIV researchers improve the quality of their abstracts:

Abdullahi Aborode, Nigeria
Abdulwasiu Tiamiyu, Nigeria
Abraham Gizaw, Ethiopia
Ahmed Cordie, Egypt
Ajeh Rogers Awoh, Cameroon
Akarin Hiransuthikul, Thailand

International Abstract Review Committee

The 24th International AIDS Conference received more than 6,200 abstract submissions, which went through a blind, peer-reviewed process carried out by an international panel of reviewers who play a critical role in designing a strong scientifc programme.

More than 700 specialists from around the world volunteered their time and expertise to serve as peer reviewers, helping to ensure that the abstracts presented were selected on the basis of rigorous review and were of the highest scientifc quality.

We extend our special thanks to the large pool of abstract reviewers for the time they dedicated to the success of the conference:

Abu Abdul-Quader, United States

Michael Zwick, United States

Table of Contents

Oral Abstract Sessions

OAA01	The view from the bench: Advances in HIV basic and translational research	16
OAA02	Responding to the virus: Advances in HIV immunology	18
OAA03	Finding the needle in the haystack: Progress in understanding the HIV reservoir	20
OAA04	Shake and bake: Promising strategies for HIV cure	23
OAB01	People at the centre	25
OAB02	Outcomes in paediatric and adolescent HIV: Beyond ART	29
OAB03	ART in evidence	31
OAB04	HIV and other conditions	34
OAC01	Real-time HIV surveillance to achieve Fast-Track milestones	37
OAC02	Colliding epidemics: HIV, NCDs, TB, STIs, COVID-19 and others	40
OAC03	Optimizing the HIV care continuum	42
OAC04	Enlightenment through estimation: New insights in HIV epidemiology	45
OAC05	Packaging HIV prevention for different populations	48
OAD01	Through the lens of community: Addressing context within strategies and interventions	50
OAD02	Pandemics: Living with HIV during COVID-19	52
OAD03	What matters? Actual and perceived sexual risk for HIV acquisition	54
OAD04	Innovations leading the way to HIV targets	56
OAD05	Is violence a breaking point for HIV?	59
OAD06	Building bridges to HIV prevention and care for children and young people: The role of the community and young people	61
OAD07	Integrated mental health approaches and care among people living with HIV	63
OAD08	Stigma interventions: Improving health and wellness for people living with HIV and key populations	66
OAE01	Innovative differentiation: How best to deliver HIV testing, treatment and prevention services	68
OAE02	Resilience: The new normal?	71
OAE03	Optimizing investments for health: Cash, cost and prices	73
OAE04	Achieving sustainability in the HIV response: Thinking differently!	75
OAE05	Client-centred care: Seamless service integration	78
OAF01	Improving access for all	81
OAF02	Nothing about us without us: Community-led responses and research	83
OAF03	Doing it right: Inclusion, diversity and policy development	86
OAF04	Not just law: Legal obstacles to an effective HIV response	88

Poster Exhibition

PESAA01-PESAA04	HIV biology (entry, replicative cycle, transcriptional expression and regulation)	91
PESAA05-PESAA06	HIV transmission and dissemination	93
PESAA07	Systemic immune activation and inflammation	94
PESAA08	HIV transmission and dissemination	94
PESAA09-PESAA12	Systemic immune activation and inflammation	95
PESAA13	Innate immunity (including NK cells)	97
PESAB01	Acute and early infection	98
PESAB02	Morbidity, mortality and life expectancy in clinical research	99
PESAB03	Adherence testing	100
PESAB04	Viral load and CD4 monitoring	100
PESAB05-PESAB06	Diagnostics of co-infections and co-morbidities	101
PESAB07	Biomarkers for the prediction of morbidity and mortality	102
PESAB08-PESAB09	Tuberculosis: Prevention, diagnosis, treatment	103
PESAB10	STIs (including HPV)	104
PESAB11	Opportunistic infections (excluding TB): Bacterial, non-TB mycobacterial, viral and parasitic infections	105
PESAB12	STIs (including HPV)	105
PESAB13	Cardiovascular disease	106
PESAC01-PESAC02	Epidemiology of HIV in the general population	108
PESAC03	Epidemiology of HIV in women	109
PESAC04	Epidemiology of HIV in infants and children	110
PESAC05	Epidemiology of HIV in adolescents	110
PESAC06-PESAC08	Epidemiology of HIV in key populations (e.g., gay men and other men who have sex with men, sex workers, transgender people, people who inject drugs and prisoners and other incarcerated people)	111
PESAC09-PESAC10	Epidemiology of AIDS events (e.g., AIDS-related opportunistic infections and cancers)	113
PESAC11-PESAC13	Epidemiology of non-AIDS infections and communicable diseases (e.g., viral hepatitis, STIs, TB, COVID-19)	114
PESAC14	Modelling the impact of service models on the HIV epidemic	116
PESAC15-PESAC16	Risk factors for acquisition, infectivity and transmission of HIV	119
PESAC17	Describing the spread of HIV through molecular epidemiology	120
PESAD01	Prisoners and other incarcerated people	121
PESAD02-PESAD10	Young key populations	121
PESAD11	Sex workers	128
PESAD12	Young key populations	127
PESAD13-PESAD16	Other populations vulnerable in specific contexts	128
PESAD17-PESAD21	Community mobilization and demand creation	131
PESAD22	Young key populations	127
PESAD23	Comprehensive sexuality education	133
PESAD24	People who inject drugs	134
PESAE01-PESAE03	Implementation science of scaling up prevention (including PrEP)	134

PESAE04-PESAE05	Implementation science of scaling up HIV testing	137
PESAE06-PESAE08	Implementation science of scaling up HIV treatment	139
PESAE09-PESAE10	Scaling up access to models of integrated services (HIV, hepatitis, STI and other services, such as harm reduction, SRHR, gender affirming care, TB, NCDs and mental health)	140
PESAE11-PESAE13	Strategies to enhance U=U communication and implementation	141
PESAE14	Implementation of HIV status-neutral approach to enhance HIV testing, HIV prevention and HIV treatment services	143
PESAE15	Innovations and lessons for supporting HIV prevention effective use and treatment adherence	144
PESAE16	Implementation science of scaling up prevention (including PrEP)	136
PESAF01-PESAF02	Laws and policies on HIV transmission, exposure, and non-disclosure	145
PESAF03-PESAF07	Laws, policies and practices impacting access to HIV testing, prevention, treatment, care and support	146
PESAF08-PESAF09	Laws and policies regulating access to drugs and medical devices (including intellectual property and trade regimes, competition law and price regulation)	149
PESAF10	Conceptualizing political drivers and their impacts	150
PESAF11	Political violence and armed conflict	151
PESAF12	Sexual- and/or gender-based inequalities, inequities and violence	151
PESUA14	Humoral immunity (including broadly neutralizing antibodies), Antibodies and B cells	152
PESUA15	Mucosal immunity	153
PESUA16-PESUA17	Host cellular factors and viral mechanisms of HIV/SIV persistence and latency	154
PESUA18-PESUA20	Identification, characterisation and Quantification of HIV/SIV reservoirs and rebounding virus	155
PESUA21-PESUA22	Strategies to reduce/eliminate viral reservoirs	157
PESUA23	Immune responses to SARS-Cov2	158
PESUA24	Neuropathogenesis	162
PESUA25	Immune responses to SARS-Cov2	159
PESUB14	Neurologic disorders (e.g. CNS malignancies)	162
PESUB15	Cardiovascular disease	107
PESUB16	Mental health (including depression and psychiatric manifestations) and HIV	163
PESUB17	Weight gain	163
PESUB18	Hepatic complications (e.g., NASH)	164
PESUB19	ART in acute, first- and second-line therapies	165
PESUB20	ART in highly treatment-experienced persons	165
PESUB21	Regimen simplification and switch studies	166
PESUB22-PESUB23	Pharmacokinetics/pharmacodynamics/ pharmacogenomics and therapeutic drug monitoring	167
PESUB24	Long-acting agents and other drug delivery systems (e.g., injectables, implants, dual therapies, microneedle patches)	169
PESUB25	Adherence	170
PESUB26	Pharmacokinetics/pharmacodynamics/ pharmacogenomics and therapeutic drug monitoring	168
PESUC18	Surveillance of HIV in key populations	171
PESUC19	Monitoring and evaluation of health systems along the HIV cascade	172
PESUC20	Modelling future healthcare needs	173
PESUC21-PESUC23	Modelling the impact of service models on the HIV epidemic	117
PESUC24	Demand creation for PrEP use	173
PESUC25-PESUC26	Scale up of PrEP	174
PESUC27	Innovative behavioural prevention interventions	176
PESUC28	Scale up of PrEP	175
PESUC29-PESUC30	HIV prevention services for key populations	176
PESUC31-PESUC32	Community-based HIV testing strategies	178
PESUD25-PESUD28	Community-based approaches (including empowerment, outreach and service delivery)	181
PESUD29	Sexual- and/or gender-based violence and exploitation (including in conflict settings)	183
PESUD30 PESUD31	Harm reduction	183
PESUD33-PESUD34	Interventions to reduce stigma and discrimination	185
PESUD35-PESUD36	Conceptualizing social and structural factors and their impacts	186
PESUD37	Dynamics of social status and power: Sex, gender, age, race/ethnicity, sexual orientation and disability	188
PESUD38	Humanitarian crises and HIV	189
PESUD39-PESUD46	Societal stigma towards people living with HIV and key populations	190
PESUD47-PESUD49	Adaptation to living with HIV for individuals, families and communities	194
PESUD50	Confronting stigma: Lessons learned	195
PESUE17-PESUE18	Innovations and lessons for supporting HIV prevention effective use and treatment adherence	
PESUE19-PESUE20	Differentiated service delivery for HIV testing, prevention and treatment	197
PESUE21	National financing analyses and financing mechanisms for HIV, hepatitis and STI programmes and services	199
PESUE22	Approaches to achieving sustainability, including sustainable financing for civil society	199
PESUE23	Costing of HIV, hepatitis and STI services	200
PESUE24	Strategies to increase retention and re-engagement in HIV services	200
PESUE25	Assessments of cost effectiveness: Provider and community perspectives	201
PESUE26	Community participation in systems for health, including community-led and key population-led health systems	201
PESUE27	Approaches to effective paediatric HIV services	202
PESUE28-PESUE29	Systems serving underserved populations	203
PESUE30	Public-private partnerships	204
PESUE31	Delivering gender-transformative programmes and tackling violence against women and girls: Programmatic lessons	205
PESUF13	Access to education	205
PESUF14	Criminalization, incarceration and living in closed settings	206
PESUF15	Law enforcement and public health	206
PESUF16-PESUF17	Access to appropriate healthcare services (including for co-infections and co-morbidities)	207
PESUF18-PESUF21	Human rights of people living with HIV and key populations	208

PESUF22	Availability and access to harm reduction (including OST and NSP)	211
PESUF23	Human rights programmes	212
PESUF24	Human rights of people living with HIV and key populations	210
PEMOA26-PEMOA28	Immunotherapy (including broadly neutralizing antibodies)	212
PEMOA29	ARVs, small molecules and immunomodulating agents - pharmacodynamics and pharmacokinetics	214
PEMOA30-PEMOA32	Immune responses to SARS-Cov2	
PEMOA33	SARS-Cov2 vaccines	215
PEMOA34	Immune responses to SARS-Cov2	161
PEMOA35-PEMOA38	SARS-Cov2 vaccines	215
PEMOB27	Adherence	170
PEMOB28	Pregnancy (clinical management issues and pharmacokinetics) and contraception	218
PEMOB29	Pharmacokinetics/pharmacodynamics/ pharmacogenomics and therapeutic drug monitoring in paediatric and adolescent populations	219
PEMOB30	ARV management strategies in paediatric and adolescent populations	220
PEMOB31	Mental health and neurocognition in paediatric and adolescent populations	220
PEMOB32	HIV-exposed uninfected children	221
PEMOB33	Clinical issues in sex workers	222
PEMOB34	Malignancies (AIDS and non-AIDS)	223
PEMOB35	Clinical issues in transgender people	223
PEMOB36	Clinical issues in people who use drugs	224
PEMOB37	Impact of COVID-19 on HIV care	224
PEMOC33	HIV prevention services for key populations	178
PEMOC34	Sexuality, gender and prevention technologies (including condoms, treatment as prevention, medical male circumcision, pre-exposure prophylaxis)	225
PEMOC35	Access to harm reduction interventions	226
PEMOC36	Combination prevention strategies	227
PEMOC37	Other new HIV prevention tools	228
PEMOC38-PEMOC39	Measuring and enhancing retention and adherence in HIV prevention programmes	229
PEMOC40-PEMOC41	Community-based HIV testing strategies	179
PEMOC42-PEMOC43	HIV self-testing	231
PEMOC44	HIV testing to support identification of new cases of people living with HIV	232
PEMOC45	Combination prevention strategies	227
PEMOC46	Strategies to improve early retention in care (first year on ART)	233
PEMOC47	Epidemiology of COVID-19	233
PEMOC48	Effects of the COVID-19 on HIV epidemiology and prevention	234
PEMOC49	Measuring and enhancing retention and adherence in HIV prevention programmes	230
PEMOD51	Growing up with HIV: Specific needs and interventions for children and adolescents	234
PEMOD52-PEMOD54	Confronting stigma: Lessons learned	196
PEMOD55	Experiences and impacts of antiretroviral therapy	235
PEMOD56-PEMOD57	Conceptualizing social and structural factors and their impacts	187
PEMOD58-PEMOD59	COVID-19 social distancing and curfews: Implications for access to HIV care	236
PEMOD60-PEMOD62	Social and behavioural aspects and approaches to COVID-19	237
PEMOD63	Sexual and reproductive health, fertility, family planning, pregnancy and abortion	240
PEMOD64-PEMOD65	Social and behavioural aspects and approaches to COVID-19	239
PEMOD66	COVID-19 social distancing and curfews: Implications for access to HIV care	237
PEMOD67-PEMOD74	Effects of the COVID-19 on key populations	241
PEMOD75	Role of social and behavioural science in biomedical responses	246
PEMOE32	Social protection: New evidence and programmatic lessons	247
PEMOE33	Innovations in behavioural data collection and use	247
PEMOE34	Approaches to using data to improve programming	248
PEMOE35	Innovative uses of data to strengthen systems and programmes	248
PEMOE36	Monitoring and reporting in the SDG era	249
PEMOE37	Impact of COVID-19 on HIV prevention services	250
PEMOE38-PEMOE39	Impact of COVID-19 on HIV testing services	250
PEMOE40-PEMOE43	Impact of COVID-19 on HIV treatment services	251
PEMOE44-PEMOE47	Optimizing HIV services (prevention, testing and/or treatment) in the COVID-19 era	254
PEMOF25-PEMOF26	Legal advocacy tools and strategies	256
PEMOF27-PEMOF28	Stigma and key populations	257
PEMOF29	Discrimination and key populations	258
PEMOF30	Punitive laws and enforcement practices directed at or impacting on key populations)	259
PEMOF31	Investing in regional HIV programmes and regional key population movements	260
PEMOF32	Ethical aspects and standards in research (including clinical trials)	260
PEMOF33	COVID-19 and politics, human rights, ethics or policy	262
PEMOF34	Impact of COVID-19 on HIV risk and HIV care among refugees, migrants, asylum seekers and internally displaced persons	263
PEMOF35	Ethical aspects and standards in research (including clinical trials)	261
PEMOF36	COVID-19 and politics, human rights, ethics or policy	262
PEMOF37	Gender equity and diversity	263

E-Posters

Track A – Basic and translational science

EPA001	Viral origins, evolution and diversity	265
EPA002-EPA005	HIV biology (entry, replicative cycle, transcriptional expression and regulation)	265
EPA006-EPA008	Viral fitness, persistence and resistance	267
EPA009-EPA018	Systemic immune activation and inflammation	269
EPA020	Correlates of HIV susceptibility, and progression versus control (biomarkers and genetics)	274
EPA021-EPA026	Innate immunity (including NK cells)	275
EPA027	Humoral immunity (including broadly neutralizing antibodies), Antibodies and B cells	278
EPA028-EPA033	Cellular immunity; T cell vaccines	279
EPA034-EPA036	Mucosal immunity	282
EPA037	Novel vectors, adjuvants and strategies	284
EPA038-EPA040	Immune mechanisms of natural or post-treatment control	285
EPA041-EPA049	Host cellular factors and viral mechanisms of HIV/SIV persistence and latency	287
EPA050-EPA057	Identification, characterisation and Quantification of HIV/SIV reservoirs and rebounding virus	292
EPA058-EPA062	Strategies to reduce/eliminate viral reservoirs	296
EPA063-EPA064	Immunotherapy (including broadly neutralizing antibodies)	298
EPA065-EPA069	ARVs, small molecules and immunomodulating agents - pharmacodynamics and pharmacokinetics	300
EPA070-EPA075	HIV and co-morbidities	303
EPA077-EPA081	HIV and co-infections (TB, viral hepatitis, SARS-CoV2, other)	306
EPA082	Neuropathogenesis	309
EPA083	SARS-Cov2 Viral origins, evolution and diversity	310
EPA084-EPA085	Immune responses to SARS-Cov2	310
EPA087-EPA094	SARS-Cov2 vaccines	312

Track B – Clinical science

EPB001-EPB002	Impact of co-factors (e.g., viral clade, tropism, genetic factors) on disease progression	318
EPB003-EPB007	Morbidity, mortality and life expectancy in clinical research	319
EPB008-EPB009	Novel assays of immune responses	322
EPB010	Novel approaches to assess viral load and ARV resistance/tropism	323
EPB011-EPB012	HIV testing, self-testing and retesting (e.g., point-of-care diagnostics)	323
EPB013	Diagnosis of HIV disease in paediatric and adolescent populations	325
EPB014-EPB021	Viral load and CD4 monitoring	326
EPB022	Adherence testing	330
EPB023-EPB029	Diagnostics of co-infections and co-morbidities	331
EPB030-EPB031	Biomarkers for the prediction of morbidity and mortality	335
EPB032-EPB044	Tuberculosis: Prevention, diagnosis, treatment	336
EPB045-EPB050	Opportunistic infections (excluding TB): Bacterial, non-TB mycobacterial, viral and parasitic infections	344
EPB051-EPB058	Viral hepatitis C and other viral hepatitis (e.g., A, B, D, E)	348
EPB059-EPB067	STIs (including HPV)	353
EPB068	Neurologic disorders (e.g. CNS malignancies)	358
EPB069-EPB084	Mental health (including depression and psychiatric manifestations) and HIV	359
EPB085-EPB091	Malignancies (AIDS and non-AIDS)	368
EPB092-EPB097	Cardiovascular disease	372
EPB098	Renal disease	376
EPB099-EPB106	Other non-communicable diseases	376
EPB107-EPB109	Metabolic, lipid and endocrine complications (including lipodystrophy)	382
EPB110-EPB121	Weight gain	384
EPB122-EPB123	Hepatic complications (e.g., NASH)	391
EPB124-EPB128	Other ART complications and adverse reactions	392
EPB129	Polypharmacy	395
EPB130-EPB133	Frailty	396
EPB134	Drug-drug interaction (DDI)	398
EPB135-EPB145	Other issues related to aging with HIV	399
EPB146-EPB153	ART in acute, first- and second-line therapies	405
EPB154-EPB160	ART in highly treatment-experienced persons	411
EPB161-EPB171	Regimen simplification and switch studies	416
EPB172-EPB177	Pharmacokinetics/pharmacodynamics/ pharmacogenomics and therapeutic drug monitoring	423
EPB178	Drug interactions	426
EPB179-EPB186	Long-acting agents and other drug delivery systems (e.g., injectables, implants, dual therapies, microneedle patches)	427
EPB187-EPB189	Adherence	432
EPB190-EPB191	Sex-specific (including cis- and transgender) issues of ART efficacy, adverse reactions and complications	434
EPB192-EPB197	Pregnancy (clinical management issues and pharmacokinetics) and contraception	435
EPB198-EPB208	ARV management strategies in paediatric and adolescent populations	439
EPB209	Cure strategies in paediatric and adolescent populations	445
EPB210-EPB216	Adherence in paediatric and adolescent populations	446
EPB217-EPB219	HIV complications and co-morbidities in paediatric and adolescent populations	449
EPB220-EPB221	HIV-associated co-infections and malignancies in paediatric and adolescent populations	451
EPB222	Behavioural health outcomes in paediatric and adolescent populations	453
EPB223	Mental health and neurocognition in paediatric and adolescent populations	454
EPB224	Transition of adolescents into adult care	455
EPB225-EPB226	Clinical issues in sex workers	455
EPB227	Clinical issues in transgender people	456
EPB228-EPB229	Clinical issues in people who use drugs	457
EPB230-EPB232	Cure interventions	458
EPB233-EPB234	Nutrition	460
EPB235-EPB253	Resistance to ART	461
EPB254-EPB266	Impact of COVID-19 on HIV care	472
EPB267-EPB271	Clinical manifestations and features of COVID-19 and HIV co-infection	481

Track C – Epidemiology and prevention science

EPC002-EPC006	Natural history, morbidity patterns and survival	485
EPC008-EPC014	Epidemiology of HIV in the general population	488
EPC015-EPC019	Epidemiology of HIV in women	493
EPC020-EPC022	Epidemiology of HIV in infants and children	496
EPC023-EPC030	Epidemiology of HIV in adolescents	497
EPC031-EPC053	Epidemiology of HIV in key populations (e.g., gay men and other men who have sex with men, sex workers, transgender people, people who inject rugs and prisoners and other incarcerated people)	502
EPC054-EPC059	Risk factors for acquisition, infectivity and transmission of HIV	515
EPC060-EPC065	Epidemiology of AIDS events (e.g., AIDS-related opportunistic infections and cancers)	518
EPC066-EPC087	Epidemiology of non-AIDS infections and communicable diseases (e.g., viral hepatitis, STIs, TB, COVID-19)	522
EPC088-EPC096	Epidemiology of non-AIDS non-communicable diseases (e.g., non-AIDS cancers, CVD)	535
EPC097	Describing the spread of HIV through molecular epidemiology	540
EPC098-EPC110	Surveillance of HIV in key populations	541
EPC111-EPC116	Determining the incidence of HIV	548
EPC117-EPC123	Detecting and monitoring acute and recent HIV infections	551
EPC124-EPC127	Measuring HIV through population-based surveys (including the undiagnosed fraction)	556
EPC128-EPC129	Measuring the population impact of prevention and treatment interventions	558
EPC130	Measuring the population-level impact of policy-level HIV interventions	559
EPC131-EPC134	Monitoring and evaluation of health systems along the HIV cascade	560
EPC135-EPC136	Describing the spread of HIV through geographical information systems	562
EPC137-EPC140	Advances in public health surveillance and new approaches	563
EPC141-EPC142	Measuring and evaluating quality of service provision and health outcomes through public health surveillance	566
EPC143-EPC152	Modelling the impact of prevention strategies on the HIV epidemic	567
EPC153	Modelling the role of syndemics on the HIV epidemic	573
EPC154	Modelling future healthcare needs	574
EPC155-EPC156	Modelling the impact of service models on the HIV epidemic	574
EPC157-EPC164	Reaching and recruiting key populations for HIV prevention services (online, offline, online-to-offline)	575
EPC166-EPC180	Demonstration and pilot projects for prevention (including PrEP, PEP, male circumcision)	580
EPC181-EPC189	Demand creation for PrEP use	588
EPC190-EPC224	Scale up of PrEP	593
EPC225-EPC228	Scale up of PEP	613
EPC229-EPC234	Scale up of medical male circumcision	615
EPC235-EPC246	Integrating STI, sexual and reproductive health and HBV and HCV services in HIV prevention programmes	619
EPC247-EPC273	HIV prevention services for key populations	626
EPC274-EPC285	Sexuality, gender and prevention technologies (including condoms, treatment as prevention, medical male circumcision, pre-exposure prophylaxis)	641
EPC286-EPC295	Access to harm reduction interventions	649
EPC296	Optimizing vertical transmission prevention programmes	654
EPC297-EPC299	Combination prevention strategies	655
EPC300-EPC305	Prevention of vertical transmission	656
EPC306-EPC311	Innovative behavioural prevention interventions	660
EPC312	Structural HIV prevention interventions	663
EPC313-EPC320	Other new HIV prevention tools	664
EPC321-EPC333	Measuring and enhancing retention and adherence in HIV prevention programmes	669
EPC334	Key population-led prevention programmes (from reach, recruit, test, treat, prevent and retain)	676
EPC335	Demand creation for HIV testing	677
EPC336-EPC339	Facility-based HIV testing strategies	678
EPC340-EPC344	Community-based HIV testing strategies	680
EPC345-EPC349	Peer-led HIV testing strategies	683
EPC350-EPC353	HIV testing with virtual and/or digital support	685
EPC354-EPC385	HIV self-testing	688
EPC386	HIV testing algorithms	706
EPC387-EPC389	HIV testing to support prevention	706
EPC390-EPC406	HIV testing to support identification of new cases of people living with HIV	708
EPC407-EPC410	Integration of HIV testing with other services	717
EPC411-EPC421	Strategies to improve HIV linkage and ART initiation	720
EPC422-EPC424	Strategies to improve early retention in care (first year on ART)	726
EPC425-EPC429	Strategies to improve retention in care beyond the first year on ART	728

OAA0102

Pharmacological enhancement of IL-15 signaling to improve 'shock-and-kill' strategies against latent HIV

J.N. Howard[1], A. Bosque[1]

[1]*George Washington University, Microbiology, Immunology, and Tropical Medicine, Washington DC, United States*

Background: Despite effective anti-retroviral therapy (ART), the largest barrier to HIV cure remains the formation of a latent reservoir early after initial infection that cannot be cleared by subsequent ART treatment.

Finding novel therapeutic strategies that can **S**hock latent HIV, enhance **T**ranslation of viral transcripts, enhance immune **E**ffector functions, and **S**ensitize reactivated cells to apoptosis could enhance **K**illing and elimination of latent HIV reservoirs.

As such, development of **STESK** strategies have the potential to improve the efficacy of current "shock and kill" strategies. Among the clinically relevant latency reversing agents (LRA) under investigation, IL-15 or the IL-15 superagonist N-803 have been shown to reactivate latent HIV *ex vivo* and *in vivo*. However, the clinical benefit of IL-15 can be hindered by the transient nature of cytokine signaling.

We previously identified a small molecule, HODHBt, that enhances the biological activity of IL-15 by increasing STAT5 phosphorylation and transcriptional activity leading to enhanced IL-15- mediated viral reactivation *ex vivo* in cells isolated from ART-suppressed participants.

Methods: We used the Connectivity Map to identify compounds with similar transcriptional profiles to HODHBt and identified five clinically relevant FDA-approved candidates. We evaluated their ability to promote viral reactivation from latency.

Results: From the 5 tested compounds, only one, a retinoid derivative, shared a similar transcriptional profile to HODHBt in CD4T cells. Next, we tested the ability of the retinoid to reactivate latent HIV in a primary cell model of latency. The retinoid (10mM) increased viral reactivation mediated by IL-15 to a similar extent as HODHBt (100mM) but unlike HODHBt, specifically promoted cell death of latently infected cells compared to controls when combined with IL-15. In contrast to HODHBt, the retinoid did not increase IL-15-induced STAT5 phosphorylation.

This indicates that the retinoid is able to reactivate latent HIV through a mechanism mediated by IL-15 but not directly dependent on STAT5 phosphorylation. There are a number of additional retinoid structural analogues, which we are now investigating for their potential LRA activity.

Conclusions: In conclusion, retinol derivatives have the potential to enhance IL-15 LRA activity and can be ideal candidates for the development of *STESK* strategies against latent HIV.

OAA0103

Pharmacological targeting of REV-ERB to modulate HIV transcription and viral outgrowth in CD4+ T cells

C.-D. Ngassaki-Yoka[1,2], D. Chatterjee[1,2], Y. Zhang[1,2], T.R. Wiche Salinas[1,2], L. Raymond Marchand[2], N. Cermakian[3,4], J.-P. Routy[5], L. Solt[6], P. Ancuta[1,2]

[1]*Université de Montréal, Montréal, Canada,* [2]*Centre de Recherche du CHUM, Montréal, Canada,* [3]*McGill University, Montréal, Canada,* [4]*Douglas Mental Health University Institute, Montréal, Canada,* [5]*McGill University Health Centre: Glen Site, Research Institute, Montréal, Canada,* [6]*The Scripps Research Institute, Jupiter, United States*

Background: Current antiretroviral drugs block the different steps of the viral replication cycle, except the transcription, a process under the control of the host-cell machinery. Residual HIV transcription in viral reservoirs (VR) persisting during antiretroviral therapy (ART) is a major cause of chronic immune activation and non-AIDS comorbidities. The Th17-polarized $CD4^+$ T cells are highly enriched in VR in people living with HIV (PLWH) receiving viral-suppressive ART. In previous studies, we demonstrated that the transcriptional signature associated with HIV permissiveness in Th17 cells includes the circadian clock components/regulators REV-ERBa/b, BMAL1 and RORC2. Of note, REV-ERB acts as a transcriptional repressor of BMAL1 (a transcriptional activator binding to E-boxes in the HIV promoter) and RORC2 (the master regulator of Th17 polarization). Thus, we hypothesized that REV-ERB regulates both BMAL1-mediated HIV transcription/replication and RORC2-mediated effector functions in Th17 cells.

Methods: To test this hypothesis, we used the REV-ERB agonist SR9011 and antagonist SR8278. Memory $CD4^+$ T cells from uninfected individuals were stimulated with CD3/CD28 antibodies and exposed to replication-competent HIV_{NbaI} and single-round VSV-G-pseudotyped HIV (HIV_{VSVG}) *in vitro* in the presence/absence of drugs. A viral outgrowth assay (VOA) was performed with memory $CD4^+$ T cells of ART-treated PLWH activated *via* CD3/CD28. Cytokines and HIV-p24 levels were measured by ELISA and/or flow cytometry. HIV-DNA integration was quantified by nested real-time PCR.

Results: CD3/CD28-mediated triggering in memory $CD4^+$ T cells resulted in a significant downregulation of both REV-ERBa/β mRNA. As expected, the expression of BMAL1 and RORC2 transcripts was upregulated. Upon HIV_{VSVG} exposure, the antagonist SR8278 increased HIV-DNA in-

tegration and intracellular HIV-p24 expression (p=0.0103, p=0.0001 respectively), revealing its latency reversing potential. However, SR8278 did not increase HIV-p24 release from HIV_{VSVG}-infected cells, which indicates a post-translational REV-ERB-dependent block in HIV replication. In contrast, the agonist SR9011 potently inhibited HIV_{NbaI} replication *in vitro* (p=0.0024) and viral outgrowth in cells of ART-treated PLWH. The antiviral effects of SR9011 coincided with a decrease of IL-17A and IFN-γ production.
Conclusions: These results provide a strong rationale for further evaluating the possibility to therapeutically target REV-ERB in an effort to modulate BMAL1/RORC2-dependent HIV transcription and subsequently improve the efficacy of current ART regimen in PLWH.

OAA0104
Interactome of HIV proteins and their host RNA interaction partners

T. Schynkel[1], W. van Snippenberg[1,2], K. Verniers[2], E.J. de Bony[2], G.M. Jang[3], N.J. Krogan[3], P. Mestdagh[2], L. Vandekerckhove[1], W. Trypsteen[1]
[1]Ghent University, HIV Cure Research Center, Ghent, Belgium, [2]Ghent University, OncoRNALab, Center for Medical Genetics (CMGG), Ghent, Belgium, [3]University of California, Department of Cellular and Molecular Pharmacology, San Francisco, United States

Background: The HIV genome encodes a limited set of proteins, depending heavily on the exploitation of host cell molecules to complete its viral life cycle and maintaining latency. Recent findings show that HIV hijacks cellular (non-coding) RNA molecules to aid in these crucial viral processes.
Therefore, this study aims to systematically determine this new layer of physical interactions of each for the 18 HIV proteins with host RNA molecules.
Methods: An RNA immunoprecipitation (RIP)-seq strategy was established in Jurkat cell lines that express a single FLAG- and streptavidin-tagged HIV protein upon doxycycline induction. For each of the 18 HIV proteins, FLAG-based immunoprecipitations (IPs) were performed (triplicate), followed by RNA purification, stranded total RNA library preparation and sequencing (50M reads/sample, Illumina NextSeq).
Background controls included mouse IgG antibody and FLAG-tagged GFP protein IP. Enriched RNA transcripts were identified after mapping (STAR), background filtering based on background controls and performing a differential expression analysis (DEseq2). For 6 HIV proteins also Streptavidin-based RIPseq was performed (triplicate).
Results: The identified interactome comprises a set of 1162 HIV protein – host RNA interactions (FC > 4 and padj < 0.05) across 8 HIV proteins: Nucleocapsid (939), Rev (94), Gag (57), Matrix (47), Tat (12), Integrase (5), Pol (5) and Protease (3). The majority of the identified RNA interaction partners are mRNAs (55%), and also include tRNAs (7%), pseudogenes (25%) and (long) non-coding RNAs (3%), indicating a wide variety of RNA families that are recruited during replication.
Furthermore, this interactome corroborates previous work, as known interactors were identified for Matrix, Gag, Rev (tRNAs) and Tat (7SKRNA). For Tat in specific, additional RNA interaction partners include mRNAs for which the translation protein products are known interactors of Tat within the super elongation complex (SEC), hinting at a regulatory role of Tat in the expression of these SEC subunits.
Conclusions: This unique and comprehensive dataset of HIV protein – human RNA interactions broadens our understanding on how HIV manipulates the RNA component of the host's cellular machinery during the course of infection and to establish and maintain latency. This information will support the search for latency reversing agents for a potent shock-and-kill strategy.

Inducibility and distribution of HIV proviruses in early treated Thai children on suppressive ART

M. Massanella[1], C. Dufour[1], A. Pagliuzza[1], C. Richard[1], J. Ananworanich[2], L. Leyre[1], T. Jupimai[3], J. Mitchell[4], P. Sawangsinth[5], M. de Souza[5], P. Suntarattiwong[6], K. Chokephaibulkit[7], L. Trautmann[4], R. Fromentin[1], T. Puthanakit[3], N. Chomont[1], HIVNAT209 and HIVNAT194 study groups
[1]Centre de Recerche du CHUM, Montreal, Canada, [2]Amsterdam Medical Center-University of Amsterdam, Department of Global Health, Amsterdam, Netherlands, the, [3]Chulalongkorn University, Center of Excellence in Pediatric Infectious Diseases and Vaccines, Bangkok, Thailand, [4]Vaccine and Gene Therapy Institute, Beaverton, United States, [5]SEARCH, Thai Red Cross AIDS research Centre, Bangkok, Thailand, [6]Queen Sirikit National Institute of Child Health, Bangkok, Thailand, [7]Siriraj Hospital - Mahidol University, Pediatrics, Bangkok, Thailand

Background: Although vertically infected infants display detectable levels of HIV DNA in CD4 T-cells, inducible assays such as QVOA and TILDA often yield negative results. These observations suggest that CD4 T-cells from children are refractory to stimulation, possibly because they mostly display a naïve phenotype. We assessed the distribution and inducibility of HIV proviruses in CD4 T-cell subsets over time, since frequencies of memory cells increase as children age.
Methods: Eight vertically-infected children who initiated ART within 5 months of life were followed longitudinally and provided blood samples collected at median ages of 1.7 (V1) and 4.3 (V2) years. Frequencies of CD4 T-cells producing msRNA and p24 protein upon PMA/ionomycin stimulation were measured by TILDA and HIV-Flow, respectively. Stimulated CD4 T-cells for HIV-Flow analy-

sis were concomitantly sorted by flow cytometry to obtain naïve (CD45RA+CCR7+CD27+), central memory (CM, CD45RA-CCR7+CD27+), transitional memory (TM, CD45RA-CCR7-CD27+) and effector memory (EM, CD45RA-CCR7-CD27-) cells. Integrated HIV DNA was quantified in sorted subsets.

Results: Despite high frequencies of naïve CD4 T-cells (>70%), naïve cells were rarely infected (median 38 [6-143] and 7 [0-12] integrated HIV DNA copies/10^6 cells at V1 and V2, respectively). Most proviruses were detected in memory subsets, and infection frequencies increased with cell differentiation (EM>TM>CM, median 2820 [176-9469], 1432 [129-6711] and 507 [142-1309] integrated HIV DNA copies/10^6 cells, respectively at V1 and 260 [74-2161], 195 [89-1350] and 100 [40-426] integrated HIV DNA copies/10^6 cells, respectively at V2).

Frequencies of infected naïve and CM cells decreased over time (p=0.05 and p=0.008, respectively). Despite the low frequency of memory cells, CM cells were the main contributor to the pool of cells carrying integrated proviruses at both visits (46% and 50% at V1 and V2, respectively). Importantly, there were no significant changes in TILDA or HIV-Flow values over time, which were barely detectable at both visits.

Conclusions: Although high levels of HIV genomes are present in memory cells from vertically infected children on ART, they do not produce detectable levels of p24 protein upon stimulation. The latent reservoir seems poorly inducible in children and inducibility does not increase over time.

OAA0202

An immunological signature for subclinical atherosclerosis in people living with HIV-1 receiving antiretroviral therapy

T.R. Wiche Salinas[1], A. Gosselin[1], Y. Zhang[1], N. Fonseca Do Rosario[1], A. Filali[1], J.-P. Routy[2], C. Chartrand-Lefebvre[3], A.L. Landay[4], M. Durand[1], M. El-Far[1], C. Tremblay[1], P. Ancuta[1]

[1]Centre de recherche du Centre Hospitalier de l'Université de Montréal, Montreal, Canada, [2]Research Institute of the McGill University Health Centre, Chronic Viral Illness Service and Division of Hematology, Montreal, Canada, [3]Université de Montréal, Département de Radiologie, Radio-oncologie et Médecine Nucléaire, Faculté de Médecine, Montreal, Canada, [4]Rush University Medical Center, Chicago, Canada

Background: Cardiovascular disease (CVD) is an important co-morbidity in people living with HIV (PLWH) receiving antiretroviral therapy (ART+PLWH). This study explores immunological patterns associated with subclinical coronary artery atherosclerosis during ART-treated HIV infection in relationship with alterations in gut-associated lymphoid tissues.

Methods: Uninfected (HIV-; n=61) and ART+PLWH (n=21) with/without subclinical atherosclerosis participants were included in the Canadian HIV and Aging Cohort Study (CHACS)/CVD Cohort. Total plaque volume (TPV), and low attenuated plaque volume (LAPV) were determined by coronary CT angiography.Markers of microbial translocation (LBP, I-FABP, sCD14, CCL20, MIF and CX3CL1), lipid profiles (LDL, HDL and triglycerides) and coagulation (D-dimer, fibrinogen) were quantified in plasma.

Flow cytometry analysison peripheral blood mononuclear cells were performed to characterize the frequency and expression of chemokine receptors involved in atherosclerotic plaque infiltration (CCR2, CCR6, CCR9, CX3CR1) in Th17 (CCR6+CD26+CD161+), Tregs (CD25highCD127-FOXP3+), classical/intermediate/non-classical monocyte (CD14/CD16/M-DC8) and myeloid (CD1c+HLA-DR+)/plasmacytoid (BDCA2+/CD123+) dendritic cells.

Results: ART+PLWH distinguished from HIV- by lower levels of HDL and higher levels of sCD14, FABP2, CCL20, MIF, CX3CL1, and triglycerides. Additionally,ART+PLWHshowed higher frequencies of Tregs and lower Th17/Treg ratios compared to HIV- participants. The stratification of ART+PLWH based on the presence (TPV+) or the absence (TPV-) of subclinical coronary atherosclerotic plaque demonstrated reduced Th17 frequencies and Th17/Treg ratios in TPV+*versus*TPV-.

Also, there was a superior frequency of non-classical CCR9- and M-DC8+ monocytes expressing high levels of HLA-DR in TPV+ *versus* TPV- ART+PLWH. A logistic regression model was used to determine the association between covariates and the presence of coronary atherosclerotic plaque. In crude analyses, the frequency of non-classical CCR9+HLADRlow [OR: 0.30 (0.15-0.63)] and non-classical CCR9-HLADRhigh [OR:3.56(1.45-8.74)] monocytes, as well as the Th17/Treg ratio [0.38(0.18-0.83)] were associated with TPV values.

After adjusting for age, smoking and LDL or statins, smoking and triglycerides, only the frequency of CCR9+HLADR low and CCR9-HLADR high monocytes remained significantly associated with coronary plaque, whereas Th17/Tregs ratio kept its significant association exclusively when adjusted for age, smoking and LDL.

Conclusions: We identified a new immunological signature associated with presence of coronary plaque that may serve in clinical practices for an improved management of CVD risk in ART+PLWH.

OAA0203
Investigating the development of T cell immunity in acute HIV-1 infection through a longitudinal analysis of the TCR repertoire

M.M. Magnoumba Legnanga[1], K. Reddy[1], T. Ndung'u[1,2], A. Leslie[1,3]
[1]*Africa Health Research Institute, Immunology, Durban, South Africa,* [2]*HIV Pathogenesis Programme, Health and Science Research, Durban, South Africa,* [3]*University College London, Immunology, London, United Kingdom*

Background: Evidence suggests that many events leading to the long-term T-cell dysfunction that is a hallmark of HIV infection, occur during the acute phase. Previous longitudinal study of individuals identified in hyper-acute infection showed those mounting a rapid and large CD8 cytotoxic T-cells (CTL) response achieved superior natural control of HIV.
However, due to sample availability, the dynamic response of the T-cell compartment during this acute phase remains poorly understood, as does the potential involvement of non-classical T-cells. Consequently, Antigen-specific T cell responses remain a key feature in understanding the relationship between the disease and host.
Methods: This study used longitudinal DNA samples of pre-infected and post infected young african women between 18-23 years of age. For TCRα sequencing, purified genomic DNA was sequenced by Adaptive Biotechnologies using the ImmunoSEQ assay.
Analysis were carried using R and python to determine TCR clusters and predict antigen-driven TCR clustering, additional methodologies like VDJtools were also used to determine the TCR repertoire diversity.
Results: In this study, we used bulk TCR sequencing to track the dynamics of the TCR repertoire longitudinally in HIV individuals sampled before infection and serially through the untreated acute phase. Using this approach, we find that, in multiple individuals, the TCR landscape is highly dynamic during the acute phase of infection. This landscape is characterised by large clonal expansions, reaching 30% frequency during Pre-infection to 60%; 51% and 52% in early, mid and late infection respectively.
Interestingly, some TCR clonotypes persist while others rapidly disappear and are replaced by new and previously unexpanded clonotypes. Antigen prediction tools are being employed to determine the specificity of persisting TCRs and those that are lost. In contrast to convention TCRs, invariant and semi-invariant clonotypes, including MAITS, iNKTs, and gamma delta TCRs, show no significant expansions during the acute phase.
This observation implies that Donor Unrestricted T-cells (DURTS) do not respond directly to HIV antigen or acute phase cytokines and that HIV-associated changes in these subsets occur during the chronic phase
Conclusions: Together these data demonstrate extensive skewing of the T-cell repertoire that occurs during acute HIV infection and may impact long-term immune health.

OAA0204
Optimization of a VLP-forming HIV-1 *env-gag*mRNA vaccine by inclusion of *gag-pol* mRNA to express the viral protease

P. Zhang[1], S. Falcone[2], G. Stewart-Jones[3], Y. Seo[1], D. Rogers[1], H. Miao[1], Q. Liu[1], Y.-T. Lai[2], I. Renzi[2], E. Narayanan[3], S. Himansu[2], A. Carfi[2], P. Lusso[1]
[1]*NIH, LIR, NIAID, Bethesda, United States,* [2]*Moderna Inc., Cambridge, United States,* [3]*Moderna Inc, Cambridge, United States*

Background: The development of a protective vaccine remains a top priority for the control of the HIV/AIDS pandemic. Taking advantage of recent advances in mRNA technology, we developed an *env-gag* mRNA vaccine that yielded promising results in macaques.
Methods: Five groups of wild-type (WT) Balb-c mice (n=8 per group) were sequentially immunized with mRNA encoding different forms of a clade-C HIV-1 envelope (Env), 426c, bearing a truncated gp41 cytoplasmic tail to enhance expression, starting with two immunizations (weeks 0, 4) with an open form lacking three N-glycans (276, 460, 463) around the CD4-binding site (3Δgly), followed at week 16 by a partially glycan-restored form lacking only the 276 glycan (Δ276), and finally at week 20 by WT 426c *env*.
The *env* mRNA was inoculated at 2.5 µg/dose either alone (Arm 1) or co-formulated with SIV *gag* mRNA at 2.5 µg/dose in order to induce the *in vivo* formation of virus-like particles (VLP) (Arm 2), or with SIV *gag* and *gag-pol*mRNA in order to express the viral protease, which is essential for processing Gag to its mature form.
To identify the optimal dose of *gag-pol*mRNA, different *gag:gag-pol*molar ratios were tested (5:1, 10:1, and 20:1, Arms 3-5). Serum was collected after each immunization and tested for trimer-binding antibodies by ELISA and neutralizing antibodies (NAbs) by the TZMbl assay.
Results: *In vitro*, co-transfection of *gag-pol*mRNA with *env* and *gag*mRNA resulted in both quantitative and qualitative improvements in VLP production. All groups of immunized mice developed trimer-binding antibodies. NAbs against 426c-3Δgly, and to a lesser extent 426c-Δ276, started to appear after the second immunization, with the highest titers in Arm 3 (with *gag-pol*mRNA at 1:5). Boosting with 426c-Δ276 enhanced NAb titers, especially against 426c-Δ276, with *gag-pol*-containing regimens showing the highest titers, followed by *env+gag*and, lastly,*env* alone. No neutralization of WT virus was observed.
Conclusions: Our results illustrate a further improvement of our VLP-forming HIV-1 *env-gag* mRNA vaccine platform through the addition of *gag-pol* mRNA to promote Gag processing. The triple mRNA co-formulation provides an optimized platform to test the efficacy of different HIV-1 Env immunogens in pre-clinical and clinical studies.

Exceptional post-treatment control associated with strong NK and Yδ cytotoxic T cells

N. Climent[1,2], J. Ambrosioni[1,2], T. González[1,2], M. Casadellà[3], M. Noguera[3], R. Paredes[3], M. Plana[1,2], J. Mallolas[1,2], J. Alcamí[1,4,2], S. Sánchez-Palomino[1,2], J.M. Miró[1,2]
[1]Hospital Clinic-IDIBAPS/University of Barcelona, HIV Unit, Barcelona, Spain, [2]CIBER of Infectious Diseases (CIBERINFEC), Madrid, Spain, [3]IrsiCaixa AIDS Research Institute. Hospital Universitari Germans Trias i Pujol, Badalona, Spain, [4]Instituto de Salud Carlos III (ISCIII)., Madrid, Spain

Background: Although ART is effective in suppressing viral replication, HIV persists in reservoirs and rebounds after stopping therapy. However, there are few patients, such as post-treatment controllers (PTC), who are able to maintain viral loads below detection limits without ART, being a realistic model for the HIV-functional-cure. We describe the mechanisms of control of an exceptional PTC (>15 years).

Methods: A 59-year woman with sexually-acquired acute HIV-infection was included in the 'Immune-mediated PHI trial' (NCT00979706), involving several interventions: short course of low doses of CsA, IL-2, GM-CSF and Peg-α-IFN followed by analytical STI.

Virological studies were performed: total and integrated HIV-1 DNA in CD4$^+$ T-cells and rectal tissue, viral outgrowth assay (qVOA), HIV-1 infectivity in PBMC and CD4$^+$ T-cells cultures and viral inhibitory activity (VIA) of autologous CD4$^+$T-cells with NK and CD8$^+$ T-cells.

NK and T-cell phenotype was determined by flow-cytometry.HLA class I, Δ32CCR5 and NKG2C alleles were genotyped.

Results: After antiretroviral and immunomodulatory treatment, the patient maintained undetectable viral load in plasma for 15 years. HIV-1 subtype was CFR_02AG, R5-tropic. We found a pronounced and progressive fall of the viral reservoir (VR): total HIV-DNA (from 4573.50 to 95.33 copies/10^6 CD4$^+$T-cells) and integrated proviral DNA (from 85.37 to 5.25 copies/10^6 CD4$^+$T-cells).VR in rectal biopsy was 3 HIV DNA total copies/10^6 cells and qVOA detected 1.61 UIMP at year 9. VIA assay showed strong inhibition of *in vitro* replication in co-cultures with autologous NK-cells or CD8$^+$T-cells at 1:2 ratio (75% and 62%, respectively). Co-cultures with NK and CD8$^+$T-cells resulted in 93% inhibition of HIV-replication. Higher levels of both NKG2C$^+$-memory-like NK-cells and NKG2C$^+$γδ$^+$T-cells than referenced data from untreated normal HIV-infected progressors were detected (46.2% versus 24.0% and 64.9% versus 19.7%, respectively). The patient has A*29:01/A*29:01, B*44:03/B*44:03, C*16:01/C*16:01 HLA-I, wt/wt CCR5 and wt/wt NKG2C alleles.

Conclusions: We describe the case of functional cure in a 59-years-old woman treated during PHI that has maintained undetectable viral load for 15 years without ART. Replication-competent HIV-1 could be isolated by qVOA. NKG2C$^+$-memory-like NK-cells and γδ$^+$CD8$^+$T-cells contribute to the control of viral-replication and functional-cure observed. Strategies able to expand these cells could help to achieve HIV-functional-cure.

[1]Université de Montréal/Centre de Recherche du CHUM, Microbiology, Infectiology and Immunology, Montreal, Canada, [2]University of Amsterdam/Amsterdam Medical Center, Department of Global Health, Amsterdam, Netherlands, the, [3]Chulalongkorn University/Center of Excellence in Pediatric Infectious Diseases and Vaccines, Bangkok, Thailand, [4]Oregon Health & Science University/Vaccine and Gene Therapy Institute, Portland, United States, [5]SEARCH/Thai Red Cross AIDS research Centre, Bangkok, Thailand, [6]Queen Sirikit National Institute of Child Health, Bangkok, Thailand, [7]Mahidol University/Siriraj Hospital, Faculty of Medicine, Department of Pediatrics, Bangkok, Thailand, [8]Chulalongkorn University, Faculty of Medicine, Department of Pediatrics, Bangkok, Thailand, [9]The HIV Netherlands Australia Thailand Research Collaboration (HIV-NAT), the Thai Red Cross AIDS Research Centre (TRC-ARC), Bangkok, Thailand

Background: Latently infected cells harboring intact HIV genomes persist in children living with HIV receiving suppressive ART. However, the dynamics of these genetically intact viral genomes over time remains unclear.

Methods: Thai children vertically infected with HIV who initiated ART within the first 6 months of life were enrolled in the HIVNAT209 & HIVNAT194 studies and followed longitudinally. We used cross sectional blood samples collected from infants before initiation of ART (n=3) as well as in virally suppressed children on ART for 2 years (n=6), 3 years (n=5) and more than 3 years (n=5). Near-full length (NFL) proviral sequences were obtained by FLIPS on enriched CD4 T cells and PacBio sequencing.

Results: We obtained a total of 939 NFL HIV genomes (200 before ART and 282, 263 and 194 after 2, 3,and>3 years of ART, respectively). Prior to ART initiation, 48% of the viral genomes were genetically intact (Fig. 1).

This proportion drastically decreased to 11%, 6% and 1% after 2, 3 and >3 years of ART, respectively, while proviruses presenting large internal deletions largely dominated (>79%). Clonally expanded proviruses (i.e., 100% identical sequences) were rare before ART initiation (7%) and observed in only 1 of the 3 samples studied.

However, the proportion of identical genomes dramatically increased to 36% after 2 years of ART and remained stable afterwards (36% and 40% at 3 and >3 years of ART, respectively). None of these clonally expanded genomes during suppressive ART were genetically intact.

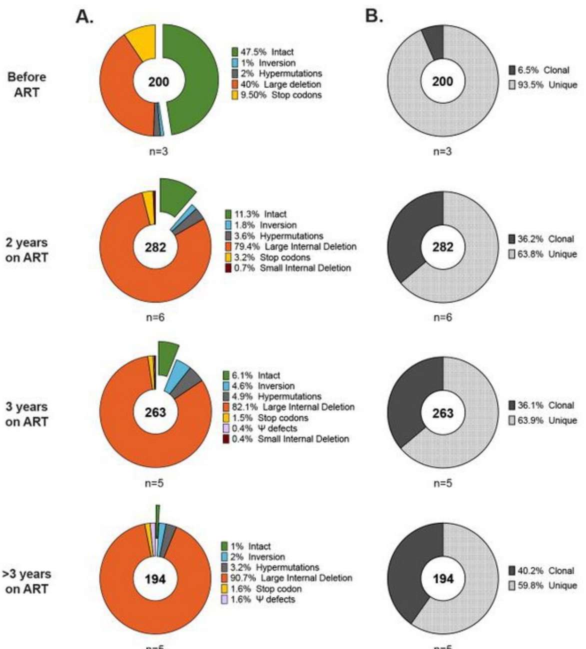

Fig. 1: *Genetic integrity and clonality of the proviral populations in vertically HIV-infected Thai children.*

A) Genetic integrity: The percentage of HIV genomes presenting a given defect is color-coded. Intact genomes are represented in green. Numbers in the centers of the pie-charts denote the number of sequences included at each time point. The number of participants at each time point is indicated below each pie-chart. B) Clonality: Unique and clonally expanded (i.e. genetically identical) HIV genomes are represented in light and dark greys, respectively.

Conclusions: These results suggest that genetically intact HIV genomes are massively depleted during the first years of ART in children who initiated treatment during the first months of life.

Although clonal expansions of defective proviruses were frequently observed during ART, genetically intact HIV genomes were scarce and always unique.

OAA0303

HIV SMRTcap, a novel single molecule, long-read sequencing assay to characterize the HIV-1 reservoir in cells and tissues across multiple subtypes

D. Sachs[1], W. Lauer[2], P. Singh[3,4], P. Warburton[1], M. Emery[1], J. Powell[1], J. Soto[1], G. Deikus[1], J. Kasule[5], J. Prodger[6], A. Tobian[7], A. Redd[8,9], S. Morgello[10], A. Engelman[3,4], R. Sebra[1,11], M. Smith[2]

[1]Icahn School of Medicine at Mount Sinai, Genetics and Genomic Sciences, New York, United States, [2]University of Louisville, Biochemistry and Molecular Genetics, Louisville, United States, [3]Dana-Farber Cancer Institute, Cancer Immunology and Virology, Boston, United States, [4]Harvard Medical School, Medicine, Boston, United States, [5]Rakai Health Sciences Program, Kalisizo, Uganda, [6]Western University, Microbiology and Immunology, London, Canada, [7]Johns Hopkins University, Pathology, Baltimore, United States, [8]Johns Hopkins University, Division of Infectious Disease, Baltimore, United States, [9]National Institutes of Health, National Institutes of Allergy and Infectious Disease, Bethesda, United States, [10]Icahn School of Medicine at Mount Sinai, Neurology, Pathology, and Neuroscience, New York City, United States, [11]Sema4, Stamford, United States

Background: HIV reservoir characterization has focused on classifying integration sites and examining the integrity of proviral genomes, many of which contain defects rendering them replication incompetent. Current methods mainly examine either integration sites or proviral integrity, and perform robustly in cell-based assays, with limited application to tissue-specific reservoirs. There has also been scant effort to expand these assays to non-subtype B samples.

To address these limitations, we developed a novel single molecule assay, HIV SMRTcap, that provides simultaneous resolution of the "HIV integron" (proviral genome and matched integration sites) in cells and tissues across all major HIV-1 subtypes.

Methods: HIV+ genomic DNA is extracted from cells or tissues and sheared into 11-15kb fragments. Oligo-based enrichment is performed using a custom panel of biotinylated 120-mers specific for HIV genomes representing all major subtypes. Oligo-bound fragments are enriched with streptavidin beads and used for sequencing library preparation. Sequencing is performed on the Sequel IIe system to obtain highly accurate (>99.99%) long reads, which allow for simultaneous characterization of the integration site, proviral intactness, and clonality.

Results: HIV SMRTcap successfully enriched HIV integron events by >2400-fold from multiple sources: *in vitro* infection, primary PBMC, multiple autopsy- and biopsy-derived tissues (including spleen, kidney, liver, lymph node, basal ganglia), and across samples infected with HIV subtypes A, B, C, and D. HIV SMRTcap resolved both intact and defective proviral genomes, demonstrating that partial

tiling of oligo baits was sufficient for capture. Intriguingly, analysis of samples using HIV SMRTcap revealed integration into repeat elements (i.e., LINEs, SINEs) absent from matched data obtained with linker-mediated PCR, likely due to limitations in mapping short-read data.

Conclusions: Standard short-read HIV reservoir measurement methods do not provide direct simultaneous evaluation of the complete HIV integron, limiting investigations of the impact of integration site on clonal expansion and retention of intact proviral genomes in patient samples.

Moreover, specialized methods that can link this information (i.e., MIP-seq) are often prohibitively expensive and labor intensive. HIV SMRTcap utilizes long-read sequencing to characterize complete HIV integrons in a cost-effective, scalable manner, and has tremendous potential to accurately investigate HIV reservoir dynamics during evaluation of HIV cure strategies.

Intact HIV proviruses persist in the central nervous system despite viral suppression with antiretroviral therapy

C. Cochrane[1,2], T. Angelovich[1,3,4], A. Guanizo[1], G. Trollope[1], L. Senior[1], E. Wanicek[1], J. Jamal Eddine[1], M. Gartner[5], E. Waring[1], J. Estes[6], B. Brew[7], S. Lewin[3,8], M. Roche[1,3], M. Churchill[1,4,9]

[1]RMIT University, School of Health and Biomedical Sciences, Melbourne, Australia, [2]University of Melbourne, Department of Medicine, Melbourne, Australia, [3]The University of Melbourne, Department of Infectious Diseases, Melbourne, Australia, [4]Burnet Institute, Life Sciences, Melbourne, Australia, [5]University of Melbourne, Department of Microbiology and Immunology, Melbourne, Australia, [6]Oregon Health and Science University, Vaccine and Gene Therapy Institute, Oregon National Primate Research Centre, Portland, United States, [7]St Vincent's Hospital, University of New South Wales, Departments of Neurology and Immunology, Sydney, Australia, [8]Alfred Hospital and Monash University, Department of Infectious Diseases, Melbourne, Australia, [9]Monash University, Departments of Microbiology and Medicine, Melbourne, Australia

Background: HIV persistence in blood and tissue reservoirs represents the major barrier to HIV cure and is a possible cause of comorbid disease. HIV is known to infect the central nervous system (CNS); however, to date the size and replication competent nature of the CNS reservoir is unclear.

Methods: Here we employed a droplet digital PCR assay to detect total HIV DNA and the intact proviral DNA assay (IPDA) to provide the first quantitative assessment of the intact and defective HIV reservoir in well-characterized brain tissues from autopsies. Further phenotypic characterization of brain reservoir cells was provided by in situ hybridization (DNAscope) targeting HIV DNA and laser capture microdissection and PCR of CD68+ brain cells.

Results: HIV DNA was present at similar levels in brain tissues from untreated viremic or antiretroviral (ART)-suppressed individuals (n=36; median: 22.3 vs 26.2 HIV *pol* copies/10^6 cells), reflecting a stable CNS reservoir that persists despite therapy.

Furthermore, 9/12 viremic and 5/8 virally suppressed individuals also harbored intact proviruses in the CNS (13.5 vs 4.63 intact copies/10^6 cells). CNS and peripheral reservoirs harbored a similar frequency of intact proviruses (~20% of proviruses). In situ hybridization (DNAscope) identified the presence of HIV DNA in brain myeloid cells and sequences of proviruses isolated from purified brain myeloid cells compartmentalized relative to those from matched peripheral lymphoid tissue reservoirs, indicating that the CNS harbors a distinct reservoir.

Conclusions: Thus, here we provide the first evidence of an intact, potentially replication competent, HIV reservoir in the CNS of virally suppressed people living with HIV.

OAA0305

SARS-CoV-2 mRNA vaccination exposes latent HIV to Nef-specific CD8+ T cells

E. Stevenson[1], S. Terry[1], D. Copertino[1], L. Leyre[1], A. Ward[1], P. Khadka[1], K. Bernard[1], G. Ellsworth[1], C. Johnston[1], M. Caskey[2], C. Gaebler[2], T. Wilkin[1], G. Lee[1], R.B. Jones[1]

[1]Weill Cornell Medicine, Infectious Diseases Division, New York city, United States, [2]Rockefeller University, New York City, United States

Background: SARS-CoV-2 mRNA vaccines activate TLR and inflammatory signaling pathways, and thus may activate transcription from HIV proviruses. We hypothesized that, in addition to virological measures, a key manifestation of this would be*in vivo*boosting of T-cell responses specific for the early gene product HIV-Nef. This was based upon our previously reported findings that Nef-specific T-cells disproportionately recognize residual antigen expression during long-term antiretroviral therapy (ART), enforcing an effector profile (granzyme-B release).

Methods: HIV RNA in PBMC supernatants was measured by RT-qPCR. T-cell responses to HIV gene products were measured at baseline and ~2 weeks after SARS-CoV-2 mRNA vaccine prime and boost in 13 ART-treated adults using IFN-gor granzyme-B ELISPOT, as well as activation induced marker (AIM) assays. Total and unspliced HIV mRNA, as well as intact and defective (IPDA) HIV DNA were measured in parallel by digital droplet PCR (ddPCR).

Results: Treatment of PBMCs from ART-treated donors with SARS-CoV-2 mRNA vaccines drove release of HIV RNA into supernatants (n=6, p=0.03). Within days of vaccinations, we observed transient*in vivo*increases in cell-associated HIV RNA. Nef-specific T-cell responses increased following vaccine-prime by granzyme-B ELISPOT (3.1-fold increase, p=0.002), with a parallel trend by AIM assay (1.5-fold, p=0.06). Analogous increases were not observed in responses to late gene products. Unspliced and total

HIV mRNA decreased modestly between baseline and 2 weeks post vaccine-boost, unspliced-1.6-fold decrease p=0.03; total-1.5-fold decrease p=0.05.
Changes in total HIV mRNA showed strong inverse correlations with Nef-specific granzyme B-producing (spearman'sr=-0.73, p=0.006) and Nef-specific CD8+ AIM T-cell responses (r=-0.76, p=0.006) following vaccine prime. Neither total nor intact HIV DNA changed significantly across the study.
Conclusions: SARS-CoV-2 mRNA vaccination induced a degree of HIV latency reversal, resulting in engagement of HIV-Nef-specific CD8+ T-cells with a cytotoxic profile. The strong correlations between increases in these responses and subsequent decreases in cell-associated HIV RNA suggest some elimination of transcriptionally-active cells. However, this was not accompanied by reductions in intact or total HIV DNA. This may reflect that only a minority of proviruses were responsible for transcription, both at baseline and following latency reversal, consistent with recent observations in the field.

OAA04 Shake and bake: Promising strategies for HIV cure

OAA0402
Potent latency reversal enables in-depth transcriptomic analyses of the HIV reservoir

M. Pardons[1], B. Cole[1], L. Lambrechts[1], S. Rutsaert[1], Y. Noppe[1], E. Nijs[2], E. Van Gulck[2], D. Boden[3], L. Vandekerckhove[1]
[1]*HIV Cure Research Center, Ghent University, Department of Internal Medicine and Pediatrics, Ghent, Belgium,* [2]*Janssen Infectious Diseases, Janssen Research and Development, Division of Janssen Pharmaceutica NV, Beerse, Belgium,* [3]*Janssen Infectious Diseases, Division of Janssen Pharmaceutica NV, South San Francisco, United States*

Background: Extensive characterization of the translation-competent reservoir has been hampered by the limited capacity of current latency reversing agents (LRAs) at inducing HIV reactivation *in vitro*. Here, we describe a new LRA combination (JNJ877+PNB) that induces potent latency reversal without inducing global T cell activation, and we took advantage of these unique properties to study transcriptomic features of the inducible reservoir.
Methods: CD4 T cells from 22 ART-treated individuals were stimulated for 24H with PMA/ionomycin (PMA/i) or with JNJ877 in combination with panobinostat (PNB). The frequency of cells expressing p24 and viral release in the supernatant were assessed by HIV-Flow and p24-SIMOA, respectively. HIV clones reactivated by JNJ877+PNB were compared to those reactivated with PMA/i using the STIP-seq assay, which allows for the simultaneous assessment of the integration site and proviral sequence from p24+ cells. Single-cell RNA-seq on sorted p24-/p24+ cells from 7 ART-treated individuals was used to study cellular and viral transcripts following stimulation with JNJ877 or JNJ877+PNB.
Results: JNJ877+PNB induced HIV reactivation in a larger fraction of CD4 T cells than PMA/i (n=22, p<0.00001, fold increase=5X). Similar results were obtained with SIMOA (n=4), confirming an effective release of viral particles in the supernatant. Clones reactivated with JNJ877+PNB were mostly shared with the ones induced by PMA/i, although some were represented in different proportions. Single-cell RNA-seq analyses showed that JNJ877 does not modify the cellular transcriptome of CD4 T cells.
Following JNJ877 treatment, p24+ cells significantly expressed higher levels of a novel long non-coding RNA, *SOD1P3*, *CCL5* and *GZMA*, while expressing lower levels of *ATG10* and *IL7R* when compared to p24- cells.
Finally, transcriptomic analyses on 321 p24+ cells revealed that proviruses with a defective major splice donor (MSD) site use alternative splice sites up- and/or downstream of the MSD, suggesting an underestimated role of these proviruses in HIV pathogenesis.
Conclusions: We report a combination of LRAs that induces latency reversal in a higher proportion of latently infected cells compared to PMA/i, without inducing global T cell activation. Therefore, JNJ877+PNB appears as a promising LRA combination to reactivate HIV *in vitro* and *in vivo*, paving the way to an HIV cure.

In vivo preclinical efficacy of MGD014 and MGD020 (HIV-1 envelope x CD3 DART molecules) and first-in-human phase 1 clinical safety evaluation of MGD014

J.L. Nordstrom[1], C.L. Gay[2], C. Bohac[1], A.R. Wahl[3], T. Morgan[3], J.L. Schmitz[4], H. Li[1], J. Cotshott[1], J. Gobburu[5], A.N. Macintyre[6], R.J. Gorelick[7], G. Ferrari[8], D.M. Margolis[2], J.V. Garcia[3]

[1]*MacroGenics, Inc., Rockville, United States,* [2]*University of North Carolina at Chapel Hill School of Medicine, UNC HIV Cure Center and Department of Medicine, Chapel Hill, United States,* [3]*University of North Carolina at Chapel Hill, International Center for the Advancement of Translational Science, Division of Infectious Diseases and Center for AIDS Research, Chapel Hill, United States,* [4]*University of North Carolina at Chapel Hill School of Medicine, Department of Pathology and Lab Medicine, Chapel Hill, United States,* [5]*University of Maryland, School of Pharmacy and School of Medicine, Baltimore, United States,* [6]*Duke University, School of Medicine and Duke Human Vaccine Institute, Durham, United States,* [7]*Leidos Biomedical Research, Inc., AIDS and Cancer Virus Program, Frederick, United States,* [8]*Duke University, Department of Surgery and Department of Molecular Genetics and Microbiology, Durham, United States*

Background: MGD014 and MGD020 are bispecific DART® molecules that bind CD3 and HIV-1 env; anti-env specificities are from non-neutralizing mAbs A32 and 7B2, respectively. They redirect CD3+ T lymphocytes to kill HIV-1-infected CD4+ T cells. We evaluated the in vivo antiviral efficacy of MGD014 and MGD020 in HIV-1-infected humanized mice on antiretroviral therapy (ART). We also completed an initial phase 1 safety study of MGD014 in persons with HIV-1 (PWH) on ART [NCT03570918].

Methods: MGD014 and MGD020 were administered (300 mcg/kg, QW) to HIV-1-infected humanized mice on ART. To assess the effects on cell-associated HIV-1 RNA (caRNA), tissues (spleen, liver, bone marrow, lymph node, organoid) were collected after 2 DART molecule doses. To assess the effects on rebound viremia, 7 DART molecule doses were administered; ART was discontinued after the 4th DART molecule dose.

The MGD014 clinical study evaluated 21 participants in Part 1 (single dose escalation, 0.1 to 300 mcg/kg) and 3 participants in Part 2 (300 mcg/kg, Q2Wx3). Endpoints included incidence of DLTs, PK, ADA, cytokines, immunophenotype, and residual plasma viremia.

Results: The efficacy study in HIV-1-infected humanized mice revealed that MGD014, MGD020, or MGD014+MGD020 [combination] reduced mean caRNA levels in tissues by 3.7-fold (p=0.0161), 1.9-fold (p=0.0132) or 6.2-fold (p <0.0001), respectively (Mann-Whitney test). Importantly, following ART discontinuation, median time to viremia rebound was 7 days for MGD014 (p=0.0444), 12 days for MGD020 (p=0.009) or 19 days for MGD014+MGD020 (p=0.0001) (Kaplan-Meier analysis). In the MGD014 clinical study, no DLT or SAE was observed. At 300 mcg/kg, MGD014 bound an average of 92% and 72% of circulating CD4+ and CD8+ T cells, respectively, without inducing activation markers or serum cytokines. MGD014 half-life was ~12 days and trough serum concentrations exceeded EC_{90} for redirected CD8+ T cell killing of HIV-infected CD4+ T cells in vitro by ≥ 20-fold.

Conclusions: Administration of MGD020+MGD014 mediated greater HIV-1 clearance activity than individual DART molecules in HIV-1-infected humanized mice. MGD014 was well-tolerated in PWH on ART. A first-in-human study with MGD020+MGD014 in PWH on ART will begin in 2022. Our data support future clinical studies combining DART molecules and latency reversing agents. Background: Latency reversal and clearance of infected cells is a major strategy for HIV cure. The IAP inhibitor AZD5582 reverses latency systemically in animal models. Here, we investigated the ability of AZD5582 in combination with a cocktail of 4 rhesus-derived SIV Env-specific monoclonal antibodies (RhmAbs) ± the IL-15 superagonist N-803 to reduce viral reservoirs in ART-suppressed rhesus macaques (RMs).

Methods: 30 RMs were infected with SIV_{mac239}. ART was initiated 8 wks after infection. After 90 wks of ART, RMs were divided into 4 groups with continuous ART exposure: ART control (n=6), RhmAbs control (n=6), RhmAbs+AZD5582

(n=9), and RhmAbs+AZD5582+N-803 (n=9). RhmAbs targeting V2, CD4 binding site, CD4 binding site proximal, and MPER were dosed twice at 20 mg/kg s.c. each; AZD5582 at 0.1 mg/kg i.v. wkly for 10 wks, and N-803 at 0.1 mg/kg s.c. twice.
Concentrations of RhmAbs were evaluated by ELISA. Plasma SIV RNA and CD4+ T-cell SIV*gag* DNA/quantitative virus outgrowth were measured to quantify latency reversal and reservoir frequency, respectively.
Results: ART was successful in suppressing viremia. Anti-SIV Env RhmAbs peaked in all treated RMs 24h after infusion with mean half-life of 7.4 ± 2d. Serum concentrations were reduced for 3/4 RhmAbs in RMs who received N-803, likely due to development of anti-drug antibodies (ADA). Latency reversal (on-ART viremia) was observed in 7/9 RhmAbs+AZD5582-treated and 9/9 RhmAbs+AZD5582+N-803-treated RMs.
At study end, RMs treated with RhmAbs+AZD5582±N-803 had reduced splenic CD4+ T-cell SIV*gag* DNA (p=0.03 for each comparison) and trended toward lower viral outgrowth compared to the combined ART and RhmAbs control groups. Only RMs that received RhmAbs+AZD5582 without N-803 showed reduced lymph node CD4+ T-cell SIV*gag* DNA (p=0.01) and virus outgrowth compared to controls (p=0.04).
Finally, increased levels of CD4+ T-cell activation/proliferation in lymph nodes following N-803 was observed.
Conclusions: Our findings give insight into HIV cure interventions in a relevant preclinical model, confirm the efficacy of AZD5582 in inducing SIV reactivation, and provide new *in vivo* data showing latency reversal in all RMs treated with the combination of AZD5582+N-803.
This study also suggests that elimination of infected cells in tissues using an IAP inhibitor and anti-SIV Env RhmAb cocktail is possible.

Background: The heavily glycosylated HIV-1 envelope glycoprotein (Env) is the sole viral antigen present on virion and infected cells, representing the main target for antibody responses. The FDA-approved small molecule temsavir acts as an HIV-1 attachment inhibitor by preventing Env-CD4 interaction. This molecule also stabilizes Env in a prefusion "closed" conformation that is preferentially targeted by several broadly neutralizing antibodies (bNAbs).
A recent study showed that an analog of temsavir (BMS-377806), affects the cleavage and addition of complex glycans on Env. In this study, we investigated the impact of temsavir on the overall glycosylation, proteolytic cleavage, cell-surface expression and antigenicity of Env.
Methods: SinceBMS-377806limits Env conformational flexibility, we first investigated temsavir's impacton overall Env processing and glycosylation by immunoprecipitation. Next, we evaluated if this alteration affected the recognition of Env at the surface of infected cells and virionsby a panel of bNAbs and non-neutralizing antibodies (nnAbs).Finally, we investigated ifthe capacity of bNAbs to eliminate infected cells by ADCC was also affected.
Results: We found that temsavir substantially impacts Env glycosylation and processing at physiological concentrations. This significantly alters the capacity of several bNAbs to recognize Env present on virions and HIV-1-infected cells. Temsavir treatment also reduces the capacity of bNAbs to eliminate HIV-1-infected cells by ADCC.
Conclusions: Temsavir has a profound impact on Env antigenicity at the surface of viral particles and infected cells.This new information needs to be considered for the development of new antibody-based approaches in temsavir-treated individuals.

Chronic injection opioid use increases the systemic inflammation and T cell immune activation in virally suppressed people living with HIV

C. Dang[1], S. Pallikkuth[1], A. Kizhner[1], C.M. Nelson[1], D. Forrest[1], D. Feaster[1], R. Pahwa[1], D. Jayaweera[1], A. Rodriguez[1], H. Tookes[1], S. Pahwa[1]
[1]*University of Miami, Miami, United States*

Background: Opioid dependence is a major health problem in the US. Our group is investigating the immunologic consequences of opioid dependence in HIV-infected (HIV+) and HIV-uninfected (HIV-) participants. We hypothesize that virally controlled HIV+ injecting opioid users manifest immune perturbations.
Methods: In an ongoing study, opioid users (OP+) are recruited from our needle exchange program and opioid non-users (OP-) from the clinics. Participants are grouped as HIV+OP+ (Gp1), HIV-OP+ (Gp2), HIV+OP- (Gp3), and HIV-OP- (Gp4), median age 48yr with 62% Male: 36% Female: and 2% Transgender Women. HIV+ were on ART with <HIV

OAB0102 Table. Opioid use and HIV infection increases activation markers, inflammation and cell adhesion.
$^*Normalized_{cytokine} + log_2(cytokine_{subj}/Median_{HealthyControlYearCytokine})$ Score = $(\sum_{cytokine}^{n} Normalized_{cytokine})/n_{cytokine}$

200 copies/mL. Statistical methods include non-parametric group comparisons (Kruskal-Wallis), Spearman correlations and Multiple regression. (Table)

Results: Plasma biomarkers showed differences in OP+ (Gp1 and Gp2) compared to Gp4 (HIV-OP-), with higher soluble activation markers (sTNFR-I, -II), inflammatory biomarkers (TNFa, IL-6, sCD25), adhesion mediators (ICAM-1, VCAM-1), monocyte chemotaxis protein (CCL2) and monocyte activation (sCD14). Cytokine scores for OP+ were higher than the OP- groups, and among the OP- groups, HIV+ (Gp3) were higher than HIV- (Gp4). In a regression model that included gender, race, ethnicity, and age, cytokine scores differed by HIV status (HIV+:higher scores, p<0.002) and opioid use (OP+:higher scores, p<0.0000001) and moderated relationship by race, p<0.02. T cell phenotype (flow cytometry) revealed inverted CD4/CD8 ratio. Immune activation (IA), measured as frequencies of HLA-DR+CD38+ T cells, was significantly higher in the CD8 compartment in OP+ groups, compared to Gp4. CD8 T cell IA positively associated with cytokine score (rho= 0.5, p<0.0001).

Conclusions: Chronic injection opioid use (Gp1 and Gp2) increases systemic inflammation and T cell immune activation. Contribution of virally controlled HIV status was less striking and limited to cytokines. Exacerbation of immune dysfunction by opioids in the syndemic of HIV and chronic injection opioid use may pose a risk for comorbidities in this population.

Impact of gender identity- and HIV-related stigmas and psychosocial resources on mental health and alcohol use among transgender women newly diagnosed with HIV in India: a longitudinal cohort study

N.S. Chopra[1], D. Datta[1], A. Gupta[2], F. Gulfam[2], J. Kaur[2], J. Ross[1], S. Reddy[2], A. Ahalawat[2], S. Safren[3], S. Golub[4], V. Chakrapani[2], V.V. Patel[1]

[1]Albert Einstein College of Medicine, Division of General Internal Medicine, The Bronx, United States, [2]HIV/AIDS Alliance India, New Delhi, India, [3]University of Miami, Psychology, Coral Gables, United States, [4]Hunter College, CUNY, Health Psychology, New York, United States

Background: Transgender women (TGW) living with HIV may be subject to intersectional stigma at multiple levels – enacted (experiences of discrimination/devaluation); anticipated (expectations of discrimination); internalized (negative self-valuation due to stigmatized status) – that are associated with negative health outcomes, as posited by the health stigma framework.

However, few studies have examined the association between stigma and mental health or hazardous alcohol use among TGW living with HIV.

We investigated the longitudinal influence of multiple stigmas on depression, anxiety, and alcohol use in TGW living with HIV in India.

Methods: We enrolled a prospective cohort of 140 TGW newly diagnosed with HIV from 11 Indian states. Participants completed surveys via telephone-interviews at three timepoints – baseline, three-months, and six-months (Aug. '20 - Oct. '21) – about enacted, anticipated, and internalized stigmas related to positive HIV status and transgender identity, as well as: gender affirmation in healthcare settings, social support, and resillency resources.

Surveys also captured depression (PHQ-9), generalized anxiety (GAD-2), and hazardous alcohol use (AUDIT-C) scores. Longitudinal analyses used multivariable regression with generalized estimating equations (which account for clustering within individuals and provide robust population-averaged estimates of the outcomes) for each of the three outcomes (results reported as β [95% CI]).

Results: Increasing anticipated HIV-stigma (3.2, [1.7,4.7], p<.001), enacted HIV-stigma (3.5, (2, 5.1), p<.001), anticipated TG-stigma (1.7 [.4, 3], p=.01), internalized TG-stigma (3.1 [1.2,4.9], p=.001), and hazardous alcohol use scores (0.1 [0.03,0.2], p=.006) were associated with increased depression; increasing resiliency resources (-0.3 [-0.5,-0.1], p=.002) and gender affirmation in healthcare (-0.08 [-0.2,-0.004], p=.039) was associated with decreased depression.

Increasing enacted HIV-stigma (0.9 [0.5,1.3], p<.001) and internalized HIV-stigma (2.1 [1.4,2.8], p<.001) were associated with increased generalized anxiety; increasing gender affirmation (-0.2 [-0.3,-0.1], p<.001), social support (-0.8 [-1.3,-0.3], p=.001.) was associated with decreased generalized anxiety.

Finally, increasing gender affirmation in healthcare-settings was associated with lower hazardous alcohol use scores (-.1 [-0.16,-0.004],p=.04).

Conclusions: Transgender identity- and HIV-specific stigmas strongly impacted depression and anxiety. Increasing levels of psychosocial resources including gender affirmation in healthcare-settings were associated with improved mental health and reduced alcohol use scores. These findings provide empirical evidence for intervention targets for addressing the well-being of TGW newly diagnosed with HIV.

OAB0104

Forty-eight week outcomes of a combined cognitive behavioral therapy and medication management algorithm for treatment of depression among youth living with HIV in the United States (IMPAACT 2002)

L. Brown[1], K. Baltrusaitis[2], B. Kennard[3], G. Emslie[3], M. Chernoff[2], S. Buisson[4], L. Levy[4], L. Whiteley[5], S. Traite[2], C. Krotje[6], K. Knowles[6], E. Townley[7], J. Deville[8], M. Wilkins[9], D. Reirden[10], M. Paul[11], C. Beneri[12], D. Shapiro[2]

Chan School of Public Health, Center for Biostatistics in AIDS Research, Boston, United States, [3]University of Texas Southwestern Medical Center, Psychiatry, Dallas, United States, [4]FHI 360, Durham, United States, [5]Brown University, Psychiatry, Providence, United States, [6]Frontier Science Foundation, Amherst, United States, [7]National Institute of Allergy and Infectious Diseases, Rockville, United States, [8]University of California, David Geffen School of Medicine, Los Angeles, United States, [9]St. Jude Children's Research Hospital, Memphis, United States, [10]University of Colorado School of Medicine, Children's Hospital Colorado, Aurora, United States, [11]Baylor College of Medicine, Texas Children's Hospital, Houston, United States, [12]Stony Brook Children's Hospital, Stony Brook, United States

Background: Studies suggest that manualized depression treatmentguided by symptom measurementis more efficacious than usual care but that its impact can wane. Our study among youth living with HIV (YLWH), ages 12-24 years at United States clinical research sites in the International Maternal Pediatric Adolescent AIDS Clinical Trials Network (IMPAACT), found a significant reduction in depressive symptoms at Week 24 among YLWH who received a manualized, measurement-guided intervention (Brown, L. JAIDS, 2021). This abstract reports outcomes at Weeks 36 and 48, after the study's intervention ended.

Methods: Eligibility included diagnosis of nonpsychotic depression and current depressive symptoms. Using restricted randomization, sites were assigned to either combination cognitive behavioral therapy and medication management algorithm (COMB-R) tailored for YLWH or Enhanced Standard of Care (ESC), which provided standard psychotherapy and medication management. Site-level mean Quick Inventory for Depression Symptomatology Self-Report (QIDS-SR) scores and proportion of youth with treatment response (>50% decrease from baseline) and remission (QIDS-SR£5) were compared across arms using t-tests.

Results: Thirteen sites enrolled 156 YLWH, with baseline demographic factors, depression severity, and HIV status comparable across arms. At Weeks 36 and 48, the mean proportion of youth with a treatment response-was greaterat COMB-R sites compared to ESC sites (52.0% vs. 18.8%, p=0.015; 58.7% vs. 33.4%, p=0.047). At Week 36,a greater mean proportion of youth at COMB-R sites re-

Oral abstracts

Poster exhibition

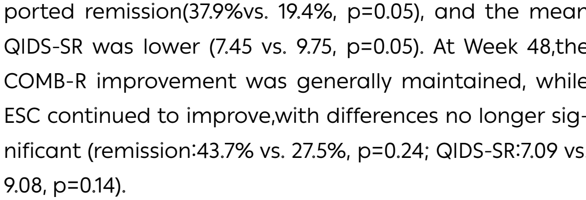
Late-breaker abstracts

Author Index



ported remission(37.9%vs. 19.4%, p=0.05), and the mean QIDS-SR was lower (7.45 vs. 9.75, p=0.05). At Week 48,the COMB-R improvement was generally maintained, while ESC continued to improve,with differences no longer significant (remission:43.7% vs. 27.5%, p=0.24; QIDS-SR:7.09 vs. 9.08, p=0.14).

Conclusions: The evidence for maintenance of the intervention's impact after the intervention concluded suggests promise. The intervention is feasible in clinic settings with existing staff and can be implemented without increasing the burden of additional clinic visits for patients.

Future research can investigate how to better prevent relapse for those who achieve remission and promote a treatment response for those whom treatment is not effective in the first 24 weeks.

OAB0105

Long-term risk of hospitalization and chronic disease among children who were HIV-exposed uninfected (cHEU) compared to population controls in Montreal, Canada

B. Jeanne[1], T. Ducruet[1], S. Taillefer[1], M.E. Metras[1], S. Valois[1], V. Lamarre[1], I. Boucoiran[1], H. Soudeyns[1], J. Puyat[2], J. Singer[2], F. Kakkar[1]

[1]CHU Sainte Justine, Université de Montréal, Montréal, Canada, [2]CIHR Canadian HIV Clinical trials Network, Vancouver, Canada

Background: While studies have demonstrated increased risk of morbidity and mortality among cHEU in early life, the need for specialized follow-up of cHEU once their HIV status has been confirmed negative is not clear.

The primary objective of this study was to determine the long-term risk of hospitalization, and incidence of chronic disease, among cHEU compared to HIV-unexposed uninfected (cHUU) controls.

Methods: Longitudinal cohort study linking data from the Centre Maternel et Infantile sur le SIDA (CMIS) cohort to administrative data from the Régie de l'Assurance Maladie du Quebec (RAMQ), a universal health system with unique single patient identifiers, covering all care services provided. ICD-9 codes were extracted and grouped by system for measures of chronic diseases and cHEU matched 1:3 by age, gender and postal code to cHUU controls. Survival analysis was used to determine risk of hospitalization and chronic disease.

Results: Among 847 cHEU enrolled in the CMIS cohort between 1988 and 2015, 726 were linked to the RAMQ database, and matched to 2178 cHUU. Median follow-up was 11.1 [6.6 – 15.9] years.

There was a significantly higher risk of hospitalization among cHEU *vs.* cHUU over their life-span (HR 1.42 [1.26 – 1.61], p<0.001), which remained significant after adjusting for gestational age (aHR 1.23 [1.08 – 1.40], p=0.001), and in a sensitivity analysis excluding prolonged (>5 days) birth hospitalization (HR 1.21 [1.06 – 1.41] (Figure 1).

Over their lifespan, cHEU had a significantly higher risk of neuropsychiatric disorders (33.3% *vs.* 26.1%, RR 1.28 [1.13 – 1.45], p<0.001) and congenital anomalies (5.5%*vs.* 3.5%, RR 1.58 [1.09 – 2.3], p=0.016), though there was no difference in risk of chronic cardiovascular, respiratory or neoplastic disease.

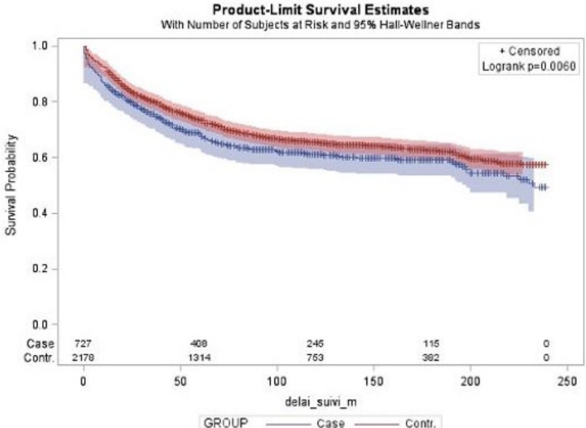


Figure 1. Hospitalization free survival - sensitivity analysis excluding first hospitalization.

Conclusions: In this resource-rich setting with universal health-care, cHEU had increased risk of hospitalization and neuro-psychiatric disorders, suggesting that cHEU would benefit from enhanced pediatric care, including early neurodevelopmental assessment.

OAB02 Outcomes in paediatric and adolescent HIV: Beyond ART

The fast and the continuous: dolutegravir-based antiretroviral therapy achieves impressive viral load suppression in CALHIV in the short- and long-term

J. Bacha[1,2,3], S. Dlamini[2,4], F. Anabwani[4], J. Gwimile[5], J.B. Kanywa[6], P.J. Elyanu[6], J. Farirai[7], M. Bvumbwe[8], M. Tsotako[9], T. Steffy[1,2,9], D. Nguywen[1,2,10], H. Haq[1,2]
[1]Baylor College of Medicine, Pediatrics, Houston, United States, [2]Baylor College of Medicine International Pediatric AIDS Initiative (BIPAI) at Texas Children's Hospital, Houston, United States, [3]Baylor College of Medicine Children's Foundation - Tanzania, Mbeya, Tanzania, The United Republic of, [4]Baylor College of Medicine Children's Foundation - Eswatini, Mbabane, Eswatini, [5]Baylor College of Medicine Children's Foundation - Tanzania, Mwanza, Tanzania, The United Republic of, [6]Baylor College of Medicine Children's Foundation - Uganda, Kampala, Uganda, [7]Botswana-Baylor Children's Clinical Centre of Excellence Trust, Gabarone, Botswana, [8]Baylor College of Medicine Children's Foundation - Malawi, Lilongwe, Malawi, [9]Baylor College of Medicine Children's Foundation - Lesotho, Maseru, Lesotho, [10]Baylor College of Medicine, Department of Education, Innovation, and Technology, Houston, United States

Background: As dolutegravir (DTG)-based antiretroviral therapy (ART) is used as the preferred ART for children and adolescents living with HIV (CALHIV), questions remain about its short- and long-term effectiveness in the real-world. We describe longitudinal viral load suppression (VLS) trends of CALHIV using DTG in six African countries.

Methods: Retrospective chart review from 2016 through 2021 analyzing clinical characteristics and VLS rates of CALHIV ages 0-19 years old prescribed DTG at clinics in Botswana, Eswatini, Lesotho, Malawi, Tanzania, and Uganda. VLS was defined as VL<1000 copies/mL. VL results were coded at 6 month intervals from DTG start date, with +/- 90 day buffer range. Initial VLS rate at 6 month post-DTG was used as the comparator for the longitudinal VLS rates and differences.

Results: 11,799 CALHIV received DTG; 56.0% (6604/11799) were female and average age of 13.4 years (SD 4.0 yr). By study end, 93.7% (11059/11799) remained active in care, 4.7% (549/11799) transferred out, 1.2% (145/11799) were lost to follow up, and 0.4% (46/11799) died. 22,577 VL results were documented, ranging from 6 months to 60 months post-DTG and average follow up time post-DTG was 22.4 months (SD 12.4). Initial 6 month post-DTG VLS rate was 92.1%, similar across sexes (Females 91.6%, Males 92.7%) and ages (Figure 1). VLS rates were maintained without significant loss across the entire cohort, by sex and by age groups (Figure 2).

Cohort of CALHIV on DTG	Time point of VL post-DTG								
	6 month	12 month	18 month	24 month	30 month	36 month	42 month	48 month	≥54 month
All CALHIV (VLs=22577)	92.1% (8120/8816)	92.7% (5917/6863)	92.4% (4177/4522)	91.0% (1888/2074)	90.0% (422/469)	89.9% (179/199)	94.9% (74/78)	95.8% (23/24)	100.0% (12/12)

0-4.99yo (VLs=37)	88.9%	11.1% [-28.8%,32.8%]	11.1% [-33.1%, 32.8%]	11.1% [-45.6%, 32.8%]	11.1% [-45.6%, 32.8%]	11.1% [-55.2%, 32.8%]	N/A	N/A	N/A
5-9.99yo (VLs=1689)	94.1%	1.8% [-0.7%, 4.0%]	-2.5% [-7.7%, 1.2%]	-2.7% [-12.8%, 2.5%]	5.9% [-11.0%, 7.6%]	-8.3% [-34.1%, 2.0%]	5.9% [-29.6%, 7.6%]	N/A	N/A
10-14.99yo (VLs=8563)	93.5%	0.2% [-1.1%, 1.4%]	-0.6% [-2.2%, 0.8%]	-3.9% [-6.6%, -1.6%]	-5.1% [-12.1%,- 0.5%]	0.6% [-9.5%, 4.6%]	1.2% [-18.2%, 5.6%]	6.5% [-32.5%, 7.4%]	6.5% [-49.7%, 7.4%]
15-19.99yo (VLs=12228)	90.5%	1.0% [-0.3%, 2.3%]	1.6% [0.2%, 2.9%]	1.2% [-0.6%, 2.8%]	-0.6% [-4.4%, 2.4%]	-1.9% [-8.5%, 2.6%]	3.7% [-6.2%, 7.6%]	4.2% [-15.2%, 8.7%]	9.5% [-23.0%, 10.4%]

Figure 2. Comparison of VLS rate differences post-DTG over time (using 6 month VLS rate as the comparator), % [95% CI]

Conclusions: DTG rapidly achieved and consistently maintained VLS for years among CALHIV in real world settings. These findings support the widespread use of DTG in CALHIV.

OAB0203

Optimal timing for ART initiation in ART-naive children and adolescents living with HIV following the diagnosis of HIV-associated TB

A. Kay[1,2], J. Mendez Reyes[1], T. Devezin[1], S. Dlamini[2], A. Msekandiana[3], T. Steffy[4,5], J. Bacha[6,1], P. Amuge[7], B. Lukhele[2,5], H.L. Kirchner[8,1], A. Mandalakas[1]

[1]Baylor College of Medicine, Pediatrics, Global TB Program, Houston, United States, [2]Baylor Children's Foundation Eswatini, Mbabane, Eswatini, [3]Baylor Children's Foundation Malawi, Lilongwe, Malawi, [4]Baylor Children's Foundation Lesotho, Maseru, Lesotho, [5]Baylor College of Medicine, Pediatrics, Houston, United States, [6]Baylor Children's Foundation Tanzania, Mbeya, Tanzania, The United Republic of, [7]Baylor Children's Foundation Uganda, Kampala, Uganda, [8]Geisinger Health System, Danville, United States

Background: There is no direct evidence in children and adolescents living with HIV (CALHIV) to guide the timing of antiretroviral treatment (ART) initiation following TB treatment. To address this gap, we evaluated the risk of mortality associated with the timing of ART initiation in ART-naive CALHIV treated for TB in a large, multinational retrospective cohort from high-burden settings throughout sub-Saharan Africa.

Methods: Data was extracted from electronic medical records of ART-naïve patients, aged 0-19 years treated for HIV-associated TB at a Baylor Center of Excellence in Botswana, Eswatini, Malawi, Lesotho, Tanzania, or Uganda between 2014 and 2020. Data was analyzed against a primary outcome of all-cause mortality with Cox proportional hazard models.

The models included time of ART initiation as a time dependent variable to limit immortal time bias and were adjusted for age, body mass index, immune status, clinical site, and location of TB disease.

Results: The study population included 731 CALHIV with variable timing of ART initiation following TB treatment initiation: ART started within two weeks of TB treatment (n=260), ART started two weeks after but in less than two months of TB treatment (n=379), ART started after two months of TB treatment (n=64) and no ART (n=28).

Adjusted Cox proportional hazard models demonstrated an increased risk of mortality by year three from TB treatment initiation in children never started on ART compared to children initiating ART between two weeks and two months from TB treatment; however, the risk of mortality did not differ in the less than two week group ((adjusted Hazard Ratio (aHR)) 0.93; 95% CI 0.30 to 2.84) or in the greater than two month group (aHR 1.87; 95% CI 0.22 to 15.96) as compared to ART initiation between two weeks and two months from TB treatment.

Conclusions: Our study demonstrates no increased risk of mortality in CALHIV initiating ART less than two-weeks from TB treatment initiation. Given the broad health benefits of ART, this evidence supports the World Health Organization recommendation for CALHIV to initiate ART within two-weeks of initiating TB treatment.

OAB0204

Subcortical brain volumes of children who are HIV-exposed and uninfected in the first three years of life: a South African birth cohort study

C.J. Wedderburn[1,2,3], S. Yeung[2], N.A. Groenewold[1], A.M. Rehman[2], S. Subramoney[1], J.-P. Fouche[1,4], S.H. Joshi[5], K.L. Narr[5], N. Hoffman[1], A. Roos[1,4], D.M. Gibb[3], H.J. Zar[1], D.J. Stein[1], K.A. Donald[1]

[1]University of Cape Town, Cape Town, South Africa, [2]London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]MRC Clinical Trials Unit at University College London, London, United Kingdom, [4]Stellenbosch University, Stellenbosch, South Africa, [5]University of California Los Angeles, Los Angeles, United States

Background: Children who are HIV-exposed and uninfected (CHEU) are at risk for early neurodevelopmental impairment. Neuroimaging studies are scarce, although recently we reported smaller volumes of basal ganglia structures in CHEU compared to children who are HIV-unexposed (CHU) at 2-6 weeks of age. However, no studies have examined subcortical brain volumes through childhood. We aimed to investigate whether the effects of *in utero* exposure to HIV/ART on subcortical brain structures detected in infancy are evident at age 3 years.

Methods: The Drakenstein Child Health Study is a population-based birth cohort in South Africa. Pregnant women were enrolled in the second trimester of pregnancy and mother-child pairs received HIV testing per local guidelines; all mothers with HIV were initiated on ART. A subgroup of children had magnetic resonance imaging (MRI) aged 2-3 years. Structural T1-weighted images were acquired on a 3T Siemens MRI scanner during natural sleep and images were processed using FreeSurfer software, blinded to HIV status. Bilateral subcortical volumes were extracted from segmented images, and CHEU and CHU groups were compared using multivariable linear regression.

Results: One hundred and sixty-two children (70 CHEU; 92 CHU) (mean age 34 months; 58% male) had high resolution scans. Socioeconomic characteristics were similar between groups. CHEU had lower overall putamen volume compared to CHU (4381 mm^3 versus 4597 mm^3, p=0.016, Cohen's d -0.37 [-0.69 to -0.06]), with similar reductions when analysed by hemisphere (left p=0.023; right p=0.018). The findings held after adjusting for multiple covariates including age, sex, socioeconomic status and intracranial volume. Compared to CHU, CHEU also had lower hippocampus volume (3043 mm^3 versus 3149 mm^3, p=0.046, Cohen's d -0.31 [-0.62 to 0.00]). The left hemisphere difference persisted after adjusting for covariates (p=0.038).

Conclusions: Altered morphometry in the basal ganglia region can be detected in CHEU across the first 3 years of life. Further, CHEU showed smaller volumes of the hippocampus at 3 years, a region known to be vulnerable to early-life exposures.

These findings suggest that *in utero* HIV/ART exposure may affect early subcortical brain development with enduring impact. Follow up studies are needed to determine the underlying mechanisms and long-term trajectories.

Sergievsky Center, College of Physicians and Surgeons, Columbia University Irving Medical Center, New York, United States, [4]Centro de Investigação em Saúde de Manhiça, Maputo, Mozambique, [5]School of Public Health, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [6]Tygerberg Children's Hospital and Family Clinical Research Unit, Stellenbosch University, Cape Town, South Africa, [7]Infection, Immunity and Inflammation Programme, UCL Great Ormond Street Institute of Child Health, London, United Kingdom, [8]Fundação Ariel Glaser Contra O Sida Pediátrico, Maputo, Mozambique, [9]SEREFO (HIV/TB Research and Training CenteHIV/TB Research and Training Center, FMOS, University of STT, Bamako, Mali, [10]PENTA Onlus, Padova, Italy, [11]Bambino Gesù Children's Hospital, Rome, Italy

Background: The mortality of early treated children born with HIV in Sub-Saharan Africa during first years of life is still higher than baseline. We assessed the probability of AIDS-related mortality of a cohort of early treated children born with HIV, and factors related to them.

Methods: EARTH-EPIICAL Cohort is underway in Mozambique, Mali, and South Africa. From May 1st, 2018 to May 1st, 2021, infants with HIV who started ART in the first 3 months of life, are followed up for 24 months. To describe the probability of AIDS-related death, a competing risk joint model was performed consisting of a multivariable mixed linear model for longitudinal CD4 trajectory and a survival Cox proportional model. The model was adjusted by ART initiation regimen, age at HIV diagnosis, and weight-for-age.

Results: 212 participants were enrolled and followed during a median time of 17 [6.8;27.5] months; 84 reached 2 years of follow-up. ART started at 34 [26;74] days of life. 23 patients (10.8%) died, at a median of 2.5 [0.6;6.8] months of age; 12 due to AIDS-related causes.

At 2 years, overall probability (P) of death was 12% (CI95%,7 to 17). The excess of mortality compared to baseline mortality was 7%; the excess of mortality due to AIDS-related causes was 5.7%, and due to non-AIDS related causes was 1.4%. According to the joint model, there was an inverse statistically significant association between the probability of AIDS-related mortality and the percentage of CD4 (%CD4) during the time to follow up and (HR:0.9 [CI95%, 0.86-0.98], p=0.046). An increase in CD4 count decrease a 10% the probability of AIDS-related mortality.

Notably, these estimates had opposite sign for the non-AIDS-attributable deaths (HR:1.09 [CI95%, 1.02-1.15], p=0.003). Interestingly, baseline VL was significantly associated with non-AIDS-related mortality (HR:4.34 (CI95%, 1.84-20.7), p=0.026).

Conclusions: Despite early treatment, excess of AIDS- and non-AIDS-related mortality remains high in children living with HIV-1. Differentiating AIDS and non-AIDS related mortality in children with HIV may allow us to understand better the risk factors associated with mortality. CD4 percentage changes over time, and it impacts the probability of death. Infants with high baseline VL and low CD4% require specific attention.

OAB03 ART in evidence

OAB0302

Efficacy and safety of dolutegravir plusemtricitabine *vs* combined antiretroviral therapy for the maintenance of viral suppression: 144-week results of the SIMPL'HIV trial

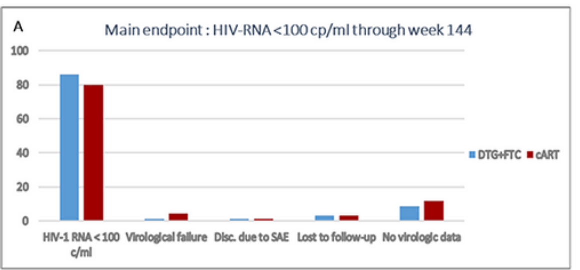
[1]Hôpitaux Universitaires de Genève, Infectious Diseases, Geneva, Switzerland, [2]Private office, Geneva, Switzerland, [3]Inselspital, Bern, Switzerland, [4]Hôpitaux Universitaires de Genève, Geneva, Switzerland, [5]University Hospital Basel, Basel, Switzerland, [6]Ospedale Regionale Lugano, Lugano, Switzerland, [7]University Hospital Zurich, Zurich, Switzerland, [8]Kantonsspital St. Gallen, St. Gallen, Switzerland, [9]Centre hospitalier universitaire vaudois, Lausanne, Switzerland, [10]Private Office, Geneva, Switzerland, [11]CTU, Bern, Switzerland, [12]University of Bern, Bern, Switzerland, [13]University Hospital of Zurich, Zurich, Switzerland, [14]University Hospital of Zuirch, Zurich, Switzerland

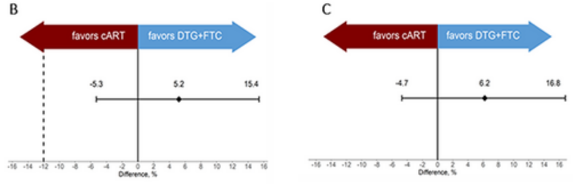
Background: Simplified treatment is needed to address challenges associated with daily oral HIV treatment in people living with HIV.

Methods: SIMPL'HIV is a phase 3, randomized, open-label, multicentre, factorial study conducted among HIV-1 infected adults on cART in Switzerland. At baseline, pa-

tients with HIV-RNA <50 copies/ml for at least 24 weeks were randomised to switching to dolutegravir (DTG) plus emtricitabine (FTC) or continuing standard combined antiretroviral therapy (cART), and to a reduced biological and medical surveillance *vs*continuation of standard 3-monthly monitoring. The main endpoint was the proportion of participants maintaining HIV-1 RNA <100 copies/mL throughout 144 weeks.

Results: 93 participants were randomly assigned to DTG+FTC and 94 to cART (mean nadir CD4 count, 259 cells/mm3 [SD=187]; 17%, female). Through 144 weeks, 3 participants in the DTG+FTC group and 6 in the cART group had HIV-RNA levels >100 copies/ml with an adjusted difference of -3.1% (95% CI -9.2-3.1%) in the intention-to-treat population.





D

Outcome	DTG+FTC (N=93)	cART (N=94)	Adj. Risk Diff. (95%-CI)
Any AE (w0 to w144)	68 (73.1%)	65 (64.9%)	
AEs occurring in >10% in either group			
• Upper respiratory Infection	20 (21.5%)	19 (20.2%)	
• Headache	10 (10.8%)	9 (9.6%)	
• Diarrhea	12 (12.9%)	2 (2.1%)	
AEs leading to study withdrawal (w48 to w144)	0	0	
AE grade 3 or 4 (w48 to w96)	5 (5.4%)	3 (3.2%)	2.2% [-3.6%;8.0%]
AE grade 3 or 4 (w48 to w144)	8 (8.6%)	6 (6.4%)	2.3% [-5.3%;9.8%]
SAE (w48 to w96)	3 (3.2%)	2 (2.1%)	1.2% [-3.5%;5.8%]
SAE (w48 to w144)	6 (6.5%)	4 (4.3%)	2.2% [-4.3%;8.7%]

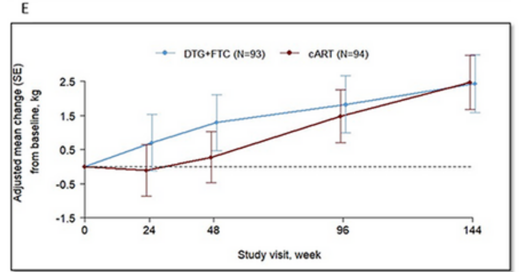


Figure 1. Efficacy and safety results. A) Primary endpoint: HIV-RNA<100 cp/ml through week 144; B) Primary endpoint: DTG+FTC non-inferior to cART (>100 cp/ml) through week 144; C) FDA snapshot: DTG+FTC non-inferior to cART (>50 cp/ml at week 144. D) Adverse events through week 144 by treatment group. E) Weight change through week 144 by treatment group.

At week 144 HIV-RNA was >50 copies/ml in one patient in the DTG+FTC group and four patients in the cART group (adjusted difference -3.2%; 95%-CI -7.7-1.5%). Mean CD4 gain between baseline and week 144 was 8.4 (±195.3) and 34.7 (±193.6) cell/mm³ with DTG+FTC and cART, respectively (adjusted difference -19.4; 95% CI -74.2-35.4).

Twelve (12.9%) participants in the DTF+FTC group and 15 (18.1%) in the cART group presented with serious AEs through week 144.

Adjusted average weight gain between baseline and 144 weeks was 2.4 (±4.7)*vs* 2.3 (±4.1) kg with DTG+FTC and cART, respectively; participants with 10% or more weight gain were 7.5% and 6.4% in the DTG+FTC and cART groups, respectively.

Conclusions: DTG+FTC remains safe and non-inferior to standard care in the maintenance of viral suppression in adults with HIV-1 at 144 weeks. No new safety signals were observed and change weight was similar between groups.

OAB0303

Dual therapy based on DRVr plus 3TC in HIV-1 naïve patients: global 48 week results from ANDES Study

M.I. Figueroa[1], O. Sued[1], P. Patterson[1], D. Cecchini[2], M. Sanchez[3], M.J. Rolon[4], G. Lopardo[5], M. Ceschel[1], G. Mernies[1], M. Destefano[1], A. Gun[6], V. Fink[1], Z. Ortiz[7], P. Cahn[7], on behalf ANDES Study Group

[1]Fundacion Huesped, Research Department, Ciudad Autónoma de Buenos Aires, Argentina, [2]Hospital Argerich, Infectious Disease Unit, Ciudad de Buenos Aires, Argentina, [3]Hospital Italiano, Infectious Disease Service, Ciudad de Buenos Aires, Argentina, [4]Hospital Juan A Fernandez, Infectious disease Division, Ciudad de Buenos Aires, Argentina, [5]Centro de Estudios Infectologicos SA (CTD Stamboulian), Research Department, Ciudad de Buenos Aires, Argentina, [6]Fundacion Huesped, Laboratory Department, Ciudad Autónoma de Buenos Aires, Argentina, [7]Fundacion Huesped, Research Direction, Ciudad Autónoma de Buenos Aires, Argentina

Background: Dual therapy has been explored in different drug combination. A generic fixed dose combination(FDC) DRV/r 800/100 mg is available in Argentina. We designed a study to compare efficacy (non-inferiority) and safety of this FDC plus 3TC to standard-of care antiretroviral therapy based on the same drugs plus tenofovir. ClinicalTrials.gov:NCT02770508

Methods: ANDES is a randomized, open-label, phase IV study designed to compare dual therapy (DT) with DRV/r 800/100mg FDC plus 3TC (300mg) vs. triple therapy (TT) with DRV/r plus 3TC/TDF (300/300mg) in treatment-naïve HIV-1 infected patients.

Primary endpoint: proportion of patients with HIV viral load (pVL) <50 copies/mL at week 48 (FDA snapshot-ITTe analysis). The study was carried out in two steps as pre-planned protocol study design. First step results were presented at CROI 2018. Final results (first step/second step) at week 48 are presented here.

Results: Out of 395 patients screened, 336 were randomized to receive: DT (n:171) or TT (n:165). Demographic characteristic were similar between arms: 94% CDC stage A, 90% males, 23% pVL >100,000 copies/mL. Median (IQR) HIV pVL log: 4.5 (4.1-5.0), Median (IQR) CD4 T-cell/uL: 415 (300-599).

At week 48, 92.7% on TT vs 90.6% on DT achieved pVL<50 copies/mL, difference (95%CI): -2.1% (-7.0; 2.9%). Patients with baseline pVL >100,000 copies/mL showed 90.3% response in TT vs. 86.7% in DT, difference (95%CI): -3.7% (-15.7;8.4%). Per-protocol population analysis: 98.7% were responder in TT vs. 98.1% in DT, difference (95%CI): -0.6% (-2.9;1.7%).

Seven patients had Protocol-Defined virologic failure: 2 at week 24 (1 TT/1 DT) and 5 at week 48 (2 TT/ 3 DT). Mean pVL at week 48 failure: 73.8 copies/mL. Mean CD4+ change from baseline: TT: +238.1 cells/uL, DT: +275.3 cells/mm3 (p:0.4). Fifty-nine grade 2-3 related adverse events (AEs) were reported among 53 patients (TT:33 / DT:20, p:0,04). Most frequent were: rash (TT: 5%; DT: 6%; p: 0.70), diarrhea (TT: 5%; DT: 1%; p: 0.06**), abdominal pain (TT: 5%; DT: 1%; p: 0.03). AEs leading to discontinuation were rare (TT:2, DT: 2). Two possible treatment-related SAEs were reported (both lipase increase G4) in TT arm. Laboratory changes from baseline to week 48 were similar except to lipid profile with higher change in DT arm: total cholesterol (TT: 8%; DT: 20%; p<0.01), LDL-cholesterol (TT: 8%; DT: 19%; p: 0.01), Triglycerides (TT: 38%; DT: 56%; p=0.05).

Conclusions: A generic FDC of DRV/r plus 3TC showed non-inferiority to standard TT with DRV/r plus TDF/3TC at 48 weeks in both ITTe and per-protocol populations. The DT strategy was safe and well tolerated and could be considered as an alternative option for treatment naïve population.

OAB0304

Dolutegravir versus efavirenz-400 as first-line ART in Cameroon: week 192 data of NAMSAL trial

M. Mpoudi-Etame[1], T. Tovar Sanchez[2], P. Omgba Bassega[3], J. Olinga[4], R. Pelloquin[2], M. Foalem[4], C. Njonkep[4], E. Mimbé[4], M. Varloteaux[4], M. Tongo[5], N. Lamare[5], M. Peeters[2], J. Reynes[6,2], E. Delaporte[6,2], S. Koulla-Shiro[4], C. Kouanfack[7,8,4], NAMSAL ANRS 12313 study group

[1]Military Hospital of Yaoundé, Yaoundé, Cameroon, [2]TransVIHMI, University of Montpellier-IRD-INSERM, Montpellier, France, [3]District of the Cité Verte Hospital, Yaoundé, Cameroon, [4]Cameroon ANRS-site, Yaoundé, Cameroon, [5]CREMER, Yaoundé, Cameroon, [6]Montpellier University Hospital Center, Montpellier, France, [7]Faculty of Medicine and Pharmaceutical Sciences University of Dschang, Dschang, Cameroon, [8]Yaoundé Central Hospital, Yaoundé, Cameroon

Background: The NAMSAL main objective was the comparison of two first-line antiretroviral treatments (ARTs) in real-life conditions in low- and middle-income countries (LMIC): dolutegravir 50 mg (DTG) and low-dose of efavirenz (ie 400 mg; EFV400) daily both combined with tenofovir-disoproxil-fumarate [TDF]/lamivudine [3TC]. The 48-week outcomes provided decision-making elements to World Health Organization (WHO) to recommend DTG as first-line ART in 2019. Outcomes were confirmed at 96 weeks. We assessed long-term efficacy and safety of these two regimens.

Methods: NAMSAL was an open-label, multicenter, randomized, phase 3 non inferiority trial conducted in Cameroon over 96-week, extended as post-trial follow-up as a prospective cohort until 192-week. HIV-1 infected ARV-naive adults with HIV-RNA viral load (VL)>1000 copies/mL were randomized and maintained in the base arm (1-DTG:1-EFV). The primary end point was the proportion of participants with a VL of less than 50 copies/mL at week 48; secondary outcomes were assessed with superiority-test.

Results: At week 192, proportions of participants with a VL of less than 50 copies/mL in intention-to-treat (ITT) were 69% (DTG: 214/310) and 62% (EFV400: 187/303) respectively (difference, 7.3%; CI-95%, [-0.20;14.83], p-value=0.057; Figure 1). *Per-protocol* results were 75% (DTG: 172/230) and 66% (EFV400: 178/271) respectively (difference, 9.1%; CI-95%, [1.13;17.07], p-value=0.027).

During the four-year of follow-up, five (DTG: 2; EFV400: 3) new virological failures (WHO-definition) without related resistance mutations and 24 new severe adverse-events (SAE) were observed (DTG: 13, EFV400: 11). Over four years, weight gain was more important on DTG group compared to EFV400 group: Median weight-gain (Women (W): DTG +8.0 Kg, EFV400 +5.0 Kg, p-value=0.010; Men (M): DTG +6.0 Kg, EFV400 +4.0 kg; p-value=0.024); Obesity incidence (W: DTG 17%, EFV400 11%, p-value=0.140; M: DTG 26%, EFV400 4%; p<0.001); Proportion of patients who had a weight-gain of at least 15% compared to their initial weight (W: DTG 43%, EFV400 31%, p-value=0.030; M: DTG 23%, EFV400 25%; p- value= 0.848; Figure2).

Conclusions: DTG-based and low dose EFV-based regimens has durable efficacy and safety for use in treatment-naïve patients with HIV-1. There was significantly more weight gain with the DTG-containing regimen.

OAB0305

Survival in advanced AIDS patients treated with efavirenz or dolutegravir in Brazil: a multicenter, observational study

C. Brites[1], M. Lacerda[2], S. Eduardo[3], M. Bay[4], G. Pinto[5], P. Azevedo[1], I. Luz[1], E. Luz[1], E. M. Netto[1]

[1]Federal University of Bahia, Medicine, Salvador, Brazil, [2]Fundação Instituto de Medicina tropical de Manaus, Infectious Diseases, Manaus, Brazil, [3]Universidade Federal do Rio Grande do Sul, Infectious Diseases, Porto Alegre, Brazil, [4]Universidade Federal do Rio Grande do Norte, Infectious Diseases, Natal, Brazil, [5]Universidade Federal de Santa Catarina, Infectious Diseases, Florianopolis, Brazil

Background: Most of studies on integrase inhibitors efficacy were conducted on healthy patients. There is scarce information on DTG use in late-presenters HIV patients. We compared the effect of ART regimens based on Efavirenz (EFV) or Dolutegravir (DTG) on survival of patients with advanced AIDS.

Methods: We enrolled symptomatic AIDS patients starting therapy with a CD4 count<50 cells/ml in 5 Brazilian cities. We compared patients starting DTG-based ART (2018 to 2020) or EFV-based regimens (2013 to 2016), as controls regarding early mortality, rates of viral suppression at 24 and 48 weeks, changes in CD4 count, incidence of adverse events, and therapy discontinuation.

Results: We included 92 patients per arm mean age 39.4 (DTG) and 37.3 years (EFV), 68 % males, mean baseline CD4 count=23 cells/ml, mean HIV viral load= 5.5 copies/ml $\log_{10}$. Viral suppression rates (<50 copies/ml) were higher in DTG than in EFV group at 24 (67% vs 42%,) and at 48 weeks (65% vs 46%, p<0.01). At 48 weeks median CD4 count was similar for DTG and EFV groups (213 cells/ml vs. 222 cells/ml), but more patients in DTG group presented with CD4 >200 cells/ml (45% vs. 29%, p=0.03). Levels of total cholesterol (189 vs 168 mg/dL), triglycerides (188 vs 129 mg/dL) and VLDL cholesterol(35 vs 26 mg/dL) were higher in EFV than in DTG group (p<0.01 for comparisons). Creatinine levels were higher in DTG (0.97 mg/dL) than in EFV (0.86 mg/dL, p=0.02) group. Survival was higher in DTG group, mostly driven by treatment changes (1% vs. 17%, p<0.0001) or loss to follow up (11% vs. 15%).

Conclusions: Advanced AIDS patients treated with DTG had a higher proportion of viral suppression/survival rate/ immune restoration, less lipids changes, and lower discontinuation rates after 48 weeks than patients treated com EFV. DTG is confirmed as a preferential option to treat advanced AIDS patients.

OAB04 HIV and other conditions

OAB0402

Efficacy and safety results in participants co-infected with HIV from TB-PRACTECAL Clinical Trial

I. Motta[1], C. Berry[1], E. Kazounis[1], M. Dodd[2], K. Fielding[2], B.-T. Nyang'wa[3], TB-PRACTECAL team

[1]Medecins Sans Frontieres UK, London, United Kingdom, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]Medecins Sans Frontieres Holland, Amsterdam, Netherlands, the

Background: Globally, TB/HIV coinfection accounts for 477461 notified cases and 456000 cases of rifampicin-resistant tuberculosis (RR-TB) are estimated. TB-PRACTECAL clinical trial (NCT02589782) evaluated the safety and efficacy of three 24-week all-oral regimens for the treatment of pulmonary RR-TB in adults and adolescents above 15 years from Uzbekistan, Belarus and South Africa. Participants were randomised to receive one of three investigational regimens or the control. BPaL arm consisted of bedaquiline, pretomanid and linezolid. Clofazimine was added in BPaLC or moxifloxacin in BPaLM arm.

The primary efficacy outcome was the percentage of patients with a composite unfavourable outcome (treatment failure, death, treatment discontinuation, recurrence, loss to follow-up) at 72 weeks post-randomization. We present the efficacy and safety of regimens in the HIV coinfected patients.

Methods: All patients were offered a HIV test and were eligible irrespective of CD4 count. Antiretroviral treatment was modified to minimise drug-drug interactions and co-trimoxazole prophylaxis offered. Pre-specified analyses were conducted for primary efficacy and safety outcomes at 72 weeks post-randomization for HIV status in mITT and ITT populations, respectively.

HIV status	Unfavourable outcome Control n/N (%)	Unfavourable outcome Experimental Arm n/N (%)	Risk difference (one-sided 98.3% CI)	Interaction p-value	Grade ≥3 and/or SAEs Control n/N (%)	Grade ≥3 and/or SAEs Experimental Arm n/N (%)	Risk difference (one-sided 98.3% CI)	Interaction p-value
BPaLM versus control								
Negative Positive	26/51 (51.0) 6/15 (40.0)	3/48 (6.3) 4/14 (28.6)	-44.7% (-∞to -28.1%) -11.4% (-∞to 25.6%)	p = 0.08	33/56 (58.9) 10/17 (58.8)	11/55 (20.0) 3/17 (17.6)	-38.9% (-∞to -20.9%) -41.2% (-∞to -9.2)	p = 0.89
BPaLC versus control								
Negative Positive	26/51 (51.0) 6/15 (40.0)	7/50 (14.0) 5/14 (35.7)	-37.0% (-∞ to -18.9%) -4.3% (-∞to 33.9%)	p = 0.10	33/56 (58.9) 10/17 (58.8)	17/57 (29.8) 6/15 (40.0)	-29.1% (-∞to -10.1%) -18.8% (-∞to 18.0%)	p = 0.60
BPaL versus control								
Negative Positive	26/51 (51.0) 6/15 (40.0)	10/46 (21.7) 4/14 (28.6)	-29.2% (-∞to -9.6%) -11.4% (-∞to 25.6%)	p = 0.37	33/56 (58.9) 10/17 (58.8)	11/51 (21.6) 4/18 (22.2)	-37.4% (-∞to -18.8%) -36.6% (-∞to -3.9%)	p = 0.97

Results: 552 patients were enrolled, of whom 153 were HIV positive. Median CD4 count at baseline was 330, 297, 326 and 250 cells/µL in BPaLM, BPaLC , BPaL and control arm, respectively. In mITT population 28.6%, 35.7%, 28.6% and 40% of HIV-positive patients experienced unfavourable outcomes in BPaLM, BPaLC, BPaL and control arm, respectively. The small sample size and P-values don't provide strong evidence of interaction. In ITT population grade 3 or above and/or serious adverse events (SAEs) were no more frequent in HIV-positive versus negative patients across arms.

Conclusions: Current TB-PRACTECAL data supports the use of 24-week regimens irrespective of HIV status. A trend towards the shorter regimens being more efficacious in HIV-negative patients was observed. However, this trend was not seen in the safety outcomes for the BPaL and BPaLM arms. The trial is accruing more data and will update at a later date.

OAB0403

Impact of a community-wide HIV test and treat intervention on population-level tuberculosis transmission in rural Uganda

C. Marquez[1], M. Atukunda[2], J. Nugent[3], E. Charlebois[1], G. Chamie[1], F. Mwangwa[2], E. Ssemmondo[2], J. Kironde[2], J. Kabami[2], A. Owaraganise[2], E. Kakande[2], R. Abbott[1], B. Ssekaynzi[2], J. Ayieko[4], T. Ruel[1], D. Kwariisima[2], M. Kamya[2,5], M. Petersen[6], D. Havlir[1], L. Balzer[3]

[1]University of California, San Francisco, San Francisco, United States, [2]Infectious Diseases Research Collaboration, Kampala, Uganda, [3]University of Massachusetts- Amherst, Amherst, United States, [4]Kenya Medical Research Institute, Nairobi, Kenya, [5]Makerere University School of Medicine, Kampala, Uganda, [6]University of California, Berkeley, Berkeley, United States

Background: HIV and TB are linked epidemics. We tested whether a community-wide universal HIV testing and treat strategy would reduce population-level TB transmission in the SEARCH trial.

Methods: SEARCH was 32-community cluster-randomized trial conducted in rural Uganda and Kenya from 2013-2017 (NCT:01864603). Intervention communities received population-level HIV test and treat; control communities received enhanced standard-of-care. We measured incident TB infection in a nested cohort of children and adults ages (≥5 years) in in 4 intervention and 5 control communities (8 and 10 parishes, respectively) in Eastern Uganda. All people in the cohort had a negative tuberculin skin test (TST) at baseline (induration <10mm or <5 mm among PWH); the cohort was enriched with PWH. Incident TB infection (primary outcome) was defined as TST conversion from negative to positive one year after baseline TST (2015-2017). Incident TB was compared between arms, adjusted for sampling and participation, and parish-level drivers of incident TB infection and accounting for clustering using Targeted Maximum Likelihood Estimation.

Results: The TST negative cohort was comprised of 3,242 persons in the intervention and 4,125 persons in the control arms; 2,922 (39.7%) were children (5-11 years) and 4,445 (60.3%) youth and adults (ages 12+ years). Within the cohort 53.3% were women, and PWH comprised 16.6% of adults, 1.1% of children.

One-year cumulative incidence of TB infections was 16% in the intervention and 22% in the control; the population-level intervention reduced risk of incident TB infection by 27% (aRR of 0.73; 95% CI: 0.58-0.93, one-sided p=0.007). The effect was largest among children aged 5-11 years (Figure 1).

Conclusions: A universal HIV test and treat intervention reduced incident TB infection, a marker of population-level TB transmission. Investments in community-level HIV interventions have direct impacts on HIV and broader population-level benefits, including reductions in TB.

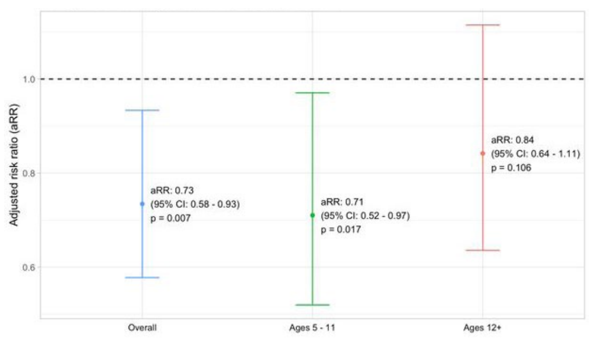

Figure 1. Relative risk of incident TB infection in the intervention vs. control arm of the SEARCH trial, overall and stratified by age.

Incident TB infection defined as tuberculin skin test conversion from negative at baseline to positive one year later. One-sided p-values to test the null hypothesis that the SEARCH intervention did not reduce TB.

OAB0404

Are people living with HIV at higher risk of severe and fatal COVID-19?

S. Bertagnolio[1], R. Silva[1], S. Nagarajan[1], S.S. Thwin[1], W. Jassat[2], R. Fowler[3], R. Haniffa[4], L. Reveiz[5], N. Ford[1], M. Doherty[1], J. Diaz[1]

[1]World Health Organization, Geneve, Switzerland, [2]National Institute for Communicable Diseases, Johannesburg, South Africa, [3]Sunnibrook Health Science Centre, Toronto, Canada, [4]University of Oxford, Oxford, United Kingdom, [5]Pan American Health Organization, Washington, United States

Background: WHO has established a Global Clinical Platform aiming to assess clinical features and risk factors for severe/fatal COVID-19 among hospitalized individuals.

Methods: Between January 2020-June 2021 anonymized individual-level clinical data from 338,566 patients hospitalized in 38 countries were reported to WHO using a standardized case report form. Descriptive and regression analyses assessed whether HIV status was a risk factor for severity at admission and in-hospital mortality among people hospitalized for COVID-19.

Results: Of 197,479 patients reporting HIV status, 8.6% (16,955) were living with HIV (PLHIV), and 94.6% (16,283) were from Africa; 37.1% were male, mean age was 45.5 years, 38.3% were admitted with severe or critical illness and 24.7% died in-hospital. 91.5% of 10,166 PLHIV were on antiretroviral therapy (ART). Compared to those without HIV, PLHIV had 15% increased odds of severe/critical presentation (aOR=1.15, 95%CI 1.10–1.20) and were 38% more likely to die in-hospital (aHR=1.38, 95%CI 1.34-1.41). Among PLHIV, male sex, age 45-75 years, and having chronic cardiac disease or hypertension increased the odds of severe/critical COVID-19. Male sex, age>18 years, diabetes, hypertension, malignancy, TB, or chronic kidney disease increased the risk of in-hospital mortality. In an exploratory subgroup analysis in a subset of 9097 hospitalized individuals reporting ART information, PLHIV on ART were 17% less likely to die (p<0.048) and 40% less likely to be admitted with severe disease than those not on ART (p<0.001). However, both PLHIV on ART (aHR=1.48, 95%CI 1.39-1.57) and those not on ART (aHR=1.79, 95%CI 1.48-2.16) had a higher risk of death relative to HIV negative people.

A similar exploratory analyses on a sample of 5793 hospitalized individuals reporting viral load (VL) information showed that both people with VL<1000 c/ml (aHR=1.77, 95% CI 1.57-1.99) and those with VL>1000 c/ml (aHR=1.45, 95% CI 1.32-1.58) have an increased risk of death compared to HIV negative individuals.

Conclusions: In this sample of hospitalized people contributing data to the WHO Global Clinical Platform, HIV was an independent risk factor for both severe/critical COVID-19 at admission and in-hospital mortality. These findings have informed the WHO COVID-19 Clinical Management Guidelines and SAGE recommendations around COVID-19 vaccination prioritization.

OAB0405

HIV/HBV coinfection in pregnancy and response to antiretroviral therapy

D. Bhattacharya[1], C. Tierney[2], A. Chang[2], D. Moodley[3], V. Govender[3], T. Vhembo[4], N. Mohtashemi[1], H. Ship[5], D. Dula[6], K. George[7], N. Chakhtoura[8], F.K. Matovu[9], M.G. Fowler[10], M. Peters[11], J.S. Currier[1]

[1]University of California, Los Angeles David Geffen School of Medicine, Los Angeles, United States, [2]Harvard TH Chan School of Public Health, Boston, United States, [3]University of KwaZulu-Natal, Durban, South Africa, [4]Uz-UCSF Collaborative Research Programme, Harare, Zimbabwe, [5]University of Miami Miller School of Medicine, Miami, United States, [6]Johns Hopkins Research Project, Blantyre, Malawi, [7]FHI 360, Durham, United States, [8]National Institutes of Health, Bethesda, United States, [9]Makerere University–Johns Hopkins University Research Collaboration, Kampala, Uganda, [10]The Johns Hopkins University, Baltimore, United States, [11]University of California San Francisco, San Francisco, United States

Background: Hepatitis B virus (HBV) affects 3-12% of pregnant women with HIV in Africa; however, the impact of HBV infection on HIV outcomes in pregnant women is unclear. We evaluated the association of HIV/HBV coinfection with HIV virologic response, CD4 cell count, and hepatotoxicity in pregnant women in secondary analyses of the IMPAACT PROMISE study.

Methods: The PROMISE study enrolled pregnant women living with HIV who were ART-naive and had not met criteria for initiating ART. Women at ≥14 weeks gestation were randomized to either: Arm A: ZDV alone, Arm B: 3TC+ZDV+LPV/r, or Arm C: FTC+TDF+LPV/r. HBV was defined as HBsAg(+). We compared women with HIV alone to HIV/HBV with outcomes of HIV viral load, CD4, and ALT elevation at delivery and through 74 weeks postpartum using Fisher's exact, t-tests. Time to ALT used the log-rank test. Analyses also compared women with HIV alone to HIV/HBV who were also HB**e**Ag(+).

Results: Among 3537 women analyzed, 138 had HBV. Median age, CD4, and HIV VL were 27 years, 505 cells/mm^3 and 4.0 Log_{10} copies/mL, respectively. Thirty-four women (26%) with HBV were HB**e**Ag(+). Median ALT at baseline was 15 and 12 IU/ml amongst HBV-infected and uninfected.

There was no statistically significant difference by HBV/HIV co-infection status in HIV VL suppression or CD4 at delivery, at one year postpartum (PP) (primary) or 74 weeks PP. Those with HIV/HBV had more frequent grade 3/4 ALT events (8% vs 3%) overall. Numerically more grade 3/4 ALT events occurred in HIV/HBV coinfected women in Arms B and C (10.4%, 10.4%) vs Arm A (2.4%) but this did not reach statistical significance.

Women with HIV/HBV also had earlier first grade 3/4 ALT elevation (hazard ratio (HR) 3.08, 95% CI: 1.56, 5.50). Compared to those with HIV alone, HBV infected women with HB**e**Ag(+) had earlier Grade 3/4 ALT elevation (HR 6.93, 95% CI: 2.70, 14.51).

Conclusions: In pregnant women with HIV initiating ART, HIV RNA suppression and CD4 cell response did not differ between HIV and HIV/HBV coinfection. However, grade 3 or 4 ALT elevations occurred at a higher rate in those with HBV, with HBeAg+ status conferring increased risk.

OAC01 Real-time HIV surveillance to achieve Fast-Track milestones

OAC0102

Progress in scaling up HIV recent infection surveillance in 13 countries: October 1, 2019 - June 30, 2021

Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [5]Centers for Disease Prevention and Control, Mbabane, Eswatini, [6]Centers for Disease Prevention and Control, Addis Ababa, Ethiopia, [7]Centers for Disease Control and Prevention, Guatemala City, Guatemala, [8]Centers for Disease Control and Prevention, Lilongwe, Malawi, [9]Centers for Disease Control and Prevention, Windhoek, Namibia, [10]Centers for Disease Control and Prevention, Abuja, Nigeria, [11]Centers for Disease Control and Prevention, Kigali, Rwanda, [12]Centers for Disease Control and Prevention, Bangkok, Thailand, [13]Centers for Disease Control and Prevention, Kampala, Guatemala, [14]Centers for Disease Control and Prevention, Hanoi, Viet Nam, [15]Centers for Disease Control and Prevention, Lusaka, Zambia, [16]Centers for Disease Control and Prevention, Harare, Zimbabwe, [17]Office of the U.S. Global AIDS Coordinator and Health Diplomacy, United States Department of State, Washington, D.C., United States

Background: In 2018, countries supported by the United States President's Emergency Plan for AIDS Relief (PEPFAR) began implementing recent HIV infection surveillance among newly diagnosed people living with HIV (PLHIV) to provide signals of ongoing HIV transmission. Recent infection surveillance uses results from rapid tests for recent infection (RTRIs) with viral load results to improve accuracy as part of a recent infection testing algorithm (RITA). We assessed global progress in recent infection surveillance in PEPFAR-supported countries.

Methods: We collected recency data for adults ≥15 years from October 1, 2019–June 30, 2021 and pooled results from 13 countries (Eswatini, Ethiopia, Guatemala, Malawi, Namibia, Nicaragua, Nigeria, Rwanda, Thailand, Uganda, Vietnam, Zambia, Zimbabwe). We described quarterly trends in RTRI site coverage (% of sites reporting ≥1 RTRI) and RTRI testing coverage (% of newly diagnosed PLHIV who had an RTRI). In a subset of seven countries (Eswatini, Nigeria, Rwanda, Thailand, Uganda, Vietnam, Zambia), we described trends in RITA site and testing coverage (% of sites and PLHIV reporting RITA results) for the October 1, 2019–June 30, 2021 study period.

Results: Among the 13 countries, RTRI site coverage increased from 10.3% (733/7,107) to 21.5% (1,900/8,818) during the study period, and RTRI testing coverage increased from 9.0% (13,864/153,268) to 18.0% (41,688/231,410).

During April 1–June 30, 2020, a quarter within the study period coinciding with the COVID-19 epidemic, RTRI site and testing coverage decreased 9.6% (22,437/234,164) to 3.2% (85,791/183,085). For the subset of seven countries, RITA site coverage decreased from 71.0% (88/124) to 48.1% (276/574) during the study period, and RITA testing coverage decreased from 70.2% (290/413) to 58.7% (1,651/2,814).

Conclusions: For the 13 countries, RTRI site and testing coverage increased during the study period but remained low. RTRI coverage decreased temporarily April 1–June 30, 2020. For the subset of seven countries, RITA site and testing coverage decreased during the study period.

These decreases may be due to COVID-19 mitigation efforts, disruptions in HIV and viral load testing, and PEPFAR guidance to temporarily pause recent infection testing. Expanding access to recent infection testing can provide data for public health action to prevent new HIV infections.

OAC0103

Use of a robust health information system to improve accuracy of recent HIV infection testing in Bangkok, Thailand, 2020-2021

S. Aungkulanon[1], C. Kittinunvorakoon[1], T. Tasaneeyapan[1], S. Tanpradech[1], S. Nookhai[1], N. Pattarapayoon[2], P. Mookleemas[2], A. Vittangkrun[3], P. Chaiphosri[4], T. Naiwatanakul[1], S. Northbrook[1]

[1]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Nonthaburi, Thailand, [2]Thailand Ministry of Public Health, Division of AIDS and STIs, Department of Disease Control, Nonthaburi, Thailand, [3]Bangkok Metropolitan Administration (BMA), Department of Medical Services, Bangkok, Thailand, [4]Bangkok Metropolitan Administration (BMA), Department of Health, Bangkok, Thailand

Background: Based on the Asia Epidemic Model, Bangkok has the highest number of estimated new HIV infections in Thailand. We integrated HIV recent infection testing into routine HIV testing services to monitor recent infection trends and accelerate efforts to ending AIDS in Bangkok.

Methods: HIV recency testing was integrated in 16 facilities in Bangkok. Blood from consenting newly diagnosed adults with HIV (PLHIV) collected during October 2020–November 2021 was tested with a rapid test for recent infection (RTRI). Because PLHIV who have suppressed viral load (VL) can produce false recent results, we tested RTRI-recent specimens with VL (recent infection testing algorithm [RITA]); specimens with VL≥1,000 copies/ml were defined as RITA-recent, <1,000 copies/ml as RITA-long term (LT). Cross-checking clinical history data with the national AIDS database (NAD) and electronic medical records was conducted for all RTRI-recent cases to enhance the validity and accuracy of results. Logistic regression was used to identify associations between recent infection and demographic variables (sex, age, population).

Demographic		% RITA recent infection (n/total)	OR	p-value
Age	15-19 years	16% (7/44)	2.5	0.04
	20-29 years	8% (23/302)	1.1	0.75
	≥30 years	7% (24/345)	1	Ref
Sex	Female	9% (14/164)	1	Ref
	Male	8% (40/532)	0.9	0.67
Population group	General	6% (23/356)	1	Ref
	MSM	10% (27/267)	1.6	0.10
	Other	4% (4/73)	0.8	0.75

Results: 694/1,291 (53.8%) newly diagnosed PLHIV provided consent and were tested for recent infection: 59 (8.5%) tested RTRI-recent and, after VL testing, 54 (7.8%) tested RITA-recent and 5 tested RITA-LT. After cross-checking with NAD, 4/5 RITA-LT cases were among 21-25 year old men who had a history of pre-exposure prophylaxis, antiretroviral treatment (ART) <28 days at the time of RTRI testing or no ART history, and no previous HIV diagnosis, suggesting potential misclassification. Young clients aged 15-19 were more likely to test RITA-recent than other age groups (OR=2.5, p<.05).

Conclusions: While 15-19 year-olds showed a high proportion of RITA positives, recent HIV infections were diagnosed in all age groups, sexes and populations, warranting continued surveillance of HIV-1 recent infections in Bangkok. Cross-checking the clinical history with other records through a robust national health information system can be used to improve the accuracy of tests for recent infection.

OAC0104

A rapid, integrated method to monitor HIV viral load, drug resistance, and transmission patterns from finger-prick blood samples

S.E. Chaudron[1], L. Zhao[2], G. Macinthyre-Crockett[1], L. Thompson[2], I. Baudi[1], M. Limbada[3], S. Floyd[4], B. Kosloff[3,5], K. Shanaube[3], S. Fidler[6], R. Hayes[4], H. Ayles[3,5], J. Herbeck[7], C. Fraser[2,1], D. Bonsall[2,1], The PANGEA Consortium, The AMPHEUS research group

[1]Wellcome Centre for Human Genetics, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom, [2]Big Data Institute, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom, [3]Zambart House, School of Medicine, University of Zambia, Lusaka, Zambia, [4]Department of Infectious Disease Epidemiology, London School of Hygiene and Tropical Medicine, London, United Kingdom, [5]Department of Clinical Research, London School of Hygiene and Tropical Medicine, London, United Kingdom, [6]Imperial College, United Kingdom and Imperial College NIHR BRC, London, United Kingdom, [7]Department of Global Health, School of Public Health, University of Washington, Seattle, United States

Background: By applying sequencing and phylogenetics to tens-of-thousands of plasma samples from various cohorts of people living with HIV, we have characterised the dominant sources and flows of HIV transmission, tracked changing patterns of drug resistance, and discovered a highly infectious HIV lineage with faster disease progression. As global incidence of HIV/AIDS declines, we need broader individual access to viral load monitoring and more-efficient molecular surveillance to track population-level changes in drug resistance and transmission.

Our findings and modelled projections incentivised development of an integrated method that monitors HIV viral load, drug resistance and co-infections, while producing anonymised HIV-transmission data to inform adaptive public health strategies.

Methods: In this study, venepuncture-derived plasma from 61 epidemiologically-characterised transmission pairs from The Partners in Prevention Transmission Study, and plasma collected from HPTN-071 (PopART) by ve-

nepuncture and 'finger-prick' sampling, were deep-sequenced using bait-capture (veSEQ). Sample processing was optimised at key steps for long-read PacBio sequencing. Transmission pairs were identified using Phyloscanner software, and drug resistance was predicted using the Stanford algorithm (HIVdb). Viral loads measurements were validated against clinically-accredited assays.

Results: Our optimised protocol generated whole-genome sequences and drug resistance predictions from 200 µl of finger-prick derived plasma, with viral loads greater than 500 copies per ml. Viral loads were obtained after 5 hours of processing from the same 'finger-prick' specimens and the overall cost of the combined assay was kept below that of commercially available viral load tests. Whole hepatitis B genomes were sequenced concurrently by the same method in a subset of samples. PacBio sequencing correctly identified the direction of transmission in 85% (52/61) of pairs compared to 36% (22/61) using Illumina sequencing. The longer reads generated by PacBio (250bp-2.5kb; 95% CI) reduced the likelihood of misreporting transmission direction.

Conclusions: Our combined sequence-based assay accurately measures HIV VL and characterises drug resistance from 'finger-prick' derived blood and generates anonymised, high-resolution, molecular-epidemiological data for public health. This low-cost combined approach could be transformative to global health management of HIV and related blood born infections in resource-limited settings.

OAC0105

Phylogenetic surveillance of HIV epidemic control from 2014 to 2020 among MSM and heterosexual groups in Quebec

B. Brenner[1], R.-I. Ibanescu[1], M. Oliveira[1], J.-P. Routy[2], R. Thomas[3], M. Roger[4], Montreal Primary HIV Infection Study Group

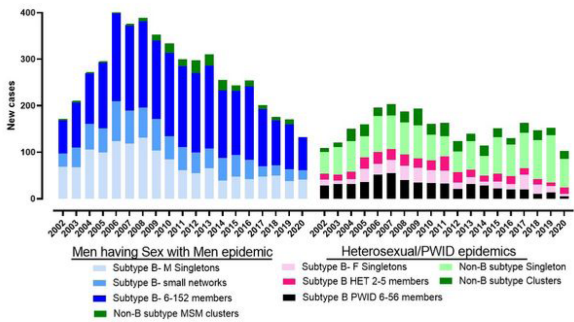
[1]Lady Davis Institute, McGill AIDS Centre, Montreal, Canada, [2]McGill University Health Centre, Montreal, Canada, [3]Clinique Médicale l'Actuel, Montreal, Canada, [4]University of Montreal, Montreal, Canada

Background: The UNAIDS 90-90-90 initiative has led to 38% declines in heterosexual (HET) epidemics in Africa since 2014. In 2019, The Ending the HIV Epidemic for America added phylogenetics as fourth pillar for epidemic control by 2030. Here, phylogenetics was combined with available epidemiological data to track drivers of HIV-1 spread among Men having Sex with Men (MSM), People Who Inject Drugs (PWID) and recent migrants.

Methods: Phylogenetic analyses, using MEGA-10 and Microbe-TRACE methodologies, ascertained the linkage of sequences obtained from newly-diagnosed persons (2002-2020). Infections were stratified into groups according to HIV-1 subtype, sex, and cluster size, including i) the subtype B MSM epidemic (male singletons/male-male clusters); ii) the subtype B PWID epidemic (mixed gender large clusters); iii) subtype B HET infections originating from the Caribbean and Americas (female singletons, mixed gender clusters) and iv) non-B subtype epidemics originating outside Canada.

Results: Amongst MSM, there were 56%, 43% and 27% declines in singleton, small (1-5 members) and large cluster networks (6-152 members) from 2014-2020 compared to 2007-2013. Epidemic control among MSM was thwarted by 35 super-spreader, large cluster micro-epidemics, adding 8-96 infections/cluster from 2014-2020. Notably, 18 clusters gained 4-12 infections during the COVID 19 era (post-2019). The subtype B epidemic among PWID is controlled showing 54% declines in new infections from 2014-2020 compared to 2007-2013.

Recent migration has led to the steady growth in the subtype B and non-B subtype HET epidemics. To date, 65% and 20% of HET epidemics were singletons or small clusters (2-4 members). PHI cohort data revealed that 28% of infected MSM born outside Canada acquired large cluster provincial variants. Of note, isolated non-B subtype HET outbreaks occurred in Quebec City, Richelieu, and Northern Quebec.



Conclusions: Declines in HIV-1 infections are promising. Public health measures must address emerging needs of vulnerable migrants and younger MSM populations.

Collision of HIV and non-communicable disease epidemics: mapping chronic health needs among a HIV hyperendemic community in rural South Africa

D. Cuadros[1], U. Singh[2], S. Olivier[2], Y. Moosa[2], A. Edwards[3], H.-Y. Kim[4], M. Siedner[5], E. Wong[2], F. Tanser[3]

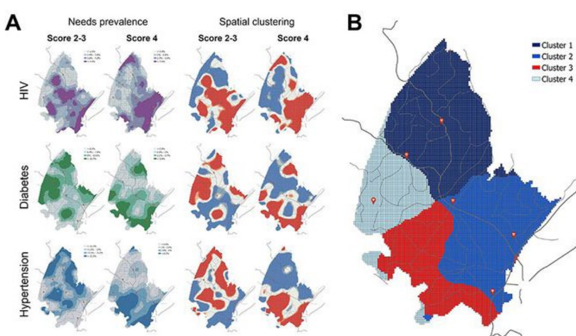
[1]University of Cincinnati, Cincinnati, United States, [2]Africa Health Research Institute, Durban, South Africa, [3]University of Lincoln, Lincoln, United Kingdom, [4]New York University Grossman School of Medicine, New York, United States, [5]Massachusetts General Hospital, Boston, United States

Background: With improvements in survival among people living with HIV (PLHIV), the co-occurrence of HIV and non-communicable diseases is emerging as a public health priority. Using a comprehensive population-based disease survey in rural South Africa (SA), we aimed to characterize the spatial structure of multimorbidity and unmet health system needs for HIV, diabetes, and hypertension.

Methods: Data for HIV, diabetes and hypertension were collected as part of the Vukuzazi study, a population-based health assessment conducted in uMkhanyakude district in KwaZulu-Natal, SA. Participants were categorized by a novel health needs scale including: healthy/absence of disease (needs score 0), diagnosed and well controlled (1), diagnosed and sub-optimally controlled (2), diagnosed and not engaged in care (3) and undiagnosed and uncontrolled (4). Scores 2-4 indicated individuals experiencing unmet needs. We explored the geospatial structure of unmet needs using different multivariate spatial clustering methods.

Results: The analytic sample included 18,041 individuals. HIV had a similar spatial structure for those with a combined needs score 2-3 (diagnosed but uncontrolled) and 4 (undiagnosed and uncontrolled), with most PLHV with unmet needs been clustered (red areas in maps Figure A) in the southern urban/peri-urban area.

Multivariate KMeans clustering analysis identified a significant overlap of all three diseases for individuals with undiagnosed and uncontrolled diseases (unmet needs score 4) in the southern part of the surveillance area (Cluster 3 in red in map Figure B).



Figures A & B

Conclusions: Areas where most PLHIV are experiencing the highest needs with undiagnosed and uncontrolled disease are also areas suffering the highest burden of unmet needs for other diseases like diabetes and hypertension in this rural community in SA. The identification and prioritization of high needs areas where health systems needs for both HIV and non-communicable diseases collide provides a rationale for policy and implementation strategies to improve health outcomes with optimal efficiency and impact.

OAC0203

The impact of COVID-19 non-pharmaceutical interventions on incidence and case-fatality ratios of sexually transmitted diseases in China

X. Wu[1], X. Zhou[1], Y. Chen[1], K. Zhai[1], G. Luo[1], B. Liang[1], C. Yang[1], H. Zou[1,2]

[1]School of Public Health (Shenzhen), Sun Yat-sen University, Shenzhen, China, [2]Kirby Institute, University of New South Wales, Sydney, Australia

Background: China implemented nationwide non-pharmaceutical interventions (NPIs) to contain COVID-19 at the early stage. We aimed to elucidate the impact of COVID-19 NPIs on incidence and case-fatality ratios of sexually transmitted diseases (STDs) in China.

Methods: Cases and deaths data for STDs by month were extracted from the notifiable disease reporting database of the official website of the National Health Commission of China between January 2015 and August 2021. We used descriptive statistics to summarize data on case and death of HIV, gonorrhea, syphilis, hepatitis B, and hepatitis C, and calculated incidence and case-fatality ratios before and after the implementation of massive NPIs (January 2020).

We used Poisson segmented regression models to estimate the immediate and long-term impacts of NPIs on these outcomes in January 2020 and August 2021, respectively.

Results: A total of 14,071,484 cases and 118,399 deaths of the five STDs were reported from January 2015 to August 2021, with an incidence of 149.10/100,000 before NPIs and 150.72/100,000 after, and a case-fatality ratio of 8.21/1000 before NPIs and 9.02/1000 after. In the Poisson model, accounting for seasonal fluctuations and long-term trends, there was a 19.2% (IRR 0.808, 95% CI 0.714-0.914) decline in overall incidence and a 20.9% (0.791, 0.680-0.921) decline in overall deaths of the five STDs in January 2020.

There was no significant change in incidence or case-fatality ratios of HIV in January 2020, but a 22.1% (0.779, 0.647-0.938) decline in deaths. Deaths and case-fatality ratios for both gonorrhea and syphilis showed an increase of 152.1%-897.6% compared with a small counterfactual in January 2020. Incidence of hepatitis B and C showed significant decreases in January 2020, but the changes in death and case-fatality ratio were not statis-

tically significant. By August 2021, the incidence, deaths, and case-fatality ratios for each of the five STDs returned to or were below expected levels.

Conclusions: During the COVID-19 pandemic, the implementation of massive NPIs had a positive impact on the overall incidence and deaths of STDs in China. However, under the current strategy of holistic NPIs in China, one should be alert to the increase in death and case-fatality ratio from gonorrhea and syphilis.

OAC0204

The effect of the COVID-19 pandemic on access to HIV Treatment and vertical transmission: results from the Canadian Perinatal HIV Surveillance Program

J. Singer[1], L. Sauve[2], A. Bitnun[3], F. Kakkar[4], J. Brophy[5], I. Boucoiran[4], D. Money[2], T. Lee[6], J. Comeau[7], A. Tse-Chang[8], W. Vaudry[8], Canadian Perinatal HIV Surveillance Program

[1]University of British Columbia, School of Population and Public Health, Vancouver, Canada, [2]University of British Columbia, Women's Hospital and Health Centre of British Columbia, Vancouver, Canada, [3]University of Toronto, Hospital for Sick Children, Toronto, Canada, [4]Université de Montréal, CHU Ste-Justine, Montreal, Canada, [5]University of Ottawa, Children's Hospital of Eastern Ontario, Ottawa, Canada, [6]Canadian HIV Trials Network, Vancouver, Canada, [7]Dalhousie University, IWK Health Centre, Halifax, Canada, [8]University of Alberta, Department of Pediatrics, Edmonton, Canada

Background: We describe demographics, antiretroviral treatment during pregnancy, and vertical transmission rates in the Canadian perinatal HIV surveillance cohort of births to women living with HIV (WLWH) and assess the effect of the COVID-19 pandemic on access to optimal therapy and perinatal transmission.

Methods: 22 Canadian pediatric and HIV centres update data including demographics, antiretroviral treatment during pregnancy, and perinatal transmission, on births in WLWH yearly each January. The results reported in this abstract reflect births up to the end of 2020 but will be updated to include 2021 results.

Results: The number of HIV exposed infants per year has increased over time in Canada, with 250 infants born in 2020; 32% came from Ontario, 24% from Quebec, 17% from Alberta, 14% from Saskatchewan, 7% from British Columbia and 4% from Manitoba; 60% were Black, 21% were Indigenous, and 13% were white. Overall, 63% of this population acquired HIV heterosexually, 13% through injection drug use and 4.4% perinatally. The proportion and number of pregnant women sub-optimally treated in May-December 2020 was 7.7% (12/155) compared to 6.6% (86/1297) in the period from 2015-2019.The corresponding transmission rates were 3.2% (5/155) versus 1.3% (17/1297), respectively. Among those who had acquired HIV through IDU, the sub-optimal treatment rate was 26.1% during the COVID-19 pandemic, versus 13.6% in the pre-COVID-19 period.

Conclusions: The perinatal transmission rate increased from 1.3% (2015-2019) to 3.2% during the pandemic, the highest reported rate in over 5 years. Pregnant women who acquired HIV through IDU may have been at highest risk of vertical transmission because of sub-optimal treatment.

These data signal disturbing problems in accessing care for addictions, prenatal care and HIV-specific care in the first waves of the pandemic. Additional attention to at-risk populations is needed as the pandemic continues to affect Canada.

OAC0205

Impact of COVID-19 on TB case findings and TB/HIV co-infection rates at a Princess Marina Hospital, Gaborone, Botswana, during the first year of COVID-19

K. Fane[1], B. Kgwaadira[1], B. Nkomo[2], T. Molefi[3], O. Fane[4]

[1]Botswana University of Maryland School of Medicine (Bummhi), TB/HIV Program, Gaborone, Botswana, [2]Ministry of Health and Wellness, HIV/AIDS Department, Gaborone, Botswana, [3]Ministry of Health and Wellness, Botswana National TB Program, Gaborone, Botswana, [4]Sir Ketumile Masire Teaching Hospital, Nursing Department, Gaborone, Botswana

Background: Tuberculous incidence in HIV infected patients has steadily decreased in Botswana from 327/100,000 in 2010 to 115/100,000 in 2020. TB/HIV co-infection rates also declined from 65% to 48%.

However, it remains unclear how the COVID-19 pandemic affected this progress following two countrywide lockdowns in 2020.

We sought to determine the impact of COVID-19 on TB/HIV case finding and TB/HIV co-infection rates through retrospective analysis of 2019 and 2020 TB and TB/HIV indicators at Princess Marina Hospital (PMH) in Gaborone, the largest urban tertiary hospital in Botswana.

Methods: TB Case finding and TB/HIV co-infection rates from 2019 and 2020, were extracted from individual patient records in electronic Integrated Patient Management System (IPMS), TB/HIV laboratory registers and admission registers.

Data was disaggregated by gender, age, use of (Anti-Retroviral Therapy) ART and (Cotrimoxazole Prophylaxis Therapy) CPT at the time of TB diagnosis.

Results: During 2020 - the first year of COVID-19 - the number of TB diagnostic tests increased.

Overall the number of TB cases decreased from 228 (65.6% TB positivity) to 79 (21.1% TB positivity). The percentage of children (≤14 years) identified with TB were similar for both years.

TB/HIV co-infection rates increased from 64% to 77.2%. ART treatment for TB/HIV patients increased from 93.8% to 100% and 100% of TB/HIV patients received CPT in both years.

	2019			2020		
Total TB tests completed:	347			373		
TB cases confirmed	228 (65.6%)			79 (21.1%)		
	97 female (42.5%)	131 Male (57.5%)		27 female (34%)	52 Male (66%)	
TB Cases	≤14 years	≥15 years		≤14 years	≥15 years	
	36 (15.8%)	192 (84.2%)		13 (16.5%)	66 (83.5%)	
HIV Status	POS	NEG	UN-KNOWN	POS	NEG	UN-KNOWN
	146 (64 %) Female: 19.8%	79 (34.6%)	3 (1.3%)	61 (77.2%) Female: 24.6%	18 (22.8%)	0(%)
TBHIV on ART	137 (93.8%)			61 (100%)		

Conclusions: During 2020, the number of TB investigations by microscopy and GeneXpert at the PMH modestly increased. However, TB/HIV co-infection rates increased by 13.3%. While it appears that the COVID-19 pandemic had a significant effect on the number of TB cases identified - likely due to social distancing and the use of masks - further surveillance and analysis of TB/HIV indicators at PMH and across the country for 2021 is required.

OAC03 Optimizing the HIV care continuum

OAC0302

The 95-95-95 UNAIDS targets mask the underlying number of people with transmissible viral load: case study of England

A. Brown[1], V. Martin[1], N. Connor[1], R. Harris[1], A. Presanis[2], D. De Angelis[2], V. Delpech[1]

[1]UK Health Security Agency, London, United Kingdom, [2]MRC Modelling and Statistics Unit, Cambridge, United Kingdom

Background: In 2020, England met the 95-95-95 UNAIDS targets with 95% of the 97,740 (95% Crl 96,400-100,060) people with HIV diagnosed, 99% diagnosed on treatment and 97% treated being virally suppressed; we explore the number of people with transmissible virus, comparing the UNAIDs method with a new approach.

Methods: The HIV and AIDS Reporting System (HARS) is the comprehensive health surveillance system for adults (<15 years) in England diagnosed with HIV. Serial records

For the UNAIDS metrics, we calculated the number of people with transmissible virus by using the Multi-Parameter Evidence Synthesis (MPES) statistical model to estimate the number of people living with HIV and using HARS data to provide: the number of people diagnosed (in care in 2020), the number diagnosed and not treated (in care in 2020 but no treatment evidence); and the number treated with detectable virus (viral load >200 copies/mL adjusted for missing information).

The novel approach also incorporated those not linked to care (diagnosed in 2020 but not in care that year); not retained in care (in care in 2019 but not 2020); and treated without viral suppression evidence (on treatment with no viral load information).

Results: Using the UNAIDS method, an estimated 9% (8,800) of people with HIV had transmissible virus. Of these, 57% were estimated to be undiagnosed, 11% diagnosed and untreated and 32% treated but not virally suppressed.

With the new approach, up to 20% (19,800) people with HIV had transmissible virus levels. Of these, 24% were undiagnosed, 37% were diagnosed but not referred/retained in care, 6% untreated, 9% treated but not virally suppressed and 24% treated with no evidence of viral suppression.

Conclusions: The UNAIDS metric masks the absolute number of people living with transmissible virus, specifically excluding those not in care and those with missing information. Using the new approach, only a quarter of people living with transmissible HIV infection in England were estimated to be undiagnosed compared to over half using the UNAIDS approach. The focus on HIV prevention must be expanded from testing to include support for those with diagnosed HIV to remain in care, on treatment and virally suppressed.

OAC0303

Characteristics associated with viral suppression among transgender women with HIV in 7 U.S. cities, NHBS-Trans, 2019-2020

J. Chapin-Bardales[1], S. Harris[1,2], S. Whitby[1], S. Masciotra[1], A. Smith[1], J. Johnson[1], K. Lee[1], E. Olansky[3], T. Finlayson[1], L. Faucher[1], C. Wejnert[1], for the NHBS-Trans Study Group

[1]U.S. Centers for Disease Control and Prevention, Division of HIV Prevention, Atlanta, United States, [2]Oak Ridge Institute for Science and Education, assigned to the Division of HIV Prevention, U.S. Centers for Disease Control and Prevention, Atlanta, United States, [3]ICF International, Atlanta, United States

Background: Sustained viral suppression can improve quality of life for transgender women with HIV. Understanding which transgender women with HIV may need additional support towards becoming virally suppressed can inform future interventions.

Methods: During 2019-2020, National HIV Behavioral Surveillance recruited transgender women via respondent-driven sampling in 7 U.S. cities (Atlanta, Los Angeles, New Orleans, New York City, Philadelphia, San Francisco, Seattle). Participants eligible for this analysis included those who were ≥18 years old, assigned male at birth or intersex, identified as a transgender woman or a woman, completed the survey, completed rapid HIV testing, had an HIV-positive result, and provided dried blood spots that were tested for HIV viral load. Viral suppression was defined as a viral load result <1000 copies/mL.

We assessed viral suppression prevalence and obtained adjusted prevalence ratios (aPR) and 95% confidence intervals (CI) for key associations using log-linked Poisson regression models with robust standard errors accounting for clustering by recruitment chain and adjusting for city and network size.

Results: Overall, 80.8% of HIV-positive participants were virally suppressed. Viral suppression was greater among participants who were Hispanic/Latina (vs. Black/African American; aPR=1.12, 95% CI: 1.02, 1.23) and had a college degree (vs. high school or less; aPR=1.13, 95% CI: 1.03, 1.24). Those who were younger (aPR[30-39 vs. ≥40 years]=0.87, 95% CI: 0.79, 0.95), experienced homelessness within the past 12 months (aPR=0.89, 95% CI: 0.83, 0.96), had not visited an HIV care provider recently (aPR=0.81, 95% CI: 0.72, 0.91), and had an unmet need for healthcare due to cost within the past 12 months (aPR=0.77, 95% CI: 0.67, 0.89) were less likely to be virally suppressed.

	Viral suppression[1]				
	n	%	aPR[2]	95% CI	P-value
Age (years)

[1]Defined as <1000 copies/mL in dried blood spot HIV viral load testing.
[2]Log-linked Poisson models with robust standard errors adjusted for city and network size and accounted for clustering by recruitment chain.
[3]Hispanics/Latinas can be of any race.

Table. Characteristics associated with viral suppression among transgender women with HIV in 7 U.S. cities, NHBS-Trans, 2019-2020 (N=496)

Conclusions: About 1 in 5 transgender women with HIV were not virally suppressed. Programs to support higher education, regular HIV care visits, stable housing, and healthcare costs could assist transgender women with HIV in becoming virally suppressed.

OAC0304

Using two-stage inverse probability weights to correct mortality estimates for LTFU among children, adolescents and young adults living with HIV in Southern Africa: results from linkage and multi-country tracing studies

P. Nyakato[1], B. Christ[2], N. Anderegg[2], J. Muhairwe[3], L. Jefferys[4], J. van Dijk[5], M. J. Vinikoor[6], M. van Lettow[7], C. Chimbetete[8], S. J Phiri[9], M. Egger[10,11], M. Ballif[12], C.T. Yiannoutsos[13], R. Kassanjee[14], M.-A. Davies[10], M. Cornell[10], M. Schomaker[10,15]

[1]Centre for Infectious Disease Epidemiology and Research, University of Cape Town, School of Public Health and Family Medicine, Cape Town, South Africa, [2]University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland, [3]SolidarMed, Maseru, Lesotho, [4]SolidarMed, Pemba, Mozambique, [5]SolidarMed, Masvingo, Zimbabwe, [6]Centre for Infectious Diseases Research in Zambia, Lusaka, Zambia, [7]Dignitas International, Zomba, Malawi, [8]Newlands Clinic, Harare, Zimbabwe, [9]Lighthouse Trust Clinic, Lilongwe, Malawi, [10]Centre for Infectious Disease Epidemiology and Research, University of Cape Town, Cape Town, South Africa, [11]Institute of Social and Preventive Medicine, University of Bern, Bern, Switzerland, [12]Institute of Social and Preventive Medicine, Bern, Switzerland, [13]R.M. Fairbanks School of Public Health,Indiana University, Department of Biostatistics, Indianapolis, United States, [14]Centre for Infectious Disease Epidemiology and Research, University of Cape, Cape Town, South Africa, [15]Institute of Public Health, Medical Decision Making and Health Technology Assessment, UMIT - University for Health Sciences, Medical Informatics and Technology, Tyrol, South Africa

Background: Our study examined the correction of mortality estimates based on additional mortality data among children, adolescents and young adults living with HIV (CAYHIV) who were lost in the International epidemiology Databases to Evaluate AIDS (IeDEA-SA) in six Southern Africa ART programs.

Methods: We estimated all-cause mortality from; five IeDEA-SA (Lesotho, Malawi, Mozambique, Zambia and Zimbabwe) and Western Cape, South Africa, IeDEA-SA ART programs. Additional mortality among patients LTFU was ascertained through tracing in the sites outside South Africa and linkage to the Western Cape Provincial Health Data Centre (WCPHDC) and the National Population Register (NPR) in South Africa. We included a total of 85,286 CAYHIV aged 0-24 years who initiated ART between 2004-2019.

We estimated mortality from ART start using:

i) Routine data without and with additional mortality ascertainment from tracing in sites outside South Africa and:

ii) Routine data in South Africa without and with additional ascertainment from linkage.

We used two-stage inverse probability weighting to correct estimates of mortality for LTFU.

Results: Tracing study: Out of a total of 79,867 CAYHIV, 46,375 were defined to be LTFU, of these 680 were randomly sampled for tracing. Of these, 462/680 were successfully traced and vital status ascertained. At two and eight years from ART start, uncorrected mortality was approximately 5% and 12% and after correction: 7% and 20% respectively (Figure 1).

Linkage study: There were a total of 5,410 children in routine Western Cape ART programs. Of these, 1,462 were LTFU and 1,048 were successfully linked to the WCPHDC and NPR. At two and eight years from ART start, uncorrected mortality was approximately 5% and 8% and after correction, it was 7% and 12%.

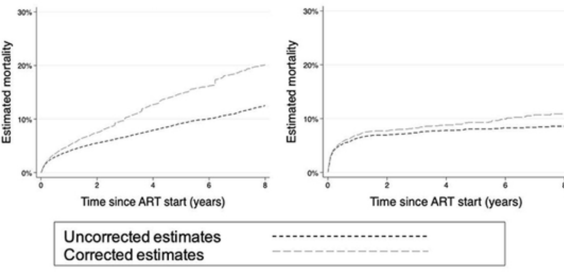

Figure 1. Corrected and uncorrected/weighted estimates of mortality: Panel 1) Rest of Southern Africa, Panel 2) South Africa

Conclusions: Mortality estimates increase when we account for unreported mortality among those LTFU. This is the first long term accurate mortality estimation in CAYHIV in Southern Africa.

OAC0305

Malawi's progress towards the UNAIDS 95-95-95 HIV testing and treatment targets: comparison of the 2015-16 and 2020-21 Malawi Population-based HIV Impact Assessments (MPHIA)

N. Wadonda[1], D. Payne[1], A. Kabaghe[1], L. Tenthani[2], C. Braccio[3], E. Kim[1], T. Dobbs[3], M. Nyangulu[1], A. Jahn[4,5], K. Brown[3], N. Kalata[1], C.A. West[3], F. Ogollah[2], F. Kayigamba[2], A. Auld[1], G. Bello[4,5], S.M. Farley[6], B. Muyunda[7], K. Mircovic[1], R. Nyirenda[4], MPHIA Study Team

[1]U.S. Centers for Disease Control and Prevention, Malawi, Lilongwe, Malawi, [2]ICAP at Columbia University, Malawi, Lilongwe, Malawi, [3]U.S. Centers for Disease Control and Prevention, Atlanta, United States, [4]Ministry of Health, Malawi, Lilongwe, Malawi, [5]University of Washington, I-TECH, Seattle, United States, [6]ICAP at Columbia University, New York, United States, [7]U.S. Centers for Disease Control and Prevention, Zambia, Lusaka, Zambia

Background: The 2015-16 Malawi Population-based HIV Impact Assessment showed notable coverage gaps in HIV diagnosis, antiretroviral therapy access and retention, and viral load suppression (VLS). Targeted interventions were implemented by the Government of Malawi, PEPFAR and other partners to close these gaps. The second MPHIA was conducted between January 2020 and April 2021 to measure progress towards the UNAIDS 90-90-90 goals.

Methods: MPHIA is a nationally representative survey, which enrolled over 23,000 participants. Participants were interviewed and a blood sample was tested for HIV infection using the national algorithm. Results were returned to participants. All HIV positive samples were tested for viral load (VL) and presence of antiretrovirals (ARV); a suppressed VL was defined as <1,000 viral copies per milliliter. All results were weighted and self-reported awareness and treatment status were adjusted to account for ARV detection results. This analysis was restricted to participants aged 15-64 years with HIV test results.

Results: HIV prevalence decreased significantly from 10.6 % [95% confidence interval (CI): 9.9%-11.2%] in MPHIA 2015-16 to 8.9% (95% CI: 8.4%-9.5%) in MPHIA 2020-21. Awareness of HIV status among all adults increased from 76.8% (95%CI: 74.7%-79.0%) to 88.4% (95% CI: 86.7%-90.1%), with females increasing from 80.2% (95%CI: 77.8%-82.5%) to 90.4% (95%CI: 88.5%-92.2%). Among 15-24-year-olds, awareness increased from 53.7% (95%CI: 45.3%-62.0%) to 76.2% (95%CI: 69.4%-83.1%). Among all adults aware of their HIV status, ART use increased from 91.4% (95%CI: 89.8%-93.0%) to 97.8% (95%CI: 97.1%-98.5%).

Viral suppression (VLS) among those on treatment increased from 91.3% (95% CI: 89.3%-93.3%) to 96.9% (95% CI: 96.0%-97.8%). Population VLS among all adults living with HIV increased from 68.3% (95%CI: 66.0%-70.7%) to 87.0% (95%CI: 85.4%-88.6%).

However, VLS remained lowest in the major urban centers of Lilongwe and Blantyre cities, and among participants aged 15–24 years.

Conclusions: Targeted investments by district and sub-population in HIV testing, ART linkage, adherence, and retention have resulted in significant progress towards achievement of the UNAIDS 90-90-90 targets. These results show that Malawi has exceeded the more recent UNAIDS 95-95-95 treatment and VLS targets. Continued targeted efforts and tailored interventions are needed to close remaining gaps, particularly among young people and in urban centers.

OAC04 Enlightenment through estimation: New insights in HIV epidemiology

OAC0402

Determinants of long-term survival in late HIV diagnosed individuals: the PISCIS Cohort study

R. Martin-Iguacel[1,2], J. Reyes-Urueña[1], J. Casabona[1], A. Bruguera[1], J. Aceiton Cardona[1], Y. Diaz Rodriguez[1], S. Moreno Fornes[1], P. Domingo[3], V. Falcó[4], A. Imaz[5], I.S. Johansen[2], J.M. Miró[6], J.M. Llibre[7], PISCIS study group
[1]Centre for Epidemiological Studies on Sexually Transmitted Infections and HIV/AIDS of Catalonia (CEEISCAT), Badalona, Spain, [2]Odense University Hospital, Infectious Diseases, Odense, Denmark, [3]Hospital Sant Pau, Barcelona, Spain, [4]Hospital de Vall d' Hebron, Barcelona, Spain, [5]Hospital de Bellvitge, Barcelona, Spain, [6]Hospital Clínic-Institut d'Investigacions Biomèdiques August Pi i Sunyer, University of Barcelona, Barcelona, Spain, [7]Infectious Diseases Department and Fight AIDS and Infectious Diseases Foundation, University Hospital Germans Trias i Pujol, Badalona, Spain

Background: Half of the people living with HIV (PLWH) in Western Countries are still diagnosed late, having a negative impact in their life expectancy and comorbidities. Neither the best determinants of their long-term mortality nor the potential impact of starting an integrase inhibitors (INSTI)-based antiretroviral treatment (ART) are completely understood.
We assessed the impact of immune recovery and INSTI-based ART in their long-term mortality.
Methods: From the PISCIS prospective cohort we included all adult treatment-naïve PLWH starting ART in 2005-2020 and surviving the first 2 years. We estimated mortality rates (MR) upon immune recovery 2 years after ART initiation and associated prognostic factors using Poisson regression. We also assessed risk-factors for incomplete immune recovery at 2 years (defined as CD4 counts ≤500cells/µL) in a nested case-control study using logistic regression with propensity score matching.
Results: We included 2719 persons (15566.8 person-years of follow-up); 1441 (53%) were late presenters, decreasing from 78.5% in 2005-2008 to 40.9% in 2015-2020 (p<0.01). Among late presenters, 44% achieved CD4 counts >500 cells/µL at 2 years. Overall, 113 patients (4.2%) died (crude all-cause MR 7.3/1000PY [95%CI:6.0-8.7]). MR were higher in late compared to non-late presenters, except for those achieving CD4 counts >500 cells/µL at 2 years (MRR 1.13 [95%CI:0.56-2.30], independent of nadir CD4 counts (test-interaction p=0.48).
In multivariate analysis, risk factors for death included: CD4 recovery <500cells/µL (<200cells/µL:aMRR 4.45 [95%CI:2.17-9.11]; 200-350cells/µL:aMRR 1.71 [95%CI:0.85-3.44]; >350-500cells/µL:aMRR 2.14, [95%CI:1.09-4.18]); viral load >200 c/ml at 2 years (aMRR 2.04 [95%CI:1.13-3.68]); Charlson comorbidity index ≥4 (aMRR 4.11 [95%CI:1.90-8.86]), heterosexual men (aMRR 1.97 [95%CI:1.12-3.46]) and injection drug use (aMRR 2.60 [95%CI:1.37-4.95]).
Overall, 979 PLWH initiated an INSTI-based regimen, which was associated with a trend towards decreased mortality compared to other regimens (aMRR 0.60 [95%CI:0.34-1.05]) and with favorable immune recovery (CD4 counts >500cells/µL, aOR 0.70 [95%CI:0.54-0.90]).
No significant changes in MR were observed over calendar time.
Conclusions: ART-associated immune recovery at 2 years was a better predictor of long-term mortality than nadir baseline CD4 counts in late ART initiators. Nearly half experienced a favorable immune recovery with a life expectancy similar to non-late presenters. INSTI-based regimens were associated with higher rates of successful immune recovery and survival.

OAC0403

High HIV incidence and mortality in a multi-site cohort of transgender women in the eastern and southern United States

A.L. Wirtz[1], E. Humes[2], K.N. Althoff[2], T. Poteat[3], A. Radix[4], K.H. Mayer[5,6], C. Beyrer[1], J. Schneider[7], J.S. Haw[7], A.J. Wawrzyniak[8], A.E. Rodriguez[9], D. Adams[1], M. Stevenson[1], E.E. Cooney[10], S.L. Reisner[5,11,12,13]

Background: Transgender women are a priority population in the US HIV strategy due to social vulnerabilities and HIV burden, yet epidemiologic monitoring of HIV, premature death, and other events to inform public health is almost non-existent.
Methods: We established a multi-site cohort for transgender women in eastern and southern US across two arms:

1) technology-enhanced site-based (Boston, New York City, Baltimore, Washington DC, Atlanta, Miami);
2) exclusively online (spanning 72 matched cities).
Eligibility criteria: transfeminine; ages>=18 years; negative baseline HIV test; not in a PrEP trial.
Participants were followed for >=24 months, completing surveys, rapid oral fluid HIV tests with confirmatory testing referrals and medical record reviews. Retention efforts (e.g., comprehensive locator, community outreach, events) permitted other event ascertainment, including death. HIV incidence and mortality rates were estimated as the number of observed events (HIV seroconversions or deaths) divided by the number of person-years(py) accumulated. We visualized Kaplan-Meier estimates of cumulative incidences (Figure) with a time-to-event approach that defines time-of-origin as study entry.

Results: Enrollment launched March 2018 in the site-based arm and January 2019 in the online arm. 1,313 participants were enrolled with 83% retention, 2,479 person-years accumulated, and 12 identified seroconversions as of December 2021. HIV incidence was 4.8/1,000py (95%CI:2.1-7.6) overall and by group: online IR:1.8/1,000py, site-based IR:7.3/1,000py, Black participants IR:15.9/1,000py, Latinx participants IR:8.6/1,000py, and residence in South IR:8.6/1,000py. Seven deaths were identified (attributed causes: homicide, suicide, overdose, unknown). Mortality rates were 2.8/1,000py overall (95%CI:1.1-5.8); site-based: 4.4/1,000py and online: 0.9/1,000py, 3.5/1,000py in Black and 8.6/1,000py in Latinx participants.

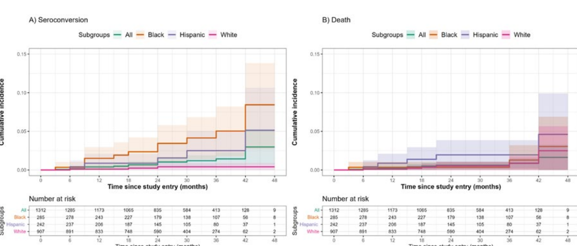

Figure.

Conclusions: HIV incidence and mortality are high in transgender women, disparate across race and ethnicity, and underscore community calls to for combination approaches that address structural and other health concerns alongside HIV.

Differences across cohort arms highlight the need for continued community and location-based efforts as HIV research and interventions are increasingly delivered online.

OAC0404

Prevalence and individual and community-level risk factors of late diagnosis among newly diagnosed people living with HIV from nine African countries

K. Ganesan[1], W. El-Sadr[1], A. Low[1]

[1]*Columbia Univeristy, Epidemiology, New York, United States*

Background: People living with HIV (PLWH) with late diagnosis (LD) (CD4 cell count <350 cells/mm^3 and no prior HIV diagnosis) are at higher risk of opportunistic infections, non-AIDS defining comorbidities, and death compared to stable patients due to delayed diagnosis.
We used Population-based HIV Impact Assessment (PHIA) survey data from Cameroon, Eswatini, Ethiopia, Lesotho, Malawi, Tanzania, Uganda, Zambia, and Zimbabwe to examine LD prevalence and identify individual and community-level correlates of LD.

Methods: The PHIAs are cross-sectional, household-based surveys that use two-stage sampling to collect nationally representative data from adults aged ≥15 years. Between 2015-2017, data from interviews, home-based HIV testing, and laboratory testing were collected.
Blood samples were analyzed for HIV RNA, detectable antiretrovirals, and CD4+ cell counts. Community-level variables were generated at each enumeration area-level using weighted data. Logistic regression using fixed-effects to account for cross-country variation was used to determine individual and community-level factors associated with LD in adults aged ≥15 years.

Results: Of 4,408 newly diagnosed PLWH, 42.8% (95% CI: 40.9-44.8) had LD. LD prevalence ranged from 29.6% (95% CI: 25.3%-34.3%) in Uganda to 53.3% (95% CI: 49.5%-57.1%) in Zimbabwe. Newly diagnosed PLWH who resided in higher LD prevalence countries such as Ethiopia, Lesotho, Malawi, Tanzania, Zambia, and Zimbabwe, were older, of male sex, and had never tested for HIV, had higher adjusted odds of LD (Figure 1).
PLWH in communities where gender norms supported a lack of health-related decision-making autonomy, had higher adjusted odds of LD.

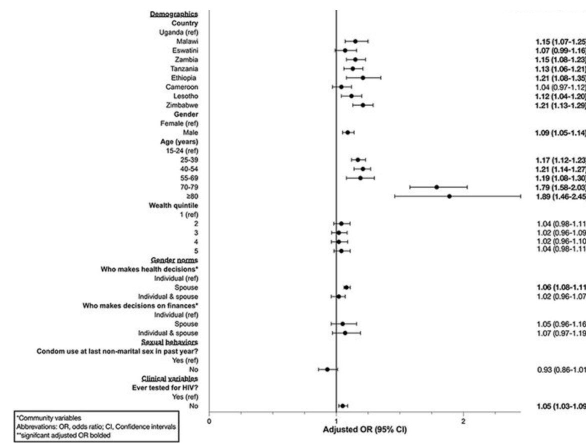

*Figure 1. Adjusted odds ratios of individual & community level correlates of late diagnosis among newly diagnosed PLWH. Adjusted OR [95% CI]***

Conclusions: Late diagnosis of HIV remains a challenge despite increases in HIV testing services. Such services should highlight the importance of early diagnosis of HIV and for individuals, particularly older men in high LD prevalence countries, to get repeatedly tested. Gender norms that inhibit health agency should be addressed by providing community-based support for promotion of health autonomy to optimize testing services.

[1]*International Training and Education Centre for Health, Lilongwe, Malawi,* [2]*Ministry of Health, Lilongwe, Malawi,* [3]*PHI/CDC Global Health Fellowship Program, Lilongwe, Malawi,* [4]*Centers for Disease Control and Prevention, Atlanta, Georgia,* [5]*Kamuzu University of Health Sciences, Blantyre, Malawi,* [6]*Centers for Disease Control and Prevention-Malawi, Lilongwe, Malawi,* [7]*The University of Washington, Seattle, United States,* [8]*National AIDS Commission, Lilongwe, Malawi,* [9]*World Health Organization, Lilongwe, Malawi,* [10]*World Health Organization, Geneva, Switzerland*

Background: Routine surveillance for birth outcomes is essential to monitor safety of antiretroviral therapy (ART) during pregnancy among women living with HIV (WLHIV). We examined the prevalence of adverse birth outcomes and major external birth defects (BDs) by maternal HIV and ART status in Malawi.

Methods: Adverse birth outcomes (prematurity, low birthweight) and BDs were recorded for all live and still-births delivered at four Malawian hospitals from January 2016 to July 2020 and July 2021 to November 2021. BDs were confirmed by experts at the Centers for Disease Control and Prevention. Maternal characteristics were collected from interviews and health records. Pooled prevalence and crude prevalence ratios (cPRs) were calculated using maximum likelihood estimates for adverse outcomes and BDs.

Results: Among 165,402 women with informative births, the median age was 24.0 years (IQR: 20.0-30.0) and 10.1% were HIV-positive. The prevalence of prematurity and low birthweight, respectively, was significantly higher for the following populations: ART naïve WLHIV (28.3%, 18.4%), WLHIV on ART (21.4%, 14.6%) and women with unknown HIV status (27.2%, 19.2%) than HIV-negative women (19.2%, 11.9%). The most prevalent BDs (excluding syndromes) were talipes equinovarus (21.4 per 10,000 births, 95% CI: 19.3, 23.8), neural tube defects (NTDs) (9.3, 95% CI: 7.8, 10.8), and hypospadias (8.2, 95% CI: 6.9, 9.7); higher prevalence of these conditions was observed among WLHIV on ART than HIV-negative women. There was a slightly higher likelihood of WLHIV on ART delivering a baby with an NTD than HIV-negative women (cPR: 1.85, 95% CI: 1.07, 2.62).

Outcome	Women living with HIV on ART N = 16,349 (9.9%)	ART naïve women living with HIV N = 321 (0.2%)	HIV-negative women N = 147,399 (89.1%)	Women with unknown HIV status N = 1,333 (0.8%)	Total N = 165,402 (100.0%)
Premature delivery (<37 weeks) (prevalence per 100 births)	**21.4** (20.8, 22.1)	**28.3** (23.5, 33.6)	**19.2** (19.0, 19.4)	**27.2** (24.8, 29.6)	**19.5** (19.3, 19.7)
Low birthweight (<2500g) (prevalence per 100 births)	**14.6** (14.0, 15.1)	**18.4** (14.3, 23.1)	**11.9** (11.8, 12.1)	**19.2** (17.1, 21.4)	**12.3** (12.1, 12.4)
Selected external birth defects under surveillance (prevalence per 10,000 births)	**60.6** (49.2, 73.7)	**31.2** (0.8, 172.3)	**48.2** (44.8, 51.9)	**75.0** (36.0, 137.5)	**49.6** (46.3, 53.1)
--Neural tube defects (anencephaly, encephalocele, spina bifida)	**15.9** (10.4, 23.3)	0.0	**8.6** (7.2, 10.3)	0.0	**9.3** (7.8, 10.8)
--Orofacial clefts (cleft lip with and without cleft palate)	**0.6** (0.01, 3.4)*	0.0	**1.1** (0.6, 1.8)	0.0	**1.0** (0.6, 1.6)
--Hypospadias	**11.0** (6.5, 17.4)	0.0	**7.9** (6.6, 9.5)	**7.5** (0.2, 41.7)	**8.2** (6.9, 9.7)
--Talipes equinovarus (clubfoot)	**26.9** (19.6, 36.1)	**31.2** (0.8, 172.3)	**20.5** (18.2, 22.9)	**52.5** (21.1, 107.9)	**21.4** (19.3, 23.8)
--Limb reduction defects	**2.4** (0.7, 6.3)	0.0	**1.2** (0.7, 1.9)	0.0	**1.3** (0.8, 2.0)
--Gastroschisis and omphalocele	**3.1** (1.0, 7.1)	0.0	**2.5** (1.8, 3.5)	0.0	**2.5** (1.8, 3.4)

Conclusions: Higher prevalence of adverse birth outcomes and BDs was observed among HIV-positive women. Further analyses are needed to understand the impact of a COVID-related data collection pause between 2020 and 2021, and to explore risk factors of HIV and ART status by ART regimen and timing for adverse outcomes and BDs among WLHIV in Malawi.

Association of prenatal PrEP exposure with neurodevelopmental and growth outcomes beyond 24 months among Kenyan children

L. Gómez[1], J. Kinuthia[2], A. Larsen[1], J. Stern[1], J. Dettinger[1], M. Marwa[2], F. Abuna[2], B. Ochieng[2], N. Ngumbau[2], P. Omondi[2], G. John-Stewart[1], J. Pintye[1]

[1]University of Washington, Seattle, United States, [2]Kenyatta National Hospital, Nairobi, Kenya

Background: Safety data of prenatal PrEP use are reassuring, yet studies to date have less than 1 year of follow-up and do not assess neurodevelopmental outcomes among PrEP-exposed infants.

Evaluating safety outcomes beyond infancy following maternal PrEP use could help complete the safety profile for PrEP use during pregnancy.

Methods: We utilized data from mother-child pairs enrolled in an ongoing evaluation of perinatal PrEP use in Western Kenya. In the parent study (NCT03070600), HIV-negative women were enrolled and offered PrEP during pregnancy at 20 public sector maternal child health (MCH) clinics and followed through 9 months postpartum regardless of PrEP status.

An extension cohort to evaluate safety outcomes enrolled mother-child pairs at 4 sites to be followed until the child's 5th birthday. Between October 2020 and January 2022, trained study nurses conducted anthropometric measurements on children and assessed neurodevelopment using the Ages and Stages Questionnaire (ASQ), an early developmental screener.

Using data from 24-30 months, we evaluated the association of prenatal PrEP exposure and growth and ASQ scores using linear regression models, clustered by facility, and adjusted for gestational age at birth.

Results: Among 472 mother-child pairs included in the analysis, median maternal age was 27.8 years (IQR: 24.6-33.0) and median child age was 25 months (IQR: 21-28) at enrollment into the extension cohort; 16.3% had any PrEP exposure during pregnancy for a median duration of 3.0 months (IQR: 2.0-4.3)**.**At 24-month visits, there was no difference in mean weight (mean difference -0.04 kg, 95% CI: -0.78, 0.70, p=0.886), mean height (mean difference -0.43 cm, 95% CI: -2.32, 1.46, p=0.520), frequency of underweight (5.6% vs. 4.0%, adjusted prevalence ratio[aPR]=1.49, 95% CI: 0.27-8.09, p=0.647) and frequency of stunting (22.2% vs. 21.4%, aPR=1.07, 95%CI: 0.64-1.78, p=0.805) between children with and without prenatal PrEP exposure.

Results were similar at 30-month visits. Prenatal PrEP exposure was not associated with overall ASQ scores at 24-months (p=0.243) or 30-months (p=0.664).

Conclusions: Among Kenyan mother-child pairs followed from pregnancy through early childhood, we found no differences in growth or neurodevelopmental outcomes between children with and without prenatal PrEP exposure. Our results support prior data indicating safety of prenatal PrEP use.

OAC0503

Introduction of gain-framed pre-exposure prophylaxis counseling increased uptake among transgender women at the Tangerine Clinic, Bangkok, Thailand

P. Srimanus[1], P. Parkpien[1], R. Janamnuaysook[1], K. Samitpol[1], A. Chancham[1], J. Kongkapan[1], T. Amatsombat[1], J. Rueannak[1], P. Getwongsa[1], W. Tasomboon[1], M. Bucha[1], M. Avery[2], S. Mills[2], P. Phanuphak[1], N. Phanuphak[1], R. Ramautarsing[1]

[1]Institute of HIV Research and Innovation, Bangkok, Thailand, [2]FHI 360, Bangkok, Thailand

Background: Transgender women continue to be disproportionally affected by HIV in Thailand. Pre-exposure prophylaxis (PrEP) remains underutilized by transgender women despite its efficacy and availability due to several barriers, including stigma related to sexual behaviors and to taking PrEP. Loss-framing counseling, in which risk behavior is emphasized, further exacerbates PrEP stigma and can impede PrEP uptake. In June 2020, Tangerine Clinic in Bangkok, Thailand, introduced gain-framed PrEP counseling to encourage clients to focus on protection and healthy behavior and ultimately increase PrEP uptake. Here we assess PrEP uptake before and after implementation of gain-framed PrEP counseling.

Methods: We analyzed data from transgender women visiting Tangerine Clinic from June 2020 through July 2021, including demographic and sexual behavioral characteristics from self-administered questionnaires, data related to HIV and sexually transmitted infections (STIs) (syphilis, gonorrhea, chlamydia). Although not the focus of counseling messages, HIV risk was determined by asking about self-perceived HIV risk and through self-reported behavioral risk factors. PrEP uptake during this period was compared to uptake before implementation of gain-framed counseling (June 2019–May 2020).

Results: From June 2020 to July 2021, 1,149 transgender women not on PrEP visited Tangerine, of whom 398 (34.6%) accepted PrEP after gain-framed counseling. Median age was 26.2 years. A total of 319 (80.2%) were new initiations, and 79 (19.8%) restarted PrEP after previous discontinuation.

Among the 398 transgender women accepting PrEP, 106 (26.6%) did not perceive themselves to be at risk for HIV, while 41/106 (38.7%) reported risk behaviors and 26/106 (24.5%) were diagnosed with an STI.

In the year before gain-framed counseling implementation, PrEP uptake was 161/1,191 transgender women (13.5%), with 13 transgender women having no self-perceived risk accounting for 8.1% of initiations, indicating an increase in PrEP uptake of 147% overall, and a 715% increase among transgender women without self-perceived HIV risk.

Conclusions: Replacing traditional risk-based counseling with empowering messages focusing on health improved PrEP uptake overall, particularly among transgender women without self-perceived risk, despite a discrepancy between self-perceived and actual HIV risk. Gain-framed messages should be integrated with PrEP counseling to optimize PrEP use and its impact on the HIV epidemic.

OAC0504

Evaluating adaptive HIV pre-exposure prophylaxis adherence interventions for young South African women: results from a sequential multiple assignment randomized trial

J. Velloza[1], N. Poovan[2], A. Meisner[3], N. Ndlovu[2], N. Khoza[2], J. Morton[1], J. Omony[2], E. Mkwanazi[2], C. Grabow[1], D. Donnell[3], J. Baeten[4], S. Hosek[5], C. Celum[1], S. Delany-Moretlwe[2]
[1]University of Washington, Global Health, Seattle, United States, [2]Wits Reproductive Health & HIV Institute, Johannesburg, South Africa, [3]Fred Hutchinson Cancer Research Center, Seattle, United States, [4]Gilead Sciences, Foster City, United States, [5]Stroger Hospital of Cook County, Chicago, United States

Background: Pre-exposure prophylaxis (PrEP) is a highly effective HIV prevention strategy for adolescent girls and young women (AGYW). Widespread PrEP delivery will require identification of layered support strategies for AGYW with diverse needs. We conducted the first sequential multiple assignment randomized trial (SMART) to evaluate stepped PrEP adherence support interventions for AGYW in South Africa.

Methods: "PrEP SMART" was conducted in Johannesburg from 2019-2022. Sexually active, HIV-negative women ages 18-25 years were offered PrEP and randomized to receive standard PrEP counseling with either weekly two-way SMS or WhatsApp support. Those with low PrEP adherence through Month 2 ("non-responders") were re-randomized to quarterly visits with drug-level feedback (DLFB) or monthly visits with issue-focused counseling.

The primary outcome was high adherence (tenofovir diphosphate [TFV-DP] ≥700 fmol/punch) from dried blood spots (DBS) at Month 9. We assessed the effects of the initial interventions on TFV-DP at Month 9, the effects of the intensified interventions among non-responders, and the optimal intervention sequence.

Results: Of 360 AGYW, the median age was 21, 31.4% had sexually transmitted infections at enrollment, and 77.5% were retained through Month 9 despite COVID-19 disruptions. Of those with DBS, 58.6% (N=164) had TFV-DP ≥700 fmol/punch at Month 2 and 24.7% (N=66) at Month 9.

At Month 9, 34/133 (25.6%) AGYW in the two-way SMS arm and 32/134 (23.9%) in the WhatsApp arm had high PrEP adherence (relative risk [RR]=1.07; 95% confidence interval [95% CI]=0.70-1.63; p=0.75). Among non-responders, 4/49 (8.2%) in the DLFB arm and 3/51 (5.9%) in the monthly counseling arm had high adherence at Month 9 (RR=1.39; 95% CI=0.33-5.88; p=0.66). Across the four dynamic treatment strategies, the estimated probability of high adherence at Month 9 was 23-27% (p=0.94).

Conclusions: In this study, PrEP adherence was higher than in comparable cohorts, despite the COVID-19 pandemic. Re-engaging non-responders after two months was challenging; individual-level interventions may not overcome structural PrEP barriers suggesting that longer-acting PrEP formulations may benefit this population.

Our data show that individual tailored adherence approaches (SMS, WhatsApp) have similar impact on PrEP adherence and PrEP programs can adopt approaches based on likelihood of scalability.

OAC0505

Pragmatically approaching social network testing (SNT): using a peer-driven community outreach model to extend reach of HIV testing services (HTS) to networks of people who inject drugs (PWID) in Ukraine

S. Leontieva[1], T. Gaborets[1], N. Roman[1], K. Gamazina[1], D. Canagasabey[2]
[1]PATH, Ukraine Country Program, Kyiv, Ukraine, [2]PATH, Washington, DC, United States

Background: The HIV prevalence among PWID in Ukraine is 20.3%, up to four times higher than other key population groups, reinforcing the need for focused HIV case-finding and linkage strategies that tap into PWID networks (2020 IBBS). The USAID/PATH Serving Life project introduced and scaled a peer-driven community outreach model, leveraging SNT principles to reach contacts of PWID peer case-finders with HTS in 12 oblasts.

Description: Project-supported non-governmental organizations (NGO) hired peer case-finders among former or soon-to-be released PWID prisoners as seed recruiters to mobilize social, sexual, and drug injecting contacts for HTS. Peer case-finders and NGO social workers provided HIV counseling, offered HIV self-testing (HIVST) services, followed up with recruited peers to confirm HIVST results, and provided referrals for treatment or prevention services. Newly identified HIV-positive peers (first outreach wave) offered index testing services to sexual/injecting partners and biological children (second outreach wave), and could be hired as peer case-finders themselves.

In 2021, to maximize reach among hidden PWID networks, NGOs prioritized hiring in underserved geographies and more frequently rotated case-finders to source new networks. We analyzed program data from October 2020 through September 2021 to understand the model's success in reaching HIV-positive PWID and their contacts.

Lessons learned: PWID peer case-finders mobilized 10,184 peers and their contacts for HTS, among whom 333 were confirmed HIV-positive (3.3% positivity) and 95% initiated on treatment. The second outreach wave was more efficient at reaching PWID contacts more likely to be HIV-positive (testing positivity: 10.6% [second wave] versus 1.3%

[first wave]; see table), given targeted outreach through index testing. There was also an increase in both volume of people tested and confirmed HIV-positive in 2021 (versus 2020) due to refinements to the SNT model.

	First wave (PWID peers)	Second wave (index testing)	Total
# tested	8,035	2,149	10,184
# confirmed HIV-positive	106	227	333
% testing positivity	1.3%	10.6%	3.3%

Conclusions/Next steps: These results highlight the promise of using a peer-driven, SNT-based outreach model to efficiently tap into networks of HIV-positive PWID and their contacts and link them to HIV services. Further expansion of this approach to reach PWID and their partners/contacts with HIV services is essential to achieving epidemic control in Ukraine.

OAD01 Through the lens of community: Addressing context within strategies and interventions

OAD0102

Turning the tide towards eliminating mother to child transmission: lessons from Murang'a County Government HIV program

J. Kisio[1], D.G. Kinyanjui[1], C. Ochola[2], E. Karanja[3]
[1]Murang'a County Government, Murang'a, Kenya, [2]Center for Health Solutions, Nairobi, Kenya, [3]Aids Health Foundation, Nairobi, Kenya

Background: According to the Kenya National Aids Control Council (NACC) 2017 HIV estimates, mother to child transmission rate for Murang'a county stood at 20.4% way above the national rate of 11.5%, in that same year 44 babies in the county were confirmed to be infected with HIV through mother to child transmission. With the help of our local implementing partners; Center for Health solutions (CHS) and Aids Health Foundation (AHF), the county HIV program embarked on a mission towards reducing the mother to child transmission rates to a rate equal or less than the national level.

Description: Health workers (HIV testing service providers, nurses and clinical officers) working in the identified 199 prevention of mother to child transmission (PMTCT) clinics were comprehensively trained on the national PMTCT guidelines with the emphasis made on the four prongs of PMTCT which are; keeping HIV negative women negative, prevention of unintended pregnancy for the already positive women, test and treat strategy for HIV positive pregnant women with issuance of prophylaxis for their HIV exposed infants and finally care and treatment for both the positive mother and the child. All pregnant women are tested for HIV at their first antenatal visit (ANC) and if they test negative, the HIV test is repeated at 3rd trimester, labor and delivery, at 6 weeks post natal clinic and after every six months during breastfeeding. Audits are done (including maternal) for all HIV exposed infants (HEI) who turn HIV positive to determine likely root for mother to child transmission.

Lessons learned: Through this strategy, the number of HIV exposed infants turning positive have been gradually declining as follows 44 in 2017, 27 in 2018, 18 in 2019, 16 in 2020 and 5 in 2021. The MTCT rate has also reduced to 9% according to the National Aids Control Council (NACC) 2020 estimates. Murang'a county has also been listed among the counties on the right gear towards elimination of mother to child transmission.

Conclusions/Next steps: Elimination of mother to child transmission can be achieved when all health care workers receive the right training and are supported to offer quality services as prescribed by national guidelines.

OAD0103

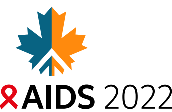
The protective association of social cohesion on sex workers' experiences of violence and access to tailored services: findings of a community-based cohort in Vancouver, Canada (2010-2019)

J. Pearson[1,2], K. Shannon[3,2], D. Kerrigan[4], A. Krüsi[2,3], M. Brachel[2], S. Goldenberg[5,2,6]
[1]University of British Columbia, Interdisciplinary Studies Graduate Program, Vancouver, Canada, [2]Centre for Gender and Sexual Health Equity, Vancouver, Canada, [3]University of British Columbia, Department of Medicine, Vancouver, Canada, [4]George Washington University, Department of Prevention and Community Health, Washington, DC, United States, [5]San Diego State University, Division of Epidemiology and Biostatistics, School of Public Health, San Diego, United States, [6]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada

Background: While community mobilization and social cohesion have been identified as key drivers of HIV prevention and improved safety for sex workers in the global south, we know less about social cohesion's impacts on safety and access to community-driven HIV prevention services in North America and under partial-criminalization models. COVID-19, in addition, has highlighted the critical need and role of community supports. Our aim was to measure recent (in the last six months) social cohesion (perceptions of mutual aid, trust and support) and its association with:

1. Sexual/physical violence, and;
2. Engagement with sex work-specific services (e.g., drop-in spaces, HIV/harm reduction outreach) among women sex workers in Metro Vancouver, Canada.

Methods: Prospective data (January 2010-August 2019) were drawn from an open cohort, operated by experiential and community-based staff, of 900+ women sex workers across diverse work environments (An Evaluation of Sex Workers' Health Access).



We used multivariable logistic regression confounder models with generalized estimating equations (GEE) for repeated measures to examine the association between social cohesion and recent outcomes of:

1. Physical/sexual violence and;
2. Use of sex work-specific services, over a ten-year period.

Results: The study sample included 860 sex workers, of whom 315 (36.6%) were Indigenous and 283 (32.9%) Black/ Women of Colour.

Overall, 36.4% identified as a sexual minority and 8.0% as gender-diverse. At baseline, the median social cohesion score was 19 (IQR 15-22), out of a possible 36. In bivariable GEE analysis, increased social cohesion was associated with formal indoor work environments, good self-rated health, and working with other sex workers as a safety strategy, and was negatively associated with living with HIV. In separate multivariable GEE confounder models, social cohesion was independently associated with lower odds of recent physical/sexual violence (Adjusted Odds Ratio (aOR) 0.99 per point on scale, 95% Confidence Interval (CI) 0.97, 1.00) and increased odds of recently using sex work-specific services (aOR 1.02 per point on scale, 95% CI 1.00, 1.04).

Conclusions: The findings affirm community calls to fully decriminalize sex work to better promote sex workers' social cohesion, physical safety and access to tailored, sex work-specific sexual health and HIV services.

OAD0104

The efficiency of index contact testing approach in community HIV case identification

A. Hoejrup[1], M. Lichtenberg[2], A. Zulu[1], J. Kanyanda[3], E. Zimunhu[4]

[1]*Development Aid from People to People in Zambia, HQ, Lusaka, Zambia,* [2]*Planet Aid Inc., Elkridge, Maryland, United States,* [3]*DAPP Zambia, Total Control of the Epidemic (TCE) in Southern Province, Pemba, Zambia,* [4]*Federation Humana People to People, HQ, Shamwa, Zimbabwe*

Background: Approximately 1.2 million people in Zambia are living with HIV. It is estimated that 92% of PLHIV know their HIV status while there is still 8% unaware that they have HIV, thereby posing risk for further HIV transmission. To speedily mitigate transmission resulting from those unaware of their HIV positive status, a more efficient community-based HIV case finding approach is essential.

Description: DAPP in Zambia partners with the Ministry of Health to implement the Total Control of the Epidemic (TCE) project, which has been under implementation since 2006 and currently implemented in four provinces. The project employs two community-based HIV testing approaches, namely;

1. Venue/Hotspot HIV testing, which involves testing individuals in their work venues such as fishing camps, etc. and;
2. Index Testing Services (ITS). The latter involves:

- Identifying known HIV positives, offering them ITS, and eliciting their sexual partners and biological children otherwise known as "Contacts";
- Screening for intimate partner violence and tracing their named "Contacts";
- Screening the traced "Contacts" for HIV testing;
- Testing and linking newly HIV positive diagnosed contacts to treatment (ART);

Offering ITS to new positives and named known HIV positive "Contacts."

Lessons learned: Results in Lusaka Province, Oct 2020-Sept 2021.

*Venue/Hotspot HIV testing:*Under this approach, 5,854 were tested for HIV and 1,476 (25%) were diagnosed HIV positive. 98% of all HIV positives were successfully initiated on ART.

Index Testing Services: Using this approach, 22,332 PLHIV were offered ITS and 99% accepted the service. 53,974 contacts were named of which 24% had a known HIV positive status. 69% of the contacts named were eligible and tested for HIV. Of those tested, 11,899 (31%) were diagnosed HIV positive and 99.5% of the positives were successfully initiated on ART.

Conclusions/Next steps: ITS had a comparatively higher positivity rate of the two approaches, proving to be a more efficient community-based HIV case finding approach than Venue/Hot Spot testing. Successful implementation of the ITS approach was due in large part to the exceptional psychosocial counseling and contact elicitation skills of DAPP TCE's psychosocial counselors.

OAD0105

Working with cultural leaders to create demand for HIV services: lessons from an engagement with Buganda Kingdom in Uganda in April 2020

D. Kwarisiima[1], R. Kabanda[1], J. Musinguzi[1], A. Mukundane[2], D. Atwine[1]

[1]*Ministry of Health, Kampala, Uganda,* [2]*John Hopkins University CCP, Kampala, Uganda*

Background: Data from routine surveillance and population surveys indicate that HIV prevalence amongst adults reduced from a peak of 18% in the 1990s to 6.2% in 2016. New HIV infections declined from 160,000 in 2010 to 52,000 in 2018. Vertical infections declined from 25,000 in 2010 to less than 4,000 in 2018. Furthermore, AIDS related mortality declined from approximately 50,000 to 25,000 in 2018. However, the central region continues to have a higher prevalence despite the combination of high impact evidence based behavioral, structural and biomedical interventions. Ministry of Health (MOH) engaged the Buganda Kingdom leadership to support in mobilising their communities to utilise available HIV services.

Description: MOH together with the Buganda kingdom leadership conducted an orientation of 180 cultural leaders/ gatekeepers, who include kingdom ministers, clan

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

heads, county chiefs, and youth leaders. The orientation equipped these leaders/ gatekeepers with Key HIV information so that they can aide the scaling down of HIV messaging in the central region community.
Following this orientation, the leaders organized fireplace discussions (ebyooto) in 118 sub counties in Buganda kingdom reaching over 4,720 young people.The trained elders imparted knowledge of HIV Prevention, care and treatment services upon the selected youth.
There is evidence that the young people did not only listen to information from their elders, but they understood it, acted on it and it changed their behavior. For example, there were less teenage pregnancies and increased uptake of HIV testing services in the central region as compared to other regions.
Lessons learned: Cultural leaders can play a significant role in behavior change however; they need to be exemplary in their way of life to influence young people. The cultural leaders also reported that use of appropriate/ slang language while communicating about HIV, was more acceptable and relatable to the young people. Finally, the cultural leaders had significant respect and a big opportunity to continuously engage their subjects on wider health issues.
Conclusions/Next steps: If cultural leaders are supported to integrate HIV awareness activities in their regular programs the results can be immense and as custodians of norms and cultural practices, they can successfully influence behaviors.

"I feel that things are out oF my hands": the impact of the COVID-19 prevention measures on the lives of young people living with HIV (YPLHIV) in Uganda

B. Ssekajja[1], R. Both[2]
[1]Reproductive Health Uganda, Gender and Youth Department, Kampala, Uganda, [2]Rutgers, International Department, Amsterdam, Netherlands, the

Background: With an estimated 1.4 million PLHIV In Uganda, youth account for 170,000 infections. These are expected to rise as the youth remain highly vulnerable to the infection. Analyses conducted by the Uganda Harm Reduction Network (UHRN) in July 2020 on the effects of the COVID-19 pandemic showed a decline in access to HIV prevention information, services and Psychosocial support.
This particular study was conducted among various groups of youth, and put emphasis on YPLHIV to examine how the COVID-19 prevention measures affected their access to HIV care information and services.
Methods: In October 2020, Rutgers coordinated a study among youth aged 18-30, using a mobile web survey to collect quantitative data from 640 respondents (326 males; 314 females), and Focus Group Discussions (FGDs) to collect qualitative data from 39 Youth (14 males, 22 females, 3 non-binary) in four districts of Eastern Uganda. Participants included YPLHIV, teen mothers, students, and LGBTQI.
Quantitative data were analyzed using descriptive statistics, while qualitative data were analyzed using a grounded theory approach which allowed for the identification of common patterns and salient themes
Results: COVID-19 interconnectedly, negatively affects YPLHIV, as responses revealed that they experienced worse outcomes than those living without HIV. Evidence shows that for YPLHIV, adherence to prevention measures was sometimes misinterpreted by others as being infected with COVID-19. Given the stigma associated with them, such accusations are difficult to bear. In vain, 65% of YPLHIV said they needed ART services, and 30% said they needed information regarding STDs/STIs.
Additional study findings indicate that the prolonged prevention measures have resulted in a reduction in HIV testing services and ART initiation.
Conclusions: Clearly, the pandemic negatively impacted YPLHIV, presenting concerns of double stigma if they test positive for COVID-19, and increased psychosocial afflictions caused by stress and isolation. Dealing with 2 pandemics resultantly affects their mental health, presenting another risk of additional barriers to care, potentially leading to further disenfranchisement.
Therefore, addressing such inequalities, challenges and barriers is critical to maintaining continuity of care and strong psychosocial support systems and YPLHIV recommended that mitigating the Pandemic's direct impact on access to HIV information and services is key.

OAD0203

Impact of COVID-19 on economic well-being, mental health and HIV risk among MSM: a mixed methods study in a north Indian city

A. Sebastian[1], V. Chakrapani[2], P. A. Newman[3], S. Rawat[4], M. Shunmugam[2], S. Mittal[5], V. Gupta[5], M. Kaur[6], G. Siddhant[4], D. Kumar[4], D. Singh[4], S. Romio[4]
[1]National Institute of Advanced Studies (NIAS), Bangalore, India, [2]Centre for Sexuality and Health Research and Policy (C-SHaRP), Chennai, India, [3]University of Toronto, Factor-Inwentash Faculty of Social Work, Ontario, Canada, [4]The Humsafar Trust, Mumbai, India, [5]Chandigarh State AIDS Control Society (CSACS), Chandigarh, India, [6]Postgraduate Institute of Medical Education and Research (PGIMER), Chandigarh, India

Background: Limited empirical data are available on the impact of the COVID-19 pandemic on the lives of sexual and gender minority communities in the global south. We

aimed to understand the pandemic's impact on economic well-being, mental health, health care access, and HIV risk among men who have sex with men (MSM) in India.

Methods: In March 2020, we conducted a concurrent mixed-methods study among MSM in Chandigarh, North India. A convenience sample was recruited through three non-governmental organizations implementing HIV prevention interventions among MSM. Maximum diversity sampling (identity, sex work status and HIV status) was used to identify MSM for in-depth interviews.

The survey assessed the impact of sexual minority stigma, internalized homonegativity and stress due to social distancing on depressive and anxiety symptoms. We used multivariable logistic regression to analyze survey data, and thematic analysis for qualitative data.

Results: Among survey participants (n=132), most (61%) identified as Kothi (feminine/receptive role), were single (79%) and college graduates (64%). Mean monthly income was INR 8375 (USD 120). 43% engaged in sex work, 34% were unemployed and 8% HIV positive.

Participants reported reduced access to condoms (19%), HIV testing (38%), and counseling services (74%) during COVID-19 lockdown. Social distancing stress was significantly associated with depressive (aOR=7.89, 95% CI 2.71–22.97, p<.001) and anxiety symptoms (aOR=5.69, 95% CI 2.73–11.86, p<.001).

Internalized homonegativity was significantly associated with both depressive (aOR = 1.31, 95% CI 1.04–1.65, p=.04) and anxiety symptoms (aOR = 1.52, 95% CI 1.09–1.62, p<.001). MSM in sex work had higher odds (aOR=8.06, 95% CI 1.49–43.57, p <.001) of reporting depressive symptoms compared to those not involved in sex work. Qualitative data (n=10) highlighted how economic distress due to job loss or income reduction and survival sex contributed to mental health distress and HIV risk.

Conclusions: The COVID-19 pandemic has significantly impacted the economic well-being and mental health of lower socioeconomic status MSM. Limited access to HIV preventive interventions among MSM involved in sex work exacerbates HIV risk due to economic hardship. Tele-counseling/prescription, low-interest loans, and better access to mental health and HIV services are needed to support MSM in India.

OAD0204

'COVID-19 should be learned through illustration': COVID-19 effects on HIV-affected youth in South Africa through participatory visual methodologies

L. Gittings[1,2], N. Ralayo[2], J. Kelly[2], S. Medley[2], Y. Price[2], A. Thomas[2], L. Cluver[3], C. Logie[1], E. Toska[2]

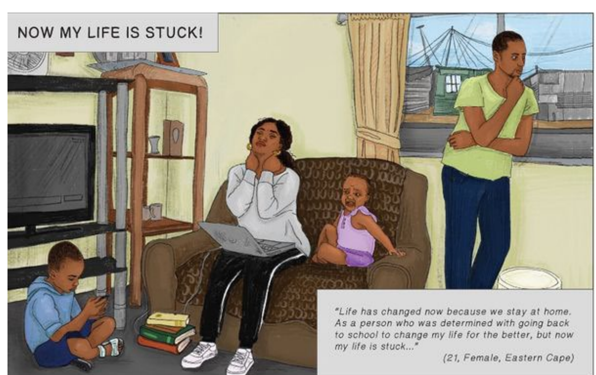
[1]University of Toronto, Factor-Inwentash Faculty of Social Work, Toronto, Canada, [2]University of Cape Town, Centre for Social Science Research, Cape Town, South Africa, [3]University of Oxford, Social Policy and Intervention, Oxford, United Kingdom

Background: Participatory visual methodologies have been used to take action against pressing social and health issues, challenge HIV-related stigma, and forefront the realities of marginalised populations. We engaged participatory visual methodologies to explore the COVID-19 experiences, challenges and coping of HIV-affected youth.

Methods: Two groups of HIV-affected adolescent advisors –recruited from studies of HIV-affected young people and adolescents living with HIV – shared their COVID-19 experiences in telephonic in-depth, semi-structured interviews (n=41), and over social media in closed Facebook groups (n= 27 activities) in 2020-2021.

We conducted thematic analysis, identifying seven themes. Each theme was visually translated into a draft illustration by a local artist. Illustrations were verified with participant groups over Facebook, and on the telephone with a sub-set of adolescent advisors (n=14).

Results: Participants included 42 youth (aged 16-29) from the Eastern Cape (n=19) and Western Cape (n=23) provinces. Themes included: feeling anxious and 'stuck' about uncertain futures; lacking basic necessities; inadequate social services; fear of COVID-19; mental health challenges; non-biomedical COVID-19 beliefs; concerns over policing; and lack of protective equipment. We created illustrations to visually depict these themes, then sought feedback over Facebook (n=27 participants) and calls (n=14) with the same group.



Participants suggested that the illustrations:

1. Visibilised and documented their experiences, making them feel 'seen' during an isolating time;
2. Helped them feel connected to other youth, even if they had not seen each other physically;

3. Elicited positive reflections on their coping strategies and abilities through COVID-19 related adversities.
They suggested that the illustrations should be engaged as a tool to advocate for improved health and social services, and that they be accompanied by an exemplary quote to contextualise visual data.
Conclusions: Visual participatory methodologies with HIV-affected youth are possible remotely, and can be engaged via social media to promote psychosocial well-being, reflection and knowledge mobilisation.

OAD0205
Pandemic déjà vu: reflections of long-term AIDS survivors and activists on the first year of COVID-19

S. Schwartz[1], J. Fockele[2], J. Flanzer[1], M. Larsen[1], K. Tinkham[1], W. Cholico[1]
[1]University of Southern California, Suzanne Dworak-Peck School of Social Work, Los Angeles, United States, [2]National AIDS Memorial, San Francisco, United States

Background: COVID-19 surfaced forty years after initial reports of the virus now known as HIV. The rapid spread of both viruses killing seemingly healthy people and early confusion about transmission has garnered attention on pandemic parallels. Current research examines similarities related to biology, disease management, social inequities, and government response. To compliment existing work, this paper explores pandemic similarities and differences from the perspectives of long-term AIDS survivors and early activists.
Methods: Using non-probability sampling methods, 52 semi-structured interviews were conducted in real time as the pandemic unfolded between April and November 2020. Fifteen follow-up interviews were completed in March and April 2021, during vaccine distribution. All interviews occurred over zoom, were recorded, and transcribed. Thematic analysis reveals insights on AIDS/COVID similarities and differences.
Results: The sample represents 8 countries, offering diverse perspectives on community response to COVID-19. Sixty-one percent identify as Male, 31% Female and 8% Transgender. Participants reflect upon several pandemic similarities to include stigma and 'othering'; health disparities; slow and inconsistent government response; and crushing fear and anxiety. Participants were quick to address a vital difference between the two pandemics specific to stigma surrounding disease transmission.
Since HIV/AIDS is spread through bodily fluids and COVID-19 through breathing, the social shaming associated with HIV is not evidenced with COVID-19. Some participants connect transmission differences with government response.
The role of media in information sharing and social isolation from support networks were also identified as chief differences in pandemic experiences. Traumatic memories from the 1980s and 1990s were triggered for all participants during COVID-19 shelter-in-place and many expressed anger over what lessons could and should have been learned from the past.
Conclusions: Alongside the physicians serving at the front lines of both pandemics are the AIDS activists and long-term survivors. These voices have received little attention despite the unique lens they offer into surviving two global pandemics. As COVID-19 continues to destabilize communities around the world, important lessons can be learned from these survivors as we navigate virus mutations and consider the long-term emotional trauma that can result from surviving a pandemic.

OAD03 What matters? Actual and perceived sexual risk for HIV acquisition

OAD0302
'Just like you would with an STI or HIV': sexual risk mitigation during COVID-19 among gay, bisexual, and other men who have sex with men (GBM) in Canada

E. Daroya[1], C. Grey[1], S. Skakoon-Sparling[2], B. Klassen[3], D. Lessard[4], J. Jollimore[3], N. Lachowsky[5], D. Moore[6], T. Hart[2,1], J. Cox[4], D.H.S. Tan[7,1], D. Grace[1]
[1]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, [2]Ryerson University, Toronto, Canada, [3]Community-Based Research Centre, Vancouver, Canada, [4]McGill University, Montreal, Canada, [5]University of Victoria, Victoria, Canada, [6]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [7]St. Michael's Hospital, Toronto, Canada

Background: The COVID-19 pandemic has impacted the sexual behaviours of gay, bisexual, and other men who have sex with men (GBM). Some GBM decreased their sexual behaviours, while others kept engaging in sex with people outside of their households or increased their number of sex partners. However, few studies have focused on how GBM who continued to engage in sexual behaviours assessed and managed risks.
We examined the strategies GBM have implemented to negotiate and mitigate sexual risks associated with COVID-19, HIV, and other sexually transmitted infections (STIs) during COVID-19 lockdowns.
Methods: We conducted semi-structured interviews with 93 GBM as part of Engage-COVID-19, a mixed-methods study examining the impacts of COVID-19 on GBM living in Vancouver, Toronto, and Montreal. Participants were recruited along four key dimensions: ethno-racial backgrounds, age, gender identity, and HIV status. Two rounds of online interviews took place between November 2020-January 2021 and June-October 2021. Interviews were transcribed verbatim and thematically coded using NVivo.

Results: Participants ranged in age from 24-76 years old. 73 participants self-identified as HIV-negative and 20 as living with HIV.

We identified four key preventive practices:

1. Asking about health status: participants who reported engaging in sexual behaviours mitigated sexual risks by inquiring about potential partners' HIV, STI, and COVID-19 status;
2. Reducing physical contact during sex: a few men implemented mask-wearing, avoided kissing, and engaged in voyeuristic masturbation to minimize physical contact;
3. Sex with regular partners: some engaged in sexual behaviours only with people they already knew and trusted; and;
4. Vaccine status sorting: most participants reported increased sexual activities after receiving COVID-19 vaccinations and used vaccine status sorting by only having sex with partners who have received COVID-19 vaccines.

Conclusions: Our results show that GBM who continued engaging in sexual behaviours during the COVID-19 pandemic implemented mitigation strategies to reduce risks associated with HIV, other STIs, and COVID-19.

Our findings shed light on how GBM are using knowledge gained from HIV prevention to inform their protective behaviours during the COVID-19 pandemic. Significant efforts are needed to provide resources acknowledging the multiple pandemics GBM are attempting to navigate at this time.

OAD0303

Syndemic factors and sexual risk behaviors among men who have sex with men in Guangzhou, China: a latent variable structural equation modeling approach

Y. Huang[1], J. Li[1], W. Cheng[2], Y. Yang[1], H. Jiang[1]

[1]*Guangdong Pharmaceutical University, Department of Epidemiology and Biostatistics, Guangzhou, China,* [2]*Guangdong Second Provincial General Hospital, Guangzhou, China*

Background: Men who have sex with men (MSM) were vulnerable to encounter syndemic factors, resulting in a higher risk of sexual risk behaviors. This study aimed to explore the interactions between the coexisting syndemic factors and condomless anal intercourse (CAI) and multiple sexual partners among MSM in Guangzhou, China.

Methods: A cross-sectional study was conducted to recruit MSM in Guangzhou from June 2017 to April 2018. Data on syndemic factors including childhood sexual abuse (CSA), intimate partner violence (IPV), depression, internalized homophobia (IH), higher level of Sexual sensation seeking (SSS), alcohol/rush popper use before sex were collected. Multi-order latent variable structural equation modeling (SEM) were performed to explore the syndemic effects of the coexisting psychosocial factors on sexual risk behaviors.

Results: A total of 500 MSM who had sex in the last 6 months were included. The proportions of CAI and multiple sexual partners in the last 6 months were 44.40% and 60.40%. The proportion of syndemic factors CSA, IPV, depression, higher level of SSS, IH, alcohol use and rush popper before sex in the last 6 months was 23.60%, 12.80%, 25.00%, 54.80%, 59.40%, 33.80% and 33.40%, respectively.

A larger number of syndemic factors was associated with higher risks of CAI (aOR=1.23, 95%CI:1.05~1.45) and multiple sexual partners (aOR=1.33, 95%CI:1.13~1.56). The second-order latent variable SEM was better than the first-order latent variable SEM with the ability to explain sexual risk behavior variation of $R^2_{\text{second order}}$=91% and $R^2_{\text{first order}}$=66%.

There was a strong linear relationship (Standard regression coefficient=0.96) between sexual risk behaviors and the syndemic burden which was formed by the potential interaction of violence (CSA and IPV), mental health (depression and SSS), and substance use (alcohol/rush popper use before sex). Mental health contributed the most to the syndemic burden ($R^2_{\text{mental health}}$=96%,$R^2_{\text{violence}}$=58%, $R^2_{\text{substance use}}$=34%).

Conclusions: MSM in Guangzhou were confronted with a high burden of multiple psychosocial problems. Multiple syndemic factors and their interactions should be fully taken into consideration when tailoring targeted interventions and health care policies to improve the effectiveness of the intervention. Mental health screening and psychological counseling should be prioritized under limited health resources.

OAD0304

Characterizing substance use typologies and their association with sexual risk behaviors: a latent class analysis among men who have sex with men in Mexico

A. Algarin[1], M. Valenzuela Lara[2], R. Baruch-Dominguez[3], M. Hernandez-Avila[4], T. Sanchez[2], S. Strathdee[1], L. Smith[1]

[1]*University of California, San Diego, Division of Infectious Diseases and Global Public Health, La Jolla, United States,* [2]*Emory University, Epidemiology, Atlanta, United States,* [3]*International Planned Parenthood Federation, Western Hemisphere Region, Mexico City, Mexico,* [4]*Mexican Institute of Social Security, Economic and Social Benefits, Mexico City, Mexico*

Background: Substance use behaviors are closely associated with increased risk for HIV and other STIs, but little has been reported about substance use among men who have sex with men (MSM) in Mexico. We characterized classes of substance use among a nationwide sample of MSM in Mexico and examined the associations between substance use classes, sexual behaviors and STI diagnosis.

Methods: The *Encuesta de Sexo Entre Hombres* study collected online survey data on substance use, sexual behavior and STI diagnosis in the past 12 months from 15,875 Mexican MSM between May-June 2017. Latent class analy-

Author Index

ses characterized substance use patterns and multiple multivariable regression models examined substance use class associations with sexual behaviors while controlling for age, education, sexuality, HIV status, and geographical region.

Results: We identified five distinct substance use classes: No Drug Use (75.4%), Marijuana Only (15.1%), Marijuana + Poppers (4.3%), Marijuana + Stimulants (4.2%), and Assorted Drug Use (e.g. Marijuana + Poppers + Stimulants + Other Substances) (1.0%). Demographic makeup of Classes were significantly different, where the Assorted Drug Use class was majority 25-39 years of age (71.4%; $p<0.001$), received a Bachelor's degree or more (73.6%; $p<0.001$), gay (89.0%; $p<0.001$), HIV negative/ unknown status (62.8%; $p<0.001$), and lived in the City/State of Mexico (50.0%; $p<0.001$)

We found that participants in substance use classes (e.g. Classes 2-5) were significantly more likely to engage in condomless anal intercourse (adjusted prevalence ratio [aPR]=1.14-1.39; all $p<0.001$), exchange sex for goods (aPR=1.37-4.99; all $p<0.001$), anonymous sex (aPR=1.22-2.01; all $p<0.001$), group sex (aPR=1.50-3.28; all $p<0.001$), and have an STI diagnosis (aPR=1.24-2.20; all $p<0.002$) in comparison to participants in the No Drug Use class, where the largest estimates were among the Assorted Drug Use class.

Conclusions: Understanding substance use groups and how group classification impacts sexual health in Mexico can better inform future interventions focused on reducing HIV incidence among MSM with varying substance use behaviors, particularly as policies begin to change following the Supreme Court ruling for the legalization of recreational marijuana in 2021 and methamphetamine use is growing exponentially.

OAD0305

Exploring the mental health experiences and perceived social and sexual risks among female sex workers in Nairobi, Kenya

M. Panneh[1], M. Gafos[1], H.A. Weiss[2], E. Nyariki[1], H. Babu[1], J. Seeley[1], P. Shah[1], J. Liku[3], M. Wanjiru[3], R. Wanjir[3], R. Kaul[4], J. Kimani[3], J. Bradley[2], T. Beattie[1]

[1]London School of Hygiene and Tropical Medicine, Global Health and Development, London, United Kingdom, [2]London School of Hygiene and Tropical Medicine, MRC International Statistics and Epidemiology, London, United Kingdom, [3]Partners for Health and Development in Africa, Nairobi, Kenya, [4]University of Toronto, Kings College Toronto Canada, Toronto, Canada

Background: Female sex workers in Kenya are at an increased risk of HIV infection, violence, poverty and harmful alcohol and other substance use, which are all linked to poor mental health and suicidal ideation/behaviours. Some of these distressful events may precipitate entry into sex work for some women. There has been limited qualitative research investigating the mental health experiences of female sex workers in Kenya. In this study we examine female sex workers' mental health experiences and perceived social and sexual risk factors over their life course.

Methods: We randomly selected 40 female sex workers enrolled in a longitudinal study in Nairobi, for baseline in-depth semi-structured interviews. Participants were asked to detail their life stories, including narrating specific events such as entry into sex work, HIV testing and diagnoses, experiences of violence, mental health, alcohol use etc. Interviews were recorded, transcribed and translated. Data were coded thematically using the Hierarchical Conceptual Framework to explore risk factors for mental health and suicidal ideation/behaviours.

Results: Based on the women's personal and second hand experiences, they related mental health to stress, depression and suicide. A few believed in the supernatural causes of mental health problems like witchcraft. Structural factors such as low levels of education, poor job opportunities, the lack of family support, harmful gender norms, intimate partner violence and subsequent relationship breakdowns, and family bereavement all contributed to poor mental health and subsequent entry into sex work. Their entry into sex work was despite the recognised risk of HIV, even though the majority were HIV negative when they started. The consequences of sex work such as sexual risks, concern about HIV acquisition, ongoing violence from police and clients, all exacerbated their poor mental health.

Conclusions: There is a need for both micro- and macro interventions to address poverty and gender-based violence among vulnerable women in Kenya, thereby reducing mental health problems, entry into sex work and risk of HIV acquisition. FSW programmes should include health promotion and screening for mental health problems to increase health seeking behaviour and access to services for FSWs.

OAD04 Innovations leading the way to HIV targets

OAD0402

Predictive modelling to determine defaulting from antiretroviral therapy (ART) services amongst adolescent girls and young women (AGYW)

M. Majachani[1], J. Murungu[2]

[1]Chinhoyi University of Technology, Graduate Businesss school, Harare, Zimbabwe, [2]University of Zimbabwe, Medicine, Harare, Zimbabwe

Background: Zimbabwe has made significant progress towards the 95%-95%-95% targets. However, outcomes are worse among adolescents and young people compared to other population groups. Only 49% of AGYW

aged 15-24 years on ART are virally suppressed compared to the national suppression rate of 90%. We therefore developed a supervised machine learning model to predict the risk of ART defaulting amongst AGYW.

Methods: Design science methodology was used to develop and assess the performance of algorithms to predict the risk of defaulting among AGYW initiated on ART between 2013 and 2016 at Mbare Polyclinic in Zimbabwe. The Cross Industry Standard Process for Data Mining (CRISP-DM) was applied to mine and analyse the data before modelling and evaluation. We used Decision Tree Classifier algorithms with neural networks to predict ART defaulting. A ten-fold cross-validated area under the receiver operating characteristic curve was used to assess the model's performance at identifying AGYW who defaulted ART. The best-performing algorithm was obtained with least absolute shrinkage and selection operator. The demographic and clinical characteristics of the 2055 patients who were filtered out were analysed.

Results: Data for 2,055 AGYW was analyzed of which 1,007 were AGYW, (median age 21 years), in the development cohort. The model was applied and successfully predicted defaulter outcomes for 606 AGYW with similar social characteristics to those who already had a defaulter outcome, and in-care outcomes for the remaining 442. Factors associated with defaulting ART included lack of disclosure and illegal cohabitation.

The predictive model yielded positive results, with the chosen algorithm's accuracy reaching 100 percent. The prediction model is likely to produce encouraging results when applied to other age groups of patients to evaluate their ART defaulting likelihood. Using factors associated with a higher risk of defaulting, the model can predict ART defaulters with accuracy and precision.

Conclusions: Automated algorithms efficiently identify patients at increased risk of ART defaulting. Integrating these models into Electronic Health Records to alert providers about patients who might default ART could improve adherence tracking.

OAD0403

Determining preferred attributes of a "virtual village" platform to halt isolation among people aging with HIV: a community-engaged project

A.L. Nguyen[1], B. Brown[2], K.Y. Greene[3], E. Ruiz[4], A.N. Polonijo[5], M. Yoo-Jeong[6], J. Taylor[7], C. Christensen[7], J.T. Galea[3]

[1]University of Southern California, Keck School of Medicine, Los Angeles, United States, [2]University of California, Riverside, School of Medicine, Riverside, United States, [3]University of South Florida, School of Social Work, Tampa, United States, [4]University of South Florida, College of Public Health, Tampa, United States, [5]University of California, Merced, Department of Sociology, Merced, United States, [6]Northeastern University, School of Nursing, Boston, United States, [7]HIV+Aging Research Project-Palm Springs, Palm Springs, United States

Background: COVID-19 exacerbated existing social isolation, depression, and anxiety among older people living with HIV (OPLWH). While the use of existing social networking platforms can help reduce social isolation, they lack specificity for addressing the needs of OPLWH. In response, we are developing a "virtual village" platform to reduce social isolation among OPLWH. As a first step, we investigated what OPLWH perceive to be the platform's most important attributes.

Methods: In collaboration with a community advisory board (CAB) of 24 OPLWH ≥50-years-old (from three sites: Palm Springs, CA, Los Angeles, CA, and Tampa Bay, FL), we constructed a list of 28 potential attributes for the virtual village.

Next, the CAB rank-ordered the attributes to identify the top-five most important and chose mutually exclusive levels (private chat [yes/no]; cost [free/paid]; sub-communities [yes/no]; social service directory [yes/no]; registration required [yes/no]) for each to create a choice-based conjoint experiment. English-speaking OPLWH ≥50-years-old who resided in a study city and had internet access were then recruited to participate in the experiment and received $50 for completion.

Participants compared eight groups of different combinations of four hypothetical virtual village "scenarios" comprised of the 5 attributes at differing levels, selecting the most acceptable scenario from each group. The relative importance of the attributes was calculated using Sawtooth Software's (2021) Hierarchical Bayesian Analysis.

Results: Participants (N=57) were 50-82 years-old (mean=59.8 years). Most (78.6%; n=45) identified as male. 64.1% (n=35) identified as White, 29.8% (n=17) as Black/African American, and 17.5% (n=10) as Hispanic/Latino/a/x. The preferred attributes for the virtual village in order of their relative preference, and their corresponding levels when compared to all other options (all p's < 0.05) were: cost (24.74%, free); chat function (22.91%, yes); communities (15.58%, yes); services (17.86%, yes); and registration (18.9%, required).

Conclusions: Participants identified the attributes/levels most important for inclusion in the Virtual Village. Continued development of our Virtual Village will prioritize these attributes during prototype development.

OAD0404

Interest of people living with HIV in injectable long-acting antiretroviral treatment: results from a flash AIDES survey

C. Lacoux[1,2], C. Rouquette[1], M. Salcedo[1,2], T. Alain[1,2], C. Le Gouez[1], D. Michels[1,2], B. Spire[1,3]
[1]*AIDES, Pantin, France,* [2]*Coalition PLUS, Community-based Research Laboratory, Pantin, France,* [3]*Aix Marseille University, Inserm, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, ISSPAM, Marseille, France*

Background: The end of 2021 in France was marked by the important therapeutic innovation of injectable long-acting antiretroviral (iARV) treatment for HIV. While healthcare professionals and pharmaceutical industries are hoping for better adherence and improved quality of life in people living with HIV (PLHIV), the latter's perceptions have not been explored.
To ensure good adherence to iARV, it is essential to identify PLHIV expectations of its benefits, their potential related fears, and obstacles they perceive to its implementation.
We aimed to identify factors associated with interest in iARV among PLHIV frequenting the French association AIDES.
Methods: From July to October 2021, an online and paper-based survey was distributed through the AIDES network via social networks and the association's newspaper *Remaides*. It comprised 16 questions collecting data on sociodemographics, interest in iARV, confidence in its efficacy, expected improvements in quality of life, and perceived potential obstacles to its implementation.
A multivariate logistic regression helped identify factors associated with a high level of interest in iARV ("very" versus "quite", "not really" and "not at all" interested).
Results: Among the 581 respondents, the majority were men (n=459; 79 %) and were born in France (n=477; 82 %). Median age was 52 years [42-59]. Approximately half (n=276, 47 %) were very interested in iARV.
Factors associated with a high level of interest were daily intake of non-ARV treatments (aOR=1.9[1.2-3.2]), cohabiting with persons unaware of the respondent's HIV status (aOR=2.3[1.3-4.1]), confidence in iARV efficacy (aOR=2.8[1.7-4.6]), expected improvements in quality of life (aOR=6.4[4.1-10.1]) and willingness to continue iARV despite potential side effects (aOR=4.4[2.6-7.6]).
In contrast, travelling to the hospital for iARV was seen as a constraint (aOR=0.6 [0.4-0.9]), while the ease of taking current (i.e., non-injectable) ARV (aOR=0.6[0.4-0.9]) was associated with a low level of interest in iARV.

Conclusions: PLHIV are interested in iARV, especially those whose current situation is complicated due to the confidentiality of their HIV status, or to difficulties following several treatments simultaneously. Having to go to hospital for iARV to ensure good adherence could constitute a barrier to uptake. One possible alternative is the use of ambulatory care providers.

OAD0405

DOTS PLUS: a promising approach to increasing adherence to tuberculosis, drug resistant tuberculosis and antiretroviral HIV treatment in Mozambique

A. Cassamo Omar Abdula[1], H. Hallstrom[2], M. Lichtenberg[3]
[1]*ADPP Mozambique, Project Implementation, Maputo, Mozambique,* [2]*ADPP Mozambique, Partnership, Maputo, Mozambique,* [3]*Planet Aid, Inc, USA, Elkridge, United States*

Background: According to World Health Organization Global Tuberculosis (TB) Report (2021), Mozambique is among the highest-burden countries for TB, TB/HIV co-infection and drug resistant TB (DR-TB), and is among 10 countries where over 75% of estimated DR-TB cases remain undetected. Currently, almost half (47%) of DR-TB cases are HIV+. Addressing barriers to treatment adherence must be a national priority to ensure people with TB are successful in completing their treatment regimens. Since 2019, ADPP Mozambique has been applying a holistic, patient centered approach through the enhanced Direct Observation Treatment Strategy (DOTS) PLUS, funded by USAID.
Description: ADPP, a local Mozambican civil society organization, leads the implementation of the Local TB Response project in four provinces of Mozambique, in partnership with FHI 360, Comusanas, Kupulumusana and DIMAGI. DOTS PLUS includes direct observation of treatment, **plus** psychosocial support, financial support (for nutrition, transport, and other costs), and provision of pill boxes to keep patients on track. It includes medication monitoring, regularly scheduled refills, home deliveries and accompanying patients to follow up appointments.
Lessons learned: During the first two years, the project identified 32,676 new TB cases (46% of all TB cases in the 50 target districts), and 86 DR-TB cases (16% of newly identified TB cases in targeted districts, and 7% at national level). From May 2020 to September 2021, 250 DR-TB patients received support from DOTS PLUS, with 99% adhering to TB and antiretroviral drug treatment (for those with HIV), and 65% achieving culture conversion upon treatment completion, with zero lost to follow up. These impressive results compare to a national average of only 60% for TB treatment completion, likely due to the added features of DOTS PLUS.
Conclusions/Next steps: Providing DOTS PLUS for TB, TB/HIV and DR-TB patients is crucial for ensuring treatment adherence as it provides more wrap around care and follow up support, improving treatment success and re-

ducing morbidity and mortality. ADPP will continue to promote DOTS PLUS for all TB and HIV response efforts, in a collaborative effort with the Ministry of Health and partners.

OAD05 Is violence a breaking point for HIV?

OAD0502
A behavior-based intervention investigating the effects of a gender-based violence (GBV) and sexual assault educational curriculum on improving male attitudes toward women in 4 sub districts in South Africa

N. Madubela[1], S. Voster[1], C. Wagner[1], M. De Vos[1], M. Vaynos[1]
[1]*NACOSA, Cape Town, South Africa*

Background: The rights of women, girls and other vulnerable populations continue to be compromised by high levels of GBV in South Africa. The prevalence of the issue, compounded by the impact of the Covid-19 pandemic, has triggered a 'secondary pandemic' marred by rising GBV and femicide (GBVf). In 2021, No Means No Worldwide (NMNW) and NACOSA launched the IMPOWER Boys program, an evidence-based intervention, delivering an educational sexual and GBV prevention curriculum.

Description: Overall, 16 male instructors were trained to facilitate an 8-hour curricular (4 classes, 2 hours each) in 4 sub districts namely: Klipfontein, Mitchells Plain, Tshwane and Bojanala. The target population was n=1120 boys (280 per sub district) aged between 10-24 years, in 7 months (August 2021 – December 2021).

The program was designed to increase gender equitable attitudes, learn skills to defend equality, avoid violence, ask for consent, and intervene when witnessing or anticipating sexual assault.

The Intervention was delivered using 3 models: In school (within school hours), after school (extracurricular) and out of school (in community spaces). Data on attitudes toward women were collected anonymously at baseline by administering pre-questionnaires and post questionnaires, and compared with baseline

Lessons learned: Overall participants had significantly higher positive attitudes toward women at follow-up. Median age is 19 years. 65% participants > 19 years. The percentage of boys who successfully intervened when witnessing violence was 78% for verbal harassment, 75% for physical threat, and 74% for physical or sexual assault. Data shows noteworthy gains in knowledge towards consent, intervening during cases of violence and gender roles shift in gender equitable attitudes with 82% able to provide desired responses. An average of 42% change between the pre/post intervention data, a significant 85% were able to accurately recollect core knowledge topics in the post questionnaires.

Conclusions/Next steps: A multifaceted response is needed to enhance the country's fight against GBVf and HIV/AIDS in a COVID-19 pandemic. This standardized 4-week training program proved to be effective in improving attitudes toward women and increasing the likelihood of successful intervention when witnessing GBV.

OAD0503
Impacts of intimate partner violence and sexual violence on antiretroviral adherence among adolescents living with HIV in South Africa

L. Cluver[1,2], S. Zhou[3,4], M. Orkin[5], S. Dzumbunu[3], F. Meinck[6,7], N. Langwenya[1,3], M. Vicari[8], L. Sherr[9], E. Toska[3,10]
[1]*University of Oxford, Department of Social Policy and Intervention, Oxford, United Kingdom,* [2]*University of Cape Town, Department of Psychiatry and Mental Health and Centre for Social Science Research, Cape Town, South Africa,* [3]*University of Cape Town, Centre for Social Science Research, Cape Town, South Africa,* [4]*University of Cape Town, Department of Public Health and Family Medicine, Faculty of Health Sciences, Cape Town, South Africa,* [5]*University of the Witwatersrand, Medical Research Council Development Pathways to Health Research Unit, School of Clinical Medicine, Johannesburg, South Africa,* [6]*University of Edinburgh, School of Social and Political Science, Scotland, United Kingdom,* [7]*University of the Witwatersrand, School of Public Health, Johannesburg, South Africa,* [8]*International AIDS Society, Geneva, Switzerland,* [9]*University College London, Institute for Global Health, London, United Kingdom,* [10]*University of Oxford, Social Policy and Intervention, Oxford, United Kingdom*

Background: We are failing to reach 95-95-95 for adolescents living with HIV (ALHIV). Adolescents in Sub-Saharan Africa are exposed to high rates of sexual violence and intimate partner violence (IPV). However, evidence on associations of sexual violence and ART adherence remains limited, with only three cross-sectional studies globally.

Methods: We conducted a longitudinal cohort, with interviews and clinical records from 1046 ALHIV aged 10-19 years, recruited from 53 government health facilities in South Africa's Eastern Cape (2014-2018; 57% female, 90% uptake, 94-97% retention, 3.4% mortality).Ethical approvals were given by the University of Cape Town, University of Oxford, provincial government and health facilities. We used a repeated-measures random effects model and marginal predicted probabilities to assess multivariable associations of self-reported sexual violence and IPV with ART adherence, validated against viral load suppression (<50 copies/ml). We fitted moderation models by gender.

Results: 51% of adolescents reported consistent ART adherence. ART adherence was associated with viral suppression (aOR 1.49, CI:1.03-2.14, p=0.033) controlling for age, sex, location, poverty, housing, and HIV acquisition mode. Exposure to IPV was associated with lower ART-adherence (aOR 0.39, CI:0.21-0.72, p=0.003), and so was sexual violence

Late-breaker abstracts

(aOR 0.54, CI:0.29-0.99, p=0.048). Marginal predicted probabilities showed that adolescents with no sexual violence or IPV exposure had a 72% (CI:0.70-0.74) probability of ART adherence compared to 38% (CI:0.20-0.56) for those exposed to both sexual violence and IPV. Moderation showed similar impacts of violence by gender.

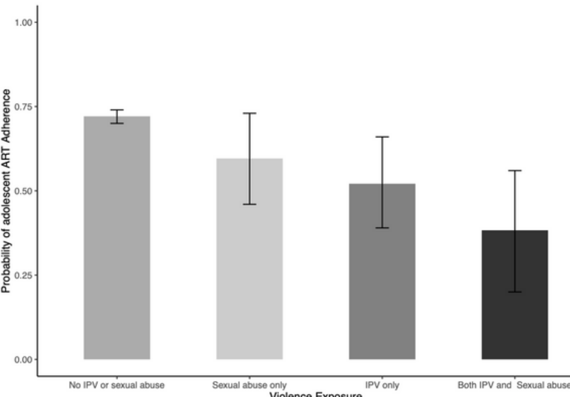

Figure 1: Adjusted predicted probabilities of past-week adherence

Conclusions: Effective sexual violence prevention and post-violence care are essential in supporting adolescent ART adherence. There is now increasing evidence of effective services across sectors, with systematic reviews identifying parenting programmes, classroom and community-based programmes in sub-Saharan Africa, and social protection such as government cash transfers in reducing sexual violence. There is an urgent need to link violence prevention and adolescent HIV services.

OAD0504

Targeted violence as a risk factor for posttraumatic stress disorder and HIV acquisition risks among cisgender gay, bisexual, and other men who have sex with men in the United States

J.M. Wiginton[1], S. Murray[2], S. Baral[3], T. Sanchez[4]
[1]San Diego State University, School of Social Work, San Diego, United States, [2]Johns Hopkins University Bloomberg School of Public Health, Department of Mental Health, Baltimore, United States, [3]Johns Hopkins University Bloomberg School of Public Health, Center for Public Health & Human Rights, Department of Epidemiology, Baltimore, United States, [4]Emory University Rollins School of Public Health, Department of Epidemiology, Atlanta, United States

Background: Posttraumatic stress disorder (PTSD) has been linked to HIV transmission risk behaviors among cisgender gay, bisexual, and other men who have sex with men (MSM) in the United States (US), and interpersonal violence carries the highest conditional risk of developing PTSD. Among MSM who have experienced interpersonal violence, characterizing risk factors for PTSD is critical to inform preventive and therapeutic intervention strategies.

Methods: Using a 2020 nationwide cross-sectional survey of 2,886 MSM (21.5% of 13,433 MSM surveyed) who reported ever experiencing interpersonal violence, we performed multivariable modified Poisson regressions with robust variance estimators to examine differences in prevalence of current PTSD by how participants attributed the experience of violence (as occurring because of one's same-sex practices, as not occurring because of one's same-sex practices, or unsure of whether or not it occurred because of one's same-sex practices).

We also examined the relationship between PTSD and past-year serodiscordant condomless anal sex. Control variables included age, education, race/ethnicity, sexual identity, urbanicity, and HIV status. Model results are reported as adjusted prevalence ratios (aPR) and 95% confidence intervals (CI).

Results: Median age of participants who experienced interpersonal violence was 27 years (interquartile range: 22-43); 78.8% identified as gay (n=2,273), and 62.2% (n=1,794) were non-Hispanic white. Interpersonal violence was attributed to same-sex practices by 45.8% (n=1,321) of participants; 46.3% (n=1,335) did not make this attribution, and 7.0% (n=203) were unsure.

Overall, 23.0% (n=665) had PTSD, and PTSD prevalence was greater among participants who attributed the violence to their same-sex practices (25.9%[342/1,321]; aPR[CI]=1.54[1.33-1.78]) or who were unsure (33.5%[68/203]; aPR[CI]=1.80[1.44-2.25]) compared to those who did not make the attribution (18.1%[242/1,335]).

Those who met criteria for PTSD were more likely to report serodiscordant condomless anal sex (27.0%[237/879] versus 21.3%[428/2,007]; aPR[CI]=1.22[1.08-1.38]).

Conclusions: Findings reveal the potential role of attribution in PTSD risk for violence-exposed US MSM and suggest a likely pathway between violence exposure, PTSD, and serodiscordant condomless anal sex.

Future research with longitudinal designs will be needed to establish temporal ordering to test this pathway. Moreover, progress on ending the US HIV epidemic will require interventions that simultaneously address mental and sexual health among violence-exposed MSM.

OAD0505

Impact of intimate partner violence on women's risk of HIV acquisition and engagement in HIV care cascade in sub-Saharan Africa: a meta-analysis of population-based surveys

S. Kuchukhidze[1], D. Panagiotoglou[1], M.-C. Boily[2], S. Diabaté[3], J. Eaton[2], F. Mbofana[4], L. Sardinha[5], L. Schrubbe[6], H. Stöckl[7], R. Wanyenze[8], M. Maheu-Giroux[1]

[1]McGill University, Department of Epidemiology, Biostatistics and Occupational Health, Montreal, Canada, [2]Imperial College London, Medical Research Council (MRC) Centre for Global Infectious Disease Analysis, London, United Kingdom, [3]Université Laval, Département de Médecine Sociale et Préventive, Quebec City, Canada, [4]Conselho Nacional de Combate ao HIV/Sida, Maputo, Mozambique, [5]University of Bristol, Bristol Poverty Institute, School for Policy Studies, Bristol, United Kingdom, [6]London School of Hygiene & Tropical Medicine, Department of Population Health, Faculty of Epidemiology and Population Health, London, United Kingdom, [7]Ludwig-Maximilians-Universität München, Institute for Medical Information Processing, Biometry, and Epidemiology, Munich, Germany, [8]Makerere University, Department of Disease Control and Environmental Health, School of Public Health, Kampala, Uganda

Background: Achieving the 95-95-95 targets for HIV diagnosis, treatment, and viral load suppression (VLS) to end the AIDS epidemic hinges on eliminating manifestations of structural inequalities, including intimate partner violence (IPV). Sub-Saharan Africa (SSA) has among the world's highest prevalence of IPV and HIV but an examination of the impact of IPV on HIV incidence, and women's engagement in HIV care cascade is yet to be conducted.

Methods: We pooled individual-level data from all available nationally representative surveys with information on physical and/or sexual IPV in SSA (2000-2020; Figure). We used generalized estimating equations with robust standard errors to estimate adjusted prevalence ratios (aPR) of lifetime and past year experience of IPV on HIV incidence (measured cross-sectionally by recent infection testing algorithm), past-year HIV testing (self-reported), antiretroviral therapy (ART) uptake, and VLS among ever-partnered women.

Models were adjusted for age, age at first sex, residence type, women's marital status, women's education, and survey as a proxy of time and country.

Results: Fifty-nine surveys were available from 30 countries, encompassing over 273,000 (N_i) respondents. Most surveys were from East Africa (48%); median survey year was 2013. Overall, 32% of women reported lifetime physical and/or sexual IPV (N_i=255,564) and 22% experienced IPV in the past year (N_i=273,603). Women exposed to past year IPV were 2.75 times (95%CI:1.26-6.00;N_i=19,852) more likely to have a recent HIV infection, adjusting for potential confounders. Past year IPV was not associated with HIV testing (aPR=1.00, 95%CI:0.98-1.01;N_i=273,603), but women living with HIV experiencing IPV in the last year were 10% less likely to be on ART (aPR=0.90; 95%CI:0.82-0.99;N_i=5,205) and to achieve viral suppression (aPR=0.90; 95%CI:0.81-0.99;N_i=5,205).

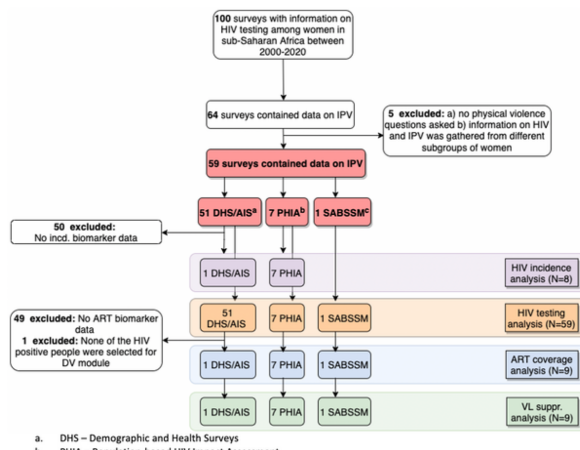

Figure.

Conclusions: IPV was associated with increased HIV incidence and, among women living with HIV, lower ART uptake and VLS. Preventing IPV is inherently imperative, and a crucial milestone in reducing population-level HIV incidence and burden.

OAD06 Building bridges to HIV prevention and care for children and young people: The role of the community and young people

OAD0602

Examining engagement in and initial efficacy of a structured peer health navigator intervention to improve HIV and related outcomes among YBMSM living with HIV

D. Gerke[1], J. Glotfelty[2], M. Freshman[2], A. Ochs[1], K. Plax[2]

[1]University of Denver, Graduate School of Social Work, Denver, United States, [2]Washington University School of Medicine in St. Louis, Pediatrics, Saint Louis, United States

Background: HIV health disparities among young black men who have sex with men (YBMSM) are often the result of a complex intersection of trauma, psychosocial cofactors, and low access to socioeconomic resources. To address these disparities and needs, the WITH U intervention employed peer health navigation that attended to behavioral health needs, linkage to services, and psychosocial support. This study reports on engagement and efficacy of the intervention.

Methods: This was a longitudinal mixed-methods single-arm study. Data were collected from enrollment and 6-month self-administered quantitative surveys with all

participants and semi-structured qualitative interviews with a sub-sample of 22 participants. Quantitative analyses included frequencies, means, and bivariate correlations. Deductive and inductive content analysis was used to analyze qualitative data.

Results: WITH U participants were 65 YBMSM, average age of 25-26 years (M=25.55,*SD*=2.51). Approximately one quarter of participants scored at or above the clinical cutoff for depression or anxiety symptoms, and over 40% reported being bothered by past traumatic stressors in the last month. More than half of participants reported food insecurity in the last three months, over a third were concerned about housing, and a quarter were unable to pay their utilities when needed.

Overall, participants reported high satisfaction with WITH U and attended an average of 5-6 of 12 possible sessions with health navigators (M=5.69, SD=3.05). Attending a greater number of sessions was significantly associated with being virally suppressed at enrollment ($rs(50)=.36$, $p<.05$) and six month-follow-up ($rs(38)=.34$, $p<.05$), as well as greater concern about housing ($rs(54)=.29$, $p<.05$) and experiencing unemployment for at least three months in the last year ($rs(54)=.29$, $p<.05$). This aligned with qualitative findings that navigator support around basic needs was critical to participants. Although participants identified mental health support from navigators as important, experiencing more depressive symptoms was significantly associated with attending fewer sessions ($rs(54)=-.32$, $p<.05$). A switch to virtual sessions due to the COVID19 pandemic was a barrier to engagement for some participants.

Conclusions: Engagement in WITH U was associated with improved health outcomes and social determinant health assistance needs. Novel methods for better engaging YBMSM virtually, especially those with depression, are needed.

OAD0603

Improving HIV outcomes amongst adolescents and young people living with HIV through adolescence and young people mentorship program

P. Ogunsanya[1], A. Ogunsanya[1], E. Kihika[1], D. Mpagi[1], J. Nampungu[1], L. Kansiime[1], Z. Timothy[1], I. Gulemye[1], C. Adongo[1], C. Ndeloa[2], D. Schlosser[2]

[1]*Alive Medical Services, Clinical, Kamapala, Uganda,* [2]*Frntline AIDS, Programs, Brighton, United Kingdom*

Background: According to the 2020 UNAIDS report there were over 170,000 adolescents and young people living with HIV (AYPLHIV) in Uganda. Viral load suppression rates were below 50% for the under 24 years and there were over 2800 AIDS related deaths a figure that has stagnated since 2015. Research has shown that poor adherence to ART, amongst AYPLHIV can be attributed to several factors including small support networks, forgetfulness, individual resilience factors and stigma.

Alive Medical Services (AMS) implemented AYP mentorship program aimed at supporting AYP with non-suppressed viral loads improve adherence and treatment outcomes.

Description: Between July-December 2021, AMS Identified consenting AYP who have achieved viral load suppression (VLS) and those with nonviral load suppressed (NVLS) matching them in groups disaggregated by age no more than 20 members. The groups met monthly at the youth corner and would dialogue, share their experiences, play in door games and offer support. VLS AYP would follow up their partners in the community with the help of the community linkage facilitator both virtually and physically. The ministry of health treatment protocols for the two groups were adhered to including intense adherence counselling sessions for the NVLS AYP. Those who suppressed at the end of the 6 months were engaged to support new AYP with NVLS

Lessons learned: Out of the 28 young people who were none suppressed at the start 22 have achieved viral load suppression and are now being engaged to support another group of young people with newly none suppressed viral loads 2 have been switched to the second line and are being followed up.

Friendships have been established, attitudes and behaviours have changed, adherence and appointment keeping has greatly improved

Conclusions/Next steps: Social factors play a crucial role in ensuring adherence to ART medication by AYPLHIV.

AMS plans to Scale up the AYP adherence mentorship program to all AYP in other facilities while working with the AYP to reach more AYP.

OAD0604

Zambia on the rise: addressing the challenges of young key populations inclusion

B.D. Nibogora[1], K. Mkandawire[2], W. Mulwanda[2]

[1]*UNDP, BPPS, Nepean, Canada,* [2]*UNDP, BPPS, Lusaka, Zambia*

Background: The linking policy to programming project in Southern Africa aimed at reducing HIV risks and improving SRHR outcomes amongst young key populations (YKP), namely young gay men and men who have sex with men, sex workers of all genders, drug users, transgender and inmates aged from 10 to 24 years.

The programme's objectives were to:

1. Build capacity for YKPs to claim their rights; (
2. Support policymakers to understand YKP needs and deliver tailored HIV and SRHR services;
3. Strengthen regional mechanisms providing standards to countries to end AIDS and achieve SRHR outcomes;
4. Generate strategic information through research for programmes' improvement.

This abstract presents lessons from Zambia.

Description: The project used a people's centred approach: putting YKPs at the centre of implementation, ensuring that project's focal staff, trainees, research personnel and advocacy task force members were from and accountable to YKPs. A regional team with expertise in policy advocacy and movement building supported in-country safe-space retreats to identify priority issues; development of a multi-stakeholders' roadmap for policy change and its roll-out by an advocacy task team. The advocacy process involved, among others, a media training to shift the narrative around sexuality and drug use. Regional convenings allowed for further sharing, exposure and learning.

Lessons learned: The programme allowed for an emergence of amore resilient movement of YKP advocates despite the hostile political context. In addition to existing groups[1], the programme strengthened new vibrant groups - such as the Intersex Society of Zambia, Umoto and Decisive Minds - led by young leaders from the intersex and gay community as well as drug users. Their engagement led to a development of an intersex model law supported by health professionals despite a hostile environment. Their media engagement also resulted in nuanced positive reporting on YKP and SRHR in Zambia.

[1] Groups such as Transbantu Zambia and Friends of Rainka

Conclusions/Next steps: The model teaches us that despite growing homophobia, investing in YKP using youth and health as entry-points is key to ending AIDS. In an era of increased online presence, positive media discourse is important to shifting social norms and acceptance of YKPs.

OAD0605

Young key populations speak out! this is what we want

A.N. Kyendikuwa[1], J. Ouma[1]

[1]*Global Network of Young People Living with HIV, Cape Town, South Africa*

Background: The Love Alliance is a five-year programme created to address the challenges in health and human rights that members of the Key Population group in all their diversities experience in their countries.In August 2021, Y+ Global alongside GNP+ convened a virtual global consultation with Young Key Populations (YKP) with the objective of understanding the advocacy visions and voices of young people within PWUD, LGBTQI, sex worker,s and PLHIV movements in the different regions to inspire Y+ Global, GNP+ and the Love Alliance in its work around young key populations living with or affected by HIV. The consultations were to provide a better understanding of the issues affecting the cohort, interventions needed and provide a focus on advocacy for the Love Alliance.

Description: The virtual consultation was attended by 31 participants, from more than 15 countries across the African continent and one country from Asia. The countries represented included; Zimbabwe, Lebanon, Kenya, Uganda, South Africa, Angola, Morocco, Nigeria, Zambia, Malawi, Burundi, Mozambique, Tanzania, Eswatini and Vietnam. The technicalities of the session including recordings and translations and identity sharing were shared with the participants. To promote inclusivity and active participation of the participants,the session had French and Portuguese translations as well as language based break out rooms.

Lessons learned: Gender inequality and criminalization, Stigma and discrimination, access to quality and YKP friendly HIV/SRH services and mental health issues are the major issues affecting YKP across the African continent hence they need revamped advocacy efforts, the main trends such as tokenistic and unethical engagement of YKP, criminalization and oppressive laws and policies such as age of consent within the spaces impact YKPLHIV advocacy and the disruptions of COVID-19.

Conclusions/Next steps: YKP need to participate in key spaces, activities and calendar moments that impact their lives. Y+ global under the love alliance continues to support the online and offline engagement of YKP and to strengthen youth-led advocacy with the recommendations that the participants provided.

OAD07 Integrated mental health approaches and care among people living with HIV

OAD0702

Social support attenuates the syndemic of poor HIV care and stigma on suicidal tendencies among South African young women living with HIV

W. Saal[1], B. Banougnin[1], L. Hertzog[1], E. Toska[1,2,3], L. Cluver[3,4]

[1]*University of Cape Town, Centre for Social Science Research, Cape Town, South Africa,* [2]*University of Cape Town, Department of Sociology, Cape Town, South Africa,* [3]*University of Oxford, Department of Social Policy and Intervention, London, United Kingdom,* [4]*University of Cape Town, Department of Psychiatry and Mental Health, Cape Town, South Africa*

Background: Young women living with HIV (YWHIV) are at increased risk of developing suicidality. Yet little is known about the combined effects of living with HIV on suicidality among YWHIV.

Methods: We analysed data from 791 YWHIV who participated in two large prospective South African cohort studies, Mzantsi Wakho (2017-2018) and HEY BABY (2018-2019). Standardised questionnaires were used to measure the syndemic factors, mental health issues (mediator), social support (moderator) and suicidality (outcome). A moderated mediation analysis was used to investigate (1) the

direct (individual and syndemic) effects of poor HIV care retention and HIV-related stigma on suicidality, (2) the indirect effects as mediated through mental health issues, and (3) the moderating effects of social support on mental health issues, and suicidality, controlling for potential confounders (age, rural residence, informal housing, household poverty, and mode of HIV acquisition).

Results: Higher HIV-related stigma (AOR=2.19, *p=0.012*) and poor HIV care retention (AOR=3.47, $p < 0.001$) were directly associated with higher suicidality. The combined direct effects of poor HIV care retention and HIV-related stigma on suicidality (14% points increased risks of suicidality, $p<0.001$) are higher than their individual effects (12% points increased risks of suicidality,$p<0.001$). Furthermore, both HIV-related stigma and poor HIV care retention were indirectly associated with suicidality via mental health issues. Social support buffered the direct and indirect effects of poor HIV care retention and HIV-related stigma on suicidality.

Conclusions: Combined effects of poor HIV care retention and HIV-related stigma are associated with higher suicidality, indicating a syndemic interaction. Programmes that simultaneously address these factors and strengthen social support services may improve mental health and reduce suicidality among YWHIV.

OAD0703

Mental health services utilization among young Black gay, bisexual, and other men who have sex with men living with HIV

K. Doraivelu[1], D. Camp[1], S. Moore[1], A. Kalokhe[1,2], M. Ali[1,2], E. Farber[2], S. Hussen[1,2]

[1]*Rollins School of Public Health, Emory University, Hubert Department of Global Health, Atlanta, United States,* [2]*Emory University School of Medicine, Atlanta, United States*

Background: Mental health (MH)comorbidities are prevalent amongyoung Black gay, bisexual, and other men who have sex with men(YB-GBMSM) living with HIV. However, it remains unclear what factors are associated with utilization of MH services among YB-GBMSM engaged in HIV care.

Methods: We conducted a cross-sectional survey of YB-GBMSM from two HIV clinics. Utilization of MH services was defined as at least one self-reported MH visit in their lifetime. Psychological symptoms were assessed using the Generalized Anxiety Disorder assessment-7, Center for Epidemiologic Studies Depression scale, Primary Care Post-Traumatic Stress Disorder Screen, and self-reported substance use in the last six months. Multivariate logistic regression models were used to evaluate covariates of lifetime MH care utilization.

Results: Among 100 YB-GBMSM, over half (51%) reported utilizing MH services, and 40% had been referred to a MH provider in the past year. In multivariate logistic regression analyses, non-organizational religious activity (OR: 1.33, CI: 1.01-1.77), severe anxiety (OR: 5.23, CI: 1.08-25.26), and homelessness in the past three months (OR: 4.03, CI: 1.08-15.07) were associated with MH care utilization. HIV stigma, discrimination in medical settings, and other psychological symptoms (depression, trauma, substance misuse) were not associated with utilization of MH services.

Conclusions: Our findings that MH utilization was associated with homelessness, NORA, and severe anxiety suggest that service providers should consider promoting MH services to a wider range of YB-GBMSM clients, specifically to clients that do not present with psychological symptom complexes. Additionally, future research should explore the complex relationships between religiosity and MH.

OAD0704

Loneliness and ARV adherence: results from a cohort study of people living with HIV in Ontario, Canada

L. Light[1], C. Hui[2,3], T. Hart[3,4], D. Brennan[5], A.E. Kroch[6,1,4]

[1]*Ontario HIV treatment Network, OHTN Cohort Study, Toronto, Canada,* [2]*Ontario Positive Asians, Toronto, Canada,* [3]*Ryerson University, Toronto, Canada,* [4]*Dalla Lana School of Public Health, University of Toronto, Toronto, Canada,* [5]*University of Toronto, Factor-Inwentash Faculty of Social Work, Toronto, Canada,* [6]*Public Health Ontario, Toronto, Canada*

Background: Social connectedness is important to human beings while loneliness can be detrimental to both mental and physical health. Our goal was to investigate the degree of loneliness experienced by people living with HIV (PLWH) and its impact on adherence to ARV medications using Ontario HIV Cohort Study (OCS).

Methods: OCS, a study of people Living with HIV (PLWH), collects clinical and socio-behavioral data from 15 HIV clinics in Ontario, Canada. In 2020, a 3-item short UCLA Loneliness Scale was added to the annual questionnaire. A loneliness score was categorized into 3 levels (low: 3-4, medium: 5-6, high: 7-9). Descriptive statistics and proportional odds models were used to identify factors correlated with loneliness. Impact of loneliness on ARV adherence was examined using logistic regression.

Results: Mean age (STD) of the 1,870 participants who completed loneliness scale was 52.2 (12.1), 22.8% were females, 57.6% gay men, 60% white, 21.7 % black, and 2.5% Indigenous. 19.6% of participants often felt lacking companionship, 13.2% felt left out, and 17.9% felt isolated.
Meanwhile, the majority hardly ever lacked companionship (49.6%), felt left out (60.7%) or isolated (53%). On the combined loneliness scale (range= 3-9, median (IQR) = 3(4-6)), 27.1% had medium level, and 20.7% had high level. Multivariable analysis reveals predictors of higher loneliness Score with OR (95%CI) are younger age 2.84 (1.80,4.48)

for <35, 3.18 (2.22,4.55) for 35-49, 2.18 (1,57,3.03) for 50-64 vs 65+ years old), being female 1.38 (1.06,1.79), single 4.04 (3.26,5.00), low income 1.51 (1.23,1.85) for <$20,000/year, and using alcohol 1.49 (1.08,2.07) and non-medicinal drugs 1.53 (1.13,2.07).

We found strong association between ARV non-adherence and higher loneliness scores [OR(95%CI) = 1.45 (1.14,1.84) for medium vs low, and 1.41 (1.08,1.85) for high vs low)], adjusted for age, sex, race, alcohol, and drug use.

Conclusions: PLWH with higher loneliness scores are more likely to skip their ARV medications. About 13% to 20% of OCS participants experienced at least one of the three aspects of loneliness, almost half have high scores on the combined loneliness scale.

More research is needed to identify relationship between loneliness and co-morbid conditions, such as substance use. Intervention strategies are need in communities of PLWH to combat loneliness, especially during current COVID-19 pandemic.

OAD0705

HIV and suicide risk across adolescence and young adulthood: an examination of sociodemographic, contextual, and psychosocial risk factors for attempted suicide in a longitudinal cohort of youth affected by HIV

P. Kreniske[1], C. Morrison[2], B.H. Spencer[3], A. Levine[4], L. Liotta[2], P.W. Fisher[5], N. Nguyen[6], R.N. Robbins[1], C. Dolezal[1], L. Kluisza[1], A. Wiznia[7], E.J. Abrams[8,9], C.A. Mellins[1]

[1]HIV Center for Clinical and Behavioral Studies, New York State Psychiatric Institute and Columbia University, Psychiatry, New York, United States, [2]HIV Center for Clinical and Behavioral Studies, New York State Psychiatric Institute and Columbia University, New York, United States, [3]Mailman School of Public Health, Columbia University, Department of Population and Family Health, New York, United States, [4]Research Foundation for Mental Hygiene, Mental Health Data Science, New York, United States, [5]New York State Psychiatric Institute and Columbia University, Child and Adolescent Psychiatry, New York, United States, [6]The Aaron Diamond AIDS Research Center, New York, United States, [7]Jacobi Medical Center, Albert Einstein College of Medicine, Bronx, United States, [8]ICAP at Columbia University, Mailman School of Public Health, New York, United States, [9]Columbia University, Vagelos College of Physicians & Surgeons, New York, United States

Background: Risk for attempting suicide increases dramatically as children become adolescents and young adults (AYA), with chronic health conditions being a risk factor. To date, no studies have examined correlates of suicidality across development in AYA living with perinatal HIV-infection (AYALPHIV) and those perinatally HIV-exposed but uninfected (AYAPHEU). Findings can inform much-needed interventions to support AYALPHIV and AYAPHEU as they age.

Methods: Data come from a longitudinal New York City-based study of health and psychosocial functioning in AYALPHIV and AYAPHEU (mean enrollment age = 12 years; current mean age = 27 years) interviewed every 12-18 months. Psychiatric disorders and first-reported suicide attempt were assessed with the DISC. Generalized estimating equations were used to examine associations between first-reported suicide attempt and sociodemographic, contextual, and psychosocial correlates measured concurrently across 6 time-points.

Results: At enrollment, 51% were female, 72% heterosexual, 57% Black, and 50% Latinx. Attempted suicide was significantly higher among AYALPHIV (27%) than AYAPHEU (16%) (OR = 1.74, p = 0.02). In the full and AYALPHIV samples, sexual minority identity, lower self-concept, negative life events, and past-year arrest were associated with increased odds of attempted suicide. For all groups, past-year anxiety, mood, or behavior disorders were associated with increased odds of attempted suicide. Among AYALPHIV, pregnancy and HIV stigma were associated with increased odds of attempted suicide. Interactions by HIV status and age group were found: substance use was more strongly associated with attempted suicide among AYAPHEU than AYALPHIV, while negative life events and higher religiosity were more strongly associated with increased odds of attempted suicide among AYA ages 19 and older than those 18 and younger.

Conclusions: Adolescence and young adulthood is a critical period when risk for attempted suicide rises precipitously. As our cohort aged into adulthood sociodemographic, contextual and psychosocial factors placed them at risk for suicidality and only higher self-concept was protective. Unique risks for attempted suicide were evident by PHIV-status with HIV stigma and pregnancy impacting AYALPHIV, and substance use a risk among AYAPHEU. Assessing for suicide risk and correlates with attention to aging can inform preventive interventions tailored to meet AYALPHIV and AYAPHEU needs.

OAD08 Stigma interventions: Improving health and wellness for people living with HIV and key populations

OAD0802
Intersecting stigma experiences among refugee youth sexual violence survivors in a humanitarian context in Uganda: implications for HIV cascade engagement in conflict settings

C. Logie[1], M. Okumu[2], A. McAlpine[1], M. Loutet[3], N. Kisubi[4], S. Odong[4]
[1]University of Toronto, Social Work, Toronto, Canada, [2]University of Illinois Urbana-Champaign, Urbana, United States, [3]University of Toronto, Toronto, Canada, [4]Uganda Refugee and Disaster Management Council, Yumbe, Uganda

Background: Youth sexual violence survivors' experiences accessing HIV services in the aftermath of humanitarian crises are understudied. This is a notable gap as refugee youth disproportionately experience sexual violence. We explored experiences accessing HIV and post-rape care among refugee youth sexual violence survivors in Bidi Bidi refugee settlement in Uganda.
Methods: We conducted a community-based qualitative study in Bidi Bidi, the world's second largest refugee settlement, implementing purposive sampling to recruit young refugee survivors (aged 16-24), community elders (aged ≥50), and service providers working in Bidi Bidi. We conducted 6 focus groups and 12 in-depth individual interviews (IDI) with refugee youth, 8 IDI with elders, and 10 IDI with service providers. We applied thematic analysis informed by the Health Stigma and Discrimination Framework to explore deductive and inductive themes associated with HIV and post-rape care engagement following sexual violence.
Results: Participants included: 60 youth (n=30 men; n=30 women; mean age: 20.9, standard deviation [SD]: 2.17) from South Sudan (83.3%) and the Democratic Republic of Congo (DRC) (16.7%), and 10 elders (n=4 women, n=4 men; mean age: 58.3, SD: 3.88) from South Sudan (87.5%) and the DRC (12.5%).
Healthcare providers (n=5 men, n=5 women; mean age 31.5, SD: 4.88) included midwives (n=4), clinical officers (n=4), a nurse (n=1) and a lab technician (n=1). Participant narratives revealed profound experiences of sexual violence stigma, including blame, shame, and mistreatment. This stigma was gendered, particularly targeting young women. Sexual violence stigma often resulted in young women's forced/early marriage to violence perpetrators. HIV stigma contributed to further violence exposure following an HIV diagnosis. Fear of HIV and sexual violence stigma presented substantial barriers to accessing post-rape care. Stigma spanned social-ecological levels, including mistreatment and rejection from family, friends, health providers and community members, contributing to internalized stigma. Limited emergency contraception access following sexual violence resulted in unwanted and early pregnancy, further exacerbating social exclusion.
Conclusions: Findings signal the intersection of sexual violence stigma, HIV stigma, and inequitable gender norms reduces post-rape care engagement and harms wellbeing among refugee youth. Gender transformative, multilevel intersecting stigma reduction strategies can both increase HIV cascade engagement and advance sexual rights with refugee youth.

OAD0803
From homophobic and sexist attitudes to tolerance toward LGBTQ+ individuals: critical consciousness as a tool against stigma

R. M. Pinto[1], C. Lee[2], M. Arthur[1], L. Windsor[1,2]
[1]University of Michigan, Social Work, Ann Arbor, United States, [2]University of Illinois Urbana-Champaign, Social Work, Urbana-Champaign, United States

Background: Research shows that Critical Dialogues (CD) after viewing illustrations of personal and historic oppression can help people develop critical consciousness and address internalized prejudices. This NIH-funded study uses data from recorded critical dialogue sessions from a behavioral group intervention to reduce substance use and recidivism among men.
We focused on homophobia and sexist attitudes as these are public health issues that predict harmful behavior. Critical consciousness raising -- understanding of and action against structural roots of oppression -- takes place when an individual moves from internalized prejudice to acceptance of self and others.
Methods: We used qualitative data collected during 13 sessions where 28 men of color with histories of incarceration and substance misuse (2-4 per group) viewed illustrations concerning gay/lesbian relationships. Four coders used NVivo to code transcripts and develop codes in an iterative process. We open-coded independently, discussed preliminary codes, and came to a 100% agreement about codes. Saturation occurred after 10 transcripts. "Member check" involved a Collaborative Board who reviewed findings and contributed to data interpretation.
Results: We identified four key themes – *Critical Appraisal* and *Critical Reactions* toward the illustrations; and *Critical Reflections* and *Critical Consciousness* around 14 subthemes. The initial discussion revolved around homophobic and sexist attitudes involving pejorative and stigmatizing terms – e.g., "*I don't like men datin' men. That's fuckin' disgustin'.*"
Halfway through the sessions, participants slowly understood that stigmatization supported oppressive structures that impacted them – e.g., *"Oh, man, why do I think like that? Are there other things that I need to consider?"*
Participants realized that clinging to beliefs/morals used

to uphold homophobia and sexism was, in their words, "crazy" – e.g., "*...because your family is a certain way, now you hate this person. How could you hate somebody if you don't even know 'em?"*

Conclusions: By engaging in CD, participants progressed from homophobic and sexist attitudes to greater understanding toward LGBTQ+ individuals and women. CD inspired by illustrations can help individuals develop critical consciousness around myriad issues that may help abate other forms of oppression, such as racism and xenophobia.

OAD0804

Partner social support and sexual satisfaction is associated with lower anticipated HIV stigma in Malawian couples living with HIV

A. Conroy[1], S. Gutin[1], A. Ruark[2], L. Darbes[3], T. Neilands[1], J. Mkandawire[4]

[1]University of California San Francisco, Center for AIDS Prevention Studies, San Francisco, United States, [2]Wheaton College, Applied Health Sciences, Wheaton, United States, [3]University of Michigan, School of Nursing, Ann Arbor, United States, [4]Invest in Knowledge, Zomba, Malawi

Background: Fear of HIV stigma can lead to non-disclosure of HIV status to partners and negative impacts on couple relationships; at the same time, partner support has the potential to reduce the harms of HIV stigma on health. Little research has focused on couples who have disclosed their HIV status and whether a supportive relationship could protect against anticipated experiences of HIV stigma outside the partnership.

We investigated the association between HIV stigma and relationships dynamics in couples living with HIV to identify dyadic targets for intervention.

Methods: Married couples (N=211) with at least one partner on antiretroviral therapy were recruited from HIV clinic waiting rooms in Zomba, Malawi. Partners completed separate surveys on anticipated HIV stigma outside of the relationship and relationship dynamics (e.g., intimacy, trust, sexual satisfaction, general social support from the partner, and couple communication patterns). Linear mixed models tested for associations between relationship dynamics and anticipated stigma, and whether this association varied by gender, after controlling for sociodemographics and relationship characteristics.

Results: Couples were together for 12.5 years, on average, and two-thirds were sero-concordant positive. In multivariable models, higher sexual satisfaction (b=-0.22, 95%CI= -0.41; -0.03, p=0.020) and partner social support (b=-0.02, 95%CI=-0.04; -0.01, p=0.006) were associated with less stigma, while negative communication styles such as withdrawal (b=0.13, 95%CI=0.04; 0.21, p=0.003), demanding (b=0.17, 95%CI=0.09; 0.24, p<0.001), and avoidant communication (b=0.26, 95%CI=0.13; 0.39, p<0.001) were associated with higher stigma. Associations did not vary by gender.

Conclusions: Couple-based interventions that promote constructive forms of couple communication, strengthen emotional and practical support within couples, and improve sexual satisfaction could reduce extra-dyadic HIV stigma and its negative impacts on the health of couples living with HIV in sub-Saharan Africa. Relationship dynamics such as sexual satisfaction and social support may be of equal importance for both men and women in efforts to reduce anticipated HIV stigma.

OAD0805

Social support, food insecurity and HIV stigma among men living with HIV in rural southwestern Uganda

I. Arinaitwe[1], H. Amutuhaire[1], D. Atwongyeire[1], E. Tusingweire[1], P.C. Kawungezi[2], G.Z. Rukundo[3], S. Ashaba[3]

[1]Mbarara University of Science and Technology, Faculty of Medicine, Mbarara, Uganda, [2]Mbarara University of Science and Technology, Faculty of Medicine, Department of Community Health, Mbarara, Uganda, [3]Mbarara University of Science and Technology, Faculty of Medicine, Department of Psychiatry, Mbarara, Uganda

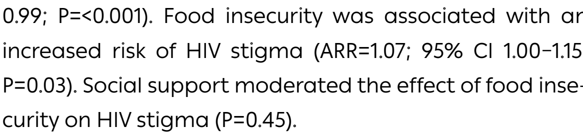
Background: HIV stigma is a significant factor in HIV/AIDS care, influencing uptake of HIV care services including HIV testing, initiation on antiretroviral therapy (ART) and retention in care. This is due to the fear of status disclosure and social discrimination. Internalized HIV stigma has been documented to be more common in men and it has the most impact on treatment adherence among people living with HIV. Information about HIV stigma and its associated factors among men living with HIV (MLWHIV) in rural Uganda is limited.

This study determined the burden of HIV stigma and its associated factors among men accessing HIV/AIDS care at a rural health facility in southwestern Uganda.

Methods: This was a clinic-based cross sectional study. We consecutively enrolled 252 adult men accessing HIV/AIDS care at a rural health centre in southwestern Uganda during the Corona virus pandemic. We collected information on sociodemographic information, HIV stigma using the Berger stigma scale, social support using the Multidimensional Scale of Perceived Social Support and food insecurity using the Household food insecurity Access Scale. We fitted modified Poisson regression models to determine the associations between social support, food insecurity and HIV stigma.

Results: The mean HIV stigma score of the study participants was 70.08 (SD 19.34) and almost half (48%) had high level HIV stigma. Most participants (75%) reported food insecurity, 5% of whom had severe food insecurity.

The risk of HIV stigma was lower among those aged 35 years and above (adjusted risk ratio [ARR]=0.89; 95% CI 0.83–0.96; P=0.003, those who had been on ART for more than 5 years (ARR=0.92; 95% CI=0.84–0.99; P=0.04), and those who had social support (ARR=0.99; 95% CI=0.98–



0.99; P=<0.001). Food insecurity was associated with an increased risk of HIV stigma (ARR=1.07; 95% CI 1.00–1.15; P=0.03). Social support moderated the effect of food insecurity on HIV stigma (P=0.45).

Conclusions: HIV stigma is common among MLWHIV in rural Uganda and is significantly associated with food insecurity. Social support moderated the effect of food insecurity on HIV stigma. We thus recommend social support interventions and economic empowerment of MLWHIV to improve their HIV treatment outcomes.

OAE01 Innovative differentiation: How best to deliver HIV testing, treatment and prevention services

OAE0102

Medical drones to support HIV differentiated service delivery in an island population in Uganda

R. Parkes-Ratanshi[1,2], J. Akullo[1], J.L. Ssemata[1], P. Ssesaazi[1], D. Masoni[1], J. Germann[3], T. Mutabazi[4], T. Pattery[5], T. Amukele[6], A. Kambugu[7], A. Kiragga[7], R. Kimbui[8]

[1]Infectious Diseases Institute, Academy for Health Innovation, Kampala, Uganda, [2]University of Cambridge, Clinical School, Cambridge, United Kingdom, [3]WeRobotics, Zurich, Switzerland, [4]Uganda Flying Labs, Kampala, Uganda, [5]Janssen, The Pharmaceutical Companies of Johnson & Johnson, Global Public Health, Beerse, Belgium, [6]Icon Plc, Dublin, Ireland, [7]Infectious Diseases Institute, Kampala, Uganda, [8]Johnson & Johnson, Supply Chain, Nairobi, Kenya

Background: Kalangala district, Uganda is comprised of 84 islands in Lake Victoria. These island-dwelling communities have the highest HIV prevalence (27%) and lost to follow up from HIV care (50%) in Uganda. Delivery of antiretroviral therapy (ART) is a challenge due to the geography and the nomadic nature of the community.

Description: Between July – September 2019 we undertook a survey of medical supply chain gaps for HIV care at health facilities in two sub-counties Bufumira and Mazinga) in Kalangala district. At baseline 5.3% of PLHIV were accessing care from differentiated service delivery (DSD). Most ART refills were managed through outreach visits to remote boat landing sites. Between 50-90% health care worker time outreaches is spent on ART refills; the remaining spent on maternal and child health and non-communicable diseases. Annual cost of outreach activities by these facilities boat is approximately $90,000. Data were used to design a quasi-experimental pilot to evaluate the feasibility and acceptability of using medical drones for ART delivery to peer support groups.

Lessons learned: Since September 2021 two DJI Matrice 300 drones have flown from Bufumira health centre to five remote landing sites previously receiving ART through boat outreaches. In September 2021 the medical drone delivered three months of ART to 43 PLHIV in seven DSD groups on three landing sites. In December 2021 drones replaced boat deliveries to 64 PLHIV in 11 DSD groups across five landing sites. Average flight time was 9.3 minutes for medical drone compared to 35 minutes per boat trip. Average distance from Bufumira to landing site was 6.6km (max 10km). Six peer support workers have been sensitised on how to prepare the drone landing pad, secure the area, safely unload ART from the drone and load documentation for return to Bufumira.

Conclusions/Next steps: The pilot will continue until June 2022, aiming to deliver to 100 PLHIV. The pilot will be evaluating:

i. PLHIV: ART stock outs, lost to follow up, viral load and:

ii. Impact on health facility: number of DSD groups, number of outreaches and impact on outreach costs.

Mazinga health centre and associated landing sites will be used as control comparison.

OAE0103

How efficient are HIV self-testing models? A comparison of community, facility, one-stop-shop and pharmacy retail distribution models in Nigeria

V.A. Adepoju[1], C. Umebido[2], Z. Hassan[3], A. Adetosoye[4], A. Olowu[5], T.E. Ademola-Kay[6], F. Quaitey[7], U. Ijeoma-Johnson[8], C. Laube[9], K. Grabbe[10], M. Strachan[11], H. Anyasi[12], D. Ndukwe[13], A. Ajijelek[14], J. Iseniyi[15], I. John-Dada[16], S. Omoighe[16], E. Atuma[17], A. Oniyire[18], A. Ikpeazu[19]

[1]Jhpiego Nigeria (an affiliate of John Hopkins University), HIV and Infectious Diseases, Abuja, Nigeria, [2]Jhpiego Nigeria, Strategic Information-HIV and Infectious Disease, Abuja, Nigeria, [3]Jhpiego, HIV and Infectious Disease, Abuja, Nigeria, [4]Jhpiego Nigeria, Technical Advisor-HIV Testing Services, TMEC/RISE Project, Abuja, Nigeria, [5]Jhpiego Nigeria, Supply chain Lead, Abuja, Nigeria, [6]Jhpiego Nigeria, HIV and Infectious Disease-STAR Project, Lagos, Nigeria, [7]Jhpiego Nigeria, HIV and Infectious Disease-STAR Project, Akwa-Ibom, Nigeria, [8]Jhpiego, HIV and Infectious Disease-STAR Project, Porthacourt, Nigeria, [9]Jhpiego, Senior Technical Advisor-HIV and Infectious Disease, Maryland, United States, [10]Jhpiego, HIV and Infectious Disease, Baltimore, Maryland, United States, [11]Jhpiego, Strategic Information Directorate, Baltimore, Maryland, United States, [12]FHI 360, Reproductive Health/HIV, Abuja, Nigeria, [13]National Agency for the Control of AIDS(NACA), Deputy Director, Prevention and SBCC, Abuja, Nigeria, [14]Jhpiego, Private Sector- Demand Side Financing, Abuja, Nigeria, [15]Jhpiego Nigeria, Laboratory Consultant-HIV Self Testing, Abuja, Nigeria, [16]Federal Ministry of Health, National AIDS/STI Control Program, Abuja, Nigeria, [17]Jhpiego Nigeria, Chief of Party-TMEC/RISE Project, Abuja, Nigeria, [18]Jhpiego Nigeria, Country Director, Abuja, Nigeria, [19]Federal Ministry of Health, National Coordinator-National AIDS/STI Control Program, Abuja, Nigeria

Background: In many Nigerian states, more than 95% of persons living with HIV now know their status. Nigeria is scaling up HIV self-testing (HIVST) to close testing gaps among populations not reached with conventional testing. Jhpiego, in close partnership with the National AIDS and STDs Control Program within the Federal Ministry of Health and National Agency for the Control of AIDS, has been providing catalytic support to enable the scale up of HIVST in Nigeria under the Unitaid-funded Self-Testing Africa (STAR) initiative since 2020.

Methods: We compared HIVST outcomes across 4 distribution models implemented by non-governmental and community-based organizations in Nigeria between October-December 2021, with technical and commodity support from STAR. A community-based distribution model targeted men, key populations (KP), adolescents, young people, and orphans and vulnerable children in hotspots within high burden Nigerian states; a facility-based model offered primary and secondary distribution via various healthcare services; KP one-stop shops (OSS) integrated HIVST distribution within their services, and a pharmacy model provided HIVST at reduced cost equivalent to USD 2.00.

Results: HIVST cascade data were collected, documented in relevant HIVST tools and descriptively analyzed as shown in table 1.

	Distributed	Results returned %	Reactive %	Linked to testing %	Concordant test %	Linked to ART
Community	33023	33023(100%)	192(0.6%)	156(81%)	124 (79%)	116 (94%)
Facility	15225	15100 (99%)	263 (1.7%)	250 (95%)	240 (96%)	235 (98%)
KP OSS	10301	10149 (99%)	340 (3.4%)	340 (100%)	338 (99%)	338 (100%)
Pharmacy	245	238(97%)	1(0.4%)	0	N/A	N/A

Table 1:

Conclusions: HIV testing yield and performance across the cascade was optimized through KP OSS. Trends warranting examination include:

1. Low yield in community and pharmacy settings suggest need for better targeting;
2. The absence of confirmatory testing following reactive tests from pharmacy distribution suggests a need for linkage support;
3. Low test concordance in community-based distribution suggests possible test or data quality issues; and,
4. High linkage to ART across models, with potential to improve following community-based HIVST.

More research is needed to understand the potential of each model as the Nigerian program advances.

OAE0104

How soon should patients be eligible for differentiated service delivery models for antiretroviral treatment?

L. Jamieson[1,2], S. Rosen[3,1], B. Phiri[4], A. Grimsrud[5], M. Mwansa[6], H. Shakwelele[4], P. Haimbe[4], M.M. Mwenechanya[7], P. Lumano-Mulenga[6], I. Chiboma[6], B.E. Nichols[3,2,1]

[1]University of Witwatersrand, Health Economics and Epidemiology Research Office, Johannesburg, South Africa, [2]Amsterdam University Medical Centre, Department of Medical Microbiology, Amsterdam, Netherlands, the, [3]Boston University School of Public Health, Department of Global Health, Boston, United States, [4]Clinton Health Access Initiative, Lusaka, Zambia, [5]International AIDS Society, Cape Town, South Africa, [6]Ministry of Health, Lusaka, Zambia, [7]The Centre for Infectious Disease Research in Zambia, Lusaka, Zambia

Background: Attrition from HIV treatment (ART) is highest during patients' first 6 months after initiation. Although ≥6 months on ART is an eligibility criterion for most differentiated service delivery (DSD) model guidelines, some patients enroll earlier. We used routinely-collected data on DSD models in Zambia to evaluate loss to follow-up (LTFU) comparing patients enrolling in DSD models early vs those who did so later (>6 months).

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Methods: We extracted data from electronic medical records for adults (≥15 years) initiated on ART between 01/01/2019 and 31/12/2019 and evaluated LTFU (>90 days late for last scheduled medication pickup) at 18 months for "early enrollers" (DSD enrolment within <6 months on ART) and "established enrollers" (DSD enrolment with >6 months on ART). We used a log-binomial model to compare LTFU risk between groups, adjusting for age, sex, urban/rural status, ART refill intervals and DSD model.

Results: For 6,340 early enrollers and 25,857 established enrollers, there were no important differences between the groups by sex (61% female), age (median 37 years), or setting (65% urban). ART refill intervals were longer for established vs early enrollers (72% vs 55% were given 4-6 month refills). LTFU at 18 months was 3% (192/6,340) for early enrollers and 5% (24,646/25,857) for established enrollers. Early enrollers were 41% less likely to be LTFU than established patients (adjusted risk ratio [95% confidence interval] 0.59[0.50-0.68]).

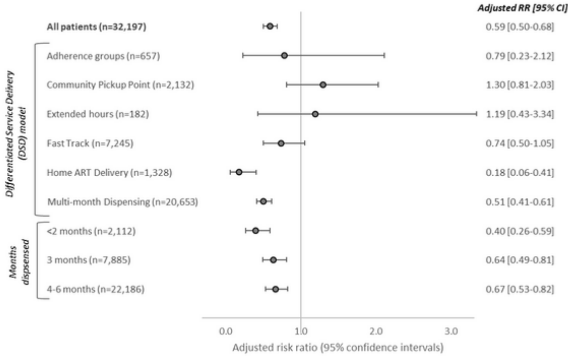

Figure 1. Relative risk of loss to follow-up within 18 months of DSD enrollment for Early Enrollers of DSD models compared to Established Enrollers, stratified by DSD model and ART months dispensed.

Conclusions: Patients enrolled early after ART initiation in DSD models in Zambia were more likely to be retained in care than patients referred after they were established on ART. A limitation of the analysis is that early enrollers may have been selected for DSD participation due to providers' and patients' expectations about future retention. Offering DSD model entry to at least some ART patients <6 months after ART initiation may help address high attrition during the early treatment period.

OAE0105

The effect of six-month PrEP dispensing supported with interim HIV self-testing on PrEP continuation at 12 months in Kenya: a randomized implementation trial

K.F. Ortblad[1], P. Mogere[2], A.R. Bardon[3,4], C. Kiptinness[2], D. Mangale[3], S. Gakuo[2], S. Mbaire[2], J. Nyokabi[2], K. Thomas[3], N.R. Mugo[5,3,2], J.M. Baeten[3,4,6,7], K. Ngure[8,2]

[1]Fred Hutchinson Cancer Research Center, Public Health Sciences Division, Seattle, United States, [2]Partners in Health and Research Development, Thika, Kenya, [3]University of Washington, Department of Global Health, Seattle, United States, [4]University of Washington, Department of Epidemiology, Seattle, United States, [5]Kenya Medical Research Institute, Center for Clinical Research, Thika, Kenya, [6]University of Washington, Department of Medicine, Seattle, United States, [7]Gilead Sciences, Foster City, United States, [8]Jomo Kenyatta University of Agriculture and Technology, Department of Community Health, Nairobi, Kenya

Background: In Kenya, HIV pre-exposure prophylaxis (PrEP) is primarily delivered at HIV clinics where client barriers to continuation include privacy concerns, long wait times, and setting-associated stigma. Six-month PrEP dispensing supported with interim HIV self-testing (HIVST) would reduce the number of clinic visits and potentially address some of these continuation barriers.

Methods: We conducted a non-inferiority trial to test this model of PrEP delivery in Thika, Kenya. Eligible participants were PrEP clients ≥18 years who returned for their first one-month follow-up visit. We randomized participants 2:1 to: 1) six-month PrEP dispensing with semiannual clinic visits and interim HIVST at three months, or 2) standard-of-care (SOC) PrEP delivery with quarterly clinic visits and clinic-based HIV testing. Pre-specified outcomes at 12 months included HIV testing (any in past six months and ≥2 times since enrollment) and PrEP refilling (at 12 months and both six and 12 months). We used binomial regression models, adjusted for sex and serodifferent partnership status, to estimate risk differences (RDs) and interpreted one-sided 95% confidence interval (CI) lower bounds (LB) ≥-10% as non-inferior.

Results: From May 2018 to February 2020, we enrolled and followed 495 participants. At 12 months, 73.3% (241/329) in the intervention and 72.3% (120/166) in the SOC arm returned to clinic. In the intervention arm, 69.9% (230/329) tested for HIV in the past six months and 72.3% (238/329) tested ≥2 times since enrollment, compared to 69.9% (116/166, RD -0.3%, 95% CI LB -7.4%) and 71.7% (119/166, RD 0.2%, 95% CI LB -6.8%) in the SOC arm, respectively. Additionally, 59.6% (196/329) in the intervention arm refilled PrEP at 12 months compared to 62.7% (104/166) in the SOC arm (RD -3.3%, 95% CI LB -10.8%, thus failing to demonstrate non-inferiority). However, 56.5% (186/329) in the intervention and 56.6% (94/166) in the SOC arm (RD -0.2%, 95% CI LB -7.9%) refilled PrEP at both at six and 12 months.

Conclusions: Six-month PrEP dispensing with interim HIVST resulted in high PrEP continuation at one year. HIV testing and PrEP refilling were generally comparable to SOC PrEP dispensing. This novel model has the potential to optimize PrEP delivery in Kenya and similar settings.

OAE02 Resilience: The new normal?

OAE0202

Responding to the challenges of a dual pandemic: how outreach mobile health clinics maintained HIV testing and linkage services in the face of COVID-19

N. Khozomba[1], J. Jere[1], M. Phiri[1], E. Geoffroy[2], M. Brostrom[2]
[1]GAIA Malawi, Limbe, Malawi, [2]GAIA Global Health, Oakland, United States

Background: In September 2021, The Global Fund declared COVID-19 a major setback in the fight against HIV/AIDS, reporting that HIV testing services (HTS) dropped 22% over the previous year globally. In Malawi, the COVID-19 pandemic threatens the dramatic progress made in recent years to achieve UNAIDS 95-95-95 targets, particularly in hard to reach communities.

Description: GAIA operates outreach mobile clinics, improving access to integrated HIV and primary health care services for communities far off the healthcare grid. In a public-private partnership with Malawi District Health Offices, seven clinics serve 35 sites weekly across three districts, where adult HIV prevalence is 16%, providing 250,000 client visits per year. In these remote regions, GAIA's HTS and linkage to care are critical to sustain epidemic control.

During the pandemic, GAIA mobile clinics maintained access to these essential health services for our vulnerable, rural clients through smart pivots. GAIA added staff to reduce client visit length and promote distancing; protected staff, clients and government partners with PPE; altered clinic workflow and care protocols to enhance safety; and improved hand-washing protocols and ventilation.

Lessons learned: In stark contrast to the global trend, HIV testing at GAIA mobile clinics increased by 22%, averaging 1272 tests per clinic between April 2020-December 2021 compared with 1042 during the 21 months prior. Of the 7,736 people tested, 86% were female and 3% tested positive (3% of females, 5% of males), of whom 90% were successfully reached for follow-up and 88% initiated ART.

During this period, the clinics operated 98% of the time, missing only 58 of 2715 clinic working days (83% COVID-related closures), providing HIV and COVID-19 related health talks to 54,761 and 242,358 attendees respectively, and facilitating vaccinations by government community health workers at mobile clinic sites.

Conclusions/Next steps: COVID-19 challenged many health providers' ability to provide HIV testing services, threatening progress in the fight against HIV/AIDS. Leveraging community trust and local government partnership, GAIA's mobile clinics maintained and increased access to high quality, easily accessible HTS throughout the pandemic. This flexible, community-based outreach approach to care provision is an effective model for rural health system strengthening and rapid crisis response.

OAE0203

Expanding role of village health workers in Lesotho: from supporting HIV patients to COVID-19 contact tracing

A.T. Andom[1], L. Ntlamelle[1], M. Matoko[1], J. Mabathoana[1], P. Chetane[1], M. Chere[1], P. Nkundanyirazo[1], T. Mohlouoa[1], S. Motsamai[1], R. Tlali[1], M. Mokoena[1], M. Msuya[1], M. Asfaw[1], M. Zulu[1], M. Ndayizigiye[1]
[1]Partners In Health, Maseru, Lesotho

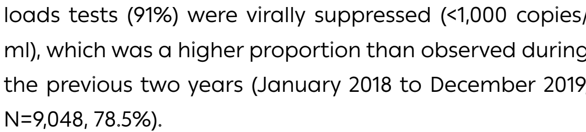
Background: The COVID-19 globally has strained health systems, particularly in developing countries like Lesotho, which have experienced a shortage of health workers during the pandemic. Since 2006, Partners In Health Lesotho (PIHL) has been supporting comprehensive HIV services at seven health centers in hard-to-reach areas of Lesotho. Prior to the pandemic, PIH had engaged and trained two village health workers (VHW) in each village, one who is dedicated to providing services to HIV patients and the second who is dedicated to maternal and child health.

Description: PIHL collaborated with the Ministry of Health of Lesotho to expand the scope of the work of the VHWs who support HIV patients to include COVID-19 screening and contact tracing. Through this intervention, 938 VHWs were trained on COVID-19 symptoms, infection prevention and control measures, contact tracing and case reporting. The VHWs received three day in-person training and personal protective equipment (PPE), including face masks, face shields and hand sanitizers. The VHW coordinator and health facility staff supervised and coached the VHWs to undertake COVID-19 related activities in addition to HIV patients' care at the community level.

Lessons learned: From May 2020 to December 2021, 87,634 people were screened for COVID-19, 430 clients were diagnosed with COVID-19, and 444 were contacts traced and isolated with the help of VHWs. During this time, VHWs continued to support 5,279 HIV patients, which was comparable to a pre-pandemic patient load (N=5168).

Between January 2020-December 2021, we completed 10,684 viral load tests, which was only a 7% reduction from the 11,533 tests performed during the two previous years (Jan 2018-December 2019).

However, average testing coverage during the pandemic remained greater than one test per patient per year. From January 2020 to December 2021, 9,737 viral



loads tests (91%) were virally suppressed (<1,000 copies/ml), which was a higher proportion than observed during the previous two years (January 2018 to December 2019, N=9,048, 78.5%).

Conclusions/Next steps: Providing VHWs with PPE and training to integrate COVID-19 infection services into their routine HIV prevention and care activities was an effective strategy to staff COVID-19 prevention and control programs without sacrificing high-quality HIV care.

OAE0204

MPOWER yourself: an online HIV self-test service to increase testing among gbMSM during COVID-19 restrictions

A. Shanley[1], D. Quinlivan[1]

[1]*HIV Ireland, MPOWER Programme, Dublin, Ireland*

Background: Opportunities to test for HIV in Ireland have increased in recent years, however, the COVID-19 crisis resulted in complete closure or significantly restricted access to HIV testing services across the country. In November 2020, the MPOWER Programme at HIV Ireland devised a free online HIV self-test ordering service to bridge the gap created by COVID-19 restrictions and increase HIV testing among gbMSM.

Description: An online portal was developed that allows gbMSM to order a free HIV self-test and have it delivered to their home address. MPOWER staff is available via helpline, WhatsApp, email, and on Zoom to assist in the use of the kit, and to offer support and referrals if needed. Demographic and behavioral data is collected during the ordering process and is stored separately from personal data. Service users receive an SMS two weeks after dispatch with a link to an evaluation survey.

Lessons learned: Such was demand, the total project supply of 2,000 HIV self-test kits were ordered within 13 days of launching the service. With the support of a mix of funding partners, the service resumed with limited weekly availability from April 2021 to the end of that year. 3,572 people in total received a self-test, 78% identified as gbMSM. 58% of users were aged 17-29. Across all users, 23% had never tested for HIV before. Notably, 95% of gbMSM were not using PrEP, of these men 32% had condomless anal sex in the 3 months prior to testing. 13 gbMSM received a reactive result, 5 reported their result through our support team, and 8 through the evaluation form. The evaluation received a response rate of 33%. Inability to access a sexual health service (20%), prefer not to attend a clinic or GP (20%), and having never tested before (28%) were cited as reasons for using the service.

Conclusions/Next steps: Online HIV self-testing services offer a unique opportunity to increase access to testing, engage first-time testers and key populations who experience barriers, including those created by COVID-19 restrictions. The development of a bespoke online portal allowed a seamless connection between data collection, analysis, kit dispatch, support, and referrals.

OAE0205

'Endeavor to reach the furthest behind first': promoting HIV prevention services using social media intervention in the era of COVID 19 among FSW in Benue State

B. Okeke[1], P.E. Durojaye[2], E. Maduabum[3]

[1]*Concerned Women International Development Initiative, Benue, Nigeria,* [2]*University of Western Cape, Cape Town, South Africa,* [3]*University of Abuja, Sociology, Abuja, Nigeria*

Background: Sex workers in Nigeria are affected by the COVID-19 pandemic . Also, lockdown and other measures by government to reduce the spread of COVID 19 limit access to HIV prevention services among sex workers. It is against this backdrop that CWIDI with support from Restless development fund uses social media to promote HIV prevention service among FSW.

Description: 20 FSW were trained as social media mobilizers to engage FSW through social networking platforms such as Facebook, WhatsApp, and Instagram. IEC materials were developed in local dialects and posted on selected social media platforms to raise awareness regarding HIV prevention strategies as well as COVID 19 prevention messages for FSW. The trained social media mobilizers engaged FSW that access these platforms through one–on-one interpersonal communication and provided HIV testing and refereed FSW for COVID-19 test.

Lessons learned: Data from August to December 2020 shows that social media is a safe space for communication among FSW and an effective tool to reach more FSW. 400 FSW were recruited through social media. 320 (80%) had not been tested for HIV within the last six months. Physical outreach reached 112 FSW; 52(46.4%) had not been tested within the last six months. Out of 320 recruited through social media who has not been tested for HIV within the last six month. 300 (93.8%) got tested for HIV, 56(18.7%) tested positive while 244(81.3%) tested Negative. Out of 52(46.4%) FSW reached through physical outreach who has not been tested for HIV within the last six months 40 (76.9%) tested negative while 12(23.1%) were positive. 20% of FSW recruited through social media engaged in inconsistent use of condoms compared to 60% identified through physical out reach. HIV positivity rate was higher among those reached through social media outreach compared to those reached through physical outreach. 100% of FSW reached through social media outreach got tested for COVID 19

Conclusions/Next steps: Linking FSW to services through social media has shown to deliver higher HIV prevention result among FSW. Hence, implementing partners should use social media as an effective tool for sharing HIV behavior change messages alongside COVID 19 messages for FSW.

OAE03 Optimizing investments for health: Cash, cost and prices

OAE0302

The effect of a conditional cash transfer program on AIDS morbidity and mortality among the poorest: a quasi-experimental study of a cohort of 22.7 million Brazilians

A.F. Silva[1,2], I. Lua[1,2], G.S. Jesus[1,3], N.S. Guimarães[1], G.A.S. Morais[1], R.V.R. Anderle[1], J. Pescarini[2], D.B. Machado[2,4], C.A.S.T. Santos[2], M.Y. Ichihara[2], M.L. Barreto[2,1], L. Magno[1,5], L.E. Souza[1], J. Macinko[6], I. Dourado[1], D. Rasella[1,2,7], DSAIDS
[1]Collective Health Institute, Federal University of Bahia (UFBA), Salvador, Brazil, [2]Center for Data and Knowledge Integration for Health (CIDACS) Gonçalo Moniz Institute, Oswaldo Cruz Foundation (FIOCRUZ), Salvador, Brazil, [3]Faculty of Medicine, Federal University of Bahia (UFBA), Salvador, Brazil, [4]Department of Global Health and Social Medicine, Harvard Medical School Boston, Boston, United States, [5]Department of Life Sciences, State University of Bahia (UNEB), Salvador, Brazil, [6]Departments of Health Policy and Management and Community Health Sciences, UCLA Fielding School of Public Health, Los Angeles, United States, [7]ISGlobal, Hospital Clinic - Universitat de Barcelona, Barcelona, Spain

Background: Poverty is a risk factor for HIV/AIDS but previous studies on the impact of conditional cash transfer programs (CCT) have shown inconsistent results. We evaluated the effects of one of the world's largest CCTs, the *Programa Bolsa Família* (PBF), on all sequential AIDS outcomes, using data from a nationwide cohort of the poorest Brazilian people on the Unified Registry for Social Programs (*Cadastro Único*).

Methods: We analyzed a cohort of 22.7 million low-income Brazilian people for the period between 2007 and 2015, comparing PBF beneficiaries and non-beneficiaries, using a quasi-experimental impact evaluation design. We used inverse probability of treatment weighting (IPTW) to adjust for selection into receipt of BFP benefits and then fitted multivariable Poisson regressions, adjusted for all relevant socioeconomic and demographic confounding variables, to estimate the effect of PBF on AIDS incidence, mortality, and case-fatality rates. We also performed subgroup analyses.

Results: Exposure to PBF was associated with a lower incidence of AIDS (RR: 0.59; 95% CI: 0.57-0.61), mortality (RR: 0.61; 95% CI: 0.57-0.64) and case-fatality rates (RR: 0.75; 95% CI: 0.66-0.85). PBF associations were significantly stronger among individuals living in extreme poverty, in comparison with those experiencing poverty (RR0.53 versus RR0.84 for incidence; RR0.54 versus RR0.90 for mortality, and RR0.72 versus RR1.00 for case-fatality). PBF impact was also stronger among females and adolescents.

Conclusions: Conditional cash transfers could significantly reduce AIDS morbidity and mortality, especially in extremely poor populations. During the current dramatic rise in global poverty, due to the COVID-19 pandemic, CCT investments could protect against potential increases in the HIV/AIDS burden, and contribute towards achieving AIDS-related Sustainable Development Goals (SDGs).

OAE0303

Cost-effectiveness of broadly neutralizing antibodies for HIV prophylaxis for all infants born in high-burden settings

Chan School of Public Health, Department of Health Policy and Management, Boston, United States

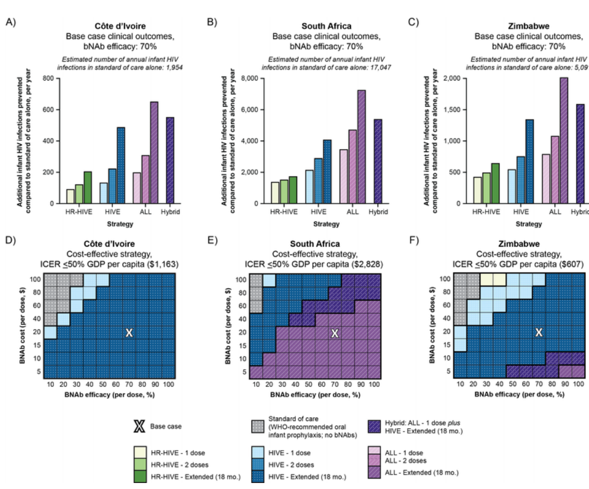
Background: Approximately 150,000 infants acquire HIV annually despite maternal antiretroviral therapy scale-up. We evaluated the potential clinical impact, cost, and cost-effectiveness of offering anti-HIV broadly neutralizing antibody (bNAb) prophylaxis, once clinically approved, to infants in various high-burden settings.

Methods: We simulated birth cohorts in Côte d'Ivoire, South Africa, and Zimbabwe using the Cost-Effectiveness of Preventing AIDS Complications (CEPAC) model. We modeled strategies offering a three-bNAb combination–

in addition to standard-of-care prophylaxis, where WHO-recommended–to infants: a) with known, WHO-defined high-risk HIV exposure at birth (*HR-HIVE*), b) with known HIV exposure at birth (*HIVE*), or c) regardless of known HIV exposure (*ALL*). Infants received one, two, or extended (every 3 months through 18 months) bNAb doses. We also modeled a strategy offering one birth bNAb dose to all infants plus extended dosing to infants with known exposure. Base-case model inputs, varied in sensitivity analyses, included bNAb efficacy (70%), efficacy duration/dosing interval (3 months), and cost ($20/dose).

Outcomes included infant HIV infections, life expectancy, lifetime HIV-related costs, and incremental cost-effectiveness ratios (ICERs, in US$/year-of-life-saved, assuming a ≤50% GDP per capita cost-effectiveness threshold).

Results: Under base-case assumptions, *HIVE* and *ALL* strategies would prevent 6-42% of infant HIV infections across settings (Figure 1A-C). Extended bNAbs for at least all known HIV-exposed infants would be cost-effective in all settings (Figure 1D-F). *HR-HIVE* strategies would result in greater lifetime costs and smaller life expectancy gains than *HIVE* strategies. At various bNAb costs and efficacies, *HIVE* strategies would be cost-effective in Côte d'Ivoire and Zimbabwe, and *ALL* strategies would be cost-effective in South Africa, partially driven by relatively higher maternal HIV prevalence (Figure 1D-F).



Conclusions: Adding long-acting bNAbs to current maternal-infant prophylaxis would be cost-effective over plausible cost and efficacy ranges, with the cost-effective target population varying by setting. Infant bNAb prophylaxis development and implementation should be prioritized in high-burden settings.

OAE0304

The relative cost-effectiveness of long-acting injectable cabotegravir versus oral pre-exposure prophylaxis: a modelled economic evaluation and threshold analysis in South Africa based on the HPTN 083 and 084 trials

L. Jamieson[1,2], L.F. Johnson[3], B.E. Nichols[4,2,1], S. Delany-Moretlwe[5], M.C. Hosseinipour[6,7], C. Russell[4,2], G. Meyer-Rath[1,4]

[1]*University of Witwatersrand, Health Economics and Epidemiology Research Office, Johannesburg, South Africa,* [2]*Amsterdam University Medical Centre, Department of Medical Microbiology, Amsterdam, Netherlands, the,* [3]*University of Cape Town, Centre of Infectious Disease Epidemiology and Research (CIDER), Cape Town, South Africa,* [4]*Boston University School of Public Health, Department of Global Health, Boston, United States,* [5]*Wits RHI, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa,* [6]*University North Carolina, Chapel Hill, United States,* [7]*UNC Project, Lilongwe, Malawi*

Background: Long-acting cabotegravir (CAB-LA), administered 2-monthly, is more effective at preventing HIV infection than daily oral tenofovir (TDF)/emtricitabine (FTC), but its cost-effectiveness in a high-prevalence setting is not known. We estimated the cost-effectiveness of CAB-LA compared to TDF/FTC in South Africa and determined the threshold price at which CAB-LA is as cost-effective as TDF/FTC.

Methods: We used deterministic HIV transmission modelling, evaluating the impact of CAB-LA provision compared to scaling up standard-of-care, TDF/FTC, to adolescent girls, young women, female sex workers, adolescent boys, young men, and men who have sex with men. We estimated the average cost by population using ingredients-based costing (costs in 2021 USD). We model the cost-effectiveness over 2022-2041, assuming two coverage scenarios (medium, high), assuming higher uptake of CAB-LA compared to TDF/FTC throughout based on preference studies. Under CAB-LA we modelled two scenarios defined by average duration of use (minimum: same duration as TDF/FTC of 5-11 months; maximum: longer duration than TDF/FTC, 12-24 months). We compare scenarios to the current baseline of low TDF/FTC roll-out.

Results: Across CAB-LA scenarios, 15%-28% of new HIV infections were averted over baseline compared to 5%-8% in oral TDF/FTC scale-up scenarios (Table 1). Assuming equivalent drug costs between CAB-LA and TDF/FTC, the incremental cost of CAB-LA to the HIV programme was higher than TDF/FTC (5%-14% vs 2%-4%) due to higher assumed uptake of CAB-LA. The cost per infection averted was $4,553-$6,803 (CAB-LA) and $6,053-$6,610 (TDF/FTC). The cost per CAB-LA injection needed to be less than twice that of a 2-month supply of TDF/FTC to remain as cost-effective, with threshold prices ranging between $8.99/injection (high coverage; maximum duration) and $14.21/injection (medium coverage; minimum duration).

Scenario	New HIV infections		Life years lost due to AIDS		CAB-LA drug cost relative to TDF/FTC drug	Total cost of the HIV programme (2021 USD)		Incremental cost effectiveness (2021 USD)	
	Number [millions]	*% averted over BL*	*Number [millions]*	*% saved over BL*		*Cost [billions]*	*Incremental cost over BL*	*Cost/ infection averted*	*Cost/ life year saved*
Baseline (BL)	3.02		37.34			41.29			
Medium PrEP coverage[1]									
TDF/FTC	2.89	4%	37.00	1%	N/A	42.08	2%	6,053	2,309

					5x	61.25	48%	23,323	8,628

Abbreviations: HIV=human immunodeficiency virus, AIDS=acquired immunodeficiency syndrome, CAB-LA =long-acting injectable cabotegravir, USD=United States dollars, BL=Baseline, PrEP=pre-exposure prophylaxis, TDF=tenofovir, FTC= emtricitabine

1. Medium PrEP coverage: TDF/FTC- 15% (female sex workers, FSW, and men who have sex with men, MSM), 5% (adolescent girls and young women, AGYW and adolescent boys and young men, ABYM); CAB-LA minimum duration- 25% (FSW, MSM), 20% (AGYW), 10% (ABYM); CAB-LA maximum duration- 40% (FSW, MSM), 35% (AGYW), 20% (ABYM)
2. High PrEP coverage: TDF/FTC- 30% (FSW, MSM), 10% (AGYW, ABYM); CAB-LA minimum duration- 50% (FSW, MSM), 40% (AGYW), 20% (ABYM); CAB-LA maximum duration- 67% (FSW, MSM), 60% (AGYW), 35% (ABYM)
3. CAB-LA minimum duration: average duration on CAB-LA to equal to that of TDF/FTC; 5 months (AGYW, FSW, ABYM) and 11 months (MSM)
4. CAB-LA maximum duration: average duration on CAB-LA assumed to be longer than that of TDF/FTC as a result of a higher preference for injectable; 12months (AGYW, FSW, ABYM) and 24 months (MSM)

Table 1. Impact and cost-effectiveness of CAB-LA and oral TDF/FT over a 20-year time horizon (2022-41)

Conclusions: CAB-LA is potentially game-changing for HIV prevention. However, for its implementation to be financially feasible across low- and middle-income countries with high HIV incidence, CAB-LA must be reasonably priced.

OAE0305

Variation in average unit prices (2020) of antiretroviral drugs in generic accessible low- and middle-income countries

D. Mattur[1], V. Habiyambere[2]
[1]UNAIDS, Geneva, Switzerland, [2]WHO(retired), Geneva, Switzerland

Background: By end 2020, 37.7 million people were living with HIV and 27.5 million people were accessing antiretroviral therapy (ART). Price transparency of anti-retroviral drugs (ARVs) will be key to optimize procurement and support in sustainable financing of HIV commodities.

Methods: Data on average ARV unit prices were extracted from reports to UNAIDS (Global AIDS Monitoring) and government customs to estimate the price trends in 2020 across 1st line and 2nd line ARV regimens & variations for ARVs in generic accessible low-and-middle-income countries (LMICs).

Estimates for person-years on treatment and unit price per person-year (ppy) were calculated from the volumes, expected dosage frequency for each regimen and price of ARV exports in LMICs. Analyses were stratified by year, regimen, income group and region.

Results: In 2020, the average unit price ppy of 1st line ARVs in LMICs was US$ 95. It was US$ 77 in low-income countries, US$ 92 in lower middle-income countries and US$ 117 in upper middle-income countries. The 1st line ART regimen was estimated to be most expensive in Eastern Europe and Central Asia with an average price of US$116 ppy. The West and Central Africa region, with an average price for 1st line ART of US$ 76 was the least expensive followed by US$82 in East and Southern Africa and US$83 in the Caribbean.

Overall, average unit price ppy of the second line ARV regimen in LMICs was US$256, 2.7 times more expensive than the 1st line ARV regimens.

The most expensive 2nd line ART regimen was Abacavir+Lamivudine+Raltegravir (US$ 747). The least expensive 2nd line ARV regimen was Zidovudine+Lamivudine+Dolutegravir with an average unit cost ppy of US$102.

Conclusions: There are large variations in average procurement prices across regions and income groups of countries. In the current environment of flat lined international resources for HIV, countries must look for options to optimize their procurement cost and thereby reallocate the resources saved through supply chain optimization to other programme needs.

OAE04 Achieving sustainability in the HIV response: Thinking differently!

OAE0402

Is local production of HIV commodities a feasible strategy for improving domestic ownership and financial sustainability of HIV epidemiological control in low- and middle-income settings?

F. Ilika[1], U. Ihekanandu[1], J. Nwizu[1], C. Ohazurike[1]
[1]Palladium, Health Policy Plus, Abuja, Nigeria

Background: Nigeria has about 1.9 million people living with HIV, with 1,228,100 on antiretroviral therapy in June 2020. Approximately US$126 million was invested in HIV commodity expenditure in 2018 with more than 81% from donors, while public and private funds accounted for 18% and 1%, respectively. Recently, HIV donor funding has decreased—from 92.3% in 2008 to 82.8% in 2018. Given this decline, the government is making efforts toward a more sustainable HIV financing approach. Local manufacture of HIV drugs was proposed as one of the sustainable strategies for mobilizing domestic resources for HIV in Nigeria's National Domestic Resource Mobilization and Sustainability Strategy for HIV (2021–2025).

Methods: A two-pronged approach was adopted to explore the feasibility of this strategy: (1) key informant interviews with multiple stakeholders, including national and state governments, pharmaceutical manufacturers and associations, biomedical companies, donors, and partner organizations, and (2) a desk review of available national reports, peer-reviewed and gray literature. This obtained understanding of the requirements, risks, and benefits of local production of ARVs in Nigeria.

Results: Local production of HIV commodities is a viable and sustainable strategy that can increase ARV access, improve efficiency, contribute to economic growth, and reduce dependence on external sources, however some challenges must be overcome. These include difficulty with obtaining prequalification approvals from the World Health Organization (WHO) and U.S. Food and Drug Administration (FDA); lack of guaranteed market for products, high import duties and taxes, financial constraints, and insufficient government commitment.
Recommendations to overcome barriers include enabling policies like direct fiscal and non-fiscal incentives by the government to local manufacturers, review of heavy tax burden, advance purchase commitment by the government, supporting pharmaceutical industries to attain prequalification, strategic joint venture with international pharmaceutical companies and multisectoral collaboration.
Conclusions: Local production of HIV commodities can be a viable and sustainable strategy for enhancing country ownership of HIV response. Local manufacturing companies are willing to take on this venture, if needed support and commitment are obtained. HIV actors in low- and middle-income settings can explore mechanisms of creating an enabling regulatory and policy environment with guaranteed buyer commitments through multisectoral partnerships.

OAE0403
Quantifying the health and economic impact of voluntary licensing of HIV medicines in low- and middle-income countries: putting numbers on additional uptake, deaths averted, and money saved by MPP licences

S. Morin[1], M. Das[2], O. Bubb-Humfryes[3], C. von Drehle[3], E. Burrone[1]
[1]Medicines Patent Pool, Geneva, Switzerland, [2]Medicines Patent Pool, Mumbai, India, [3]Cambridge Economic Policy Associates, London, United Kingdom

Background: Public-health licences enable the development, manufacturing, and uptake of generic versions of patented medicines in low- and middle-income countries (LMICs) before patent expiry. Generic competition reduces prices and supports accelerated uptake of optimal treatment regimens, leading to positive health outcomes.
However, quantifying this impact has seldom been done. Here, we build on previous work and present a thorough modelling study quantifying the health and economic impact in LMICs of Medicines Patent Pool (MPP) voluntary licences for multiple HIV medicines.
Methods: Building on a rigorous, evidence-based methodology previously applied to MPP licences for dolutegravir (DTG) and daclatasvir (Morin et al., The Lancet Public Health, 2021), we present an adaptation of the model, now applied to other MPP licences for HIV medicines and with updated results on DTG reflecting the most recent uptake data. Results for atazanavir (ATV), DTG (now also for paediatric use), lopinavir/ritonavir (LPV/r), and tenofovir disoproxil fumarate (TDF), together representing > 95% of MPP impact so far, are presented.
Results: By the end of 2020, MPP licences for HIV medicines ATV, DTG, LPV/r, and TDF are modelled to have led to an additional uptake of 1.0 [0.86 – 1.7] million patient-years treated, 830 [470 – 1,500] million USD saved, 7,500 [1,800 – 16,000] deaths averted, 63,000 [15,000 – 150,000] DALYs averted and 79,000 [17,000 – 190,000] virological failures averted. Results for each licence, including projections until 2030, are presented in Table 1.

	Additional uptake (patient-years treated)	Costs saved (million USD)	Deaths averted	DALYs averted	Virological failures averted
ATV	* 240,000 by 2020 * 330,000 by 2030	* 67 by 2020 * 76 by 2030	* 300 by 2020 * 410 by 2030	* 7,900 by 2020 * 11,000 by 2030	* 9,600 by 2020 * 13,000 by 2030
DTG (adult use)	* 710,000 by 2020 * 16,000,000 by 2030	* 280 by 2020 * 2,800 by 2030	* 7,000 by 2020 * 160,000 by 2030	* 50,000 by 2020 * 1,100,000 by 2030	* 64,000 by 2020 * 1,500,000 by 2030
DTG (paediatrics)	**No uptake as of 2020* * 42,000 by 2030	**No uptake as of 2020* * 61 by 2030	**No uptake as of 2020* * 180 by 2030	* *No uptake as of 2020* * 4,700 by 2030	**No uptake as of 2020* * 5,700 by 2030
LPV/r (adult use)	* 0 by 2020 * 0 by 2030	* 89 by 2020 * 89 by 2030	**Not applicable* * *Not applicable*	* *Not applicable* * *Not applicable*	**Not applicable* * *Not applicable*
LPV/r (paediatrics)	* 36,000 by 2020 * 36,000 by 2030	* 7 by 2020 * 7 by 2030	* 92 by 2020 * 92 by 2030	* 2,400 by 2020 * 2,400 by 2030	* 2,900 by 2020 * 2,900 by 2030
TDF	* 49,000 by 2020 * 49,000 by 2030	* 380 by 2020 * 380 by 2030	* 87 by 2020 * 87 by 2030	* 2,300 by 2020 * 2,300 by 2030	* 2,800 by 2020 * 2,800 by 2030
Total for MPP licences for HIV medicines	***1,000,000 by 2020** *** 17,000,000 by 2030**	***830 by 2020** *** 3,400 by 2030**	***7,500 by 2020** *** 160,000 by 2030**	***63,000 by 2020** *** 1,200,000 by 2030**	***79,000 by 2020** *** 1,500,000 by 2030**

Table 1. Disaggregated impact results – achieved by 2020 and projected until 2030 – for MPP licences for ATV, DTG, LPV/r, and TDF

Conclusions: Modelling the impact of MPP licences for HIV medicines offers visibility on the overall contribution to the global HIV response of the MPP model of public-health oriented voluntary licensing and a means to assess the investment (additional expenditure) that would be needed for the same level of optimal drug uptake without MPP licences: 22 billion USD in cumulative theoretical expenditures avoided by 2030.

OAE0404
Estimated costs to address unmet financial needs for HIV pre-exposure prophylaxis, United States, 2018

R. Bonacci[1], M. Van Handel[2], R. Huggins[1], D. Smith[1]
[1]U.S. Centers for Disease Control and Prevention, Division of HIV Prevention, Atlanta, United States, [2]U.S. Centers for Disease Control and Prevention, National Center for HIV, Viral Hepatitis, STD, and TB Prevention, Atlanta, United States

Background: An estimated 1.2 million persons in the United States (US) had indications for pre-exposure prophylaxis (PrEP) in 2018. The cost of PrEP medications and care

are frequently cited as barriers to increased PrEP uptake. We sought to understand the burden of financial needs for PrEP care and the cost to address them.

Methods: Using population-based surveys and published information, we modeled the number of persons who had unmet financial needs for PrEP care among US adults with PrEP indications, stratified by transmission risk group (men who have sex with men [MSM], heterosexual males [HET males] and females [HET females], and persons who inject drugs [PWID]), insurance status, and income level. We estimated the annual cost to address unmet financial needs for PrEP medication, clinical visits, and lab testing based on the 2021 PrEP clinical practice guideline.

Results: Of 1.2 million US adults with PrEP indications, we estimated that 64% had private insurance, 21% had public insurance, and 15% were uninsured. In total, 49,860 (4%) persons required PrEP financial assistance, including 32,350 MSM, 7,600 HET females, 5,070 HET males, and 4,840 PWID (Table).

	MSM	HET Females	HET Males	PWID	Total
Persons needing financial assistance for medication, clinical visits, labs[1](n)	2,020	460	680	0	3,160
PrEP medication, cost per person[2]	$5,324	$5,324	$5,324	$5,324	$16,822,660
Clinical visits, cost per person[3]	$671	$671	$671	$671	$2,120,390
Lab testing, cost per person[3]	$1,458	$478	$478	$506	$3,490,150
Total, cost per person	$7,453	$6,472	$6,472	$6,501	$22,433,200
Persons needing financial assistance for clinical visits and labs only[4](n)	30,330	7,140	4,390	4,840	46,700
Clinical visits, cost per person[3]	$671	$671	$671	$671	$31,336,170
Lab testing, cost per person[3]	$1,458	$478	$478	$506	$52,185,520
Total, cost per person	$2,129	$1,149	$1,149	$1,177	$83,521,690
Grand Total					$105,954,890

Table. Estimated cost for PrEP medication, clinical visits, and labs for adults with unmet financial needs, by HIV transmission risk group — United States, 2018

Abbreviations: HET, heterosexual; MSM, men who have sex with men; PrEP, pre-exposure prophylaxis; PWID, persons who inject drugs

[1]Persons with income ≥500% of the federal poverty line (FPL) were ineligible for medication assistance programs and needed assistance for PrEP medication, clinical visits, and lab testing

[2]Medication costs calculated as weighted average of 340B price for Truvada, Descovy, and generic tenofovir disoproxil fumarate/emtricitabine

[3]Costs obtained from Centers for Medicare & Medicaid Services

[4]Persons with income <500% FPL were eligible for medication assistance programs and needed assistance for PrEP clinical visits and lab testing only

Of those, 3,160 required assistance for PrEP medications ($16.8 million), clinical visits ($2.1 million), and lab testing ($3.5 million) at a cost of $22.4 million (Table); 46,700 required assistance only for clinical visits ($31.3 million) and lab testing ($52.2 million) at a cost of $83.5 million. The total annual cost to address unmet financial needs for adults with PrEP indications was $106.0 million.

Conclusions: The number of persons with unmet financial needs for PrEP is <5% among adults with PrEP indications, but costs to meet those needs are significant. Population size estimates and costs to address unmet needs can inform policy makers about resources needed to overcome financial barriers for PrEP.

OAE0405

Thailand national PrEP program: moving towards sustainability

C. Lertpiriyasuwat[1], S. Jiamsiri[1], R. Tiramwichanon[2], F. Langkafah[3], P. Prommali[1], Y. Srikhamjean[1], C. Manopaiboon[3], S. Northbrook[3]

[1]Ministry of Public Health, AIDS and STIs Division, Nonthaburi, Thailand, [2]National Health Security Office, Bangkok, Thailand, [3]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Nonthaburi, Thailand

Background: In Thailand, PrEP drugs are provided free of charge through government health care providers and key population-led health services (KPLHS) with external donor funding from The Global Fund, Thai Red Cross, and research projects. Thailand aims to gradually increase government funding and integrate PrEP service in the universal health coverage (UHC) benefit package, provided by the National Health Security Office (NHSO).

Description: To address PrEP service sustainability through government funds, the country worked on key systems health requirements including sharing evidence-based advocacy with policy makers, building capacity for health care staff, identifying and replicating best practice model to deliver PrEP, establishing a national PrEP monitoring system and PrEP targets, and developing PrEP implementation guidelines.

Lessons learned: By December 2021, current PrEP users in Thailand was 15,546; corresponding to a 7.3-fold increase from 1,865 in 2017. Starting in 2020, NHSO fund was allocated to pilot free PrEP as part of UHC; the fund accounted for 15% of PrEP users that year. In 2021, 44% of current PrEP users were from NHSO funding; almost three-fold increase from when NHSO program was first introduced in 2020, and three times more than the 5,000 PrEP user target set by NHSO.

Capacity building based on PrEP national guidelines was provided to 154 hospitals; 91 (59%) of these successfully set up PrEP service. 82% of current PrEP users in 2021 (n= 15,546) received PrEP services at KPLHS sites.

To increase sustainability and replicate the KPLHS best practice model, government is working on a KPLHS certification process to enable KPLHS sites to establish a formal partnership with government facilities to accelerate uptake of PrEP service. Despite these enabling policies and excellent health care infrastructure, Thailand current PrEP users only reached 35% of its 44,697 PrEP 2022 implementation goal.

Conclusions/Next steps: Thailand has built the foundations for PrEP program through evidence-based policy advocacy and guidelines, showing commitment through government financing of PrEP. Accelerating and promoting PrEP access and uptake through speeding PrEP service at KPLHS sites and government facilities will be key to support the scale up of PrEP in the country.

OAE0406

The economic returns of achieving the 2021-2030 AIDS targets to end the AIDS epidemic by 2030

E. Lamontagne[1,2], M. Over[3], J. Stover[4], A. Yakusik[1]
[1]UNAIDS, Strategic Information, Geneva, Switzerland, [2]Aix-Marseille University, School of Economics, Marseille, France, [3]Center for Global Development, Washington, DC, United States, [4]Avenir Health, Glastonbury, United States

Background: In 2019, several countries have achieved or were on track to end AIDS. Despite progress towards that goal, AIDS remains a global crisis. The gains achieved are still fragile in many countries. In June 2021, the General Assembly of the United Nations adopted the Political Declaration on HIV and AIDS: Ending Inequalities and Getting on Track to End AIDS by 2030. We estimated the benefits and costs of this ambitious commitment.

Methods: We estimated the incremental costs benefits and economic returns of a scenario which fulfils the AIDS targets stated in the Political Declaration, compared to a counterfactual scenario defined as maintaining coverage of HIV-related services at 2020 levels. The benefits are calculated using the full-income approach, which values both the change in income and in mortality. We value both the health gain and the intervention cost to each HIV-affected country from the perspective of that country, converting national benefits and costs to purchasing-parity-equivalent (PPP) 2019 US dollars.

We estimated the value of the projected reduction in the mortality rate of the HIV programmes as the amount an average person would pay to reduce their risk of death by one in 10,000 for one year. From the literature, this amount varies between 1.0 and 1.6% of GDP per capita. We allowed the income-elasticity of the willingness to pay for mortality risk reduction to decline at either 1% or 1.5% for every percentage decline of the country's income.

Results: Using the full-income approach, we found that each additional dollar invested between 2021 and 2030 generates US$ 7.37 [4.52-11.79] in economic returns. Returns on investment vary substantially between countries, regions, and income categories. Returns are higher in countries with higher purchasing power as measured by their GDP per capita. The benefits of investment are also highly correlated with the total number of adults living with HIV.

Conclusions: Using the latest scientific evidence in terms of benefit-cost analysis, it appears that investing to achieve the 2025 targets in the UNAIDS Strategy and the 2030 target in the Agenda for Sustainable Development provides significant returns from both human and economic perspectives.

[1]University of North Carolina at Chapel Hill, Department of Maternal and Child Health, Chapel Hill, United States, [2]University of North Carolina at Chapel Hill, Department of Epidemiology, Chapel Hill, United States, [3]Columbia University, Department of Psychiatry, New York, United States, [4]Vanderbilt University Medical Center, Department of Medicine, Nashville, United States, [5]University of Bordeaux, National Institute for Health and Medical Research, Research Institute for Sustainable Development, Bordeaux Population Health Research Centre, Bordeaux, France, [6]Indiana University School of Medicine, The Ryan White Center for Pediatric Infectious Disease and Global Health, Department of Pediatrics, Indianapolis, United States, [7]University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland, [8]TREAT Asia/amfAR, The Foundation for AIDS Research, Bangkok, Thailand, [9]Clinical Research Education and Networking Consultancy, Yaounde, Cameroon, [10]Johns Hopkins University, Bloomberg School of Public Health, Baltimore, United States, [11]Groupe Haitien d'Etude du Sarcome de Kaposi et des Infections Opportunistes (GHESKIO), Port au Prince, Haiti, [12]Centre Medical de Suivi de Donneurs de Sang/CNTS/PRIMO-CI, Abidjan, Cote D'Ivoire, [13]Moi Teaching and Referral Hospital, Department of Mental Health, Eldoret, Kenya, [14]University of Cape Town, Centre for Infectious Disease Epidemiology & Research (CIDER), School of Public Health & Family Medicine, Cape Town, South Africa, [15]National Center for Global Health and Medicine, Division of the AIDS Medical Information of AIDS Clinical Care, Tokyo, Japan, [16]CTA Brazzaville, Brazzaville, Congo, the, [17]City University of New York, Institute for Implementation Science in Population health, New York, United States, [18]The Ohio State University, Department of Epidemiology, Columbus, United States

Background: Common mental disorders (CMDs), including depression, anxiety, and post-traumatic stress disorder (PTSD) are highly prevalent among people living with HIV and associated with poor HIV treatment outcomes.

Integrating screening and treatment of CMDs into HIV care can improve mental health, HIV treatment outcomes, and quality of life. Data regarding the availability of mental health screening and treatment at HIV clinics remain scarce.

Methods: We describe the reported availability of mental health screening and treatment from a survey of HIV treatment sites in Africa, the Asia-Pacific, the Caribbean, Central and South America, and North America regions participating in the International epidemiology Databases to Evaluate AIDS (IeDEA) consortium. The survey captured information on site characteristics and reported availability of screening and treatment for depression, anxiety, and PTSD in 2020.

Results: Among the 223 HIV treatment sites that completed the mental heath portion of the survey, 67% were located in urban settings, 50% served adult and pediatric populations, and 38% served only adults. Most sites (78%) were located in low- or middle-income countries (LMIC). Overall, 50%, 14%, and 12% of sites reported using a validated instrument to screen for depression, anxiety, and PTSD, respectively. Screening and counseling/psychotherapy were available for treatment of depression, anxiety, and PTSD at 46%, 13%, and 11% of sites, respectively. Screening and psychiatric medication was available for the treatment of depression, anxiety, and PTSD at 36%, 11%, and 8% of clinics, respectively. Screening and treatment for all disorders assessed was more commonly reported at urban compared to rural sites and at sites in high-income countries compared to sites in LMIC.

	All n=223 n (%)	Low-income countries n=51 n (%)	Middle-income countries n=121 n (%)	High-income countries n=51 n (%)
Depression Screening	112 (50)	27 (53)	48 (40)	37 (73)
Screening and counseling	102 (46)	24 (47)	44 (36)	34 (67)
Screening and psychiatric medication	80 (36)	18 (36)	27 (22)	35 (69)
PTSD Screening	27 (12)	3 (6)	14 (12)	10 (20)
Screening and counseling	24 (11)	3 (6)	12 (10)	9 (18)
Screening and psychiatric medication	17 (8)	2 (4)	6 (5)	9 (18)
Anxiety Screening	32 (14)	2 (4)	17 (14)	13 (25)
Screening and counseling	29 (13)	2 (4)	16 (13)	11 (22)
Screening and psychiatric medication	24 (11)	2 (4)	10 (8)	12 (24)

Conclusions: Substantial gaps exist in the availability of mental health services at HIV treatment sites, particularly in rural and LMIC settings. Identification of barriers and implementation of feasible and sustainable strategies to integrate mental health services into HIV care is needed.

OAE0503
Using the RE-AIM framework to evaluate the implementation and effectiveness of a WHO HEARTS based implementation strategy to integrate the management of hypertension into HIV care in Uganda

M. Muddu[1], F.C. Semitala[1], I. Kimera[1], M. Mbuliro[1], R. Ssenyonjo[1], S. Kigozi[2], R. Katwesigye[1], F. Ayebare[2], C. Namugenyi[1], F. Mugabe[3], G. Mutungi[3], C. Longenecker[4], A. Katahoire[5], J. Schwartz[6], I. Ssinabulya[7]
[1]Makerere University Joint AIDS Program (MJAP), Clinical Servcies, Kampala, Uganda, [2]Infectious Diseases Research Collaboration (IDRC), Kampala, Uganda, [3]Uganda Ministry of Health, NCDs, Kampala, Uganda, [4]University of Washington, Washington, United States, [5]Makerere University College of Health Sciences, Kampala, Uganda, [6]Yale School of Medicine, Medicine, New Haven, United States, [7]Uganda Heart Institute, Kampala, Uganda

Background: World Health Organization (WHO) HEARTS packages are increasingly used to control hypertension. However, their feasibility for hypertension control in persons living with HIV (PLHIV) is unknown. We studied the effectiveness and implementation of a WHO HEARTS based implementation strategy to integrate the management of hypertension into HIV care.

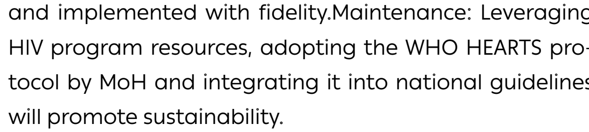
Methods: This was a mixed methods study at Uganda's largest HIV clinic. Components of the implementation strategy were: lifestyle counseling, free hypertension medications, hypertension treatment protocol, task shifting and monitoring tools. We used a pre-post study to determine effectiveness of the implementation strategy on hypertension and HIV outcomes among PLHIV over 21 months. The RE-AIM framework evaluated implementation of the strategy from stakeholders' perspectives. We conducted four focus group discussions with PLHIV (n=42), in-depth interviews with PLHIV (n=9), health care providers (n=15) and Ministry of Health (MoH) policy makers (n=2).

Results: Reach: WHO HEARTS based integrated hypertension-HIV care was acceptable as all 48 (100%) healthcare providers in the clinic were trained. All 15,953 (100%) adult PLHIV were screened and 3,892 (24.4%) diagnosed with hypertension. Of these, 1,084 (28%) initiated HTN treatment compared to 39 (1%) at baseline. Among enrolled patients, mean age was 51.5±9.7 years and 679 (62.6%) were female.

Effectiveness: Among patients treated, controlled hypertension improved from 5% to 75% ($p<0.0001$), mean systolic BP 152.9 ± 0.7 to 130.2 ± 0.9 mmHg ($p<0.0001$) and mean diastolic BP 96.7 ± 0.5 to 83.7 ± 0.6mmHg ($p<0.0001$).

Overall, 1098 (95.6%) of patients were retained by month 21. HIV viral suppression remained high, 97% to 100% ($p=0.063$). Patients who received integrated hypertension-HIV care felt healthy and saved more money.

Adoption: Training healthcare providers on WHO HEARTS, task shifting, synchronizing clinic appointments for hypertension and HIV and relative advantage promoted adoption. Implementation:WHO HEARTS strategy was feasible



and implemented with fidelity.Maintenance: Leveraging HIV program resources, adopting the WHO HEARTS protocol by MoH and integrating it into national guidelines will promote sustainability.

Conclusions: WHO HEARTS implementation strategy promoted integration of hypertension management into HIV care. It was acceptable, feasible and effective in controlling hypertension and maintaining optimal viral suppression among PLHIV. Integrating this strategy into national guidelines will sustain the implementation.

OAE0504

Successful transition to tenofovir/lamivudine/dolutegravir (TLD) in PEPFAR-supported countries

J. da Silva[1], S. Vallabhaneni[1], R. Pati[1], H. Chun[1], C. Malati[2], D. Kiesa[2], J. Rosenfield[2], M. Belayneh[2], K. Fisher[1,1], G. Siberry[2], E. Raizes[1], C. Godfrey[3]

[1]Centers for Disease Control and Prevention, Division of Global HIV and Tuberculosis, Atlanta, United States, [2]United States Agency for International Development, Washington, DC, United States, [3]Office of Global AIDS Coordination, Washington, DC, United States

Background: PEPFAR begun supporting the transition to tenofovir/lamivudine/dolutegravir (TLD) for people living with HIV (PLHIV) in 2017. In 2018, the possible association of maternal DTG use and offspring neural tube defects delayed uptake of TLD. In 2019, based on reassuring additional data, PEPFAR renewed efforts to transition several million supported clients to TLD. We describe the lessons learned and the results of a massive multisectoral effort to provide optimized treatment to all PLHIV.

Description: From 2017 to 2021, PEPFAR promoted policies and programmatic interventions among its 35 supported countries to increase the uptake of TLD. Key elements were the removal of programmatic barriers such as pre-transition viral load (VL) test and the streamlining of technical guidance by recommending TLD as preferred regimen for naïve, suppressed, non-suppressed and individuals with unknown VL status, and to male and female adults, adolescents and eligible children, thus simplifying supply chain and implementation at site level.

Lessons learned: Based on routine PEPFAR programmatic data on antiretroviral dispensation, TLD made up 41% of drugs dispensed to adults in PEPFAR-supported countries in April 2020, this proportion doubled to 81% by October 2021. For all but one PEPFAR-supported country with >1 million PLHIV, TLD accounted for at least 80% of antiretrovirals dispensed. Viral suppression has increased in all age bands since TLD rollout begun, but remains lowest among children.

Conclusions/Next steps: Roll out of DTG-based regimens to children should be prioritized with the recent pediatric formulations approval. Strategies to improve adherence among PLHIV non-suppressed on TLD may be needed to achieve the 3rd 95 UNAIDS target.

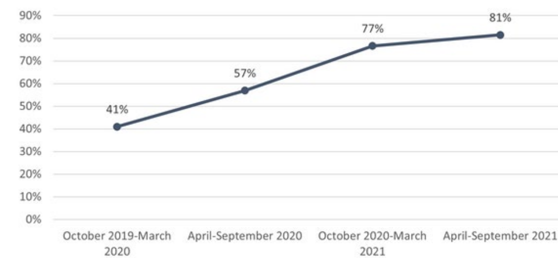


Figure. Proportion of TLD among all antiretrovirals dispensed to adults in PEPFAR-supported countries.

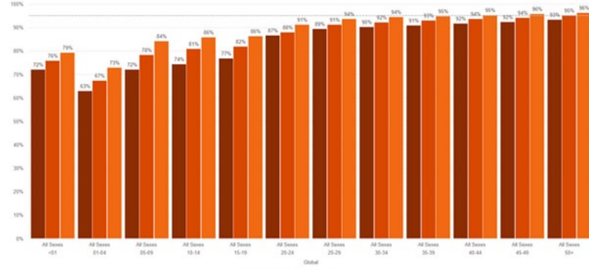

Figure.

OAE0505

Integration of hepatitis B and C testing into HIV services: an opportunity to achieve dual elimination of viral hepatitis and HIV in Vietnam

B. Vu Ngoc[1], K. Do Tuan[1], A. Tran Khanh[1], L. Tran Khanh[1], K. Green[1], K. Nguyen Trong[2], P. Cao Duc[2], N. Ngo Thuy[1], L. Tran Thi Huong[1], K. Do Quang[3], P. Nguyen Anh[4], T. Le Van[5]

[1]PATH, SE Asia, Hanoi, Viet Nam, [2]Vietnam Administration of Medical Services, Ministry of Health, Hanoi, Viet Nam, [3]Galant Clinic, Ho Chi Minh City, Viet Nam, [4]My Home Clinic, Ho Chi Minh City, Viet Nam, [5]Glink Clinic, Ho Chi Minh City, Viet Nam

Background: Testing is the gateway for access to hepatitis prevention and treatment services, but there remains a large burden of undiagnosed hepatitis B (HBV) and C (HCV) infection in Vietnam. We implemented HepLINK initiative to demonstrate integration of HBV/HCV testing into HIV services to accelerate access to viral hepatitis treatment among key populations (KPs) in Hanoi and Ho Chi Minh City.

Description: We engaged 9 KP-led community-based organizations (CBOs) and 18 clinics (12 public; 6 private) in providing community-based testing (CBT) and facility-based testing (FBT) and linkage to HBV/HCV care and treatment. Clients seeking HIV testing, pre-exposure prophylaxis (PrEP), antiretroviral therapy (ART), and methadone maintenance treatment (MMT) were offered HBV/HCV screening using a single blood-based rapid diagnostic test. Those with a reactive result were linked to confirmatory testing and treatment.

Lessons learned: From April-October 2021, we reached 8,840 KP, of which 86.9% accepted HBsAg testing, yielding 689 (9%) positive cases. CBT yielded a higher HBsAg posi-

tivity rate than FBT (11.5% and 4.9%, respectively), whereas FBT had a higher rate of enrollment on treatment than CBT (90% and 62.1%, respectively). HBsAg+ infection rate was highest in female sex workers-FSW (20.8%), followed by people injecting drugs-PWID (11.1%), drug users-DU (9.5%), men having sex with men-MSM (5.9%) and transgender women-TGW (2.6%).
HBV-HIV co-infection rate was 9.6%. Of 689 people with HBsAg+, 45.4% received evaluation for treatment eligibility, and 69.9% of those eligible enrolled on HBV treatment or TDF containing ART or PrEP.
Of 8,840 KP offered testing, 94% accepted anti-HCV testing, yielding 941 (11.3%) positive cases. CBT reached and tested more people, but unlike with HBV, yielded lower positivity rate than FBT (6.7% and 18.4%, respectively).
Anti-HCV positivity rate was highest in PWID (20.9%), followed by DU (6.8%), FSW (3.9%), TGW (2.6%), and MSM (1.9%). HCV-HIV co-infection rate was exceptionally high (28.4%). Of 941 people with anti-HCV+, 55.3% received confirmatory testing, and 38.1% of those confirmed initiated HCV treatment.
Conclusions/Next steps: Community-based and HIV integrated HBV/HCV testing is a promising approach to accelerate HBV/HCV case finding and treatment access among KPs. Further work is needed to improve access to and affordability of HBV/HCV confirmatory testing and treatment.

OAF0102
Ensuring HIV treatment continuity for Haitian migrants to the Dominican Republic during the COVID-19 pandemic

E. Emmanuel[1], G. Guethina[1], L. Daniel[1], L. Jutile[1], N. Bernadine[1], M.L. Excellent[1,2], M. Léonard[1], J.W. Domerçant[1]
[1]*Institut pour la Santé, la Population et le Développement (ISPD), Pétion-Ville, Haiti,* [2]*University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States*

Background: Nearly 75% of People Living with HIV/AIDS (PLHIV) in the Caribbean live either in Haiti or the Dominican Republic (DR). Individuals of Haitian descent represent 36.8% of all PLHIV in DR, the largest priority group. Historically, migration flows from Haiti to DR, except during the deportation campaigns. During the covid-19 pandemic, the flow was inverted. From 17 March 2020 to 31 July 2021, 711,736 movements were observed from Haiti to DR compared to 921,103 from DR to Haiti - including 337,147 voluntary returns. With an HIV prevalence of 3-5% among Haitian migrants, these population movements represent a potential challenge for epidemic control in both countries.
Description: With USAID funding, BRIDGE project was implemented to increase access to comprehensive HIV services for mobile populations while strengthening program collaboration between Haiti and DR. In collaboration with the Ministry of Health, ISPD implemented two HIV service delivery points at the main entry points (Malpasse, Ouanaminthe) and a coordination committee comprised of organizations intervening on the border. Comprehensive HIV services are provided to deportees, migrants, drivers, police officers, FSW, and their clients working in the border area.
Lessons learned: During FY21, 944 individuals were reached (284 deportees and 235 other migrants) of which 434 received assisted HIV Self-testing and 414 received standard HIV-testing. Twenty individuals who were newly identified as HIV-positive (9 males-11 females) and two who interrupted treatment were enrolled in care. Clinical management is challenging as many patients returned symptomatic (AIDS stage 4) or had no documentation of their treatment history. Haiti and DR have different ART first-line regimens.
Additionally, migrants do not stay near the border, they move to other parts of the country and the deportees plan their returning back to DR right away. Follow-up and proper tracking of those who received HIV services are further complicated.
Conclusions/Next steps: In order to accelerate the process towards the UNAIDS 95-95-95 goal, there is a need to build a partnership between Haiti and the Dominican Republic to provide better options to the Haitians crossing the border through improved referrals and establishing accessible ART dispensing points.

OAF0103
The use of community paralegals to improve the HIV and TB treatment cascade: comparing approaches in Mozambique, Senegal, Ghana, Indonesia, and Kyrgyzstan

J. Amon[1], N. Sun[2], K. Hinman[2], J. Csete[3], M. Golichenko[4], C. Kazatchkine[4], D. Lohman[5], M. McLemore[6], S.K.H. Chu[4]
[1]*Drexel University Dornsife School of Public Health, Philadelphia, United States,* [2]*Drexel University, Philadelphia, United States,* [3]*Columbia University, New York, United States,* [4]*HIV Legal Network, Toronto, Canada,* [5]*Consultant, New York, United States,* [6]*Consultant, Philadelphia, United States*

Background: The Global Fund's *Breaking Down Barriers* (BDB) initiative provides support in 20 countries to scale-up to comprehensive levels programs to remove human rights-related barriers to HIV and tuberculosis (TB) services.
Description: A mid-term evaluation was conducted from 2020-21. One of the program areas assessed was increasing access to legal services. Within this area, the Global Fund provides support to a range of access to justice activities, including the use of community paralegals.

Lessons learned: Community paralegals are community members trained to advocate for the rights of individuals and to liaise with legal professionals when necessary. With the support of the BDB initiative, community paralegals in many countries work to address rights violations that impede access to HIV and TB services.
We compared approaches used in five BDB countries during the assessment period (from 2017-2021).
In Mozambique, with Global Fund support, community paralegal programs had expanded significantly during the period assessed, with NGOs training and deploying paralegals in 11 provinces.
In Senegal, NGOs have trained 118 sex workers as paralegals.
In Ghana, paralegal trainings had been conducted for 88 persons living with HIV, sex workers, MSM and former TB patients.
In Indonesia, the 4 Pillars program used paralegals in outreach teams to support key populations.
In Kyrgyzstan, "street lawyers", most of whom are from key populations themselves or have extensive experience working directly with them, expanded, amidst the COVID-19 pandemic, to provide online services to HIV NGOs.
Paralegals in these programs were able to advocate for treatment access, negotiate with police for the release of key population members, conduct anti-stigma programs with communities, address discrimination in schools and workplaces, and ensure access to medicines in closed settings.
Conclusions/Next steps: Community paralegals can address a diverse range of barriers to HIV and TB services, strengthen trust and build relationships between communities and the health system.

OAF0104
Differentiated service delivery for people with HIV and non-communicable diseases: South African policy enabler for integration

M. Manganye[1], Z. Pinini[2], L. Seshoka[1], L. Malala[1], D. Gavhi[1], T. Nyawasha[1], T. Molewa[1], M. Pilusa[1], M. Mkhize[1], M. Kgokolo[1], T. Dladlama[1]
[1]National Department of Health, Care and Treatment Directorate, Pretoria, South Africa, [2]National Department of Health, HIV/AIDS & STI Cluster, Pretoria, South Africa

Background: Non-communicable diseases (NCDs), are undoubtedly leading cause of mortality and disabilities in the world accounting for about half of global disease burden. NCDs are increasingly causing health threats for people living with HIV. Whilst South Africa has the largest ART programme worldwide with over 5.5 Million people on ART. The rising burden of NCDs is placing considerable strain and presenting challenges of maintaining high-quality public health care services. The overall prevalence of hypertension was 14.3% in 2017, while the overall prevalence of diabetes was 3.2% in 2017. As South Africa scale-up differentiated service delivery (DSD), this optimization presents an opportunity to integrate HIV and management of NCDs into DSD models.
Description: DSD is the framework of the Adherence Guidelines (AGL) for HIV, TB and NCDs adopted in March 2020. It aims to strengthen linkage, adherence, and retention in care using a patient-centered approach throughout the treatment cascade for both HIV, TB, and NCDs patients. It makes provision for the three DMoCs (Facility Pick Up Points (FAC PuP), External Pick-Up Points (EX-PuP), and Adherence Clubs (AC) both at facility and community based) for those who are established in ART care and living with hypertension and/or diabetes.
Lessons learned: FAC-PuP model allows for direct and quick access to the pharmacy for healthy and stable clients on treatment. AC is facility and community-based and allows stable patients to be grouped, voluntarily for routine check-ups. EX-PuP model takes various forms, but all involve the patient collecting their treatment supply individually outside of the facility or from an automated system; thus, including from private pharmacies, lockers, etc.
As of the end of October 2021, data by DSD and type of patient showed a significant number of clients decanted (2 901 452). EX-PuP showed a high proportion of 60% (1 486 684) followed by FAC-PuP 25% (658 671) and lastly, the AC at 15% (500 590).
Conclusions/Next steps: DSD policy on HIV and NCDs provides the opportunity to optimize 90% of people on ART including the Integration of NCDs, TB/HIV services into less-intensive. Conduct the comprehensive review of AGL Policy to inform on options to strengthen the HIV and NCDs integration.

OAF0105
Legal self-defense and access to justice for people who use drugs

A. Levin[1], D. Subeliani[2], A. Fedosik, L. Vinc
[1]UnMode, Moscow, Russian Federation, [2]UnMode, Tbilisi, Georgia

Background: In Russia, the equality of all citizens before the law is legally enshrined. However, people who use drugs (PWUD), due to their marginal status, do not have access to high-quality legal assistance. As a result, in most cases they are deprived of access to a fair trial, replenish the prison population and contribute to the increase in the incidence of HIV in the penitentiary system.
In 2021, there were 509 thousand prisoners in Russia. 165 thousand of them were convicted under anti-drug articles. 53 thousand prisoners live with HIV, which is more than 10% of the total prison population.
Description: RuNPUD (Russian-language Network of People Who Use Drugs) is a regional network that protects PWUD rights, including in Russia. In the current situation RuNPUD directs its efforts to reduce prosecution and

protect the rights of PWUD in the country. RuNPUD trains PWUD to be defenders of their rights and interests along with lawyers. RuNPUD teaches these people the basics of legal self-defense, provides basic knowledge on the current anti-drug legislation, provides mentoring support in protecting their rights, the rights of their loved ones, the rights of those people who do not yet have the resource to protect themselves on their own.

In addition, RuNPUD members themselves act as public defenders in drug-related criminal cases, which is allowed by Russian law, and are engaged in strategic support of court cases to the European Court of Human Rights (ECHR).

Lessons learned: As part of this work, 349 consultations on drug-related cases and more than 100 representations in courts were held in 2021. This efficiency is due to the fact that Runpad members have stable connections and a high level of trust on the part of PWUD. All members of RuNPUD are successfully socialized people with similar life experiences (imprisonment, criminal prosecution, including for drug use).

Conclusions/Next steps: RuNPUD is changing discriminatory practices towards democratic positive changes not through political decisions and changes in the current legislation from above, but through grassroots democracy - the practice of applying this legislation on the ground, by ensuring access to justice for detainees, suspects and accused under anti-drug articles.

Trained community peers enhance access to justice, response to violence, discrimination and structural inequities for LGTBiq+ communities in India

R. Lairikyengbam[1], M.S. Mudaliar[2], N. Senapati[3], T Mahender[4], S. Yumnam[1], K. Patnaik[3], R. Dash[3], A. Moirangthem[1], K. Golmei[1], N. Nampalli[5], K. Shivakumar[4], T. Behera[6], S. Dash[3], S. Swain[3], K. Gollapalli[4], L. Athokpam[1], J.R. Pasupula[5], S.C. Mohanty[6], L. Ramakrishnan[7], S.S. Raghavan[8]

[1]Solidarity and Action Against The HIV Infection in India (SAATHII), East Imphal, India, [2]Solidarity and Action Against The HIV Infection in India (SAATHII), Nagpur, India, [3]Solidarity and Action Against The HIV Infection in India (SAATHII), Bhubaneswar, India, [4]Solidarity and Action Against The HIV Infection in India (SAATHII), Hyderabad, India, [5]Modern Architects for Rural India (MARI), Secunderabad, India, [6]RRDC, Mayurbhanj, India, [7]Solidarity and Action Against The HIV Infection in India (SAATHII), Chennai, India, [8]Solidarity and Action Against The HIV Infection in India (SAATHII), New Delhi, India

Background: LGBTIQ+ communities in India face multiple human rights violations including violence, discrimination, and exclusion (VDE) due to prevailing cis-binary-heteropatriarchal norms across families, institutions, and service providers. Despite the existence of protective laws and policies, low community awareness concerning rights and VDE redressal mechanisms, compounded by the limited sensitivity of law-enforcement and legal service authorities, collectively impede access to justice.

Description: The SAATHII-led consortium implemented project Sangraha with support from the EU, to reduce VDE and promote access to justice and social protection among LGBTIQ+ communities in 11 districts of Manipur, Odisha, and Telangana states, between 2018 - 2021. The project served 3,679 LGBTQI+ individuals including 53% trans women, 37% cis gay, bi, and other queer men, 7% trans men, 2% cis lesbian, bi, and other queer women, and 1% Intersex individuals and gender non-conforming children.

The project interventions included;

a) peer-led capacity building of community members on current laws on decriminalisation, transgender rights, and domestic violence,

b) sensitisation of and advocacy with 5,911 stakeholders on promoting access to LGBTIQ+ inclusive justice, social protection, education, and gender-affirmation services,

c) crisis redressal, and d) facilitating access to social protection, legal and law enforcement services.

Lessons learned: Trained LGBTIQ+ peers (one per district) were instrumental in increasing community awareness and successfully advocating with the stakeholders, which

helped report 542 incidents of VDE and redressal of 468 of these crises. They facilitated 968 LGBTIQ+ members access social protection services and 628 transgender persons change their name and gender legally.

A large proportion (37%) of VDE was found to be perpetrated by the general community, followed by natal family (17%), community peers (17%), and intimate partners (15%). Most crises (78%) were resolved through counseling and mediation by the peer teams and community leaders and 22% through the police and legal service authorities.

Key social protection services facilitated included obtaining government identity, voter, labor and food security cards, domicile certificates, housing schemes, insurance and bank loans to individuals and self-help groups, admission to colleges, and access to vocational training and livelihood opportunities.

Conclusions/Next steps: Scaling-up, financing, and mainstreaming of community-led interventions are critical for reducing VDE and promoting LGBTIQ+ Inclusive services.

OAF0203

Sex worker led campaigns to decriminalise sex work in Australia

J. Kim[1]

[1]Scarlet Alliance Australian Sex Workers Association, Sydney, Australia

Background: Decriminalisation of sex work has been recognised as definitively linked to the reduction of HIV risk and rates yet progress has been slow. NSW, Australia was the first jurisdiction in the world to decriminalise sex work and recently there has been growing momentum throughout Australia towards positive sex work law reform. Strong partnerships between sex workers and government and supported by allied organisations and unions has led to the decriminalisation of sex work in NT in 2020 and a commitment to decriminalise in VIC and QLD.

This paper outlines the sex worker led campaigns to decriminalise sex work, how it has impacted on sex workers lives and why it is essential for the rights, health and safety of sex workers.

Description: Scarlet Alliance, Australian Sex Workers Association is the national peak organisation representing sex workers and sex worker organisations throughout Australia. Scarlet Alliance and our member orgs throughout the country have been leading the push to fully decriminalise sex work.

This has involved public awareness campaigns, lobbying and briefing of politicians, government departments and allies, involvement in submissions processes, motions and bills and most importantly ensuring that local sex workers lead, inform and guide in all stages and levels of the law reform process.

Lessons learned: There are a number of misconceptions of what decriminalisation of sex work is, what it does and does not mean and how it works in practice. Through lessons learnt in all stages of the decriminalisation process, from initiation of campaigns to the implementation of decriminalisation, we will share our experiences and demonstrate why decriminalisation of sex work is the best practice model of sex work regulation.

Conclusions/Next steps: It is widely recognised that decriminalisation is the optimal model for sex work legislation. A decriminalised framework removes police as regulators of the sex industry, repeals criminal laws specific to the sex industry, regulates sex industry businesses through standard business, planning and industrial codes, and does not single out sex workers for specific legislation. In doing so, a decriminalised system removes barriers to HIV prevention, amplifies opportunities for health promotion and magnifies capacities for peer education.

OAF0204

Integration of a peer-led depression screening and linkage-to-care intervention among transgender women living with and at risk for HIV at a transgender-led health clinic in Bangkok, Thailand

R. Janamnuaysook[1,2], K. Janthawilai[1], S. Wainipitapong[3], P. Srimanus[1], A. Tangmunkongvorakul[4], J. Ross[5], A.H. Sohn[5], C.A. Mellins[6,7], M.L. Wainberg[8], M.M. Philbin[7], N. Phanuphak[1,2]

[1]Institute of HIV Research and Innovation, Bangkok, Thailand, [2]Center of Excellence in Transgender Health, Chulalongkorn University, Bangkok, Thailand, [3]Chulalongkorn University and King Chulalongkorn Memorial Hospital, Bangkok, Thailand, [4]Research Institute for Health Sciences, Chiang Mai University, Chiang Mai, Thailand, [5]TREAT Asia, amfAR, Bangkok, Thailand, [6]HIV Center for Clinical and Behavioral Studies, New York State Psychiatric Institute and Columbia University, New York, United States, [7]Columbia Mailman School of Public Health, Columbia University, New York, United States, [8]Department of Psychiatry, New York State Psychiatric Institute and Columbia University, New York, United States

Background: We aimed to demonstrate the feasibility of mental health service integration by implementing a peer-led depression screening and linkage-to-care intervention at the Tangerine Clinic in Bangkok, Thailand, which provides transgender-led and gender-affirming health services for HIV prevention and treatment and sexual health for transgender women (TGW) living with and at risk for HIV.

Description: We used the Consolidated Framework for Implementation Research (CFIR) to develop strategies to integrate depression screening, diagnosis, and linkage-to-treatment services into routine clinical practice. Implementation strategies were developed in consultation with transgender clinic staff and peer counselors, includ-

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

ing 1) identifying early adopters; 2) collaborating with a psychiatrist to strengthen the capacity of clinic staff; 3) developing a formal implementation blueprint; 4) providing access to ongoing psychiatric consultation.

We piloted an intervention to conduct these activities with four transgender counselors and two nurses, trained by a psychiatrist. Screening tools included the Patient Health Questionnaire (PHQ2/PHQ9).

Participants with PHQ-9 score ≤4 received psychosocial support counseling; those with more severe symptoms were referred to a psychiatrist. Safety planning for mental health emergencies and referral systems for diagnosis and treatment were established. Implementation outcomes included the numbers and proportions of TGW screened, identified with depressive symptoms, and referred for specialist care.

Lessons learned: From 10/2021-1/2022, clinic staff recruited 205 TGW; 177 (86%) agreed to depression screening, of whom 2.3% were living with HIV and 47% were taking HIV pre-exposure prophylaxis (PrEP).

Overall, 51% met clinical cut points on PHQ-2 requiring PHQ9 administration; 80% reported none-to-minimal symptoms (PHQ-9 score ≤4), 10% mild symptoms (score=5-9), and 6.7% moderate to moderately severe symptoms (score ≥10). Those with none-to-minimal symptoms received psychosocial support counseling by trained transgender counselors or nurses. Those with more severe symptoms were all successfully linked to psychiatric evaluation and treatment.

The high rates of acceptance of screening and linkage-to-care showed that integration of peer-led mental health services into our transgender clinic was feasible and acceptable.

Conclusions/Next steps: Development of mental health care implementation strategies that are adapted to local cultural contexts and available resources can expand available health resources. Qualitative data are needed to guide further development of mental health service integration strategies.

OAF0205

Human rights violations faced by women from key populations in Ukraine: evidence collected through the community-based monitoring approach

N. Semchuk[1], O. Pashchuk[1]

[1]ICF "Alliance for Public Health", Monitoring and Evaluation, Kyiv, Ukraine

Background: Women who belong to vulnerable communities such as injecting drug users, people living with HIV, sex workers, opioid substitution therapy (OST) patients and other are widely experiencing multiple stigma and discrimination in Ukraine. Human rights related barriers influence actual availability of HIV and other health services, as well as has an overall impact on HIV-related national outcomes.

Methods: Data was collected using the Rights - Evidence - ACTion (REAct) system that allows to document barriers and rights violations of the key groups in their access to HIV and other health care services, as well as to respond to those barriers identified. REAct is implementing in 18 regions out of 24 in Ukraine by 70 community-based organizations.

Results: More than 2000 cases of violations were registered in total in the REAct system in 2021, among them 818 cases were registered among women who belong to key populations. Disaggregation by key population is presented in the Table.

Key populations	% of all registered cases in REAct among women (N=818) in 2021
People living with HIV	37%
OST patient	23%
People who inject drugs	17%
Sex worker	13%
People living with TB	6%
Homeless person	1%
Ex-Prisoner	1%

Table.

Key types of human rights violations identified are: verbal abuse, denial in health services, in particular general primary and secondary outpatient health care, OST provision, denial in social services, denial of police to investigate a case of human rights violation, extortion and blackmail from the partner, sex client or police worker.

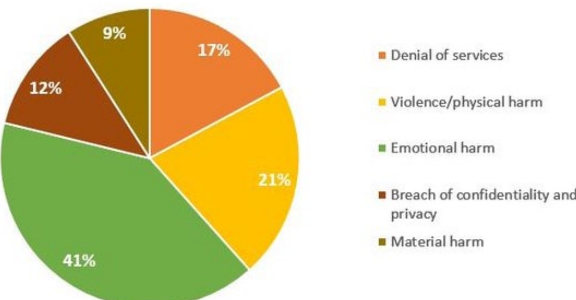

Figure. Types of human rights violations among women from key communities in Ukraine (REAct, 2021)

Conclusions: Understanding of human rights violations among women from key populations enable to identify their actual needs in health and legal services, ensure access to HIV-related, sexual and reproductive health services, facilitate women empowerment and gender equality in the context of HIV, as well as to produce evidence-informed recommendations to promote effective HIV response.

OAF03 Doing it right: Inclusion, diversity and policy development

OAF0302
Missing: meaningful trans inclusion in HIV national strategic plans in Eastern and Southern Africa

E. Castellanos[1], E. Lankiewicz[2], A. Ogeta[3], J. Mulucha[4], S. Reggee[5], N. O'Connor[1], J. Sherwood[2]
[1]*GATE, Global Action for Trans Equality, New York, United States,* [2]*amfAR, The Foundation for AIDS Research, Washington DC, United States,* [3]*Jinsiangu Transgender, Intersex, Non-binary Kenya, Nairobi, Kenya,* [4]*Fem Alliance Uganda, Kampala, Uganda,* [5]*Transbantu Association Zambia, Lusaka, Zambia*

Background: Trans people are disproportionately impacted by HIV, but rarely prioritized in HIV programming. The inclusion of trans people in policy and planning documents, including HIV National Strategic Plans (NSPs), is a crucial step towards increasing the national prioritization of trans people and guiding international investments.
We investigate the current state of trans inclusion in NSPs in Eastern and Southern Africa through a mixed methods approach to highlight gaps and opportunities for meaningful trans inclusion.
Methods: NSPs from 16 high HIV prevalence countries in Eastern and Southern Africa (current as of January 2021) were reviewed for trans-inclusion in five sections: NSP narratives, epidemiological data, monitoring and evaluation (M&E) indicators and targets, activities, and budgets. In-depth interviews with government officials (n=2) and trans organizations (n=3) in Kenya and Uganda were conducted. Key informants were community-selected experts and interviews focused on challenges and successes in trans engagement during strategic planning. Virtual interviews were recorded, transcribed, and reviewed for key themes.
Results: The majority (68%, 11/16) of NSPs mentioned trans people in at least one of the five key sections, however no NSPs mentioned them in all key sections. Trans people were most often included in the narrative (63%, 10/16), followed by indicators/targets (19%, 3/16) and activity (19%, 3/16) sections of NSPs. No NSPs included trans-specific epidemiological data or provided budgets for trans programming. In-depth interviews revealed stakeholders were hesitant to elevate the needs of trans people where they did not have epidemiological data to demonstrate need. Barriers to community engagement with government included the under-funding and under-capacitation of trans organizations. Successes occurred when trans groups built within-country coalitions, when governments explicitly involved trans people in working groups, and when international stakeholders helped push governments on critical advocacy points.
Conclusions: Inclusion of trans people in NSPs in Eastern and Southern Africa is low, with critical gaps in epidemiological data and budgeting for trans programming. In addition to moving towards inclusion of trans people in all key sections of NSPs, government and international funders have roles to play in funding trans epidemiological data studies and creating accessible opportunities for trans engagement in strategic planning.

OAF0303
Disability inclusion in the national response to HIV/AIDS in Nigeria: an analysis of the national strategic plan and framework

A. Ibrahim[1], D.E. Lucero-Prisno III[2]
[1]*University of Ilorin, Pharmacy, Ilorin, Nigeria,* [2]*Global Health Focus, London, United Kingdom*

Background: National Strategic Plans (NSP) and National Strategic Frameworks (NSF) provide the tools and blueprints for ensuring a comprehensive national response to HIV/AIDS. Often, people with disabilities (PWDs) have been overlooked in the context of HIV risk, prevention, and services due to the common assumption that they are not at risk for HIV. Research indicates that people with disabilities (PWDs) are at an equal, if not greater, risk of HIV compared to their non-disabled peers. As such, this paper analyzes the extent to which disability is included in the national response to HIV in Nigeria while suggesting good examples to follow.
Methods: A review of the most recent Nigeria National Strategic Plans (2017-2021) and National Strategic Framework (2019-2021) was conducted to determine the extent to which disability is included. The six principles employed in an earlier study, which was based on relevant rights in the UN Convention on the Rights of Persons with Disabilities, the UNAIDS International Guidelines on HIV and Human Rights, and the UNAIDS Disability and HIV Policy Briefs, were used in the analysis process as key focus areas.
Results: The most recent National Strategic Plan and Framework failed to integrate the needs of people with disabilities into the national response to HIV/AIDS. While provisions and plans were put in place for other vulnerable and special groups, there is little to no provision for treatment, care, and support services for persons with disability in the context of HIV and AIDS. PWDs were not recognized in the documents, not as key populations or even vulnerable groups.
Conclusions: Disability inclusion in the Nigeria NSP and NSF is extremely poor, particularly when compared with some other African countries like Niger or Ghana, and is indicative of the need for a review. As they are truly due for a review, it provides an opportunity to implement disability-focused approaches, inclusive policies and strategies in the national response toward HIV/AIDS in the country as could be seen in the NSPs of Niger and Ghana. Achieving this requires utilizing a rights-based approach, involvement of disability-focused organizations and individuals, and the allocation of financial resources.

OAF0304

Meaningful inclusion and effective participation of people who use drugs in shaping access to HIV/AIDS services: implications of a donor funding policies in 11 Latin American countries

C. Brentari[1], S. Shirley-Beavan[2], P. Cymerman[3], R. Torruella[4], E. Cortes[5], L.V. Russo[6]

[1]Harm Reduction International, London, United Kingdom, [2]Harm Reduccion International, London, United Kingdom, [3]Intercambios, Buenos Aires, Argentina, [4]Intercambios, San Juan, Puerto Rico, [5]Lanpud, San Josè, Costa Rica, [6]LANPUD, Buenos Aires, Argentina

Background: The Global Fund to Fight AIDS, Tuberculosis and Malaria (the GF) has long influenced the programming of funding on HIV/AIDS in Latin America. The GF recognises people who use (but do not inject) drugs (PUD) are a key population for HIV. Within a GF Community, Rights and Gender (CRG) short-term technical assistance, Harm Reduction International, at the request of Lanpud – the Latin American Network of PUD, sought to understand why PUD are not included as key populations in any of the 11 GF Country Coordination Mechanisms (CCMs) analysed in Latin America.

Description: There are 5.5 million people who use non-injected drugs in Latin America and the Caribbean; the number of people who inject drugs is low compared to other regions. CCMs, GF staff and civil society report that PUDs face barriers to accessing health services and are more vulnerable to HIV: they are a key population.

The GF recognises key population representation as essential within CCMs. Qualitative multi-stakeholder consultation evidenced the absence of PUD within the 11 CCMs. CCMs reported insufficient evidence for a link between people who do not inject and vulnerability to HIV/AIDS: they currently emphasize people who inject drugs based on historical data. PUD are considered ineligible for representation. Civil society, CCMs and representatives of PUD also agreed there is a grave lack of data on the link between HIV and non-injecting drug use.

Lessons learned: Evidence on HIV and tuberculosis among people who use but do not inject drugs is needed, on prevalence but also on accessibility of HIV prevention, treatment and care due to stigma, discrimination and criminalisation and the lack of harm reduction. Greater co-ordination among networks of PUD is needed and with other key populations for their voices to be heard.

Conclusions/Next steps: The GF and the CCMs can play an important role in ensuring PUD are represented in relevant fora through active engagement, supporting evidence gathering and capacity building.

OAF0305

Towards more inclusive and feminist approaches in HIV programming evaluations: transforming principles into practice

S. Shahi[1], J. Whitbread[2], C. Nyambura[3], M. Tholanah[4], J. Tatenda Bhila[5], N. Lahouel[6], M.M. Shadie[7], C. Rodriguez[8], L. Benjamin Mwakyosi[9], E. Boucicault[10], M. Jean[11], T. Khaydarova[12], A. Oktariani[13], M. Iacono[8], B. Rivona[13], F. Hale[14], E. Bell[14], J. Feather[15], V. Ahlenback[16]

[1]International Community of Women living with HIV Asia Pacific (ICWAP), Kathmandu, Nepal, [2]International Community of Women living with HIV, Toronto, Canada, [3]ATHENA Network, Nairobi, Kenya, [4]Making Waves Network, Harare, Zimbabwe, [5]Zimbabwe Young Positives, Bulawayo, Zimbabwe, [6]Association El Hayet des personnes vivants avec le VIH, Alger, Algeria, [7]AFI Santé, Kinshasa, Congo, Democratic Republic of the, [8]International Community of Women living with HIV - ICW Argentina, Buenos Aires, Argentina, [9]DARE Organization, Dar-es-Salaam, Tanzania, The United Republic of, [10]Fondation Esther Boucicault Stanislas, Saint Marc, Haiti, [11]AFIAVIH (Association de Femmes Haitiennes vivant avec et affectées par le VIH), Port au Prince, Haiti, [12]Tajik network of women living with HIV, Dushanbe, Tajikistan, [13]IPPI Indonesian Network of Women living with HIV, Jakarta, Indonesia, [14]Making Waves Network, London, United Kingdom, [15]Social Development Direct, Bristol, United Kingdom, [16]Social Development Direct, London, United Kingdom

Background: In 2020, UNAIDS contracted SDDirect to conduct aGlobal Evaluation of the Joint Programme's work addressing linkages between HIV and VAWG. Data was collected in nine countries. Its strategic recommendations on integrating VAWG and HIV were accepted by the Co-Sponsors'Management Response.

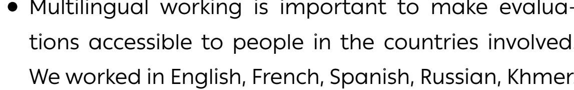
To achieve lasting change in the HIV response, our approach aimed to address structural inequalities inherent in standard evaluation practice, be guided by priorities of women and girls living with and affected by HIV, and be accountable to them and their networks.

Description: 'Nothing about us without us' is vital to HIV programming, research and evaluation, following principles ofGreater Involvement of People living with HIV/AIDS(GIPA), and Meaningful Involvement ofWomen living with HIV/AIDS (MIWA).

To embed these principles, SDDirect worked with ICW and ATHENA Network to establish the accountability and advisory group (TAAG), a group of 13 women living with / affected by HIV, from the 9 case study countries. They supported the evaluation process, interviewed members of networks and CSOs, and reviewed findings and recommendations.

Lessons learned:

- All evaluations should be guided by members of communities. TAAG ensured community members' priorities were addressed and broadened the scope of who was consulted.



- Multilingual working is important to make evaluations accessible to people in the countries involved. We worked in English, French, Spanish, Russian, Khmer.
- Proper compensation for women's and girls' (and their networks/organisations) contributions is essential. This recognises the value of their expertise, time and commitment, and can help remove barriers to participation when paid in advance.
- Flexible internal systems facilitate involvement. Drawing on feminist practice, SDDirect adapted contracts, Conflict of Interest statements, and payment modes, funded data bundles, and translated critical elements.
- Promoting transformative change: This approach aids accountability to women and girls in the implementation of evaluation recommendations.

Conclusions/Next steps: To meaningfully promote anti-racist approaches, community and feminist leadership, and embrace GIPA/MIWA, concepts of 'independent evaluation' should be revisited. Women and girls who are active in their communities have commitment to lasting change and a wealth of expertise. They can play a vital role in evaluations as evaluators & experts. This needs to be properly facilitated, compensated and recognised.

OAF04 Not just law: Legal obstacles to an effective HIV response

OAF0402
Bad blood: why blood donations by people living with HIV should not be a crime

E. Hatt[1], S. Beaumont[1], E. Bernard[1]

[1]*HIV Justice Network, Amsterdam, Netherlands, the*

Background: At least 23 countries have laws that criminalise blood donations by people living with HIV, despite the removal of blood donation bans for gay men due to scientific advances in screening for HIV. Although these laws are invariably implemented with the legitimate objective of protecting public health, we seek to demonstrate that they fail to meet this objective and are discriminatory.

Methods: The HIV Justice Network's Global HIV Criminalisation Database contains case reports of HIV-related criminal cases and criminal laws that target people living with HIV.

Following recent reports of blood donation-related prosecutions in Russia, Singapore, and the United States, we undertook desk-based research between September to November 2021, collating and categorising all known country and jurisdictional laws that specifically criminalise blood donations by people living with HIV, and known prosecutions under these laws. We analysed these laws and cases using a global policy guidance and human rights law framework, informed by international and state-level scientific data assessing risks of transmission via blood transfusion.

Results: The Global Commission on HIV and the Law, UNAIDS and UNDP all state that the use of criminal law in relation to HIV can only be legitimate where harm is intentionally caused, there is actual risk of harm, and harm actually occurs. Although some prosecutions involved people aware they were living with HIV, others - notably in Singapore - involved gay men who *ought to have known* their HIV status. In addition, due to advances in blood screening capabilities allowing for the removal of blood donation bans for gay men in a growing number of countries, there is now an extremely low risk of transmission through blood donations, especially in countries with advanced health systems.

Conclusions: These laws and prosecutions fail the proportionality test due to the low risk of transmission and the fact that they single out people with HIV. Ultimately these laws and prosecutions fail to achieve their stated aim of protecting public health, cause harm through their stigmatising effect, and violate international human rights law as they discriminate based on a characteristic protected under international law. These laws should be repealed.

OAF0403
Measuring potential impacts of parental consent laws on adolescent HIV testing globally: multinational insights from 51 population-based surveys

J.G. Rosen[1], E.M. Stone[2], M.T. Mbizvo[3]

[1]*Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States,* [2]*Johns Hopkins Bloomberg School of Public Health, Health Policy and Management, Baltimore, United States,* [3]*Population Council, Lusaka, Zambia*

Background: HIV testing remains imperative to close gaps in both the prevention and treatment cascades, but pervasive social and structural barriers—including national policies—inhibit HIV testing uptake among priority populations, including adolescents. We assessed the relationship between age-of-consent laws for HIV testing and adolescent HIV testing prevalence in 51 low- and middle-income countries.

Methods: We pooled 51 nationally representative household surveys (Demographic and Health Surveys, AIDS Indicator Surveys, and Population-Based HIV Impact Assessments) from 2010 to 2020. We estimated the weighted country-level prevalence of lifetime HIV testing separately for adolescent girls and boys (ages 15-19). We then abstracted age-of-consent laws for HIV testing across countries. Using multivariable linear regression, we estimated the average difference in national HIV testing coverage estimates for adolescent girls and boys by age-of-consent restrictions for HIV testing.

Results: National HIV testing coverage estimates were substantially heterogeneous, ranging from 0.7% to 72.5% among girls and 0% to 73.2% among boys in Pakistan and Lesotho, respectively. Median national HIV testing prevalence estimates were 18.0% among girls and 7.5% among boys.

Adjusting for region, World Bank income classification, and per-capita health expenditure, HIV testing coverage in countries requiring parental consent for HIV testing in individuals younger than 18 years was, on average, 7.8% lower (95%CI: −14.6% to −1.0%) among girls and 8.2% lower (95%CI: −14.6% to −1.9%) among boys.

Comparing countries with more restrictive (age-of-consent: 18 years) to less restrictive (age-of-consent: 14 years or younger) HIV testing laws, HIV testing prevalence was significantly lower among girls (β = −7.7%, 95%CI: −15.1% to −0.3%) and boys (β = −8.3%, 95%CI: −15.2% to −1.3%) in countries with more restrictive parental consent policies.

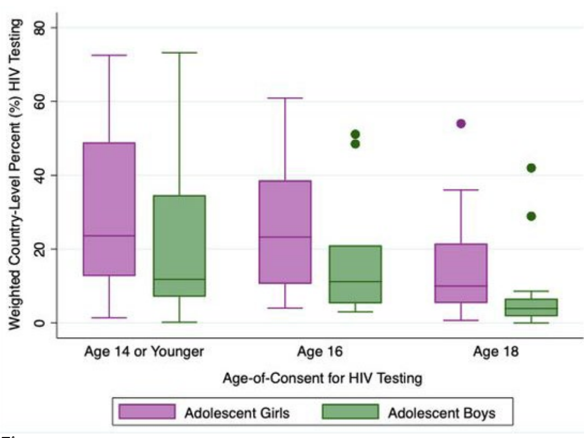


Figure.

Conclusions: Age-of-consent laws are persistent obstacles to adolescent HIV testing. Revoking parental consent requirements for HIV testing is needed to expand coverage and ensure equity.

OAF0404

Ending inequalities in access to justice: scaling up and sustaining judicial sensitization across sub-Saharan Africa

M. Tabengwa[1], K. Grant[1], O. Dingake[2], F. Githiru[3], S. Mia[1], M. Ngugi[3]

[1]UNDP, Johannesburg, South Africa, [2]UNDP, Johannesburg, Seychelles, [3]UNDP, Nairobi, Kenya

Background: In 2019, the African Regional Judges' Forum initiated and developed a Judicial Training Manual, the first of its kind in Africa, to expand sustainable judicial sensitization on HIV, law and human rights affecting key and vulnerable populations across sub-Saharan Africa, and to promote rights-focused jurisprudence that challenges laws discriminating against women and young people, and criminalizing HIV transmission, drug use, sex work, same-sex sex and transgender people.

Description: The Forum, initiated by prominent African judiciary and supported by UNDP, arose out of the Global Commission on HIV and the Law's recommendations. It allows for sharing expertise, sensitizing judiciary and promoting judicial excellence. It has contributed to progressive jurisprudence repealing punitive laws or practices, and strengthened enabling environments, human rights and access to justice for populations in Africa, consistent with national bills of rights, regional and global commitments.

In 2019, noting the limited resources available and wishing to draw on successes and scale up efforts, the Forum worked with national judicial training institutes(JTIs) to develop the innovative Manual. The consultative process drew on the expertise and networks of the Forum and its partners, and included a Judicial Roundtable with JTIs,a needs assessment and ongoing feedback.

Lessons learned: The regular engagement and judicial sensitization by and amongst judges over the years has yielded rich pro-rights jurisprudence in the region. This engagement also enriched and informed the format, methodological approach and content of rights-based training materials including e.g. (i) the focus on criminalization of HIV and key populations as well as gender-based violence; (ii) the inclusion of scientific and medical evidence; (iii) the importance of involving affected populations in methodologies; and (iv) materials capable of updating and adaptation to national contexts and differing jurisprudential systems within Francophone, Anglophone and Lusophone Africa.

Conclusions/Next steps: Critical next steps include working with JTIs to create awareness and disseminate the Manual, including on online platforms, and to identify technical support needs for its adaptation, integration and use within national judicial training, to expand judicial sensitization and mitigate the impact of stigma, discrimination and violence on key and vulnerable populations in the African justice sector.

OAF0405

The race to end AIDS: Ghana's prospects in light of a proposed anti-LGBTQ bill

P. Ayamah[1], K. Atuahene[1], F. Nana Poku[1], R. Sackitey[1], S. Abbah[2], B. Adjei[2]

[1]Ghana AIDS Commission, Accra, Ghana, [2]Micdak Charity Foundation, Kumasi, Ghana

Background: UNAIDS has identified inequality as a foremost factor for many countries' inability to reach the 90-90-90-targets by 2020. Discriminatory laws and policies drive inequality which hinders the achievement of health goals especially relating to HIV. Ghana's Parliament is currently considering a bill to among others "proscribe LGBTQ+ and related activities; proscribe the promotion, propagation of, advocacy for, support of or funding" of LGBTQ+ activities."

In this study, we explored Ghana's prospects at ending AIDS from the perspectives of key stakeholders in light of the proposed bill. Relevant data were analysed for context.

Methods: This was a qualitative cross-sectional study. Data collection done virtually (via zoom and phone call/ WhatsApp); respondents selected by convenience and snow-balling. There was focus-group discussions with peer-educators(n=19); semi-structured interviews with service-providers(n=15) and independent experts (n=2). Transcripts were coded, themes identified and analysed.

Results: Ghana's HIV prevalence as at 2020 was 1.68% with an estimated 346,120 PLHIV; total new infections was 18,928; ART(15+) and PMTCT coverage stood at 63% and 72% respectively. Regarding the 90-90-90, by 2020, 63.20% of all PLHIV knew their status, 95.46% and 72.97% of which were on ART, and had achieved viral-suppression respectively. Ghana has an estimated MSM-population of 54,759; 52% being bisexual (bridging-population) with a very high HIV prevalence (18%) among same. Against this background, key stakeholders contend that the ensuing law will exacerbate Ghana's difficulties at attaining the 95-95-95 targets by 2025 and ending AIDS by 2030. Peer-educators and service-providers have noted a spike in violence-and-stigma against KPs since the bill was introduced. HIV service-providers contend that the ensuing law will undermine their mandate, drive KPs underground and stifle external funding. Independent experts and other opponents contend that it will "establish a system of state-sponsored discrimination and violence" against sexual-minorities.

Conclusions: There's unanimity among respondents that the ensuing law (whose passage they deem 'very likely') will pose a structural-barrier and deepen inequality against KPs thereby posing a considerable obstruction to Ghana's prospects at ending AIDS by 2030. Stakeholders should advance necessary amendments to assuage its impact and commission a study to determine the actual impact if passed into law.

HIV biology (entry, replicative cycle, transcriptional expression and regulation)

PESAA01
PICH115: a new potential target to control HIV latency

M. Da Rocha[1], T. Habib[1], A. Delannoy[1], E. Wilhelm[1], B. Bell[1]
[1]*Université de Sherbrooke, Département de Microbiologie et d'Infectiologie, Sherbrooke, Canada*

Background: Latency is the main obstacle toward Human Immunodeficiency Virus (HIV) eradication. Current approaches to fight latency, Shock and Kill and Block and Lock, both focus on modulating HIV gene expression.
Our laboratory recently identified a cellular protein complex, the *Pre-Initiation Complex of HIV* (PICH), that binds the HIV promoter. Mass spectrometry was then used to identify PICH proteins, and depletion of PICH proteins by siRNA demonstrated their positive impact on HIV gene expression. PICH are potential drug targets and understanding their role on HIV transcription could help develop molecules to control latency.
Here, we present new data on PICH115, a protein known to interact with Tat.
Methods: First, we mapped the interaction site between Tat and PICH115. We designed plasmids coding for the different domains of GST-Tat and His-PICH115 to produce recombinant proteins for GST-Pulldowns.
In cellulo experiments have also been performed, by overexpressing the different domains of PICH115-HA and a Tat-Flag protein in HEK293T to perform a Co-ImmunoPrecipitation with the protein extracts.
Then, we studied the impact of PICH115 on the interaction between Tat and the viral TAR RNA, which is essential for HIV transcription. To determine if PICH115 influence this interaction, we performed ElectroMobility Shift Assays using a fluorescent TAR RNA probe incubated with recombinant Tat and PICH115.
Results: *In vitro*, a direct interaction happens between the core domain of Tat and both the N-acetyltransferase and the tRNA-Binding domains of PICH115. *In cellulo*, the N-acetyltransferase and the tRNA-Binding domains of PICH115 are required for the interaction with Tat.
Our data further show that the presence of PICH115 increases the binding of Tat to TAR *in vitro*.
Conclusions: In conclusion, we identified the interaction site between Tat and PICH115 and demonstrated its enhancement of the Tat-TAR interaction.
In the future, we will investigate the potential role of PICH115 on viral mRNA post-transcriptional modification and its impact on HIV gene expression.
This could lead to a better understanding of the role of this cellular protein on HIV replication and could allow the development of new Shock and Kill or Block and Lock strategies. Indeed, an inhibitor of PICH115 have been identified recently.

PESAA02
Novel roles for PSGL-1 in HIV infection: virions with incorporated PSGL-1 can be captured by selectins and transferred to permissive cells

J. Burnie[1,2], A.T. Persaud[1,2], L. Thaya[1,2], Q. Liu[3], H. Miao[3], S. Grabinsky[1], V. Norouzi[1], P. Lusso[3], V.A. Tang[4], C. Guzzo[1,2]
[1]*University of Toronto Scarborough, Biological Sciences, Toronto, Canada,* [2]*University of Toronto, Cell and Systems Biology, Toronto, Canada,* [3]*National Institute of Allergy and Infectious Diseases (NIAID), Viral Pathogenesis Section, Laboratory of Immunoregulation (LIR), Bethesda, United States,* [4]*University of Ottawa, Faculty of Medicine, Department of Biochemistry, Microbiology, and Immunology, Ottawa, Canada*

Background: P-selectin glycoprotein ligand-1 (PSGL-1/CD162) was recently identified as a restriction factor present within the HIV envelope. While it strongly inhibits infection in viruses generated through transfection to over-express PSGL-1, viruses produced through infection with endogenous levels of PSGL-1 remain infectious. To date, no studies have shown whether PSGL-1 is present on a range of viral isolates or on viruses circulating *in vivo*.Similarly,it is unknown whether virion-incorporated PSGL-1 can bind its natural receptors (selectins), which may have implications on the ability of HIV to traffic *in vivo*.
Methods: Using transfection and infection, we generated viruses that express differential levels of PSGL-1. With these viruses we compared the antiviral effect of PSGL-1 and quantified levels of PSGL-1 on virions using virion capture assays and flow virometry. Finally, we assessed the capacity of virion-incorporated PSGL-1 to facilitate binding to selectins, and whether selectin-captured viruses could be transferred to nearby cells for infection.
Results: PSGL-1 was far more abundant on our viruses produced through transfection compared to viruses produced through infection of primary cells. Infectivity assays confirmed the dose-dependent antiviral activity of PSGL-1 in viruses engineered to express varying levels of PSGL-1, while viruses produced through infection of T cells remained infectious. Notably, virion-incorporated PSGL-1 was present in viruses of all clades tested, including a range of clinical isolates. Most importantly, we found that PSGL-1 on virions could be captured by selectins, and that captured virus could be transferred to nearby permissive bystander cells.
Conclusions: PSGL-1 is a potent antiviral when expressed at high levels in the HIV envelope, however, it is less efficacious at endogenous levels on virions. These results caution interpretations of the effects of PSGL-1 on HIV

Oral abstracts

infection when using viruses produced through transfection. The presence of PSGL-1 on a broad range of viral isolates and patient samples demonstrates the importance for further studies of how PSGL-1 can impact HIV biology. Strikingly, our finding that virion-associated PSGL-1 can facilitate capture by its cognate receptors and subsequent transfer to bystander permissive cells, suggests that PSGL-1 may have additional roles in facilitating HIV infection, in addition to its antiviral activity.

The HCV infection in HIV patients drives chromosome 14 microRNA cluster (C14MC) dysregulation

D. Valle Millares[1], Ó. Brochado-Kith[1], L. Martín-Carbonero[2], L. Domínguez[3], P. Ryan[4], I. De los Santos[5], S. De la Fuente[6], J.M. Castro-Álvarez[2], M. Lagarde[3], G. Cuevas[4], M. Mayoral-Muñoz[2], C. Crespo-Bermejo[1], V. Lara-Aguilar[1], M.Á. Jiménez-Sousa[1], S. Resino[1], V. Briz[7], A. Fernández-Rodríguez[1]
[1]Institute of Health Carlos III, Unit of Viral Infections and Immunity, Majadahonda, Spain, [2]Hospital La Paz Institute for Health Research (IdiPAZ), Madrid, Spain, [3]Research Institute Hospital 12 de Octubre (i+12), Internal Medicine Service, Madrid, Spain, [4]Infanta Leonor Teaching Hospital, Department of Infectious Diseases, Madrid, Spain, [5]Hospital Universitario de La Princesa, Internal Medicine Service, Madrid, Spain, [6]Hospital Puerta de Hierro, Internal Medicine Service, Madrid, Spain, [7]Institute of Health Carlos III, Laboratory of Reference and Research on Viral Hepatitis, Majadahonda, Spain

Background: Around 2.75 million of HIV individuals worldwide are co-infected with hepatitis C virus (HCV), showing higher rate of cirrhosis, liver failure, and hepatocellular carcinoma among others. miRNAs have a key role in post-ranscripcionally regulating these biological processes. The chromosome 14 miRNA cluster (C14MC) in the 14q32 region is one of the largest miRNA cluster of the genome, harbouring more than 50 maternally imprinted miRNAs-encoded genes. Dysregulation of this cluster have a key role in cancer prognosis, and pathogenesis of non-alcoholic liver diseases, but the impact of viral infections in the C14MC remains unknown.
We aim to analyse the C14MC in HIV patients with different exposure to HCV, to explore their possible association with risk of cancer development and sex bias.
Methods: SmallRNA sequencing analysis was performed in PBMCs from 117 HIV+ infected patients: 45 HIV+ patients chronically infected with HCV (HIV/HCV+), 36 HIV+ that spontaneously clarified HCV after an acute infection (HIV/HCV-) and 36 HIV+ patients without previous HCV infection (HIV+). Thirty-two healthy patients were used as controls (HC). Significantly differentially expressed (SDE) miRNAs were calculated (fold-change > 1.5 and p-value < 0.05 adjusted by Benjamin-Hochberg correction). Only those SDE miRNAs located at the C14MC were considered.
Results: Significant clinical differences were observed between HIV patients for the HIV transmission route (p < 0.001). There were no differences in CD4+ or CD8+ T-cell parameters between any HIV+ patients. We identified SDE miRNAs of the C14MC with respect to healthy controls in HIV (n=22), HIV/HCV+ (n=25) and HIV/HCV- (n=32). After analyzing each group of patients by gender, we found that the dysregulation of C14MC was mainly limited to a strong upregulation in males rather than females.
The highest differences were observed for HIV/HCV- male patients, where 41 out of 54 miRNAs of the C14MC were dysregulated (37 up and 4 down-regulated).
Conclusions: Our findings indicate that HCV exposure strongly disrupts C14MC expression. Furthermore, we found a sexual bias in the dysregulation of miRNAs at the C14MC especially in male HCV spontaneous clarifiers. Additional studies should be performed to decipher the role of C14MC in infectious diseases and HCV-cancer related development.

PESAA04

The host factor p32 facilitates HIV infection by stabilizing the HIV-1 transcriptionaltrans-activatorTat protein

L. Mori[1], C. Li[1], S. Lyu[1], A. Getzler[1], M. Pipkin[1], S. Valente[1]
[1]Scripps Florida, Department of Microbiology and Immunology, Jupiter, United States

Background: Following HIV integration into the host genome, viral expression is modulated by the combinatorial activity of the HIV transcriptional activator Tat, host transcription factors and chromatin remodeling complexes. To expand our knowledge of the mechanisms regulating HIV transcription, we sought to identify novel proteins associating with the HIV promoter.
Methods: We used a chromatin affinity purification approach that takes advantage of specific single guide RNAs (sgRNAs) and endonuclease deficient Cas9 (dCAS9) to enrichonintegrated HIV promotersfollowed by mass spectrometry (ChAP-MS).
Results: We identified a total of 161 proteins that were ranked based on their enrichment in active versus transcriptionally silenced promoters with theTat inhibitor, didehydro-Cortistatin A (dCA). Among the top 30 hits enriched in active promoters we identified several Tat interacting proteins and subunits of RNAPII holoenzyme, while in latent promoters we identified several histones (H1, H2, H4), an expected outcome since dCA promotesheterochromatinization of theHIV promoter. Genes chosen for follow-up were prioritized based on novelty in HIV transcriptional regulation, reproducibility and biological insight as to potential function(s). p32, also called ASF/SF2 splicing factor-associated protein, wasenriched inactively transcribing HIV promoters and absent in silenced ones. Chromatin immunoprecipitation analysis confirmed the presence of p32 on active HIV promoters and its recruitment enhanced by Tat. The RNA interference of p32 sig-

nificantly reduced HIV transcription in primary CD4+T cells as well as in HIV chronically infected cells, independently of either HIV splicing or p32 splicing activity.

Conversely, overexpression of p32 specifically increased Tat-dependent HIV transcription. In effect, p32 was found to directly interact with Tat's basic domain enhancing Tat stability and half-life. The stabilization of Tat by p32 converged in an increased Tat association with the HIV LTR and RNAPII.

Conclusions: Using a novel chromatin affinity purification strategy, we identified p32 as a novel host factor that physically interacts and stabilizes Tat protein enhancing Tat-dependent HIV transcription. These results highlight p32 as a potential novel target for HIV transcriptional modulation and furthered our understanding of the mechanisms regulating Tat mediated transcription.

HIV transmission and dissemination

PESAA05
Activation of anti-viral innate immunity in epithelial cells as a potential cellular mechanism for preferential R5 transmission at genital mucosa

A. Nazli[1,2], M. Atif Zahoor[1,2], C. Kaushic[1,2]

[1]McMaster University, Department of Medicine, Hamilton, Canada, [2]McMaster University, McMaster Immunology Research Center, Hamilton, Canada

Background: Women make up approximately half the population living with HIV/AIDS. Majority of HIV-1 transmission in women occurs through heterosexual intercourse via the female reproductive tract (FRT). Although both CCR5-tropic (R5) and CXCR4-tropic (X4) HIV-1 strains are present in semen, primary infection in FRT occurs almost exclusively through R5 HIV-1. The mechanism underlying this preferential selection of HIV-1 R5 during mucosal transmission is not completely understood.

We examined the interactions between X4 and R5 HIV-1 and genital epithelial cells (GECs) to gain a better understanding of the preferential selection of R5 strains.

Methods: This study was conducted on primary GECs isolated from tissues obtained from women undergoing hysterectomy in McMaster Hospital, following informed consent. Fluorescently labelled X4 and R5 HIV-1 was added to primary GECs and virus coming through cells on basolateral side was titrated on TZMb-I cell line. HIV-1 was measured by P24 ELISA. Intracellular trafficking of HIV-1 was studied by immunofluorescence microscopy. Expression of interferon stimulated genes (ISGs) was measured by quantitative PCR. Interferon-β production was measured by ELISA.

Results: GECs showed significantly higher interferon-β production, IFNAR1 and ISG expression in response to X4 HIV-1, compared to R5 strains. The IFN-β response against X4 HIV-1 was mediated through TLR2 signaling in the endosomal compartment. TLR2 pathway activation resulted in upregulation of BST-2 and ISG-15, resulting in sequestration of the virus in the endosomal compartment for more than 96 hours. Blocking endosomal pathway blocked the anti-viral response and sequestration of X4 virus. Blocking BST2 and ISG15 by siRNA inhibited sequestration of X4 HIV-1. In contrast, R5 virus was rapidly transcytosed through the cells to the basolateral side, avoiding recognition through TLR2, and with minimal activation of IFN-β and ISGs.

Further examination showed that X4 and R5 viruses were directed into different cellular compartment through differential binding to CXCR4 and CCR5 co-receptors, respectively.

Conclusions: Our results indicate thatX4 HIV-1 induces a robust anti-viral immune response, resulting in entrapment of virus within GECs, while R5 HIV-1 evades the innate immunity resulting in preferential selection of R5 HIV-1 for mucosal transmission. Understanding the mechanism of transmission will help develop prevention strategies.

PESAA06
Dual role of HIV-1 Envelope Signal Peptide in immune evasion

C. Upadhyay[1], P. Gadam Rao[1], R. Feyznezhad[1]

[1]Icahn School of Medicine at Mount Sinai, Medicine, New York, United States

Background: The HIV-1 Env signal peptide (SP) initiates Env biogenesis and is an important contributor to Env glycosylation and functions. HIV-1 Env is generated from Vpu/Env encoded bicistronic mRNA such that the 5`end of Env N-terminus, that encodes for Env SP overlaps with the 3` end of Vpu. Env SP displays high sequence diversity, which also translates into high variability in Vpu sequence.

This study was aimed to understand the effect of sequence polymorphism in the Vpu-Env overlapping region (VEOR) on the functions of two vital viral proteins i.e., Vpu, and Env.

Methods: We used infectious molecular clone (IMC) pNL4.3-CMU06 (WT) and swapped its SP (i.e., VEOR) with that from other HIV-1 isolates (MW, 398F1, CH119 and 271.1). We examined the effects of VEOR on Env (as SP) and Vpu functions.

Results: Swapping VEOR did not affect virus production in the absence of tetherin however, presence of tetherin significantly altered the release of virus progeny compared to the WT. Notably, MW VEOR abrogated Vpu's ability to augment the release of progeny virions from infected cells. When MW VEOR was tested in context of two other HIV-1 isolates (SF162 and REJO) similar reduction in virus release was observed. Swapping VEOR also changed Vpu's ability to down-modulate surface expression of human CD4.

We next tested the effect of these swaps on Env properties and functions. Analyzing the binding of monoclonal antibodies to membrane-embedded HIV-1 Env revealed changes in the antigenic landscape of swapped Envs vs

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

the WT and also altered the virus sensitivity to antibody-mediated neutralization. These swaps affected the oligosaccharide composition of N-glycans as shown by changes in DC-SIGN-mediated virus transmission. Importantly, all IMCs differ only in their VEOR and otherwise have identical sequences.

Conclusions: Collectively, this study shows that polymorphisms in the VEOR has direct implications on HIV-1 infection. This overlapping region

1. Regulate Vpu functions and Vpu-host interactions, facilitating virus replication and infection establishment,
2. Impact Env glycosylation altering Env interaction with antibodies as Env-SP; facilitating immune escape and virus transmission via DC-SIGN.

Thus, by incorporating changes in this region the virus uses it as another mechanism for immune evasion.

PESAA08

Estradiol inhibits HIV-1_{BaL} infection and induces CFL1 expression in peripheral blood mononuclear cells and endocervical mucosa

N. Verma[1], S. Mukhopadhyay[1], P. Barnable[1], M.G. Plagianos[1], N. Teleshova[1]
[1]*Population Council, HIV, New York, United States*

Background: Although several reports suggested an inhibitory effect of estradiol (E2) on HIV infection, the mechanism of this effect remains understudied. Analysis of endocervical transcriptome in proliferative and secretory phases of the menstrual cycle demonstrated upregulated gene expression of actin-binding protein CFL1 in the E2-dominated proliferative phase. Actin cytoskeleton plays an integral role in the regulation of HIV infection.

This study was designed to explore the role of CFL1 in E2-mediated effects on HIV infection in PBMCs and endocervical mucosa.

Methods: PBMCs were isolated from anonymous healthy HIV uninfected blood donors. Human endocervical tissues without gross pathological changes from 32-50 years old subjects were obtained from routine hysterectomies through the National Disease Research Interchange. PBMCs and endocervical tissue explants were incubated with E2 (100-10000 pg/ml) for 48h and then challenged with HIV-1_{BaL} (1000 $TCID_{50}/10^6$ PBMCs and 500 $TCID_{50}$/explant), washed and cultured for 14 days in the presence of E2 (vs. untreated control).

Select experiments included 3TC, Raloxifene (selective estrogen receptor modulator), and LIMKi3 (LIMK1/2 inhibitor blocking CFL1 phosphorylation). The infection was monitored by HIV *gag* one-step qRT-PCR. CFL1 expression was analyzed by qRT-PCR, Immunofluorescence microscopy (IF) and Western Blot (WB). p24 expression was monitored by IF. Cytokines and chemokines in infected tissue supernatants were measured using 25-plex Luminex kit.

Results: E2 dose-dependently inhibited HIV-1_{BaL} infection in PBMCs and endocervix ($p<0.01$). Raloxifene blocked E2-mediated HIV-1_{BaL} inhibition. No consistent significant increase in CFL1 mRNA expression was induced by E2. At the protein level, E2 augmented total CFL1 and phosphorylated CFL1 (pCFL1) and increased the pCFL1/CFL1 ratio in uninfected and infected PBMCs and endocervix. LIMKi3 reverted the phenotype and restored infection levels; blocked E2-induced increase in total CFL1 and pCFL1; and decreased the pCFL1/CFL1 ratios in PBMCs and endocervix.

Additionally, Luminex analysis revealed decrease in pro-inflammatory chemokines CXCL10 and CCL5 in endocervix incubated with E2 ($p<0.05$).

Conclusions: Our data propose a link between E2-mediated anti-HIV activity and CFL1 expression in PBMCs and endocervical mucosa. The data support exploration of cytoskeletal pathway targets for development of prevention strategies against HIV.

Systemic immune activation and inflammation

PESAA07

Overt IL-32 isoform expression at intestinal level during HIV-1 Infection is negatively regulated by IL-17A *via* PPAR gamma and retinoic acid-dependent mechanisms

E. Moreira Gabriel[1,2], T. Wiche Salinas[1,2], A. Gosselin[1,2], E. Larouche-Anctil[2], M. Durand[2], A. Landay[3], M. El-Far[2], C. Tremblay[1,2], J.-P. Routy[4], P. Ancuta[1,2]
[1]*Université de Montréal, Departement de Microbiologie, Infectiologie et Immunologie, Montréal, Canada,* [2]*CHUM-Research Centre, Montréal, Canada,* [3]*Rush University Medical Center, Chicago, United States,* [4]*McGill University Health Centre, Montréal, Canada*

Background: The interplay between intestinal epithelial cells (IEC) and Th17 cells is key for mucosal immunity homeostasis. HIV infection is associated with impaired intestinal barrier functions leading to chronic immune activation, a process not normalized by antiretroviral therapy (ART). Such alterations coincide with the overexpression of interleukin (IL)-32, a cytokine family composed of multiple isoforms. IL-32 overexpression was associated with the loss of HIV control in elite controllers and linked to non-AIDS co-morbidities, such as cardiovascular disease (CVD). The involvement of specific IL-32 isoforms in HIV gut pathogenesis remains poorly investigated.

Methods: Sigmoid colon biopsies (SCB) and blood were collected from ART-treated PLWH (HIV+ART; n=17; median age: 55 years; CD4 counts: 679 cells/ml; ART: 72 months) and age-matched HIV-uninfected controls (HIVneg; n=5). Cells were isolated by enzymatic digestion/gradient centrifugation. The IEC HT-29 line was exposed to TNF-α, IL-17A, and HIV, in the presence/absence of T0070907 (PPARγ antagonist) and/or *all-trans* retinoic acid (ATRA). IL-32α/β/γ/d/ε/θ and IL-17A mRNA were quantified by real-

time RT-PCR. IL-32 protein was quantified by ELISA. The IEC HIV*trans*-infection capacity was assessed upon co-culture with CD3/CD28-activated CD4+ T-cells.

Results: Among all isoforms tested, IL-32β was the predominant one, with expression levels upregulated in SCB of HIV+ART compared to HIVneg. IL-17A mRNA levels negatively correlated with IL-32β levels. IL-32β/γ/ε isoforms were also detected in HT-29 exposed to TNF-α and HIV. IL-17A significantly decreased IL-32 β/γ/ε mRNA and cell-associated IL-32 protein expression induced by TNF-α. IL-17A increased HIV *trans*-infection. ATRA boosted the IL-17A effects and further increased HIV *trans*-infection with coincidental reduction of IL-32 expression; T0070907 exhibited opposite effects.

Conclusions: Our results provide a cartography of IL-32 isoform expression in the colon and blood of ART-treated PLWH. They also reveal the capacity of the Th17 hallmark cytokine IL-17A to attenuate overt IL-32 expression in inflamed IEC, while promoting HIV dissemination *via*PPARγ and RA-dependent mechanisms. This is consistent with the documented antiviral properties of IL-32.

Our results support a model in which inflamed IEC are an important source of IL-32, especially upon HIV-mediated Th17 depletion, and reveal the opposite role of IL-17A in reducing overt IL-32 expression and favoring HIV dissemination at intestinal level.

PESAA09

Excess BAFF alters the Breg potential of human marginal zone B-cells in the context of HIV-1 infection

K. Doyon-Laliberté[1,2], M. Aranguren[1,2], M. Byrns[1,2], J. Chagnon-Choquet[1,2], M. Paniconi[3], J.-P. Routy[4], C. Tremblay[1,2], N. Brassard[2], M.-C. Quintal[5,6], D. Kaufmann[7,2], J. Poudrier[1,2], M. Roger[1,2]

[1]*Université de Montréal, Microbiologie, Infectiologie et Immunologie, Montréal, Canada,* [2]*CRCHUM, Montréal, Canada,* [3]*Université de Montréal, Faculté des Arts et Sciences, Montréal, Canada,* [4]*Université McGill, Département de Médecine, Montréal, Canada,* [5]*Université de Montréal, Département de Chirurgie, Montréal, Canada,* [6]*CHU Sainte-Justine, Montréal, Canada,* [7]*Université de Montréal, Département de Médecine, Montréal, Canada*

Background: We have previously reported that excessive levels of B-cell activating factor (BAFF) are concomitant with increased frequencies of precursor-like marginal zone (MZp) B-cells in the blood of HIV-infected progressors, despite antiretroviral therapy (ART).

Recently, we have shown that MZp from healthy individuals possess strong Breg capacities, which are characterized by high expression levels of NR4A1, NR4A2, NR4A3 and CD83 among others, as well as Breg function involving CD83 signals. Our objective was to better understand the impact of HIV-infection and excess BAFF on the Breg potential of MZp.

Methods: We have performed transcriptomic analyses by RNA-seq of MZp sorted from the blood of HIV-infected progressors from the Montreal Primary HIV Infection (PHI) cohort. Furthermore, the Breg profile and function of blood MZp B-cells from HIV infected progressors, with or without HAART, were also assessed by flow-cytometry and high content screening (HCS) analyses, respectively.

In addition, the effects of high amounts of soluble recombinant BAFF on the Breg profile of MZp B-cells from healthy donors was investigated *in vitro*.

Results: We report highly significant downregulation of NR4A1, NR4A2, NR4A3 and CD83 gene transcripts in blood MZp B-cells from HIV-infected progressors when compared to elite controllers (EC) and healthy individuals. Accordingly, NR4A1, NR4A3 and CD83 protein expression levels and Breg function are also downregulated in blood MZp B-cells from HIV-infected progressors and not restored by HAART.

Importantly, we observe decreased expression levels of NR4A1, NR4A3, CD83 and IL-10 by MZp B-cells following treatment with excess BAFF, which significantly diminished their regulatory function.

Conclusions: Our data thus suggest that excess BAFF contributes to the reduced immune surveillance that precipitates the development of co-morbidities such as atherosclerosis in the context of HIV and is likely to do so in other chronic inflammatory diseases where BAFF is found in excess.

Cerebrospinal fluid cellular inflammatory gene expression profile in people with acute HIV-1 infection

K. McGuckin Wuertz[1,2], V. Sharma[1,3], A. Yates[1,3], M. Creegan[1,3], P. Chan[4], C. Sacdalan[4], N. Phanuphak[4], K. Benjapornpong[4], P. Prueksakaew[4], S. Spudich[5], S. Vasan[1,3], D. Bolton[1,3], on behalf of the RV254/304 Study Team

[1]*Walter Reed Army Institute of Research, U.S. Military HIV Research Program, Silver Spring, United States,* [2]*University of Washington, Center for Innate Immunity and Immune Diseases, Seattle, United States,* [3]*Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States,* [4]*Institute of HIV Research and Innovation (IHRI), SEARCH, Bangkok, Thailand,* [5]*Yale University, Department of Neurology, New Haven, United States*

Background: Despite effective antiretroviral therapy, neurocognitive dysfunction associated with HIV-1 infection remains a significant source of morbidity.The mechanisms underlying the impairment are unclear, though likely involve widespread inflammation and early HIV-1 replication within the central nervous system (CNS).

We aimed to identify sources of CNS inflammation through transcriptional analysis of cerebrospinal fluid (CSF) cells from people living with HIV-1 (PLWH) in acute infection.

Oral abstracts

Late-breaker abstracts

Author Index

Methods: PBMC and CSF were obtained from PLWH in the RV254 acute HIV-1 cohort (Thailand), during untreated Fiebig stages III-IV (n = 9, male, median age 23 ± 2.8) and from age and sex matched Thais without HIV-1 (PWOH) (n = 2 (PBMC) and 5 (CSF)). CD4+ T cells and monocytes were FACS sorted in replicate (n = 4-8) for targeted 96-gene expression profiling by multiplexed RT-qPCR. Gene expression differences were assessed using Welch test on the means.

Results: Median HIV-1 RNA values in PLWH were 6.1E6 copies/mL in plasma and 1.4E4 copies/mL in CSF. Median peripheral blood CD4+ T cell counts were 310 cells/uL, with a median CD4:CD8 ratio of 0.33. Multiple host genes involved in type I interferon regulation were upregulated in monocytes and CD4+ T cells in the CSF during acute HIV-1 infection compared to PWOH, including *IFI44, IFIT1, RSAD2, STAT1, USP18* and *OAS* family members ($P < 0.05$).

These genes were upregulated 2-8-fold in CD4+ T cells and 5-40,000-fold in monocytes. Cell cycle regulatory genes were also increased. Cytokines and chemokines involved in cellular recruitment and inflammation, *CCL2, CXCL9* and *TNF,* were only upregulated in monocytes (30-100,000-fold).

Similar results were observed in PBMC, though interestingly, the magnitude of the response in monocytes was more limited than that in CSF. These results indicate a robust antiviral inflammatory response in both CSF and peripheral blood.

Conclusions: Our findings provide unique insight into the cellular signaling pathways initiated within the CNS during the earliest stages of HIV-1 infection. Greater understanding of these early events will inform therapeutic strategies designed to limit HIV-1-associated neurologic inflammation and disease.

PESAA11

A longitudinal assessment of the impact of antiretroviral therapy and HIV-1 associated inflammation on neurocognitive outcomes in perinatally infected (PHIV) children in South Africa

S. Naidoo[1], B. Laughton[1], T. Maponga[1], K. Veldsman[1], M. Cotton[1], R. Glashoff[1]
[1]*Stellenbosch University, Cape Town, South Africa*

Background: Early diagnosis and improved treatment options in paediatric HIV-1 infections necessitates comprehensive characterisation of the neuropathology of HIV-associated neurocognitive disorders (HAND) during viral suppression. Longitudinal studies on clinical and immunological biomarker associations with neurological outcomes in PHIV children are limited.

Methods: A dual longitudinal and cross-sectional study design was implemented to investigate the impact of clinical, immunological, and virological parameters on neurodevelopmental outcomes in PHIV children from the Children with HIV Early antiRetroviral (CHER) randomised trial. Longitudinal neurocognitive assessments included the Griffiths Mental Development Scales (GMDS) administered at 11, 18, 30, 42 and 60 months of age and included assessments of locomotor, personal-social, hearing, language and eye-hand co-ordination. The Beery-Buktenica Development Test for Visual-Motor Integration (Beery-VMI) was implemented at 5, 7 and 9 years of age. Forty immunological plasma biomarkers were measured by Luminex®Multiplex Assays and ELISA. A sensitive qPCR adapted for HIV-1 subtype C targeting the integrase gene was implemented for the measurement of total HIV-1-cell-associated DNA (CAD).

Results: A total of 139 participants were assessed. We observed significant positive associations between pro-inflammatory biomarkers including IL-1β (*r*=0.39;p=0.01), sCD14 (*r*=0.34;p=0.03), sCD163 (*r*=0.45;p<0.01), IL-18 (*r*=0.36;p=0.02) and LBP (*r*=0.32;p=0.04) and early Locomotor and General Griffiths scores. These biomarkers indicate innate immune activity of monocyte/macrophage activation and PAMP stimulation and may depict a neurological protective response.

Negative associations with neurodevelopmental outcomes were observed for IL-1RA (*r*=-0.50;p<0.01), IL-6 (*r*=-0.42;p<0.01), MCP-1 (*r*=-0.35;p=0.02), MIP-1α (*r*=-0.36;p=0.02) and IFN-α (*r*=-0.37;p=0.02). Interleukin-17F (*r*=-0.20;p=0.02), IL-12 (*r*=-0.19;p=0.04), IL-13 (*r*=-0.19;p=0.03), MIP-1α (*r*=-0.20;p=0.02) and TNFβ (*r*=-0.18;p=0.04) may serve as early predictors of late neurodevelopmental outcomes whereas IL-13, IFN-α, IL-6 and TGF-β_2 can predict both early and late neurodevelopmental parameters.

Early measures of HIV-1-CAD were significantly associated with Locomotor and General Griffiths scores. Early clinical parameters showed significant associations with both early and late neurodevelopmental outcomes. These include time-to-viral suppression (*r*=0.34;p=0.03), gestation (*r*=0.33;p=0.03), %CD8 at birth (*r*=0.41;p=0.03), CD8 count at birth (*r*=0.40;p=0.02), time-to-therapy initiation (*r*= -0.41;p<0.01) and %CD4 at birth (*r*= 0.36;p=0.02).

Conclusions: Neurocognitive outcomes can be predicted by early immunological, virological and clinical parameters. Early initiation of and continuous cART is important for mitigating excess inflammation and immune activation which significantly impacts the neuro-immune relationship.

PESAA12

No evidence that ongoing HIV-specific immune responses contribute to persistent inflammation and immune activation in persons on long-term suppressive ART

A. Ward[1], A. Thomas[2], E. Stevenson[3], S.-H. Huang[3], S. Keating[4], R. Gandhi[5], D. McMahon[6], R. Bosch[7], B. Macatangay[6], J. Cyktor[6], J. Eron[8], J. Mellors[6], R.B. Jones[1], ACTG A5321 Team

[1]Weill Cornell Medicine, Medicine, New York City, United States, [2]Boston University School of Medicine, Boston, United States, [3]Weill Cornell Medicine, New York City, United States, [4]GigaGen, Inc., San Francisco, United States, [5]Massachusetts General Hospital, Boston, United States, [6]University of Pittsburgh School of Medicine, Pittsburgh, United States, [7]Harvard T.H. Chan School of Public Health, Boston, United States, [8]University of North Carolina at Chapel Hill, Chapel Hill, United States

Background: People with HIV (PWH) have persistently elevated levels of inflammation and immune activation despite suppressive antiretroviral therapy (ART), with specific biomarkers showing associations with AIDS- and non-AIDS-defining morbidities and mortality. Because adaptive immune responses against HIV also persist in PWH on ART, and show evidence of ongoing antigenic stimulation, we hypothesized that they contribute to this clinically-relevant inflammatory profile. We therefore investigated potential associations between HIV-specific T-cell and antibody responses with on-ART inflammation and immune activation.

Methods: T-cell responses (IFN-γ ELISPOT) to each HIV gene product as well as to CMV-pp65, along with HIV-specific antibody concentrations, were measured in n=101 virally suppressed participants from the AIDS Clinical Trials Group A5321 cohort at study entry (median 7 years on ART). HIV persistence measures including cell-associated (CA)-DNA, CA-RNA, plasma HIV RNA by integrase single-copy assay (iSCA), and intact proviral DNA assay (IPDA, in a subset of n=33 participants) were also assessed at study entry. Plasma inflammatory biomarkers and T-cell activation and cycling biomarkers were measured at a pre-ART time point and at study entry.

Results: Magnitudes of HIV-specific T-cell responses, CMV-pp65-specific responses, and HIV antibody levels were not correlated with levels of inflammatory or immune activation biomarkers, including hs-CRP, IL-6, neopterin, sCD14, sCD163, or %$CD38^+HLA\text{-}DR^+$ or %$Ki67^+$ $CD8^+$ and $CD4^+$ cells – including after adjustment for pre-ART biomarker level (all Spearman $|r| < 0.20$, $p > 0.05$). Magnitudes of T-cell responses to HIV-Pol were correlated with TNF-α levels, but this was confounded by several factors including pre-ART plasma viral load, $CD4^+$ T-cell count, and years on ART at A5321 entry. iSCA levels were correlated with $CD8^+$ T-cell activation (Spearman $r = 0.25$, $p = 0.027$), and defective (but not intact) HIV DNA levels with $CD4^+$ T-cell cycling (%$Ki67^+$; $r = 0.51$, $p = 0.003$), but other HIV persistence parameters were not associated with these biomarkers.

In statistical mediation analysis, relationships between HIV persistence parameters and inflammatory biomarkers were not influenced by HIV-specific T-cell responses or antibody levels.

Conclusions: HIV-specific immune responses do not appear to contribute to the elevated inflammatory and immune activation profile associated with morbidity and mortality in PWH on long-term suppressive ART.

Innate immunity (including NK cells)

Soluble interferon receptor (sIFNAR2) inhibits HIV-1 infection in macrophages through IFN-β-independent pathways

E. Calonge[1], F. Diez-Fuertes[1], I. Hurtado[2], O. Fernandez[3], B. Oliver[4], J. Alcamí[1]

[1]Institute of Health Carlos III. National Centre of Microbiology, AIDS immunopathology, Madrid, Spain, [2]Biotech Research & Innovation Centre (BRIC), University of Copenhagen, Copenhagen, Denmark, [3]Institute of Biomedical Investigation (IBIMA), Malaga, Spain, [4]Institute of Biomedical Investigation (IBIMA), Malaga, Spain

Background: The soluble IFN-β receptor (sIFNAR2) plays an immunomodulatory role in autoimmune diseases by reducing inflammation and tissue damage at the same levels as IFN-β. Besides IFN-β interferes with HIV replication mainly in monocyte-derived macrophages (MDM).
This study aims to evaluate the impact of sIFNAR2 on HIV-1 infection in MDM and to compare the biochemical pathways induced by sIFNAR2 and IFN-β.

Methods: MDM were infected with the YU2 HIV-1 strain for 72h and infection was assessed by p24 levels in infection supernatants in the presence of IFNAR (30µgr/ml) or IFN-β (20U). Soluble IFN binding protein B18 was used to exclude IFN-β activation by SIFNAR2. Differential gene expression was measured by RNAseq of cells treated with IFNAR2 and IFN-β (Illumina).
Changes in protein expression were analyzed by quantitative phosphoproteome analysis (LC-MS/MS and isobaric labeling with TMT)

Results: sIFNAR2 does not affect cell viability in culture. HIV-1 infection of macrophages and PBLs was inhibited by at least 85% when sIFNAR was added to cultures at similar levels as IFN-β. sIFNAR2 reduced the production of inflammatory cytokines (CXCL9,10,11) in MDM. sIFNAR2 effects were independent of IFN-β activation since its action was not affected by treatment with the IFN inhibitor B18
Differential gene expression measured by transcriptome sequencing shows that sIFNAR2 generates a functional pattern totally different from the profile shown by IFN-β (Image) and remarkably, the Jak-STAT pathway was not induced by sIFNAR2.

Phosphoproteome analysis demonstrates activation of the IL37 pathway while classical IFNα/β signaling pathways, ISG15 antiviral mechanism or OAS antiviral response were not altered.

Conclusions: sIFNAR2 interferes with HIV-1 replication in MDM and decreases the production of proinflammatory cytokines. Transcriptomic and proteomic analysis confirmed that the sIFNAR2 mechanism of action is different from the pathways elicited by INF-β. The use of sIFNAR2 in the treatment of HIV-1 infection deserves further consideration.

Acute and early infection

Successful recruitment of Youth with untreated HIV infection in Adolescent Trials Network 147: early treatment of acute HIV infection

T. Kerin[1], R. Cortado[1], S. Paiola[1], S.E. Abdalian[2], D. Swendeman[3], M. Ocasio[2], R. Bolan[4], B. Ark[1], Y. Bryson[1], K. Nielsen-Saines[1], ATN CARES Team

[1]David Geffen UCLA School of Medicine, Division of Infectious Diseases, Department of Pediatrics, Los Angeles, United States, [2]Tulane University School of Medicine, Department of Pediatrics, New Orleans, United States, [3]University of California, Los Angeles, Department of Psychiatry and Biobehavioral Sciences, Los Angeles, United States, [4]Los Angeles LGBT Center, Los Angeles, United States

Background: Gay, bisexual, transgender, and African-American adolescents are at elevated risk of acquiring HIV infection but diagnosis is often delayed. Early antiretroviral treatment (ART) of acute HIV infection can reduce viremia and viral reservoir burden, promoting long-term HIV control. Adolescent Trials Network (ATN) 147 aimed to identify and recruit youth with acute/recent HIV infection for early ART. Baseline demographic and clinical data for the cohort are reviewed.

Methods: Treatment-naïve, recently identified HIV+ youth, aged 12 to 24 years, from Los Angeles and New Orleans were recruited from community centers, clinics, social media, and a high-risk seronegative cohort (n=1727, ATN 149) using point-of-care assays. Acute HIV infection was determined by Fiebig staging. HIV RNA viral load (VL) and CD4 cell counts were assessed at enrollment.

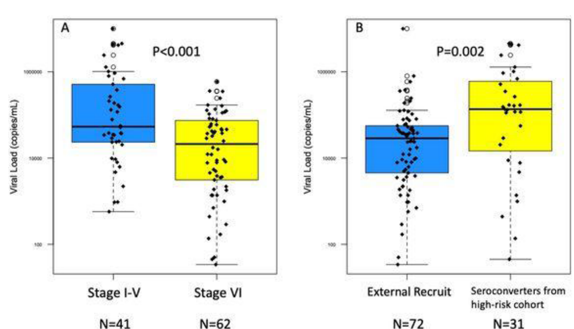

Figure. Viral Log at baseline by Fiebig Stage (A) and Recruitment (B)

Results: Between July 2017-July 2021, 103 newly diagnosed youth were enrolled and started ART within a week. Mean age was 20.8 years (sd:2.4); 90.3 % of youth identified as cis-male, 83.5% were single or in casual relationships, 71.8% were gay, bisexual, and other MSM, and 60.2% were Black. One-fourth (24.3%) reported homelessness ever; 10.7% within the last 4 months.

At enrollment, median VL was 37,313 copies/ml (IQR:5849-126162) and median CD4 count 445.5 cells/mm3 (IQR:357-613). 40% of youth reported acute retroviral symptoms

prior to or at enrollment. Median VL differed significantly by Fiebig stage and recruitment source (Figure). Acutely-infected, seroconverting youth had higher VL. STI co-infections were present at enrollment in 63%, with syphilis most frequent (39%).

Conclusions: Despite challenges in identification and recruitment of youth with HIV infection to clinical studies, ATN 147 successfully enrolled youth at the time of HIV diagnosis. A high STI burden was present in recently HIV-infected youth, likely facilitating HIV acquisition. Acute retroviral symptoms were reported by only 40%, demonstrating that broad universal HIV screening is needed for better identification of recent infection in youth.

Morbidity, mortality and life expectancy in clinical research

PESAB02

In-hospital mortality among persons with HIV (PWH) in the US and Canada, 2005-2018

[1]UNC Chapel Hill, Chapel Hill, United States, [2]Johns Hopkins University, Baltimore, United States, [3]Kaiser Permanente Northern California, Oakland, United States, [4]Kaiser Permanente Mid-Atlantic States, Rockville, United States, [5]University of California, San Francisco, United States, [6]Yale University, New Haven, United States, [7]Southern Alberta HIV Clinic, Calgary, Canada, [8]University of Texas Southwestern Medical Center, Dallas, United States, [9]Emory University, Atlanta, United States, [10]University of California, San Diego, United States, [11]National Cancer Institute, Bethesda, United States, [12]Veterans Affairs Connecticut Healthcare System, West Haven, United States, [13]Case Western Reserve University, Cleveland, United States, [14]University of Toronto, Toronto, Canada

Background: In-hospital mortality can reflect incidence of severe events, quality of inpatient and outpatient disease management, and delayed presentation to care for acute or chronic illness. Examining in-hospital mortality among PWH can help identify potential areas for improvement in preventing disease progression in the context of increasing age and comorbidity burden.

Methods: For hospitalizations in 2005-2018 among PLWH in care in six cohorts of the NA-ACCORD, we categorized ICD codes for the primary discharge diagnosis using modified Clinical Classifications Software (CCS). Using Modified Poisson regression, we estimated calendar time trends in the probability of in-hospital death overall and by diagnostic category, adjusting for age, gender, race/ethnicity, HIV risk factor, CD4 count, HIV viral load (VL), and NA-ACCORD cohort, all measured at hospitalization.

Results: We examined 26,600 hospitalizations among 9,076 PLWH who were 73% cisgender men, 38% White, 37% Black, and 19% with IDU risk factor. PLWH hospitalized in 2018 vs. 2005 were older (median 54 vs. 44 years), likelier to have VL<400 copies/mL (83% vs. 48%), and had higher CD4 counts (median 469 vs. 267 cells/µL).

Over the study period, unadjusted in-hospital mortality was 1.9% (95% CI 1.7%-2.1%) for all-cause hospitalizations and ranged from 0.3% (0.1%-0.6%) for psychiatric to 3.7% (2.9%-4.8%) for non-AIDS-defining cancer hospitalizations (Fig. 1).

For all-cause hospitalizations, unadjusted in-hospital mortality decreased from 2.3% (1.7%-3.2%) in 2005 to 1.6% (1.1%-2.4%) in 2018. The age-adjusted relative change in in-hospital mortality was -4.5% (-6.7% to -2.2%) per year for all-cause hospitalizations.

In fully adjusted analyses, the relative change per year was -3.3% (-5.5% to -1.0%) for all-cause, -3.9% (-7.3% to -0.4%) for non-AIDS infection, and -13.8% (-23.0% to -3.4%) for AIDS-defining illness hospitalizations.

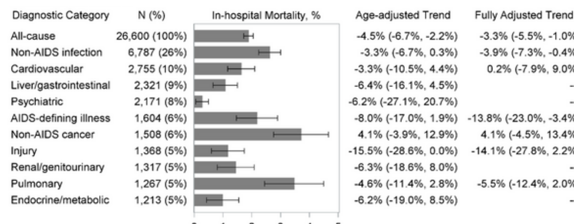

Fig. 1. Unadjusted in-hospital mortality and calendar time trends (relative change per year). Numbers not shown could be estimated.

Conclusions: Among PLWH in care, in-hospital mortality decreased over 2005-2018. Further research should investigate risk factors and potential prevention strategies for hospitalizations with higher mortality, e.g. for pulmonary conditions.

High accuracy of an enzyme-linked immunoasssay for detection of tenofovir alafenamide: implications for point-of-care antiretroviral adherence monitoring

M. Spinelli[1], W. Rodrigues[2], G. Wang[2], J. Chen[2], K.A. Johnson[1], D.V. Glidden[1], M. Morrow[3], H. Okochi[1], P.L. Anderson[4], M. Gandhi[1]

[1]*University of California, San Francisco, San Francisco, United States,* [2]*Abbott Rapid Diagnostics, Pomona, United States,* [3]*Colorado School of Public Health, Aurora, United States,* [4]*University of Colorado Anshutz Medical Campus, Aurora, United States*

Background: We previously developed a urine point-of-care (POC) immunoassay to measure urine tenofovir (TFV) levels for patients on tenofovir disoproxil fumarate (TDF) as an objective adherence metric. Tenofovir alafenamide (TAF), a prodrug of TFV, is metabolized intracellularly and gives ~80% lower urine TFV levels than TDF. Previous modelling demonstrated that 300 ng/mL of TFV is an optimal cut-off for detecting non-daily adherence to TAF.

The goal of this study was to demonstrate accuracy of the enzyme-linked immunoassay (ELISA) for TFV from TAF compared to liquid chromatography tandem mass spectrometry (LC-MS/MS) at this cut-off.

Methods: The TAF-DBS study recruited HIV-negative participants to take TAF/emtricitabine using directly-observed-therapy. The Point-of-Care Urine Monitoring of Adherence (PUMA) Study collected urine from people with HIV using TAF-based ART. Ten urine samples were included as negative controls from healthy participants on no medications. A previously validated ELISA using the anti-TFV antibody was recalibrated for concentration ranges appropriate for individuals taking TAF and levels compared to those from LC-MS/MS.

Results: Overall, 131 samples from 94 participants were included. TAF-DBS included 36 participants (17 cisgender women) providing 2 samples, median age 29 (range 18-41); PUMA included 48 participants providing one sample (6 cisgender women, 2 transgender women, 1 transgender man), median age 56 (range 26-73); Controls included 10 participants not on TAF (5 cisgender women), median age 32 (range 25-45).

Of the 109 samples with TFV levels above the 300 ng/mL cut-off by LC-MS/MS, 107 were above 300 ng/mL via ELISA, with 98.2% sensitivity (95% confidence interval (CI): 93.5-99.8%). Of 21 samples with TFV levels below the cut-off by LC/MS/MS, 20 were below via ELISA, with 95.2% specificity (95% CI: 76.2-99.9%). ELISA was 97.7% (95% CI: 93.4-99.5%) accurate compared to LC-MS/MS (**Fig.**). The log-transformed correlation coefficient between the two methods was 0.86 (p<0.001).

Conclusions: As TAF uses expands for PrEP and ART, a POC urine assay for TAF adherence is needed. We demonstrate that an immunoassay can accurately measure TFV in urine above and below an appropriate cut-off for TAF with high accuracy compared to LC-MS/MS. The assay is now optimized to support development of a lateral flow POC adherence test for TAF.

Viral load and CD4 monitoring

PESAB04

Comparison of Advanced HIV Disease identification using CD4 results from a semi-quantitative CD4 point of care test and CD4 flow cytometry in Nigeria

Wiwa[4], P. Nwaokenneya[5], C. Adesigbin[5], A. Ikpeazu[5], G. Olorunfemi[6], R. Oladele[7], O. Agbaji[8], S. Akanmu[7]

[1]*Clinton Health Access Initiative, HIV Access Program, Abuja, Nigeria,* [2]*Clinton Health Access Initiative, HIV Access Program, Kigali, Rwanda,* [3]*Clinton Health Access Initiative, HIV Access Program, Boston, United States,* [4]*Clinton Health Access Initiative, Global Resources for Health, Abuja, Nigeria,* [5]*Federal Ministry of Health, National AIDS and STIs Control Program, Abuja, Nigeria,* [6]*University of Witwatersrand, Division of Epidemiology & Biostatistics, Johannesburg, South Africa,* [7]*Lagos University Teaching Hospital, Lagos, Nigeria,* [8]*Jos University Teaching Hospital, Jos, Nigeria*

Background: CD4 testing is critical in identifying people living with HIV with Advanced HIV Disease (AHD) and is conducted at enrollment/re-enrollment into care. Nigeria introduced VISITECT CD4 Advanced Disease rapid test (VISITECT), a semi-quantitative point of care test prequalified by WHO, to address gaps in CD4 coverage. Conducting VISITECT test requires time-sensitive procedural steps and visual acuity for interpretation, and there was no experience with its use in Nigeria. To allay concerns of the impact of operational differences on the quality of VISITECT results in the Nigerian context, we compared results from VISITECT to CD4 flow cytometry, the current gold standard in-country.

Methods: We recruited patients >10years old enrolling into HIV care across 4 states (Akwa-Ibom, Anambra, Lagos, Rivers) implementing the AHD package of care between February and June 2021. Venous or capillary blood samples were collected at enrollment, and parallel CD4 tests were conducted via VISITECT and CD4 flow cytometry platforms (BD FACSPresto and Partec Cyflow).

We determined how many results reported by healthcare workers (HCWs) as <200cells/mm^3 (AHD), or ≥200cells/mm^3 by CD4+ cell flow cytometry was correctly identified by VISITECT. The paired tests were tested for agreement using Cohen's Kappa test.STATA version 16 was used for analysis.

Results: 603 patients were recruited from 10 ART facilities. The prevalence of CD4 <200cells/mm³ was 47.6%, (95% CI: 43.6% - 51.6%, 287/603) and 50.9% (95% CI: 46.9% - 54.9%, 307/603) on the flow cytometry and VISITECT respectively. In all, 268 of 307 VISITECT results that were <200cells/mm³ were identified as correct by the gold standard, giving a positive predictive value of 87.3%. 277 of 296 VISITECT results ≥200cells/mm³ were identified as correct by the gold standard, with giving a negative predictive value of 93.6% (Kappa = 0.81, Agreement =90.38%, P= <0.001).

Conclusions: The observed high agreement between VISITECT and flow cytometry results demonstrates that VISITECT can correctly identify patients with AHD and has the potential to improve access to CD4+ testing and linkage to care.

The findings show that operational differences have minimal effect on the accuracy of VISITECT results at facilities and Nigeria can deploy the test across the country with minimal concerns.

Diagnostics of co-infections and co-morbidities

Circulating mir21 and mir125b in women living with human immunodeficiency virus: utility of biomarkers for monitoring cervical carcinogenesis

J. Okoye[1], C. Onyenekwe[2], A. Ngokere[2], O. Omotuyi[3]
[1]Faculty of Health Sciences and Technology, Nnamdi Azikiwe University, Nnewi Campus, Medical Laboratory Science, Nnewi, Nigeria, [2]Nnamdi Azikiwe University, Medical Laboratory Science, Nnewi, Nigeria, [3]Adekunle Ajasin University, Biochemistry, Akungba, Nigeria

Background: As of 2018, the prevalence of Human immunodeficiency virus (HIV), and cervical cancer (Ca) attributable to HIV was higher in Africa than in other continents. Identifying individuals at a high risk of developing Ca among immunocompromised persons, using less invasive techniques, remains a major challenge.

The study evaluated HIV infection-associated dysregulation of Ca-linked oncomirs (miR-21, miR-146a, miR-155, miR-182, and miR-200c) and tumor suppressors (miR-let-7b, miR-125b, miR-143, miR-145, and p53 gene), in a bid to identify early indicators of genetic instability, and biomarkers for monitoring of high-risk individuals.

Methods: This case-control study included 173 women without abnormal Pap smear; confirmed HIV seropositive women (HIV+ = 103) and HIV seronegative women (HIV- = 70). Relative expressions of miRNAs and p53 gene in blood and cervical cells) were determined following RNA extraction, reverse transcriptase Polymerase Chain Reaction (PCR), and gel electrophoresis. T-test was used to compare the data from HIV+ and HIV- women. Significance was set atp≤ 0.05.

Results: Similar pattern of miR-21, miR-146a, miR-182, miR-200c, miR-125b, and miR-145 expression was observed in both samples. Higher expressions of miR-155 and p53 gene were observed in cervical cells of HIV+ women compared with HIV- women (p= 0.046, and 0.033, respectively) whereas lower expressions of miR-155 and p53 gene were observed in the blood of HIV+ women compared with HIV- women (p= 0.539 and 0.049, respectively). In both blood and cervical cells, higher miR-21 expression (p= 0.032 and 0.198, respectively) and lower miR-125b expression (p= 0.050 and 0.004, respectively) were observed in HIV+ women compared with HIV-women. In blood, a lower expression of miR-146a was observed in HIV+ women compared with HIV- women (p= 0.036) whereas in cervical cells, lower expressions of miR-182 and miR-200c were observed in HIV+ women compared with HIV- women (p= 0.035 and 0.045, respectively). The higher expression of miR-21, and lower expression of miR-125b and p53 could be early indicators of genetic instability prior to epithelial transformation.

Conclusions: This study suggests that circulating high expression of miR-21 and low expression of miR-125b and p53 gene could be used in identifying individuals at risk of developing Cervical cancer, especially among immunocompromised patients.

Background: Routine laboratory testing for cryptococcal meningitis currently consists of Cryptococcal antigen (CrAg) testing in blood and cerebrospinal fluid (CSF), CSF India ink, and CSF fungal culture. Quantitative cryptococcal culture (QCC) is labor intensive and not feasible in most settings. We evaluated quantitative (qPCR) and reverse transcriptase qPCR (RT-qPCR) assays to quantify

cryptococcal load in CSF, plasma, and blood. We investigated the dynamics of fungal DNA and RNA detection during antifungal treatment.

Methods: We developed a qPCR assay that can differentiate serotypes A, D and B/C of*Cryptococcus neoformans*and*Cryptococcus gattii*based on the amplification of a unique nuclear Quorum sensing protein 1 (QSP1) and a multicopy 28S rRNA gene and evaluated the assays on 205 patients samples from the AMBITION-cm trial in Botswana and Malawi (2018-2021). CSF, plasma and whole blood samples were stored per patient and were sampled at day 0 (baseline), day 7 and 14 for CSF and at day 1, 3 and 7 for plasma and whole blood post antifungal treatment initiation. A Roche LightCycler480 and Graph pad prism were used for data analysis.

Results: Using the *QSP1* qPCR, 138 (81.7%) were serotype A, 28 (16.6%) were serotype B/C and 3 (1.8%) were a mixed infection of serotype A and B/C. There was no amplification with 36 (17.6%) samples. QCC showed a good correlation with *QSP1* qPCR (slope=0.797, R^2=0.73) and with 28S rRNA qPCR (Slope=0.771, R^2=0.778) assays.

The fungal load at D0 was significantly higher in patients who died at week 10 (w10) as compared to patients who survived post week 10 (p<0.01). Detection of *Cryptococcus* DNA (28S rRNA qPCR) in plasma or whole blood within the first 24 hours of treatment was significantly associated with early mortality at w10 (p<0.01). *QSP1* RT-qPCR showed that detection of DNA was due to viable fungal cells as the quantification of*QSP1* whole nucleic acids was systematically higher (2 to 5-fold) than that of DNA.

Conclusions: Quantification of *C. neoformans*and*C. gattii* load in CSF and plasma at D0 is useful in identifying patients at risk of death and may be a promising tool for monitoring treatment response in the future.

Biomarkers for the prediction of morbidity and mortality

Antenatal systemic inflammation and mortality of children born to mothers with HIV in rural Zimbabwe

C. Evans[1,2], B. Chasekwa[1], K. Mutasa[1], S. Rukobo[1], M. Govha[1], P. Mushayanembwa[1], F.D. Majo[1], N.V. Tavengwa[1], J.H. Humphrey[1,3], A.J. Prendergast[1,2,3]
[1]Zvitambo Institute for Maternal and Child Health Research, Harare, Zimbabwe, [2]Queen Mary University of London, Blizard Institute, London, United Kingdom, [3]Johns Hopkins Bloomberg School of Public Health, Department of International Health, Baltimore, United States

Background: Despite increasing availability of antiretroviral therapy (ART) and falling vertical transmission rates, children born to mothers living with HIV have higher mortality than children born to mothers without HIV. We tested the hypothesis that maternal systemic inflammation during pregnancy is associated with mortality of children born to mothers with HIV.

Methods: Women from the SHINE trial in rural Zimbabwe were recruited during pregnancy and infants were followed for 18 months. C-reactive protein (CRP) and soluble CD14 (sCD14) were measured in plasma by ELISA at a median of 16 gestational weeks. Cox regression models were used to estimate hazard ratios (HR) for infant mortality. Covariates for adjusted models included maternal HIV viral load, CD4 count, cytomegalovirus co-infection, antiretroviral therapy exposure, gestational age at blood sampling and randomised trial arm.

Results: Among 636 children born to mothers with HIV, 82% had ART exposure antenatally. The median maternal CRP was 4.72mg/L (interquartile range (IQR) 1.54, 11.85), and was higher in mothers of children who died by 18 months (9.18mg/L, IQR 5.28, 18.02) compared to mothers of children who survived (4.35mg/L, 1.50, 10.99).

After adjusting for plausible confounders, risk of child mortality doubled for each log rise in maternal CRP (adjusted HR (aHR) 2.12, 95%CI 1.33, 3.40; *P*=0.002). By contrast, maternal CRP was lower among 1744 mothers without HIV (2.67mg/L, IQR 1.04, 6.02) and was not associated with the risk of infant mortality (aHR 1.05, 95%CI 0.76, 1.46; *P*=0.763). Maternal sCD14 was not associated with the risk of mortality in children born to mothers with HIV (aHR1.65, 95%CI 0.25, 10.80; *P*=0.600) or without HIV (aHR1.62, 95%CI 0.26, 10.19; *P*=0.606).

Conclusions: We show for the first time that that maternal systemic inflammation measured by CRP is independently associated with infant mortality in HIV-affected mother-child pairs.

This finding has two major public health implications.

First, CRP is cheap and simple to measure, meaning antenatal point-of-care CRP could be utilised to identify those most at risk of child mortality.

Second, antenatal anti-inflammatory interventions may be required to improve clinical outcomes of children born to mothers with HIV.

Tuberculosis: Prevention, diagnosis, treatment

PESAB08

Viral suppression among adults with HIV receiving dolutegravir-based antiretroviral therapy and 3HP in Kampala, Uganda

L. Chaisson[1], F. Semitala[2], D. Dowdy[3], K. Aman[4], S. Steinmetz[3], D. Armstrong[5], B. Opira[4], M. Kamya[2], P. Phillips[6], C. Yoon[6]

[1]University of Illinois at Chicago, Medicine, Chicago, United States, [2]Makerere University College of Health Sciences, Medicine, Kampala, Uganda, [3]Johns Hopkins University, Epidemiology, Baltimore, United States, [4]Infectious Diseases Research Collaboration, Kampala, Uganda, [5]Johns Hopkins University, Pathology, Baltimore, United States, [6]University of California San Francisco, Medicine, San Francisco, United States

Background: A Phase I/II study evaluating the pharmacokinetics of TB preventive therapy with 3HP (3 months weekly rifapentine/isoniazid) co-administered with dolutegravir (DTG)-based antiretroviral therapy (ART) found 3HP to be well-tolerated and that 3HP could be given without dose adjustment of DTG, although DTG clearance was increased. We assessed

1. Safety of DTG-based ART and 3HP and
2. 6-month viral suppression, in a routine setting.

Methods: TB SCRIPT is an ongoing Phase 3 randomized trial comparing TB screening with point-of-care C-reactive protein versus symptoms among adults with CD4≤350 cells/µL initiating routine ART in Kampala, Uganda. TB screen-negative participants without contraindications are referred for self-administered 3HP two weeks following ART initiation. HIV viral load (VL) is measured at 6-month follow-up. Here, we evaluated 3HP discontinuation due to drug toxicity and 6-month viral suppression among participants without prevalent TB at baseline who initiated once-daily DTG-based ART.

Results: From 11/2020-10/2021, 381 participants without TB initiated TDF/3TC/DTG (TLD), of whom 143 (37.5%) initiated 3HP. Median pre-ART CD4 and BMI were higher for participants who initiated 3HP (Table). To date, 129/143 (90.2%) TLD+3HP participants completed 3HP; reasons for discontinuation included drug toxicity (rash, n=1), pregnancy (n=1), and active TB diagnosis (n=3). Six-month VL testing was completed by 164/381 (43.0%) participants, including 62/143 (43.4%) TLD+3HP participants and 102/238 (42.9%) TLD only participants. TLD+3HP participants had higher median VL than TLD only participants (p=0.03). Furthermore, compared to TLD only participants, a higher proportion of TLD+3HP participants were viremic at >200 (21.0% [13/62] vs. 9.8% [10/102], p=0.06) and >1000 copies/mL (9.7% [6/62] vs. 5.9% [6/102], p=0.37), although the differences were not statistically significant.

A. Baseline characteristics	TLD+3HP N=143	TLD N=238	p-value
Female sex	86 (60.1%)	159 (66.7%)	0.27
Median age, years (IQR)	31 (25-38)	30 (26-37)	0.86
Median pre_ART CD4 count (IQR)	216 (117-287)	168 (73-249)	0.002
Median BMI (IQR)	23.0 (21.3-26.1)	22.3 (20.3-24.7)	0.01
B. 6-month follow-up	**TLD+3HP N=62**	**TLD N=102**	**p-value**
Female sex	34 (54.8%)	76 (74.5%)	0.01
Median age, years (IQR)	30 (25-39)	28 (25-36)	0.55
Median pre_ART CD4 count (IQR)	233 (132-301)	193 (80-271)	0.06
Median BMI (IQR)	22.9 (21.2-25.4)	22.2 (20.1-25.1)	0.13
Median $\log_{10}$ viral load (IQR)	1.70 (1.70-2.17)	1.70 (1.70-1.70)	0.03
Viral suppression ≤200 copies/mL	49 (79.0%)	92 (90.2%)	0.06
Viral suppression ≤1000 copies/mL	56 (90.3%)	96 (94.1%)	0.37

ART: antiretroviral therapy, TLD: TDF/3TC/DTG or tenofovir/lamivudine/dolutegravir, 3HP: 3 months of weekly isoniazid and rifapentine, IQR: interquartile range, BMI: body mass index

Table. Baseline characteristics (A) and 6-month viral suppression (B) among patients receiving dolutegravir-based ART (TDF/3TC/DTG [TLD])

Conclusions: Co-administration of 3HP with DTG-based ART was well-tolerated. Viral suppression was high overall, but early evidence suggests that receipt of 3HP with once-daily DTG-based ART may be associated with a lower probability of achieving viral suppression within 6-months.

DTG concentrations in healthy volunteers by 33 – 66%. We investigated the effect of RIF on DTG exposure when dosed at 50 mg once daily with food. DTG 50mg once daily could be more convenient than 50 mg twice daily and generic FDC of TDF/3TC/DTG (TLD) could be easily used without extra 50 mg DTG.

Methods: Forty ARV-naïve HIV-positive participants with newly diagnosed TB receiving stable RIF-based anti-TB therapy in Bangkok, Thailand were randomized to initiate 50 mg once-daily with food (study arm; TLD 1 pill/day) or DTG 50 mg twice-daily (control arm; TLD 1 pill plus additional DTG). Intensive PK was scheduled at week 4. Blood samples were collected pre-dose, 1, 2, 4, 6, 8, 12, and 24-hour post-dose (by study arm). HIV-1 RNA, liver and renal function tests were monitored. DTG concentrations were determined by validated LC-MS/MS. PK parameters were estimated by WinNonLin.

Results: The majority of the participants were male (87.5%); with median age of 32 years; and median body weight was 60.4 kg. Median baseline CD4 was 194 (IQR 46-238) cells/µL. Median baseline HIV-1 RNA was 4.9 (IQR 3.6-5.6) log_{10}copies/mL; 43% had HIV-1 RNA >100,000 copies/mL. Table 1 shows that GMR (90%CI) trough concentration (C_{trough}), maximal concentration (C_{max}) and area under curve ($AUC_{0-\tau}$) were not within the bioequivalence range of 0.8-1.25: [0.19 (0.1-0.35), 0.72 (0.49-1.06) and 0.42 (0.28-0.64)] respectively. In addition, 70% and 95% of study and control arm participants had DTG C_{trough}>0.064 µg/mL. At week 48, 90% of the participants in the study arm (18/20) and control arm (18/20) had HIV-RNA <40 copies/mL using ITT analysis. Premature study discontinuation occurred in 2 cases (1 in study arm: RIF-induced cholestasis; 1 control arm: hypersensitivity reaction).

Conclusions: Although there was substantial reduction in DTG concentration when co-administered with RIF, DTG once-daily regimen with food had robust virological suppression at week 48. Larger study of once-daily and twice-daily DTG is underway to confirm this finding.

Sitafloxacin therapy for mycoplasma genitalium in men who have sex with men

N. Ando[1], D. Mizushima[1], M. Takano[1], T. Aoki[1], Y. Yanagawa[1], K. Watanabe[1], H. Uemura[1], M. Mitobe[2], K. Kobayashi[2], H. Kubota[2], H. Miyake[2], T. Shinkai[2], K. Sadamasu[2], H. Gatanaga[1], S. Oka[1]

[1]*National Center for Global Health and Medicine, AIDS Clinical Center, Shinjuku-ku, Japan,* [2]*Tokyo Metropolitan Institute of Public Health, Laboratory, Shinjuku-ku, Japan*

Background: *Mycoplasma genitalium* infection has been recognized as an alarming STI in recent years. Reportedly, 89.6% and 68.3% of the strains detected in Japan carried mutations associated with macrolide and quinolone respectively. Due to these high rates of macrolide-resistance strains, sitafloxacin monotherapy is used as the first choice for treating *M. genitalium* infections in Japan. In this study, we aimed to assess the efficacy of sitafloxacin monotherapy for rectal and urogenital *M. genitalium* infection.

Methods: Patients diagnosed with *M. genitalium* infections in National Center for Global Health and Medicine between 2019 and 2021 were treated with sitafloxacin 200 mg for 7 days. A rectal swabs and/or urine sample were collected for assessing quinolone- and macrolide-resistance associated mutations(*parC*, *gyrA* and *23S-rRNA*) before treatment. Test of cure was recommended at approximately four weeks post-treatment.

Results: Among 114 patients included in this study, the mean age was 34 year-old, all were MSM, and 49.0% were HIV-positive. *M. genitalium* was detected in 91 rectal samples and 24 urine samples were observed. Among the strains diagnosed with *M. genitalium*, 70.3% (78/111) were successfully analyzed for *parC* mutations, 59.5% (66/111) for *gyrA* mutations and 78.4% (87/111) for *23S-rRNA* mutations. Microbiological cure rate of whole strains was 88.6% (101/114). That of the strains carrying *S83I* was 80.0% (44/55). Among them, the rate of the strains carrying *S83I*-without*gyrA* mutations was 90.3% (28/31). The cure rate of the wild type strains was 100% (15/15). There was no significant difference in cure rate by anatomical site.

ParC mutation (AAA)	Cure rate for each *parC* mutated MG infection	*GyrA* mutation (AAA)	Cure rate for combined parC and *gyrA* mutated MG infection	Cure rate for rectal MG infections	Cure rate for urogenital infections	Cure rate for concurrent rectal and urogenital
G248T (S83I)	80% (35/44, 95CI 64.7-90.2)	**G285T (M95I)**	77.8% (7/9, 95CI 40.0-97.2)	71.4% (5/7, 95CI 29.0-96.3)	100% (2/2, 95CI 15.8-100)	
		G277T (G93C)	0% (0/2, 95CI 0-84.2)	0% (0/2, 95CI 0-84.2)		
		G295A (D99N)	0% (0/1, 95CI 0-97.5)		0% (0/1, 95CI 0-97.5)	
		G285C (M95I) & G295A (D99N)	0% (0/1, 95CI 0-97.5)	0% (0/1, 95CI 0-97.5)		
		Wild type	90.3% (28/31, 95CI 74.2-98.0)	87.5% (21/24, 95CI 67.6-97.3)	100% (6/6, 95CI 54.1-100)	100% (1/1, 95CI 2.5-100)
Wild type	100% (15/15, 95CI 78.2-100)	**Wild type**	100% (15/15, 95CI 78.2-100)	100% (14/14, 95CI 76.8-100)	100% (1/1, 95CI 2.5-100)	
Others	95% (51/55, 95CI 83.1-99.4)	**Others**	95% (51/55, 95CI 83.1-99.4)	96.6% (39/42, 95CI 82.2-99.9)	90.9% (12/13 95CI 58.7-99.8)	
Total	88.6% (101/114, 95CI 81.3-93.8)		88.6% (101/114, 95CI 81.3-93.8)	87.8% (79/90, 95CI 79.2-93.7)	91.3% (21/23, 95CI 72.0-98.9)	100% (1/1, 95CI 2.5-100)

AAA: amino acid substitution, MG:Mycoplasma genitalium

Table.

Conclusions: The efficacy of sitafloxacin therapy for wild type *M. genitalium* infections was very high. However, the cure rate for the strains carrying both *parC* and *gyrA* mutations was limited. Resistance profile of both*parC* and *gyrA* is important to predict clinical course. According to the result of this study, we can treat rectal MG infections in the same way as urogenital infections.

PESAB12

Efficacy of cefixime for the treatment of *Neisseria gonorrhoeae* infection at three anatomic sites: a systematic review and meta-analysis

K.J. Yang[1], N. Kojima[2], J. Klausner[1]
[1]Keck School of Medicine of the University of Southern California, Los Angeles, United States, [2]UCLA David Geffen School of Medicine, Department of Internal Medicine, Los Angeles, United States

Background: *Neisseria gonorrhoeae* infection is the most common co-infection among patients with HIV. Additionally, rectal gonorrhea increases the risk of HIV infection acquisition. *Neisseria gonorrhoeae* is also highly prone to developing antibiotic resistance; thus, identification of effective antibiotics for treatment is important.
We conducted a systematic review and meta-analysis to describe the efficacy of the cephalosporin cefixime in treating gonorrhea at different anatomic sites.
Methods: We searched PubMed using the query "("Gonorrhea") AND ("Cefixime")." Reports published between January 1, 1980, and December 7, 2022, were included. We excluded studies that were not in English, not accessible, non-human, did not specify the cefixime dose/frequency, or case reports/series.
Of the included reports, we abstracted treatment success rates and cefixime dosage/frequency. One investigator reviewed each article. The relevance and assessment of bias and cohort characteristics for each article was determined by two investigators.
We performed a meta-analysis on a minimum of 3 studies to determine the overall success of cefixime in treating urogenital, rectal, and pharyngeal gonorrhea. Via OpenMeta[Analyst] software (Brown University, Rhode Island), we then calculated 95% confidence intervals using a binary random effects model.
Results: Of the 347 studies returned by PubMed, 15 met our inclusion criteria.
Of patients who received a 400 mg single dose of cefixime, 756 of 777 patients with urogenital infections (estimate: 98.0%; CI: 97.0%-99.0%), 107 of 112 patients with rectal infections (estimate: 95.9%; CI: 92.3%-99.4%), and 183 of 218 patients with pharyngeal infections (estimate: 86.0%; CI: 76.9%-95.0%) were cured.
Of patients who received a 800 mg single dose of cefixime, 224 of 228 patients with urogenital infections (estimate: 98.7%; CI: 97.3%-100%) and 21 of 26 patients with pharyngeal infections (estimate: 81.3%; CI: 66.3%-96.2%) were cured. There were fewer than 3 studies of rectal infections treated with 800 mg.
Conclusions: Cefixime was found to be an effective treatment for gonorrhea. At both single 400 mg and 800 mg doses, cefixime is most effective at treating urogenital infections and least effective at treating pharyngeal infections.

Opportunistic infections (excluding TB): Bacterial, non-TB mycobacterial, viral and parasitic infections

PESAB11

The acceptability of the AMBITION treatment regimen for HIV-associated cryptococcal meningitis: findings from a qualitative study of patients and providers in Botswana and Uganda

D.S. Lawrence[1,2], A. Ssali[3,4], N. Moshashane[2], G. Nabaggala[3], L. Maphane[2], T.S. Harrison[5,6,7], D. Meya[8], J.N. Jarvis[1,2], J. Seeley[3,4]
[1]London School of Hygiene and Tropical Medicine, Department of Clinical Research, London, United Kingdom, [2]Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana, [3]MRC/UVRI & LSHTM Uganda Research Institute, Social Aspects of Health Programme, Entebbe, Uganda, [4]London School of Hygiene and Tropical Medicine, Department of Global Health and Development, London, United Kingdom, [5]St George's University London, Institute of Infection and Immunity, London, United Kingdom, [6]St George's University Hospitals NHS Foundation Trust, Clinical Academic Group in Infection and Immunity, London, United Kingdom, [7]University of Exeter, MRC Centre for Medical Mycology, Exeter, United Kingdom, [8]Makerere University, Infectious Diseases Institute, Kampala, Uganda

Background: HIV-associated cryptococcal meningitis remains a significant contributor to AIDS-related mortality. The AMBITION trial found a single, high-dose of intravenous liposomal amphotericin (AmBisome) given alongside 14-days of oral flucytosine and fluconazole non-inferior in terms of all-cause mortality when compared to 7-days of intravenous amphotericin B deoxycholate and flucytosine followed by 7-days of fluconazole. The AmBisome regimen was associated with significantly fewer adverse events. We explored the acceptability of the AmBisome regimen.
Methods: We embedded a qualitative study within the AMBITION sites in Gaborone, Botswana and Kampala, Uganda. We conducted in-depth interviews with trial participants, surrogate decision makers, and researchers and combined these with direct observations. Interviews were transcribed and translated and data underwent thematic analysis.
Results: We interviewed 38 trial participants, 20 surrogate decision makers and 31 researchers. Participant understanding of the intricacies of the treatment regimens was limited however there was a broad preference for the AmBisome regimen due to the single intravenous doses and fewer side effects, with some in the control arm stating that they would have preferred the single dose.
The single AmBisome dose took roughly 30 minutes to reconstitute compared to 5-10 minutes for each daily amphotericin B deoxycholate dose. The AmBisome regimen was associated with fewer episodes of amphotericin related rigors, a reduced need for intravenous hydration, fewer cases of thrombophlebitis and a reduction in the

number of intravenous cannulae required. The reduced toxicity profile resulted in less intensive monitoring and management of participants in the AmBisome arm.
A particular challenge was accessing blood transfusions which were needed more often in control arm participants who has significantly higher rates of anaemia. A challenge of the AmBisome arm was the extended duration of oral flucytosine which was given six hourly and involved participants taking a dose in the night.
Conclusions: Participants, surrogate decision makers and researchers found the AmBisome arm to be highly acceptable, being simpler to administer despite the initial time investment required. The single dose was well tolerated and associated with less toxicity and resultant management and monitoring. Widespread implementation of this regimen would reduce the clinical workload of caring for patients with HIV-associated cryptococcal meningitis.

Background: Ongoing HIV-1 replication despite antiretroviral therapy (ART) use may contribute to higher burden of aging-related non-AIDS comorbidities (NACM) among women living with HIV (WLWH) versus women without HIV. We evaluated effects of cumulative HIV-1 viremia copy-years (VCY) on NACM among WLWH.
Methods: We included WLWH in the Women's Interagency HIV Study through 9/13/2019 with ≥2 HIV-1 RNA viral loads (VL) <200 copies/mL within a two-year-period (baseline) following self-reported ART use.
Primary outcome was multimorbidity (≥2 NACM accrued of 5 assessed: hypertension, dyslipidemia, diabetes, cardiovascular disease, kidney disease); presence of any NACM at baseline was exclusionary. VCY measures were calculated using the trapezoidal rule as area-under-the-VL-curve. A Cox proportional hazard model with time-dependent covariates was fit to estimate the association of time-updated cumulative VCY and multimorbidity, after

adjusting for age, race/ethnicity, body mass index ≥30 kg/m^2, income, smoking, alcohol, and cocaine use, CD4 count, CD4 nadir, enrollment site, yearly number of viral copies.

Results: 806 WLWH contributed 6,892 women-years, with median 12 (Q1-Q3 7-23) VL measured per participant on a median interval of 182 (Q1-Q3 167-197) days. Baseline characteristics were median age 39 years, 56% Black, 36% reported smoking, and median CD4 count of 534 cells/mm^3. Median time-updated cumulative VCY was 5.4 (Q1-Q3 4.7-6.9) log_{10} copy-years/mL. Of 211 (26%) WLWH who developed multimorbidity, 324 (40%) had hypertension, 193 (24%) dyslipidemia, 69 (9%) diabetes, 66 (8%) cardiovascular and 44 (5%) chronic kidney disease.

Compared with WLWH who had time-updated cumulative VCY <5 log_{10}, multimorbidity was associated with an adjusted hazard ratio of 2.03 (95% CI 1.29-3.20) and 3.63 (95% CI 2.04-6.44) for those with VCY 5-6.9 and ≥7 log_{10} copy-years/mL, respectively (overall *p*<0.0001) (Figure).

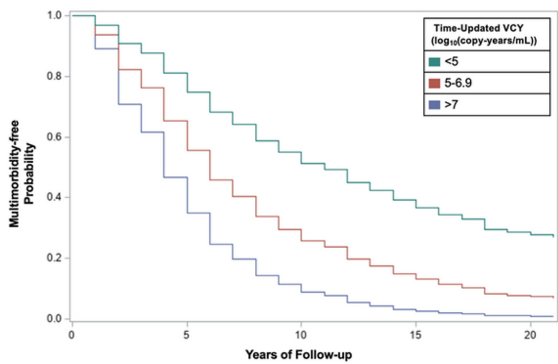

Figure. Cox proportional hazard model of multimorbidity (≥2 NACM accrued after baseline of 5 total assessed: hypertension, dyslipedemia, cardiovascular disease, chronic kidney disease) among 806 women living with HIV on antiretroviral therapy stratified by category of time-updated viremia copy-years (VCY). The survival curve was adjusted for age, race/ethnicity, body mass index ≥30 kg/m^2, income, smoking, alcohol and cocaine use, CD4 nadir, enrollment site, and yearly number of viral copies; and weighted for prior VCY and study visit non-attendance.

Conclusions: Among women on ART, time-updated cumulative VCY was associated with multimorbidity and hence may be a prognostically useful biomarker to assess risk for aging-related NACM in this population.

PESUB15

Incidence of and risk factors for heart failure subtypes in women and men living with HIV

D.B. Hanna[1], C.A. Bravo[2], M.A. Weinreich[3], S. Murthy[1], P.O. Chavez[1], K. Anastos[1], M.J. Feinstein[4], M.S. Ginsberg[1], I.L. Pina[5], U.R. Felsen[1], P. Mirhaji[1], M.J. Fazzari[1], R.C. Kaplan[1,6], J.R. Kizer[7,8]

[1]Albert Einstein College of Medicine, Bronx, United States, [2]University of Washington, Seattle, United States, [3]University of Colorado, Fort Collins, United States, [4]Northwestern University, Chicago, United States, [5]Central Michigan University, Mount Pleasant, United States, [6]Fred Hutchinson Cancer Research Center, Seattle, United States, [7]University of California San Francisco, San Francisco, United States, [8]San Francisco Veterans Affairs Medical Center, San Francisco, United States

Background: People living with HIV (PLWH) have increased heart failure (HF) risk, but HF subtypes among PLWH remain less well-characterized, especially among women. We estimated incidence of HF with preserved ejection fraction (HFpEF) and reduced ejection fraction (HFrEF) among PLWH receiving care in a large urban U.S. health system, and determined factors associated with each subtype.

Methods: We followed adult PLWH in outpatient care, defined as 2+ visits in 2011-2015, from the Einstein-Rockefeller-CUNY CFAR Clinical Cohort Database of PLWH in the Montefiore Health System (Bronx, NY). Incident HF cases were identified for review using diagnosis codes and NT-proBNP levels, and confirmed independently by two cardiologists using MESA criteria (k=0.70). HF was categorized as HFpEF or HFrEF based on left ventricular EF (≥50% vs. <50%).

We estimated the age-standardized incidence of HFpEF and HFrEF, and determined factors associated with each using Poisson regression, adjusting for time-varying demographic, behavioral, and cardiometabolic characteristics.

Results: Among 8,199 PLWH (44% women, 44% Black, 41% Hispanic, 67% with suppressed viremia <200 copies/mL) contributing 31,612 person-years, 123 incident HF cases were confirmed (53% HFrEF, 37% HFpEF, 10% EF unavailable).

Age-standardized HF incidence rates per 10,000 person-years (95% CI) were 27.3 (21.6-32.9) overall, 14.2 (10.2-18.2) for HFrEF and 9.3 (6.1-12.5) for HFpEF. Men had higher HFrEF incidence than women (16.8 vs 11.1/10,000), whereas HFpEF incidence was more similar by sex (8.0 vs. 11.3/10,000).

At HF diagnosis, median age was 56 for both subtypes; median BMI was 25.1 for HFrEF and 24.7 for HFpEF. NT-proBNP, a marker of HF prognosis, was lower in HFpEF vs. HFrEF (median 2,686 vs. 4,075 pg/mL, p=0.26).

After adjustment, time-varying hypertension history and diabetes were associated with HFpEF (incidence rate ratio, IRR 2.92, 95% CI 1.31-6.53 and 2.03, 95% CI 1.07-3.88), whereas male sex and unsuppressed viremia were asso-

ciated with HFrEF (IRR 1.96, 95% CI 1.12-3.44 and 2.25, 95% CI 1.32-3.83). Lower CD4 count was associated with both HFpEF and HFrEF.

Conclusions: We identified differential risk factors associated with incident HFpEF and HFrEF among PLWH. Given the aging HIV population, HF prevention through virologic suppression and hypertension and diabetes control should be prioritized.

Epidemiology of HIV in the general population

PESAC01

Prevalence and individual and community-level risk factors of advanced HIV disease among people living with HIV from nine African countries

K. Ganesan[1], W.M. El-Sadr[1], A. Low[1]

[1]*Columbia Univeristy, Epidemiology, New York, United States*

Background: People living with HIV (PLWH) with advanced HIV disease (AHD) (CD4 cell count <200 cells/mm³) are at higher risk of opportunistic infections, non-AIDS defining comorbidities, and death. We used Population-based HIV Impact Assessment (PHIA) survey data from a random sample of the population in Cameroon, Eswatini, Ethiopia, Lesotho, Malawi, Tanzania, Uganda, Zambia, and Zimbabwe to examine prevalence of AHD and identify individual and community-level correlates of AHD among PLWH aware of their status (PLWHA).

Methods: Between 2015-2017, data from interviews and home-based HIV testing were collected. Blood samples were analyzed for HIV RNA, detectable antiretrovirals, and CD4+ cell counts. PLWH were considered aware of their status based on self-report or if antiretrovirals were detectable. Community-level variables were created at each enumeration area (EA)-level.

Logistic regression using weighted data and clustered analysis to account for cross-country and EA variation was used to determine individual and community-level factors associated with AHD among PLWHA aged 15-59 years.

Results: Of 14,329 PLWHA, 11.6% (95% CI: 10.9%-12.4%) had AHD. AHD prevalence ranged from 6.59% (95% CI: 5.59%-7.76%) in Eswatini to 15.3% (95% CI: 13.7%-17.0%) in Zimbabwe. By sex, 17.4% (95% CI: 15.8%-19.0%) of men and 8.63% of women (95% CI:7.91%-9.41%) had AHD.

In multivariable analysis, higher odds of AHD was associated with male PLWHA, those aged 25-54 years, reporting individual-level stigmatizing behavior, not having sexual intercourse in the last year, not being on antiretroviral therapy (ART), and residing in communities where there was denial of health services due to HIV status (Figure 1).

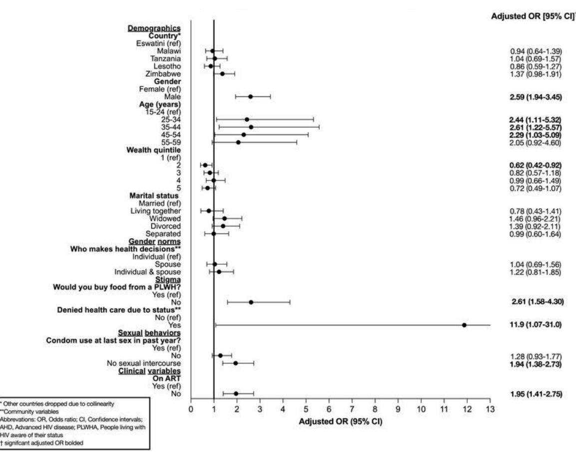

Figure 1. Adjusted odds ratios of individual & community level correlates of AHD among PLWHA

Conclusions: AHD among PLWHA remains a common challenge despite increased access to ART. Interventions are needed to enhance early diagnosis and sustained care, particularly among older men. Stigma at the community and health facility-level hinders access and engagement in care, suggesting the need to implement and scale-up community and health-systems focused HIV stigma interventions.

Background: As of September 2021, 775.805 individuals were on antiretroviral therapy (ART) in Brazil. Until January 2017, the only Integrase Strand Transfer Inhibitor (INSTI) available in Brazil was Raltegravir, mainly used for salvage therapy when resistance to protease inhibitors (PIs) was detected. In January 2017, dolutegravir was introduced for first-line treatment. We evaluate the national prevalence of transmitted drug resistance (TDR) mutations in treatment-naïve patients initiating ART.

Methods: The HIV Threshold Survey methodology was utilized. From September 2020 to February 2022, subjects were selected from seven highly populated cities representative of all Brazilian macro-regions: Belem (North),

Salvador (Northeast), Brasilia (Central), Rio de Janeiro and Santos (Southeast), and Itajai and Porto Alegre (South). Dried Blood Spots were collected on SS903 cards and transported to a central laboratory for genotyping of the reverse transcriptase, protease, and integrase of the *pol* gene.

Results: Of 244 individuals analyzed, 56 (22.95%) harbored TDR mutations. The mean CD4+T-cell count was 425 cells/µL, and the mean viral load was 312.923 copies/mL. The regional TDR prevalence was 16.66% in the Northeast, 22.05% in the Southeast, 14.89% in the Central region, 35.71% in the North, and 24% in the South.

Overall, TDR prevalence was 4.09% for nucleoside reverse transcriptase inhibitors, 11.47% for non-nucleoside reverse transcriptase inhibitors, 2.87% for PIs, and. 2.05% for INSTI (Table). TDR to two and three antiretroviral classes was 0,82% and 0.41%, respectively. The prevalence of Non-B subtypes was 32.79%, being 20.49% of C, 4.92% of F, and 7.38% of recombinants.

"MENTORS MOTHERS"! The Link between community and health facilities for PMTCT Programs in Tanzania

N. Makyao[1], A. Maro[1], A. Nyirenda[1], A. Kosia[2]
[1]Amref Health Africa, Prevention, Dar es Salaam, Tanzania, The United Republic of, [2]Cristian Social Services Council, Prevention, Dar es Salaam, The United Republic of Tanzania

Background: In the implementation of GF 2020-2023, the target is to eliminate new HIV infection among HIV exposed infants from 8% in 2018 to below 5% in 2023 and to increase access to ART among HIV infected children from 60% in 2016 to 95% by 2023. The use of the community approach through mentor mothers is a new strategy to ensure early identification and linkage, retention throughout the cascade of care. The intervention is implemented in a total of 10 regions, 57 councils, and 330 health facilities.

Description: Selection of MM was done with program team in collaboration with facility PMTCT supervisors. Criteria's for selection were developed including having good adherence to clinics, willingness to disclose or have disclosed status and influential who can perform the task. MM were responsible for giving one-on-one support to HIV-infected pregnant/postpartum women; encourage enrollment, adherence and retention in HIV care, perform tracing for women who miss clinic visits; and educate on PMTCT and health-related topics. Sites positivity rates of more than 5% with HIV pregnant or breastfeeding attending PMTCT were identified. Each facility selected a total of 4 MM and one facility supervisor who attended a special 10 days training using National curriculum.

Lessons learned: Findings indicated that majority of participants, their male partners, and health care providers accepted the intervention. Our community-based mentor mothers have contributed to filling the critical gap in the quality and continuum of care for mothers living with HIV. One year of implementation indicated an increase for early ANC booking, couple counseling and HIV testing as well as early infant diagnosis. We reached 49,171 women who tested for HIV. 540 were HIV+ which is 1.1%, their male partners reached were 30,845 and 395 were HIV positive which is 1.3% yield.

Conclusions/Next steps: We learnt that there was high acceptance of use of mentor mother intervention as strategy for linkage between facility and community. This is in agreement with previous studies which have found that task shifting to lay health workers who are also HIV patients is acceptable and results in increased early identification, linkage, adherence and retention to HIV care.

HIV incidence and death among orphaned and non-orphaned children and adolescents living in family-based settings in Western Kenya

D. Apedaile[1], A. DeLong[2], E. Sang[3], D. Ayuku[4], L. Atwoli[4,5], P. Braitstein[1,3,4]

[1]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, [2]Brown University, School of Public Health, Providence, United States, [3]Academic Model Providing Access to Healthcare, Eldoret, Kenya, [4]Moi University, School of Medicine, Eldoret, Kenya, [5]Aga Khan University, Medical College, East Africa, Nairobi, Kenya

Background: In Kenya, most of the 1.8 million orphaned children live with members of their extended family. These households can face severe poverty and have difficulty meeting the needs of all the children in their care. While children have reported experiencing discrimination at home and in their communities based on their status as orphans, little is known about the health outcomes of orphans compared to non-orphaned children.

The objective of this analysis was to compare HIV incidence and death among orphaned children to non-orphaned children.

Methods: A random sample was taken of 300 households caring for at least one orphaned child in Uasin Gishu County, Kenya. From each household, all orphaned and non-orphaned children were enrolled in a prospective cohort study between May 2010 and April 2013. Annual follow-up visits, including HIV testing, were conducted until 2019. Mixed-effects survival analyses with a random slope to account for clustering within households were used to estimate the association between orphan status, defined by the number of parents the child had lost (none, 1, or 2), and HIV incidence, death, and combined HIV incidence or death.

Results: The study enrolled 1488 children, including 487 double orphans, 743 single orphans, and 258 non-orphans. At enrollment, 52% of participants were female, the median age was 10.4 years old, and 23 participants were HIV-positive (0 non-orphans, 15 single orphans, 8 double orphans). Over the course of the study, 16 participants died (0 non-orphans, 8 single orphans, 8 double orphans) and 11 acquired HIV (0 non-orphans, 6 single orphans, 5 double orphans). Among participants who were HIV-negative at enrollment, having one more deceased or missing parent was strongly associated with incident HIV or death (AHR 2.34 per parent, 95% CI: 1.17-4.71) after accounting for gender and age at enrollment.

Conclusions: Within similar households, orphans experience a higher risk of HIV and death than non-orphans. This indicates that both orphans themselves and the families caring for them need additional support to prevent serious health outcomes.

Epidemiology of HIV in adolescents

Stigma in youth with HIV is associated with depression, school dropout and adult clinic attendance

C. Mugo[1], M. Kumar[2], J. Badia[3], J. Kibugi[3], K. Agot[3], J. Dyer[4], P. Kohler[4], D. Wamalwa[5], G. John-Stewart[4]

[1]Kenyatta National Hospital, Research and Programs, Nairobi, Kenya, [2]University of Nairobi, Psychiatry, Nairobi, Kenya, [3]Impact Research and Development Organization, Kisumu, Kenya, [4]University of Washington, Global Health, Seattle, United States, [5]University of Nairobi, Pediatrics and Child Health, Nairobi, Kenya

Background: Few studies have looked at the risk factors and outcomes of HIV stigma among youth with HIV (YWHIV) in sub-Saharan Africa.

Methods: YWHIV in nine Western Kenya facilities were enrolled in an observational cohort in 2019-2020. Participants completed an enrollment survey assessing their sociodemographics, HIV history, adherence, depression (PHQ-9), exposure to physical, emotional and sexual violence and HIV stigma (10-item scale by Wright 2007). Correlates of overall HIV stigma (overall score: 10-50) were assessed using generalized linear models. We report mean differences (MD) adjusted for age and gender, and bootstrapped 95% confidence intervals (95%CI) and p values accounting for clustering by facility.

Results: Of 1,011 YWHIV (aged 15-24), 59% were 15-19 years old, 69% were female, 22% had dropped out of school, and 59% received care in adolescent/youth clinics. Twenty-one percent had missed ≥2 days' medication, and 64% reported ever having sex. Eighteen percent had mild depressive symptoms, while 3% had moderate/severe symptoms; 28% experienced physical violence, 18% emotional violence and 7% sexual violence. The median (interquartile range) overall stigma score was 25 (21-29).

Compared to YWHIV receiving care in adolescent/youth clinics, those in general/adult HIV clinics had higher stigma scores (MD: 1.58 [95%CI: 0.13-3.04], p=0.042). YWHIV who had dropped out of school had higher stigma scores compared to those in school (2.56 [0.81-4.31], p=0.016), as was those ever in a sexual relationship (2.59 [1.43-3.73], p=0.004). YWHIV who had missed ≥2 days' medication had higher stigma scores compared to those fully adherent (2.16 [0.92-3.41], p=0.011). Those with mild, and moderate/severe depression had higher stigma scores (3.37 [2.57-4.17], p<0.001 and 7.08 [1.32-12.84], p=0.028) compared to those with no depression. YWHIV who experienced any violence before the last 6 months, and within the last 6 months had higher stigma scores compared to those with no experience of violence (2.51 [-0.12-5.13], p=0.058 and 2.91 [1.38-4.44], p=0.002).

Conclusions: This study identified intrapersonal, interpersonal and structural factors to consider when developing HIV stigma interventions for YWHIV. This includes expo-

sure to violence, sexual relationships, and service points in facilities. Possible outcomes targeted by these interventions may include depression, adherence and keeping YWHIV in school.

Epidemiology of HIV in key populations (e.g., gay men and other men who have sex with men, sex workers, transgender people, people who inject rugs and prisoners and other incarcerated people)

PESAC06

Alcohol use among people who inject drugs living with HIV in Kenya is associated with needle sharing, more sex partners, and poor engagement in care

N. DesLauriers[1], N. Ludwig-Barron[2,3], B. Sambai[4], L. Mbogo[4], D. Bukusi[4], E. Juma[4], B. Chohan[2,5], R. Bosire[5], H. Kingston[6], E. Wilkinson[7,8], E. Gitau[9], W. Sinkele[9], S. Masyuko[2,10], J. Herbeck[2], B. Guthrie[2,3], C. Farquhar[1,2,3], A. Monroe-Wise[2]

[1]University of Washington, Department of Medicine, Seattle, United States, [2]University of Washington, Department of Global Health, Seattle, United States, [3]University of Washington, Department of Epidemiology, Seattle, United States, [4]Kenyatta National Hospital, HIV Testing and Counseling and HIV Prevention, Nairobi, Kenya, [5]Kenya Medical Research Institute, Centre for Clinical Research, Nairobi, Kenya, [6]University of Washington, Institute for Public Health Genetics, Seattle, United States, [7]University of KwaZulu-Natal, KwaZulu-Natal Research and Innovation Sequencing Platform, Durban, South Africa, [8]Stellenbosch University, Centre for Epidemic Response and Innovation (CERI), School of Data Science and Computational Thinking, Stellenbosch, South Africa, [9]Support for Addictions Prevention and Treatment in Africa, Nairobi, Kenya, [10]Kenya Ministry of Health, Nairobi, Kenya

Background: People who inject drugs living with HIV (PWID-LWH) are a high-risk population in the HIV epidemic in Kenya. It is essential to elucidate factors contributing to risk behavior and suboptimal care among PWID-LWH to decrease HIV transmission. Within an assisted partner services implementation science study, we evaluated the association between alcohol use and HIV risk behaviors and care outcomes among a cohort of PWID-LWH in Kenya.

Methods: Participants were recruited through 8 sites in Nairobi and coastal Kenya with the following eligibility criteria: age ≥18 years, injected drugs within the past 30 days, HIV-positive, and willing to provide partner contact information. Participants reported type and frequency of alcoholic beverages consumed in the past 30 days and use was stratified into heavy (>14 drinks/week for men, >7 for women), moderate (any lesser amount), or none based on CDC/NIAAA definitions. Logistic regression was used to calculate odds ratios for factors associated with alcohol use.

Results: Of 870 PWID-LWH, 527 (60.6%) reported no alcohol use, 210 (24.1%) moderate use and 133 (15.3%) heavy use. 49.8% were female, 7.8% reported needle sharing within the past 30 days, 18.6% had more than 3 new sex partners in the past 3 months, 13.7% were not enrolled in HIV care, and 18.5% were not on ART. Of 510 PWID-LWH on ART from whom viral load was obtained, 28.2% were virologically unsuppressed. In bivariate analysis, heavy alcohol use was associated with needle sharing (OR=3.87, 95%CI:2.13-7.01).

In multivariate analysis (table), heavy alcohol use was independently associated with more new sex partners. Moderate and heavy alcohol use were independently associated with not being on ART and non-enrollment in care. Among those on ART, there was no association between alcohol use and viral non-suppression.

Variable	>3 new sex partners in past 3 months	Needle sharing	Not enrolled in HIV care	Not on ART	Unsuppressed Viral load‡
	Adjusted odds ratio (95% confidence interval) *				
No alcohol use	1 (ref)	1 (ref)	1 (ref)	1 (ref)	1 (ref)
Moderate alcohol use	1.47 (0.89, 2.43)	0.98 (0.47, 2.00)	**2.23 (1.33, 3.72)**	**1.88 (1.18, 2.97)**	0.82 (0.48, 1.37)
Heavy alcohol use	**1.76 (1.01, 3.07)**	1.89 (0.91, 3.89)	**2.04 (1.10, 3.76)**	**1.99 (1.15, 3.43)**	0.63 (0.30-1.27)

*Adjusted odds ratios from logistic regression models controlling for age, sex, region, history of sex work, khat use (associated with alcohol use), and number of substances used in the past 30 days. Needle sharing, non-enrollment in care, ART, and viral load aORs also control for enrollment in a methadone clinic.

‡Among participants on ART

Conclusions: Alcohol use is prevalent among PWID-LWH in Kenya and a potential risk factor for suboptimal care and HIV risk behavior. Our findings reinforce the importance of addressing alcohol use among this group through expanded clinical and public health interventions.

Methods: We pooled data from five 2019-2021 cross-sectional data sources in Washington State. We considered three self-reported outcomes: past year HIV/STI testing, current PrEP use, and a composite measure of HIV/STI positivity (past year bacterial STI diagnosis and/or HIV positive). We defined groups by gender and race/ethnicity and calculated the risk difference (RD) for each outcome (reference=White transgender men).

For transgender women and non-binary participants of color, we used Poisson regression to estimate two surrogate measures of additive interaction--the attributable proportion (AP) and ratio of the observed to expected relative joint effects (RJE)--that measure the excess risk attributable to the intersection of gender and race/ethnicity.

Results: Our analysis included 1648 transgender participants (70.4% White, 10.7% Latinx, 5.8% Black). HIV/STI positivity was statistically significantly higher among transgender women and non-binary people assigned male at birth (AMAB) compared to White transgender men (RD, Table).

From the AP, we estimated that 50% and 67% of the excess HIV/STI prevalence among Black and Latinx transgender women, respectively, was attributable to the intersection of gender and race/ethnicity.

Although the RJE was not statistically significant for any outcomes/groups, it suggests that, compared to White transgender men, HIV/STI prevalence is 101% and 206% higher among Black and Latinx transgender women, respectively, than what would be expected if gender and race/ethnicity alone were sufficient to explain it. Similar patterns were observed for HIV/STI testing and PrEP use.

Gender Identity	Race / Ethnicity	N	HIV/STI Positive (%)	Risk Difference RD (95% CI)	Attributable Proportion AP (95% CI)	Ratio of observed to expected relative joint effects RJE (95% CI)
Trans Men	White [ref]	242	4.1	ref	ref	ref
Trans Women	White	212	7.5	-0.06 (-0.16, 0.03)	NA	NA
Trans Women	Black	37	5.4	**0.43 (0.25, 0.60)**	**0.50 (0.07, 0.93)**	2.01 (0.27, 3.76)
Trans Women	Latinx	32	46.9	**0.21 (0.10, 0.33)**	**0.67 (0.27, 1.08)**	3.06 (-0.70, 6.83)
Non-binary People Assigned Male at Birth	White	165	21.2	**0.39 (0.11, 0.67)**	NA	NA
Non-binary People Assigned Male at Birth	Black	22	31.8	**0.27 (0.02, 0.52)**	-0.18 (-2.68, 2.31)	0.84 (0.27, 1.42)
Non-binary People Assigned Male at Birth	Latinx	12	30.8	**0.29 (0.15, 0.43)**	0.29 (-0.83, 1.40)	1.40 (0.13, 2.68)
The null value for RD and AP is 0, and the null value for RJE is 1.						

Table. Quantitative Intersectionality Analysis for Self-reported HIV/STI Positivity among Transgender and Non-binary People in Washington State, 2019-2021

Conclusions: Our findings highlight the heterogeneity in HIV/STI positivity, testing, and PrEP use within the transgender population.

We observed that a large proportion of the increased HIV/STI risk among transgender women of color is explained by intersection of gender and race/ethnicity.

PESAC08

Sexual behavior and HIV prevalence among Venezuelans immigrants in Peru: a study among men who have sex with men (MSM) and transgender women (TGW) screened for pre-exposure prophylaxis (PrEP)

O.A. Elorreaga[1], K.A. Konda[1], J. Guanira[1], G.M. Calvo[1], S.K. Vargas[1], A. Borquez[2], C.F. Caceres[1], for the ImPrEP Study Group

[1]Universidad Peruana Cayetano Heredia, Centro de Investigación Interdisciplinaria en Sexualidad, SIDA y Sociedad, Lima, Peru, [2]University of California San Diego, La Jolla, United States

Background: The Venezuelan economic crisis has generated an unprecedented migratory wave. According to World Bank estimates, Peru is now home to 1.2 million Venezuelan immigrants.

However, little is known about the epidemiological profile of MSM and TGW Venezuelan immigrants, who may be at risk of acquiring or transmitting HIV due in part to challenging social and economic circumstances.

Methods: Between May 2018 and February 2021, participants answered a structured questionnaire on sexual behaviors and were tested for STI/HIV to determine eligibility for PrEP services as part of ImPrEP, a demonstration project implemented in six Peruvian cities. All participants were MSM/TGW, 18+ years-old, and provided informed consent.

We compared social and behavioral characteristics among participants who screened HIV-positive and were therefore ineligible for PrEP enrolment. Differences were assessed using Chi-square tests.

Results: Among the 2526 participants screened for ImPrEP, we identified 623 (24.7%) immigrants, of whom 590 (94.7%) were Venezuelan. Among all immigrants, 74 (11.9%) were HIV positive, of which all (74/74, 100%) were Venezuelan.

Comparing the HIV prevalence among participants screened for ImPrEP, Venezuelans (12.5%, 95%CI 10.1-15.5) had twice the HIV prevalence of Peruvians (6.8%, 95%CI 5.7-7.9).

Comparing Peruvian and Venezuelans, among all HIV positive participants (N=205), Venezuelans were older and more educated (p=0.001), reported more insertive condomless anal sex ($p<0.001$), condomless sex with HIV+ partners (p=0.016), and more MSM who engaged in sex work (23.0% vs 15.3%, p=0.021), which may increase their risk for HIV transmission.

Characteristics of the n=205 participants who tested HIV positive during PrEP screening		Peruvians (N=131) N (column %)	Venezuelans (N=74) N (column %)	Chi-2 p-value
Age (years)	▪<25 ▪25 or more	70 (53.4%) 61 (46.6%)	21 (28.4%) 53 (71.6%)	0.001
Schooling	▪<= Complete secondary ▪Completed tertiary	16 (12.2%) 38 (29.0%)	1 (1.4%) 38 (51.4%)	0.001
Sex w/o condom	▪Insertive condomless anal sex	75 (57.3%)	63 (85.1%)	<0.001
Sex with HIV+ partner w/o condom	▪None ▪Yes, with partner of unknown HIV status ▪Yes, with HIV+ partner	16 (12.2%) 106 (80.9%) 9 (6.9%)	12 (16.2%) 48 (64.9%) 14 (18.9%)	0.016
Sex work	▪Non sex workers ▪MSM sex workers ▪TGW sex workers	100 (76.3%) 20 (15.3%) 11 (8.4%)	57 (77.0%) 17 (23.0%) 0 (0.0%)	0.021

Table.

Conclusions: The Venezuelan migrant crisis demands adequate health policies and services in host countries. Our findings suggest that HIV prevalence among Venezuelan MSM/TGW is high, and engagement in sex work and HIV-associated risk behaviors are common in this vulnerable group. Free and easily accessible HIV testing and treatment must be made available. Likewise, HIV prevention opportunities, including PrEP, should be made available within the public health program.

Cervical cancer screening among women living with HIV: a systematic analysis of population-based surveys in sub-Saharan Africa

L. Yang[1], M.-C. Boily[2], M. Rönn[3], S. Delany-Moretlwe[4], D. Obiri-Yeboah[5], I. Morhason-Bello[6], N. Meda[7], T. Gauthier[8], P. Mayaud[9], M. Pickles[2], M. Brisson[10], M. Maheu-Giroux[1]
[1]McGill University, Montreal, Canada, [2]Imperial College London, London, United Kingdom, [3]Harvard University, Cambridge, United States, [4]University of the Witwatersrand, Johannesburg, South Africa, [5]University of Cape Coast, Cape Coast, Ghana, [6]University of Ibadan, Ibadan, Nigeria, [7]Centre Muraz, Bobo-Dioulasso, Burkina Faso, [8]Ministère de la Santé, Ouagadougou, Burkina Faso, [9]London School of Hygiene & Tropical Medicine, London, United Kingdom, [10]Université Laval, Québec, Canada

Background: Cervical cancer (CC) is the leading cause of cancer death in women in sub-Saharan Africa (SSA) where 1 in 5 CC cases can be attributable to HIV. Screening for CC is highly effective in reducing disease burden and is essential to the global CC elimination strategy, but estimates of screening uptake in SSA are limited. We aim to estimate CC screening coverage for women in SSA by HIV status.

Methods: We collected all publicly available nationally representative surveys with CC screening information from SSA. We estimated screening coverage using a Bayesian multilevel model (levels: survey, country, region), accounting for the recall period, age groups, and time trends (nested within regions). The effect of living with HIV on screening was modeled using country-level random slopes.
For surveys without HIV biomarkers, standardization with the UNAIDS HIV prevalence estimates was used. Post-stratification was used to aggregate estimates among women aged 25-49y for countries with HIV biomarker data.

Results: We pooled 46 surveys across 25 countries (253,285 respondents) between 2000-2019, of which 12 countries (132,629 respondents) had HIV biomarker data. In 2019, the proportion of women ever screened for CC varied by region and was higher for WLHIV than women without HIV in Central/Western Africa (WLHIV=7% [95% Credible Intervals (CrI): 3-15%] vs. 4% [95%CrI: 2-8%]) and Eastern Africa (WLHIV=21% [95%CrI: 15-27%] vs. 9% [95%CrI: 6-12%]), but similar in Southern Africa (WLHIV=48% [95%CrI: 33-65%] vs. 50% [95%CrI: 34-65%]). Odds ratios (age-adjusted) for CC screening among WLHIV compared to women without HIV ranged from 0.93 (95%CrI: 0.84-1.05) in South Africa to 2.80 (95%CrI: 2.28-3.50) in Tanzania.

Conclusions: WLHIV have equal or greater odds of being screened for CC in comparison to those not living with HIV. However, overall coverage remains low in SSA. These findings are aligned with current practises as many CC screening initiatives have been introduced alongside existing HIV care structures. As funding and priorities shift away from HIV, these screening rates among WLHIV may not be sustained. Greater investment and improved approaches to screening are essential, particularly for WLHIV, to improve coverage, and reduce disparities in CC burden between women living and not living with HIV.

PESAC10

National and regional rates of hospitalizations and in-hospital mortality for opportunistic infections for people with HIV in the United States, 2012-2018

C. Bielick[1], A. Strumpf[1], K. McManus[1]
[1]University of Virginia, Infectious Diseases and International Health, Charlottesville, United States

Background: Contemporary rates of hospitalizations for Human Immunodeficiency Virus (HIV)-related Opportunistic Infections (OIs) in the United States (US) are unknown. We aimed to quantify the national and regional OI hospitalization rate and OI hospitalizations' in-hospital mortality rate for people with HIV (PWH) in the US for 2012-2018.

Methods: All hospitalizations in the Agency for Healthcare Research and Quality's National Inpatient Sample that included an HIV diagnosis and an OI diagnosis (as defined

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

by the Centers for Disease Control and Prevention's (CDC) Stage-3-Defining OIs) during 2012-2018 were included. For the hospitalizations, we analyzed demographics (age, sex, race) and the in-hospital mortality rate. Using the number of PWH from CDC data, we estimated national and regional OI hospitalization rates per 100,000 PWH-years with 95% Poisson confidence intervals.

Results: There were 145,710 total weighted hospitalizations for PWH with an OI diagnosis. PWH with OI hospitalizations were predominately male (68.7%), 45-55 years-old (31.7%) and Black (52.6%). The national rate of OI hospitalization per 100,000 PWH-years declined from 2,664.0 (95% CI, 2,664.3-2,665.6) in 2012 to 1,784.5 (95% CI, 1,783.9-1,785.1) in 2018 (Figure 1). Regionally, the South had the highest rate every year which declined from 3,074.4 (95% CI, 3,073.4-3,075.4) in 2012 to 2,125.4 (95% CI, 2,124.5-2,126.3) in 2018. The percentage of OI hospitalizations in the US resulting in in-hospital mortality was 6.4% in 2012 and 6.0% in 2018.

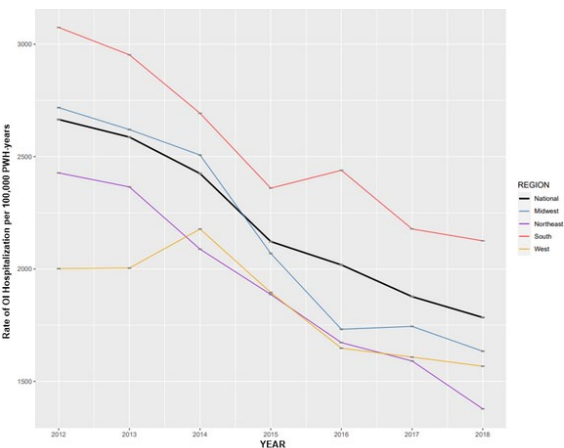

Figure 1. National and regional rates of hospitalizations for opportunistic infections for people with HIV in the United States, 2012-2018

Conclusions: OI hospitalization rates for PWH in the US declined from 2012-2018, but there are regional disparities with PWH in the South experiencing the highest burden of OI hospitalizations. Studies should examine what gaps in services are contributing to these OI hospitalizations. Communities and clinics may need region-specific interventions. Additionally hospitalizations due to specific OIs may also contribute to these regional disparities and should be investigated.

Background: Pre-exposure prophylaxis(PrEP) can prevent HIV, but could lead to behavioral changes increasing risk of other sexually transmitted infections (STIs). We evaluated changes in STI incidence and associated risk factors in men eligible for PrEP.

Methods: The prospective, multicenter BRAHMS study enrolled participants without HIV, 18-55 years, who reported recent STI or condomless anal intercourse with ≥2 male partners with HIV or unknown status. Every three months, participants were offered PrEP, completed behavioral questionnaires, and were screened and treated for STIs including syphilis as well as *Chlamydia trachomatis* (CT), *Mycoplasma genitalium* (MG), and *Neisseria gonorrhoeae* (NG) at the rectal, urethral and pharyngeal sites. We calculated three-months-incidence rates and used multi-level mixed effects logistic regression to calculate odds ratios (ORs) and 95%-confidence intervals (CIs) for factors associated with any STI.

Results: From 6/2018-3/2021, 1,017 participants were followed with mean age 33 years, 99.1% cisgender men, and 96.8% gay/bisexual. PrEP was used at enrollment 54.0%, 82.2% at any point during follow-up.

Between 3-month and 12-month visits, MG incidence was higher than other STIs and relatively stable (figure). CT incidence decreased by 27.2% among PrEP users and 49.2% for non-PrEP users, NG incidence by 28.1% and 21.7%. Syphilis incidence was lowest and decreased by 2.2% and 15.4%. Incidence was higher in PrEP-users only for anorectal localizations.

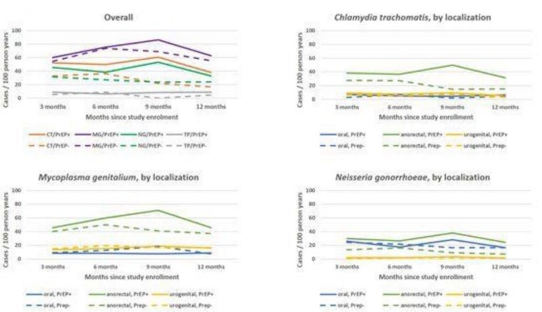

Figure. 3-month sexually transmitted infection incidence rates, by pre-exposure prophylaxis status

STI incidence was independently associated with PrEP use (OR=1.3;CI:1.1-1.6), condomless anal sex with >5 casual partners (OR=1.8;CI:1.5-2.2), STI-related symptoms (OR=1.8;CI:1.4-2.3), recreational drug use (OR=1.7;CI:1.4-2.0), born outside of Germany (OR=1.5;CI:1.2-1.9), and moderately or largely increased self-perceived risk of HIV (OR=1.3;CI:1.1-1.6 and OR=1.4;CI:1.1-1.8).

Conclusions: A structured test-and-treat setting appears to have reduced CT and NG incidence in men with sexual risk behavior. Besides other behavioral factors, PrEP use increased STI risk in our cohort slightly, and services providing PrEP may be an effective setting for intensive STI-related risk reduction counselling considering the risk factors identified.

Background: Direct-acting antivirals (DAA) may reduce HCV incidence through a treatment-as-prevention effect. Reinfection incidence after successful treatment has been a major concern for HCV elimination, particularly among people with HIV (PHIV). We aim to assess changes in HCV reinfection incidence following limited and broad DAA introduction among PHIV.

Methods: We used data from six cohorts from the International Collaboration on Hepatitis C Elimination in HIV-coinfection (InCHEHC), including data from the Netherlands, Switzerland, Australia, Spain, and France (2010-2019). Participants were considered at risk of reinfection if they had a HCV positive test followed by spontaneous or treatment clearance.

We measured the incidence of first reinfection per participant. Time zero was the first negative HCV RNA test indicating treatment or spontaneous clearance. Data were censored at the last negative HCV RNA test or infection date, which was estimated as the midpoint between the last negative and first positive test dates.

The rate of reinfection was compared between three periods: prior to DAA access, and during limited access, and broad access to DAA in each jurisdiction using a piecewise exponential survival model, with a fixed effect for risk group (men who have sex with men [MSM], people who inject drugs [PWID] vs. other/unknown) and a random intercept at the cohort level.

Results: Overall, 2,818 (57%) MSM, 1237 (25%) PWID, and 880 other participants were included. The median (IQR) age at spontaneous or treatment clearance was 47 (40-53). During 13,527 person-years (py), we observed 790 reinfections (5.8 per 100py, 95%CI 5.4-6.3). Relative to the pre-DAA period, reinfection incidence was 25% lower in the limited DAA access period (IRR: 0.75, 95%CI 0.62-0.91), and 44% low-

er in the broad access period (IRR: 0.56, 95%CI 0.48-0.66). Compared to MSM, reinfection incidence was 54% lower in PWID (IRR=0.46, 95%CI 0.37-0.56), and 57% lower in those with other/unknown risks (IRR=0.43, 95%CI: 0.34-0.55).

Conclusions: HCV reinfection rates among PHIV were high prior to DAA introduction, particularly among MSM. Our data suggests that DAA introduction was associated with declines in HCV reinfection incidence rates among PHIV. With HCV treatment uptake resulting in a growing pool of individuals at risk of reinfection, continued monitoring is warranted.

PESAC13

Pooled estimates of hepatitis C incidence among gay and bisexual men using PrEP by country-level availability of hepatitis C DAA treatment: a systematic review and meta-analysis

M. Traeger[1,2], B. Harney[1,2], J. Doyle[1,3], M. Hellard[1,2,3], M. Stoové[1,2]

[1]Burnet Institute, Melbourne, Australia, [2]Monash University, School of Public Health and Preventive Medicine, Melbourne, Australia, [3]Alfred Health and Monash University, Department of Infectious Diseases, Melbourne, Australia

Background: Sexual transmission of hepatitis C virus (HCV) among gay and bisexual men (GBM) has been historically concentrated among people living with HIV, but concerns exist that the widespread scale-up of PrEP may increase HCV incidence among HIV-negative GBM. Given community-level HCV viremia at the time of PrEP scale-up is likely to moderate risk among PrEP users, we examined the impact of broad DAA availability on HCV incidence in studies of GBM using PrEP.

Methods: We searched PubMed, Medline, EMBASE and relevant conference databases to 9th August 2021 for studies reporting HCV incidence among GBM using PrEP (daily or event-driven). Cohort studies and open-label clinical trials were included. Pooled estimates of HCV incidence were calculated using random-effects meta-analysis.

Using a literature and policy review of the timing of broad/universal HCV DAA availability in included countries, we conducted a subgroup analysis of PrEP studies that commenced participant follow-up before or after country-level DAA availability.

Results: Seventeen studies published between 2015-2021 reported on HCV incidence among GBM using PrEP and were included; all were from high-income countries. One study reported HCV incidence among daily and event-driven PrEP users separately and was included as two observations in the meta-analysis.

Overall 18,363 participants were included; 145 incident HCV infections were captured over 24,023 person-years. The pooled estimate of HCV infection across studies was 0.91 per 100 person-years (range, 0.00 to 2.93/100py). Heterogeneity was high across studies (I^2=84.0%, χ^2 p<0.001).

Twelve studies (5,186 individuals) commenced follow-up before broad-access to DAAs, with a pooled incidence of 1.27/100py (95% CI, 0.69-1.86; I^2=81.8%, χ^2p=0.187) and five studies (13,177 individuals) started follow-up after broad-access to DAAs, with a pooled incidence of 0.30/100py (95% CI, 0.11-0.50; I^2=33.2%, χ^2p=0.187).

Conclusions: Our pooled estimates of HCV incidence among PrEP users were lower than reported in a previous meta-analysis (1.48/00py), and lower in settings where broad access to DAAs had occurred prior to study initiation.

Findings suggest that reductions in community-level HCV viremia driven by DAA uptake among respective GBM populations, which occurred prior to changes in sexual networks and behaviours associated with PrEP uptake, may have contributed to lower HCV transmission among PrEP users.

Modelling the impact of service models on the HIV epidemic

PESAC14

Decision analytic model estimates of the predicted benefits and anticipated costs associated with HIV self-testing versus standard provider-administered testing modalities if implemented in Kenya

B. Akasreku[1], E. Kelvin[2,3], N. Sabounchi[4,5]

[1]CUNY Graduate School of Public Health and Health Policy, Community Health and Social Science, New York City, United States, [2]CUNY Graduate School of Public Health and Health Policy, Epidemiology and Biostatistics, New York City, United States, [3]CUNY Institute for Implementation Science in Population Health, New York City, United States, [4]CUNY Graduate School of Public Health and Health Policy, Health Policy Management, New York City, United States, [5]Center for Systems and Community Design, New York City, United States

Background: To reach the UNITAIDS 95-95-95 goals by 2030, countries need information about the potential benefits and costs associated with various HIV testing modalities to make informed policies.

We used decision-analytic modeling to estimate the benefit and cost of HIV self-testing (HIVST) relative to the standard provider-delivered HIV testing (HTC).

Methods: We developed a decision-analytic model to estimate the predicted number of HIV-diagnosed infected individuals and on treatment and the estimated cost associated with the following scenarios if implemented in Kenya:

1. Provider-supervised HIVST,
2. Un-supervised HIVST, and;
3. HTC.

The model focused on the 2020 Kenyan population aged 15-64 (n=31,671,946), who were assumed to be sexually active. We conducted a literature review to determine costs for all points in the HIV care continuum (testing, treatment for those who test positive, PrEP for those at high risk who test negative) from the provider perspective in US dollars and probabilities of accessing each stage in the HIV care continuum (i.e., probability that someone will test, probability that someone who tests positive will access treatment and that someone who is high risk and tests negative will access PrEP).

Results: Among the three scenarios, unsupervised HIVST resulted in correctly diagnosing and initiating treatment for more than twice the number of people living with HIV (PLWH) (n= 102,389 PLWH on treatment) than for supervised HIVST (n= 42185) and HTC (n= 38470).

However, the estimated cost for both provider-supervised and unsupervised HIVST was higher ($60,117,771 and $57,597,242, respectively) than HTC ($20,203,585). Offering unsupervised HIVST over provider-supervised HIVST resulted in a cost-saving of $0.27 per additional person tested.

All these costs were sensitive to changes in the cost of testing, the number who test under each scenario and the linkage to care and treatment initiation rates.

Conclusions: Unsupervised HIVST had a cost advantage over provider-supervised HIVST and led to a higher number of PLWH on treatment than supervised HIVST and HTC.

Countries should consider the benefits of making unsupervised HIVST easily available for free but take into consideration preferences for supervised vs. non-supervised testing among different population groups and the relatively higher cost of getting more people into care.

PESUC21

Life years gained with improved HIV care among non-Hispanic Black and White people who have ever injected drugs (PWID) with HIV: a modeling study

K. Rich[1], F. Shebl[1,2], A. Pandya[3], J. Chiosi[2], A. Ciaranello[1,2], E. Losina[1,4,5], K. Freedberg[1,2,3], E. Hyle[1,2]

[1]*Harvard Medical School, Boston, United States,* [2]*Massachusetts General Hospital, Boston, United States,* [3]*Harvard T.H. Chan School of Public Health, Boston, United States,* [4]*Brigham and Women's Hospital, Boston, United States,* [5]*Boston University School of Public Health, Boston, United States*

Background: HIV remains a major health burden among people who have ever injected drugs (PWID). We projected life expectancy among non-Hispanic Black and White PWID with HIV (PWID-HIV) and assessed the impact of improving the HIV care cascade on life expectancy.

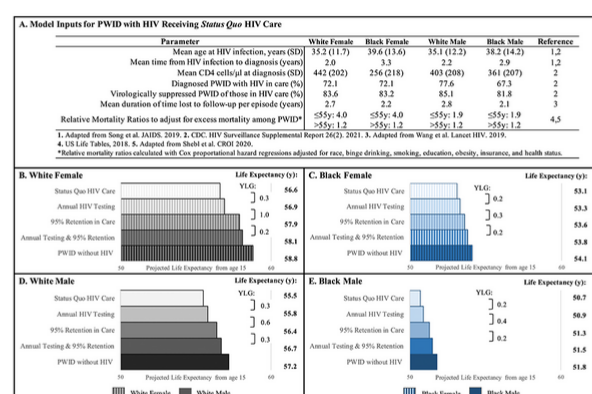
Methods: We applied race- and sex-stratified data for US PWID to the validated CEPAC microsimulation model (Figure 1A).

Race- and sex-specific life tables for non-HIV-related mortality were adjusted for excess all-cause mortality among PWID. We projected life expectancy from age 15 years among PWID-HIV under four scenarios:

1) *status quo* HIV care,
2) annual HIV testing,
3) 95% retention in HIV care, and
4) annual testing and 95% retention in care.

We also compared life expectancy of PWID-HIV to PWID without HIV.

Results: Among PWID-HIV who receive *status quo* care, we projected life expectancy from age 15 to be highest among White females (56.6y) and lowest among Black males (50.7y) (Figure 1B-E). With annual HIV testing, years of life gained (YLG) were higher among White PWID (females: 0.3y, males: 0.3y) than Black PWID (females: 0.2y, males: 0.2y). Increased retention in care (to 95%) would also result in additional YLG for White PWID (females: 1.0y, males: 0.6y) than Black PWID (females: 0.3y, males: 0.4y) compared with annual testing. When combining annual testing and 95% retention, YLG ranged from 0.2y to 0.3y. Comparing PWID-HIV receiving *status quo* care to PWID without HIV, White PWID had a greater difference in LE (female: 2.2y, male: 1.7y) than Black PWID (female: 1.0y, male: 1.1y).



A. Model Inputs for PWID with HIV Receiving *Status Quo* HIV Care

Parameter	White Female	Black Female	White Male	Black Male	Reference
Mean age at HIV infection, years (SD)	35.2 (11.7)	39.6 (13.6)	35.1 (12.2)	38.2 (14.2)	1,2
Mean time from HIV infection to diagnosis (years)	2.0	3.3	2.2	2.9	1,2
Mean CD4 cells/µl at diagnosis (SD)	442 (202)	256 (218)	403 (208)	361 (207)	2
Diagnosed PWID with HIV in care (%)	72.1	72.1	77.6	67.3	2
Virologically suppressed PWID of those in HIV care (%)	83.6	83.2	85.1	81.8	2
Mean duration of time lost to follow-up per episode (years)	2.7	2.2	2.8	2.1	3
Relative Mortality Ratios to adjust for excess mortality among PWID*	≤55y: 4.0 >55y: 1.2	≤55y: 4.0 >55y: 1.2	≤55y: 1.9 >55y: 1.2	≤55y: 1.9 >55y: 1.2	4,5

1. Adapted from Song et al. JAIDS. 2019. 2. CDC. HIV Surveillance Supplemental Report 26(2). 2021. 3. Adapted from Wang et al. Lancet HIV. 2019. 4. US Life Tables, 2018. 5. Adapted from Shebl et al. CROI 2020.
*Relative mortality ratios calculated with Cox proportional hazard regressions adjusted for race, binge drinking, smoking, education, obesity, insurance, and health status.

Figure 1 A-E: CEPAC model inputs (A) and projected life expectancy (B-E) from age 15 years among non-Hispanic Black and White people who have ever injected drugs (PWID) stratified by HIV care scenario.

Conclusions: Among most PWID-HIV, improving retention in care would gain more life-years than increased testing, yet disparities in life expectancy between Black and White PWID-HIV would persist. Attaining equivalent HIV testing and retention rates across Black and White PWID would be insufficient to address disparities in life expectancy.

PESUC22
Is Thailand on track to achieve 95-95-95 targets by 2025?

S. Aungkulanon[1], M. Vasantiuppapokakorn[2], S. Northbrook[1], R. Triamwichanon[3], T. Naiwatanakul[1], A. Kanphukiew[1], W. Kiatchanon[1], B. Baipluthong[1], C. Lertpiriyasuwat[2]

[1]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Nonthaburi, Thailand, [2]Thailand Ministry of Public Health, Division of AIDS and STIs, Department of Disease Control, Nonthaburi, Thailand, [3]National Health Security Office, Bangkok, Thailand

Background: Thailand made progress in expanding coverage of antiretroviral treatment (ART) for people living with HIV (PLHIV). We developed a model to predict national HIV cascade trends and estimate effort needed to achieve 95-95-95 targets in 2025.

Methods: We developed a Markov model on disease progression to project national HIV cascade trends from 2022 to 2025 using current epidemic (Model A) and accelerated response trends (Model B). The cycle of the Markov model was 1 year. We used 2021 National AIDS Program (NAP) data to classify PLHIV into six states:
1. Diagnosed but not initiated ART,
2. Initiated ART but not on ART,
3. On ART but not tested for VL,
4. Tested for VL but not suppressed(VL>1,000),
5. Virally suppressed, and
6. Death.

We calculated the probability of moving from one state to another or remaining in the same state by analyzing patient data from 23 health facilities. We applied a linear trend using NAP data from 2014 to 2021 to estimate the number of new and undiagnosed HIV-infections from 2022 to 2025 and added them to the model.

While we used the probability matrix from 2021 to develop Model A, we applied the exponential growth of the annual transition probability from current state to state 3 and state 5 by 1% to 10% to develop Model B.

Results: Of 503,459 PLHIV who knew their HIV status in 2021, 81% (405,634) were on ART and, of these, 81% (327,577) were virally suppressed. Under Model A, we projected ART coverage and VLS to increase to 86% and 84% in 2025, respectively. Under Model B, we achieved 2nd and 3rd 95 targets after intensifying treatment and viral suppression efforts by 5% each year.

Year	Model B: Increase 5% annually					Model A	
	PLHIV Alive Diagnosed	On ART	Virally Suppressed	Second 95	Third 95	Second 95	Third 95
2022	509,263	431,472	367,259	85%	84%	83%	83%
2023	514,395	457,112	406,412	89%	89%	85%	83%
2024	518,395	478,936	443,798	92%	93%	86%	84%
2025	521,086	492,929	466,684	95%	95%	86%	84%

Table.

Conclusions: Current efforts will increase ART coverage and viral suppression but are insufficient to achieve 95-95-95 targets. Defining which populations, geographic areas, and interventions to intensify efforts are needed to optimize resource allocation and control the HIV epidemic.

PESUC23
Characterising the HIV care cascade in Saskatoon, Saskatchewan, 2018 - 2021

C. Spence[1,2], S. Sanche[1,3], B. Wudel[1,3], L. Kiesman[4], S. Takaya[1,3], M. Klein[2], S. Kogilwaimath[1,3]

[1]University of Saskatchewan, Medicine, Saskatoon, Canada, [2]McGill University, Medicine, Montreal, Canada, [3]Saskatchewan Health Authority, Infectious Disease, Saskatoon, Canada, [4]Westside Community Clinic, Saskatoon, Canada

Background: Saskatchewan has experienced a unique HIV epidemic in Canada, driven largely by injection drug use and disproportionately affecting younger women through heterosexual transmission. HIV care in Saskatoon is primarily accessed at two clinical sites: the Royal University Hospital (RUH) and the Westside Community Clinic (WSCC). While the clinic at RUH is a specialized Infectious Diseases clinic, WSCC provides community-based access to primary care and addictions support. These clinics serve over 1200 active patients living with HIV. Offering different, yet complementary clinical care, the HIV care cascades of these two sites offer insights into the HIV epidemic over time, specifically, the characteristics of each of the care models; patient populations; intersectional considerations; and the impact of the COVID-19 pandemic on patient outcomes.

Description: With demographic and clinical data for diagnosed Persons With HIV (PWH) across the two clinic sites over a four-year period, from 2018 – 2021, care continuum data is compared across the two sites during the four-year time periods, characterizing the HIV care cascade for Saskatoon, SK. The data demonstrates where the gaps in care exist between the two models.

Lessons learned: The community-based care model has seen a progressive advancement in cascade outcomes, while being relatively undisrupted during the COVID-19 period, with a consistent 79% PWH engaged in care.

However, the pandemic period adversely impacted cascade outcomes for the hospital-based clinic, reflected by a drop from 67% to 56% of patients on ART, and an overall trend of moderate cascade outcomes over the four-year period of analysis. The rates of virologic suppression are noted to be lowest during the peak period of the pandemic lockdown in May 2020 for both clinic sites, (65% and 46% respectively) indicating a clear impact of the pandemic lockdown mandate. A marked shift in patient demographics over the analysis period includes an increase of younger females with new infections.

Conclusions/Next steps: Gaps in the care continuum offer insights to advocate for adaptation of the community-based delivery model to develop targeted solutions to expand outreach, supporting the petition for more resources for access and engagement in care for a large cohort of PWH seeking care in Saskatoon.

Risk factors for acquisition, infectivity and transmission of HIV

PESAC15

Recent HIV acquisition and age-disparate relationships predict rapid repeated pregnancies among adolescent mothers in a large South African cohort

W. Saal[1], E. Toska[1,2], J. Tolmay[1], N. Langwenya[2], J. Jochim[2], C. Wittesaele[2], L. Cluver[2]

[1]University of Cape Town, Centre for Social Science Research, Cape Town, South Africa, [2]University of Oxford, Department of Social Policy and Intervention, Oxford, United Kingdom

Background: Pregnant/breastfeeding adolescent girls and young women are at greater risk of HIV infection, poor retention in care, and higher rates of secondary transmission. Understanding the timing and predictors of rapid repeated pregnancies is critical to ensuring HIV service provision aligns with their HIV prevention and reproductive needs.

Methods: We analysed data from 1,045 young mothers who had their first child before <20 years old, 30% of whom were living with HIV (88% recently infected). Participants were recruited in the HEY BABY cohort through a six-prong sampling approach including health facilities, schools, community organizations and referrals, to minimise selection bias (>95% enrolment for each recruitment channel). Self-reported HIV status was verified through medical records where available. Ethical approvals were given by the Universities of Cape Town and Oxford, local government, and participating facilities.

We explore factors experienced during and post first childbearing associated with rapid repeated childbearing, using multivariate regression models in STATA16.

Results: 99% of first-child pregnancies were unintended. 8.8% of participants had multiple children, with 18.5% among adolescent mothers living with HIV experiencing multiple pregnancies. Rapid repeated pregnancies, occurring when first child is <=2, were 5.3% in the overall study, 9.9% among participants living with HIV.

A quarter of first children were born while the mother was an in age-disparate relationship (5+ years older partner), this rose to 50% among adolescent mothers living with HIV. In multivariate analyses, adolescent mothers with children <=2 years (aOR=4.71 95%CI2.76-8.05, p<0.001), who recently acquired HIV (aOR=2.54 95%CI1.41-4.57, p=0.002), and who had their first child in an age-disparate relationship (aOR=1.83 95%CI1.10-3.04, p=0.02) had higher odds of rapid repeated pregnancies. These risks were cumulative: 14.1% of participants who recently acquired HIV and had their first child in an age-disparate relationship were at risk of rapid repeated childbearing, compared to 3.9% among adolescent mothers who were HIV-free and did not have their first child with a significantly older partner.

Conclusions: Adolescent mothers, especially those living with HIV need access to consistent family planning and dual protection urgently. Young mothers with recently-acquired HIV need additional support to time future childbearing, remain retained in care and attain positive HIV outcomes.

PESAC16

FCGR3Agene duplication, FcγRIIb-232TT and FcγRIIIb-HNA1a associate with an increased risk of vertical acquisition of HIV-1

J. Ebonwu[1,2], R. Lassaunière[3], M. Paximadis[1,4], R. Strehlau[5,6], G.E. Gray[7,8], L. Kuhn[9], C.T. Tiemessen[4,1]

[1]University of the Witwatersrand, Faculty of Health Sciences, Johannesburg, South Africa, [2]National Institute for Communicable Diseases, Division of Public Health Surveillance and Response, Johannesburg, South Africa, [3]Statens Serum Institut, Department of Virus and Microbiological Special Diagnostics, Copenhagen, Denmark, [4]National Institute for Communicable Diseases, Centre for HIV &STIs, Johannesburg, South Africa, [5]Rahima Moosa Mother and Child Hospital, Empilweni Services and Research Unit, Johannesburg, South Africa, [6]University of the Witwatersrand, Pediatrics and Child Health, Faculty of Health Scinces, Johannesburg, South Africa, [7]University of the Witwatersrand, Perinatal HIV Research Unit, Faculty of Health Sciences, Johannesburg, South Africa, [8]South African Medical Research Council, Cape Town, South Africa, [9]Mailman School of Public Health, Columbia University, Gertrude H. Sergievsky Centre, College of Physicians and Surgeons, and Department of Epidemiology, New York, United States

Background: Different mother-to-child transmission (MTCT) studies suggest that allelic variations of Fc gamma receptors (FcγR) play a role in infant HIV-1 acquisition, but findings are inconsistent. To address potential confounding of small samples sizes, the present study investigates the association between perinatal HIV-1 transmission and FcγR variability (*FCGR* point mutations and gene copy number variation) in a large cohort of South African infants born to women living with HIV-1.

Methods: This retrospective, nested case-control study combines *FCGR* genotypic data from three perinatal cohorts at two hospitals in Johannesburg, South Africa. Children with perinatally-acquired HIV-1 (cases, n=395) were compared to HIV-1-exposed uninfected children (controls, n=312). All study participants were black South

E-posters

Late-breaker abstracts

Author Index

Africans and received nevirapine for prevention of MTCT. Functional variants were genotyped using a multiplex ligation-dependent probe amplification assay and Sanger sequencing, and their representation compared between groups using logistic regression analyses.

Results: *FCGR3A* gene duplication independently associated with HIV-1 acquisition (OR=3.70; 95% CI 1.05-12.99; *P*=0.041). The FcγRIIb-232TT genotype significantly associated with increased odds of HIV-1 acquisition in a multivariate model, which controlled for *FCGR3A* copy number and *FCGR3B* genotype (AOR=1.72; 95% CI 1.07-2.76; *P*=0.024). When adjusted separately for *FCGR2C* c.134-96C>T that associated with infant HIV-1 acquisition in a different South African cohort, the strength of association increased (AOR=2.28; 95% CI 1.11-4.69; *P*=0.024).

Homozygosity for FcγRIIIb-HNA1a did not significantly associate with HIV-1 acquisition in a univariate model (OR=1.42; 95% CI 0.94-2.16; *P*=0.098); however, it attained significance after adjustment for *FCGR3A* copy number and *FCGR2B* genotype (AOR=1.55; 95% CI 1.01-2.38; *P*=0.044). Both FcγRIIb-232TT (AOR=1.84; 95% CI 1.11-3.03; *P*=0.017) and homozygous FcγRIIIb-HNA1a (AOR=1.67; 95% CI 1.06-2.62; *P*=0.028) retained significance when birthweight and breastfeeding were added to the model. We did not observe an association between the common *FCGR2A* and *FCGR3A* polymorphisms and HIV-1 acquisition.

Conclusions: Collectively, our findings suggest that the FcγRIIb-232TT genotype exerts a controlling influence on infant susceptibility to HIV-1 infection. We also show a role for less studied variants – *FCGR3A* duplication and homozygous HNA1a. These findings provide additional insight into a role for FcγRs in HIV-1 infection in children.

Describing the spread of HIV through molecular epidemiology

The association of HIV-1 subtypes and transmission clustering with late diagnosis: the first nationwide study in Japan

T. Shiino[1,2], M. Otani[2,3], M. Nishizawa[2], A. Hachiya[4,5,6], H. Gatanaga[7], D. Watanabe[8], R. Minami[9], M. Imahashi[4], K. Yoshimura[10], W. Sugiura[1], T. Matano[2,3], T. Kikuchi[2], Japanese Drug Resistance HIV-1 Surveillance Network

[1]National Center for Global Health and Medicine, Center for Clinical Sciences, Tokyo, Japan, [2]National Institute for Infectious DIseases, AIDS Research Center, Tokyo, Japan, [3]University of Tokyo, Institute of Medical Science, Tokyo, Japan, [4]National Hospital Organization Nagoya Medical Center, Clinical Research Center, Aichi, Japan, [5]Tokyo Medical University, Tokyo, Japan, [6]Nitobe Bunka College, Tokyo, Japan, [7]National Center for Global Health and Medicine, AIDS Clinical Center, Tokyo, Japan, [8]National Hospital Organization Osaka National Hospital, AIDS Medical Center, Osaka, Japan, [9]National Hospital Organization, Kyushu Medical Center, Internal Medicine, Clinical Research Institute, Fukuoka, Japan, [10]Tokyo Metropolitan Institute of Public Health, Tokyo, Japan

Background: Late HIV diagnosis is a major concern worldwide. While previous studies in some countries have reported association of late diagnosis with qualitative and/or demographic factors, clinical and phylogenetic factors remain unclear.

In the present study, we conducted a large-scale analysis to explore the demographic, clinical, and phylogenetic factors associated with late HIV diagnosis in Japan.

Methods: Japanese Drug Resistance HIV-1 Surveillance Network collects anonymized demographic, clinical, and sequences data for about 40% of newly diagnosed HIV cases in Japan from collaborating hospitals nationwide.

Of the 9,866 newly diagnosed cases enrolled in the surveillance network between 2003-2019, 7,853 cases with available CD4 count at diagnosis were included. Late diagnosis was defined as HIV diagnosis with a CD4 count below 350 cells/μL. Factors associated with late diagnosis were determined using Logistic regression. Molecular transmission clusters were identified by HIV-TRACE with genetic distance threshold 1.5%.

Results: The study population was predominantly male (95.0%) and Japanese (90.8%). Median age at diagnosis was 37 (IQR: 30-45) years, and 5,594 (71.2%) and 3,636 (46.3%) were diagnosed with CD4<350 cells/μL and with CD4<200 cells/μL, respectively. Demographic and clinical factors independently associated with late diagnosis were period of diagnosis (2009-2014: aOR 1.16, p<0.05, versus 2015-2019), transmission risk (Heterosexual: aOR 1.37, p<0.01, Other risk and Unreported: aOR 2.15, p<0.0001, versus MSM), older age (≧45 years: aOR 2.13, p<0.0001, 30 to 44: aOR 1.43, p<0.0001, versus ≦29), geographical area

(other than Tokyo: aOR 1.20, p<0.01, versus Tokyo), and HCV co-infection (aOR 1.42, p<0.05). Individuals in molecular transmission clusters were less likely to be diagnosed with CD4<350 cells/µL than those not in clusters (aOR 0.80, p<0.01). HIV-1 CRF07_BC was negatively associated with late diagnosis (aOR 0.24, p<0.001, versus subtype B). Country of origin, gender, or HBV co-infection was not associated with late diagnosis.

Conclusions: It was revealed that over 70% of newly diagnosed HIV cases in Japan were diagnosed with CD4<350 cells/µL. This study indicates for the first time the association of late HIV diagnosis with HCV co-infection, HIV-1 subtypes, and transmission clustering. Consideration of these factors would contribute to efficient enhancement of early diagnosis of HIV.

Prisoners and other incarcerated people

PESAD01

Improving HIV knowledge and gender-based attitudes amongst male inmates through football in correctional facilities in Zambia, Malawi and Zimbabwe

P. Dias[1], J. Haney[2], M. Wolfe[2], T. Ponde[3], C. Gamble[4], P. Diouf[5]
[1]Umunthu Foundation, Blantyre, Malawi, [2]TackleAfrica, Lusaka, Zambia, [3]Volunteer Services Overseas, Harare, Zimbabwe, [4]TackleAfrica, Brighton, United Kingdom, [5]Volunteer Services Overseas, Phnom Penh, Cambodia

Background: In Southern Africa, incarcerated people experience higher HIV prevalence than the general population and have been identified as a critical group for HIV programming in order to achieve the "95-95-95" goals. However, preliminary data collected from VSO and TackleAfrica, in a pilot program across 11 correctional facilities in Malawi, Zimbabwe and Zambia in 2019, suggested that both HIV knowledge and positive attitudes towards women was low.

We report the results of an inmate led, football-based intervention designed to improve HIV and SRHR knowledge and positive attitudes towards women amongst male inmates.

Methods: The program was implemented over two years in ten-week blocks. Baseline and end-line surveys were collected before and after each block by youth volunteers working with inmate coaches. HIV knowledge was measured using the UNAIDS Comprehensive HIV Knowledge indicator. Questions around SRHR and attitudes to women were based on similar DHS & WHO indicator questions.

Results: Over 2 years, 126 inmates were trained as peer football coaches to reach 2920 male inmates with 1047 football sessions integrated with sexual health messaging. 1,109 male inmates completed baseline surveys, of which 562 (51%) completed end-line surveys. The primary reason for leaving the program was release or transfers. Comprehensive HIV knowledge improved from 35% at baseline (n=1109) to 51% at end-line (n=562). Knowledge of STIs improved from 52% (n=1109) at baseline to 65% at end-line (n=491).

The question, "Should a girl be able to refuse unwanted sex from her husband or boyfriend?" saw an increase from 76% to 88% at end-line in Zambia (n=531/n=230), while in Malawi and Zimbabwe the question "having sex with many women is a sign of man-hood" saw a correct answer increase from 64% at baseline (n=656) to 76% at end-line (n=278).

Conclusions: Football based interventions are an effective mechanism to engage with male inmates in Southern Africa around sensitive issues related to HIV, SRHR and attitudes towards women.

While issues associated with inmate transfer and release may disrupt program completion, inmate-led sports-based interventions represent a sustainable and valuable mechanism to engage with a highly disenfranchised and alienate group that are critical to reaching UNAIDS targets.

Young key populations

PESAD02

Survey measurements of community norms on Adolescent Girls and Young Women's (AGYW) sexual behaviour and use of condoms for HIV prevention in Manicaland, East Zimbabwe

S. Gregson[1], T. Dadirai[1], R. Maswera[1], L. Moorhouse[2], T. Museka[1], P. Mandizvidza[1], F. Dzamatira[1], B. Tsenesa[1], C. Nyamukapa[1], M. Skovdel[3]
[1]Biomedical Research and Training Institute, Manicaland Centre for Public Health Research, Harare, Zimbabwe, [2]Imperial College London, Department of Infectious Disease Epidemiology, London, United Kingdom, [3]University of Copenhagen, Copenhagen, Denmark

Background: Qualitative data suggest pre-marital sex stigma presents a major obstacle to AGYW's use of HIV prevention methods. Lack of social acceptability therefore is included as a barrier to motivation to use condoms in HIV prevention cascades. Representative survey data on community norms are rare but necessary to test the validity of this assumption and measure their contributions to gaps in prevention cascades.

Methods: General-population survey participants in Manicaland (ages ≥15, N=9803) were asked if they agreed/disagreed with statements on social norms. AGYW were asked whether community views are an obstacle to their using condoms. Proportions agreeing/disagreeing with these statements were calculated, variations in community members' views were investigated in multivariable

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

logistic-regression models, and the association between AGYW's perceiving negative community norms and condom use was measured.

Results: 93.5% (95%CI,93%-94%) of respondents agreed that 'Many young women have sex before marriage these days'. 57% (56%-59%) of men and 70% (69%-71%) of women disagreed that 'If I have a teenage daughter and she has sex before marriage, I would be ok with this'; and 41% (40%-43%) of men and 57% (56%-59%) of women disagreed that 'If I have a teenage daughter, I would tell her about condoms'. Fathers but not mothers were more likely to disagree with their daughters having sex before marriage (Figure).

Similar proportions of parents and other community members were against telling daughters about condoms. 68% (61%-75%) of sexually-active unmarried AGYW said negative community views were unimportant in decisions to use condoms. Condom use didn't differ between those who agreed/disagreed that negative community views are important (46.9% vs. 50.0%; AOR=0.88, 95% CI,0.48-1.62; N=202).

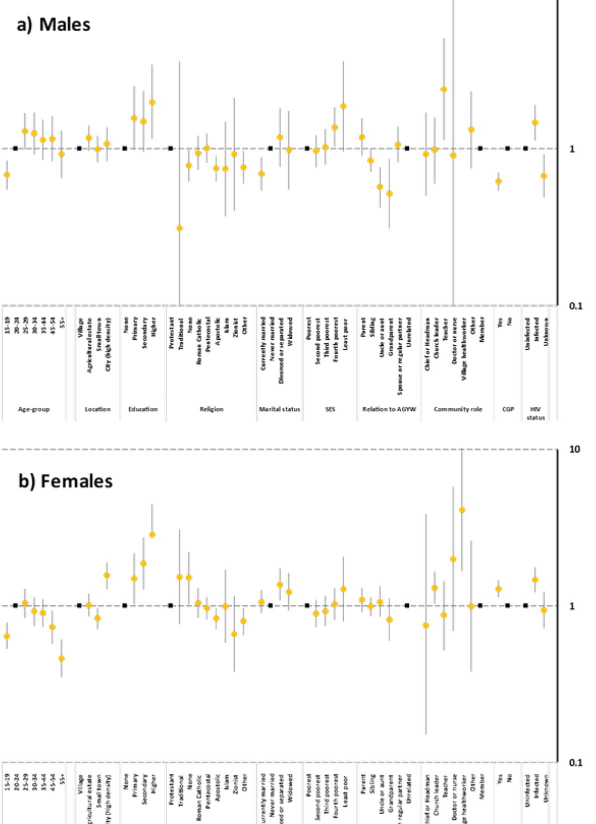

Figure. Variation in community members agreement on telling teenage daughters about condoms by relationship to an AGYW, community role and participation, and socio-demographic characteristic: adjusted odds ratios from multivariable logistic regression. Yellow points above / below the central line indicated higher / lower odds of agreement. Whiskers indicate 95% confidence intervals.

Conclusions: Community resistance to condom promotion based on pre-marital sex stigma may be weakening as a barrier to AGYW's motivation to use condoms in Manicaland. Community-led interventions to accelerate this dynamic in social norms and support AGYW's agency could reduce HIV incidence.

PESAD03

From mobile phone to health center: WhatsApp as persuasive tools towards HIV testing among college students of the remote district of Pakistan

F. Ahmad[1], M.N. Qaisar[2]

[1]University of Okara, DOMS, Okara, Pakistan, [2]NUML, Islamabad, Pakistan

Background: HIV testing targets in remote areas of Pakistan remain low. Due to this issue, many people were unable to know about their status and cannot be linked to HIV care. The objective of this study was to check the effectiveness of interventions using WhatsApp as a platform to improve HIV testing among college students in the Larkana district of Pakistan.

Methods: We used a randomized controlled trial approach, and recruited, HIV-negative, 18 years or older college students, who did not get HIV testing in the last 6 months. These were recruited online and randomly were assigned to two groups i.e. an intervention or control group. Participants were recruited using google forms. After being recruited online, participants completed a short baseline survey. Later, a trained health worker used the mobile application WhatsApp to follow each participant for 8 weeks. They shared different topics of interest with an emphasis on HIV prevention in the second half of the period of follow-up. Participants in control groups received standard of care. The main outcome was the number of participants who got an HIV test at one of the health centers of the research project.

Results: Participants were recruited between Jan and March 2021. 500 participants were randomly assigned to the intervention group (n=250) or the control group (n=250). 91 participants (36.4%) in the intervention group and 19 (7.6%) in the control group went to the health center to receive an HIV test (adjusted odds ratio: 7.54; 95% CI: 4.1 -13.4).

Conclusions: This strategy where trained health workers using a mobile application for follow-up, was good to divert traffic towards health centers for HIV testing. It is important to use WhatsApp through mobile to get traffic for HIV testing, mobile applications are already been widely used in remote parts of Pakistan as well.

PESAD04

Structural level factors and PrEP stigma influence on PrEP use among Black MSM (18 to 29) in the US

D. Boyd[1], G.M. Abubakari[2], J. Allen[3]

[1]The Ohio State University, Social Work, Columbus, United States, [2]Yale University, School of Public Health, New Haven, United States, [3]Wayne State University, Social Work, Detroit, United States

Background: Albeit the proven efficacy of PrEP to prevent HIV transmission and reduce spread among HIV key populations such as Black men who have sex with men (MSM), uptake may remain slow among such populations due to structural and individual-level factors in the United States (US). As such, we examined the relationships between structural factors (food insecurity, homelessness, employment), PrEP stigma on PrEP use among a national sample of Black MSM between the ages 18 to 29.

Methods: The survey was programmed for two sampling and social media sites (Twitter, Facebook) with Qualtrics software, targeting 400 Black MSM between 18 and 29 years. The survey was completed directly on the Qualtrics portal for the Qualtrics sampling site, and a link was provided for M-Turk sampling site. The research team distributed an anonymous link to the survey embedded on the flyer posted on social media. Respondents were recruited for all three locations from December 1, 2021, to January 31, 2022. We used a logistic regression analysis to examine whether structural factors and PrEP stigma correlate with the outcome variable PrEP use.

Results: Our results from our logistic regression indicated that Black MSM who scored higher on the PrEP stigma scale were less likely to use PrEP (OR:0.73; 95%CI:0.52,0.99). Black males who stated that they lost their job due to Covid 19 were 2.9 times more likely to use PrEP than those who did not (OR: 2.93; 95%CI:1.36,6.29).

Individuals who reported reducing the number of meals at least once or twice were more likely to use PrEP (OR:4.28, 95CI:2.17,8.42). Lastly, those who reported being homeless in the past 12 months were more likely to use PrEP than those who never reported being homeless (OR: 1.00; 95%CI: 1.00,1.00).

Conclusions: Our results suggest reduced uptake of PrEP among BLMSM who experience PrEP stigma but show an increased uptake among those who are food insecure or homeless. Thus, highlighting that despite possible available resources that link low-income BMSM to PrEP, stigma remains a key issue that would continue to impede use, hence, the need for innovative interventions to address PrEP stigma among BMSM in the US.

PESAD05

Young Heroes Initiative – High Five (YHI-HF): Creative Contributory Contest (CCC) and social innovation hackathon as an entry point in engaging adolescents for HIV and AIDS

A. Dicto[1], J.C. Arana[1], J.C. Borja[2]

[1]Council for the Welfare of Children, Quezon City, Philippines, the, [2]Positive Youth Development Network, Iloilo, Philippines, the

Background: In December 2020, the HIV and AIDS and Art Registry of the Philippines recorded 273 (25%) cases among the youth 15-24 years old. The Integrated HIV and Behavioral and Serologic Surveillance presented that HIV knowledge is lowest among 15-20 years old. Both evidence shows adolescents' risky sexual behaviors start when they have insufficient knowledge on HIV and AIDS and less access to ASRH services. In December 2020, with funding from the Council for the Welfare of Children (CWC), Unicef, and UNAIDS, YHI-HF was launched.

Description: The intervention has 3 phases. Phase 1 is the Creative-Contributory-Contest, where teams (4 adolescents, one adult mentor) are asked to submit their 2030 Vision of Young People and HIV and AIDS using creative outputs. Thirty-two (32) teams joined this phase with outputs varying from dances to paintings.

Phase 2 is the social innovation hackathon where they build on their creative outputs to pitch for concrete solutions. Mentors and experts were tapped to help them fine-tune their ideas utilizing the Human-Centered Design. Six teams proceed on the final phase, the project implementation. They are given 2,000 USD to implement their social innovation for a year with the local CWC office. The projects include traveling play, magazine publication, audience-led performing arts, and a musical designed for and by adolescents.

Lessons learned: There were 451,428 directly engaged adolescents in the project. An increase of 54% from baseline in basic knowledge and awareness about HIV and AIDS was observed among participants. 48% showed increased health-seeking behavior, as indicated by their willingness to be tested, and an increase of 72% in the level of knowledge and awareness in condom use, PREP, and combination methods was also observed.

Psychological safety (32%), fun and creative environment (63%), and peer-to-peer approach (55%) were among the top 3 identified reasons why adolescents joined the project.

Conclusions/Next steps: CCC and Hackathon are effective approaches to attract adolescents to HIV-related activities. Children can implement effective HIV interventions if given the proper support and resources.

The next phase of the project is to design a training module for duty-bearers working on HIV on how they can effectively engage adolescents in their area.

PESAD06

Perspectives and Preferences for multi-purpose prevention technologies (MPTs) to address sexual and reproductive health (SRH) needs among adolescent girls and young women (AGYW) in Kenya and Uganda

L.L. Lunani[1], S. Namukwaya[2], S. Lipesa[1], B. Kombo[1], D. Omondi[1], J. Shikuku[1], C. Omom[1], A. Maina[1], R. Malogo[1], K. Katumba[2], I. Kayesu[2], Z. Nabalwanyi[2], R. Naluwooza[2], Y. Mayanja[2], G. Omosa-Manyonyi[1], O. Anzala[1], P. Indravudh[3], M. Quaife[3], L. Gao[4], M. Kuteesa[5], Y. Machira[6], A. Kamali[5], M. Gafos[3]

[1]KAVI-ICR, University of Nairobi, Nairobi, Kenya, [2]MRC/UVRI & LSHTM Uganda Research Unit, Entebbe, Uganda, Entebbe, Uganda, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]Busara Center for Behavioral Economics, Nairobi, Kenya, [5]International AIDs Vaccine Initiative (IAVI), Entebbe, Uganda, [6]International AIDS Vaccine Initiative (IAVI), Nairobi, Kenya

Background: Adolescent girls and young women in Sub Saharan Africa are disproportionately affected by high rates of HIV, sexually transmitted infections (STIs) and unintended pregnancies. To inform development of MPTs and delivery of SRH services, an innovative behavioral science research project (UPTAKE) seeks to determine factors that facilitate future acceptability and uptake of long-acting (LA) technologies to prevent HIV and unintended pregnancy among AGYW in Nairobi, Kenya and Kampala, Uganda.

Methods: We conducted in-depth interviews with 30 AGYW aged 15-24 years in Nairobi and Kampala. We explored participants' perceptions of future MPTs, building on their experiences and views of existing family planning (FP) and HIV prevention products. Interviews were audio recorded, transcribed, and translated. Data were analyzed thematically in NVivo and reconciled iteratively during reflective sessions with the research teams.

Results: An interim analysis shows that AGYW generally have a limited understanding of the FP and HIV prevention options available to them. Most of them report early sexual debut, premature school dropout, a lack of family and social support, and engaging in age-disparate sexual relationships, transactional sex or sex work. Participants reported unintended pregnancies and initiated FP only after childbirth.

There were misconceptions and a lack of trust in modern HIV prevention methods, with some viewing PrEP as a drug for HIV positive individuals. Only AGYW engaging in sex work were aware of PrEP. In terms of future MPTs, most participants preferred long-acting injectable, for >1-year, inserted in the arm, providing HIV and pregnancy prevention.

Participants expressed limited interest in prevention for other STIs, which they considered treatable. Government facilities were the preferred choice for future delivery of MPTs due to affordability. AGYW described themselves as decision-makers in relation to their SRH, while acknowledging the need for new products citing women's' limited ability to negotiate HIV testing and condom use with male partners.

Conclusions: Long-acting MPTs offer considerable potential for reducing HIV infection and unintended pregnancies among AGYW. Product developers should consider MPTs during manufacturing. Policy makers and programme planners need to make these products and their information readily available and accessible to AGYW using youth friendly health services and other approaches.

PESAD07

Body image dissatisfaction is positively associated with poorer mental health outcomes but not linked to HIV risk behaviours among young gay, bisexual, transgender and queer men in Singapore

A. Tyler[1], Z.H. Mah[2], D. Le[1], A. Tan[1], C. Tan[1], C. Kwok[1], S. Banerjee[1], A.R. Cook[3], M.L. Wong[3], R.K.J. Tan[3,4]

[1]Action for AIDS Singapore, Singapore, Singapore, [2]National University of Singapore, Yong Loo Lin School of Medicine, Singapore, Singapore, [3]National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore, [4]University of North Carolina Project-China, Guangzhou, China

Background: No prior study has been published on the impact of body image dissatisfaction in the Gay, Bisexual, Transgender and Queer (GBTQ) community in Singapore. Furthermore, while many studies have found a positive link between poor mental health outcomes and HIV risk behaviours, few have explored the role of body dissatisfaction in driving such risks.

This study aims to explore associations between varying measures of body image dissatisfaction with measures of mental and sexual health risks, including depression severity, suicidal ideation and attempts, as well as recent condom-less anal intercourse.

Methods: Data were derived from a cross-sectional follow-up survey of the Pink Carpet Y Cohort Study, Singapore's first prospective cohort study among young GBTQ men. Participants comprised HIV-negative, young GBTQ men aged 18-25 years old. Body image dissatisfaction was measured through the Male Body Attitudes Scale (MBAS-R), Drive for Muscularity Scale (DMS), and two measures of distance between perceived and ideal body types: Body Fat Difference (BFD) and Muscularity Difference (MD). Higher scores indicate greater dissatisfaction. Multivariable logistic and linear regression were employed.

Results: The study recruited a total of 396 participants. Multivariable analyses revealed that MBAS-R (Coeff. = 0.08, 95% CI 0.04, 0.12) and BFD (Coeff. = 0.04, 95% CI 0.01, 0.08) were positively correlated with depression severity. MD (aOR = 1.02, 95% CI 1.00, 1.03) was positively associated with ever having suicidal ideation, whereas DMS (aOR = 0.97, 95% CI 0.96, 1.00) was negatively associated with suicidal ideation. Analyses also revealed that MBAS-R (aOR = 1.03, 95% CI 1.01, 1.05) and BFD (aOR = 1.02, 95% CI 1.00, 1.03)

were positively associated with ever having attempted suicide. No measures of body dissatisfaction were significantly associated with recent condom-less anal intercourse.

Conclusions: Body image dissatisfaction in young GBTQ men was positively associated with negative mental health outcomes. Future health promotion interventions should be targeted at developing a positive body image in young GBTQ men, in hopes of achieving better mental health outcomes.

Given that poor mental health outcomes may drive syndemics of HIV acquisition, further research into the lasting impact of body image dissatisfaction on sexual risk in young MSM is warranted.

PESAD08

Integrating human-centered design, public health, and behavioral science to improve access to HIV services among young men who have sex with men in Kenya

A. Beeman[1], J. Levine[2], R. Hope[2], A. Lacorazza[2], S. Olabode-Dada[2], M. Omondi[3], J.M. Wambui[4], T. Gibbs[2]

[1]Youth Development Labs (YLabs), Kigali, Rwanda, [2]Youth Development Labs (YLabs), Berkeley, United States, [3]Men Against AIDS Youth Group (Maaygo), Kisumu, Kenya, [4]Health Options for Young Men on HIV/AIDS/STI (Hoymas), Nairobi, Kenya

Background: The criminalization and stigmatization of same-sex sexual activity contribute to social, community, and healthcare-related barriers that prevent young men who have sex with men (YMSM) from accessing high-quality HIV services. Using a human-centered design (HCD) approach, research and design firm YLabs partnered with community YMSM-serving organizations Maaygo and Hoymas to develop an HIV self-testing (HIVST) campaign and service delivery model.

The pilot aimed to expand programmatic reach to YMSM ages 15-24 in Nairobi and Kisumu counties, Kenya, not currently engaged in services to increase access to HIV prevention and care.

Description: The program consisted of a behavior change-informed digital and physical demand generation campaign co-designed with YMSM. This included YMSM-focused messaging to address common fears about HIV testing; an automated SMS messaging platform to connect YMSM to peer educators for delivery of HIVST kits and incentives at convenient pick-up points; and streamlined, confidential access to sensitized clinicians to encourage reporting of HIVST results and facilitate linkage to follow-up care.

Lessons learned: Compared to 2019 data, the pilot demonstrated a 265% increase in testing of new YMSM clients to participating clinics, an 834% increase in YMSM who had never tested for HIV, and a 123% increase in YMSM who had not tested within 12 months. Successful engagement strategies included paid advertisements with YMSM-specific language across multiple social media platforms promoted by LGBTQ influencers. Distinct differences in engagement by YMSM by geography, social media channel, campaign subscription channels, and preferred incentives illustrated the need to tailor programming to subpopulations of YMSM. Barriers to HIVST kit use included supply chain shortages of tests, emotional preparedness to accept a positive result, and low willingness to report results to clinic personnel.

Conclusions/Next steps: The success of this pilot indicates the value of using HCD to create customized programming that engages key populations such as YMSM in the development of interventions intended to serve them. The tailored demand generation approaches and messaging addressed key fears and barriers to testing, enabling the program to test harder-to-reach youth.

Preferred awareness channels and testing incentives differed between YMSM geographically, emphasizing the need to tailor future programs' contextual nuances to maximize reach and effectiveness.

PESAD09

Factors associated with initiation of selling sex as a minor among adult female sex workers in Eswatini

A. Grosso[1], B. Sithole[2], S. Maziya[3], M. Akinmade[4], S. Matse[5], S. Baral[6]

[1]Rutgers University Rutgers Institute for Health, Healthcare Policy and Aging Research, Urban-Global Public Health, New Brunswick, United States, [2]FHI 360, Mbabane, Eswatini, [3]HealthPlus 4 Men, Mbabane, Eswatini, [4]Rutgers University Rutgers Institute for Health, Healthcare Policy and Aging Research, New Brunswick, United States, [5]Ministry of Health, National AIDS Program, Mbabane, Eswatini, [6]Johns Hopkins School of Public Health Center for Public Health and Human Rights, Epidemiology, Baltimore, United States

Background: Eswatini has a population of 1.16 million; 26.8% of all adults and 61% of female sex workers (FSW) are living with HIV. There have been recent reports of underage girls selling sex due to economic hardships during COVID-19 and while schools were closed.

Moreover, an estimated 800+ children in Eswatini have lost a parent due to COVID-19, and in a 2014 study, adult FSW in Eswatini who were orphaned before the age of 18 were more likely to have started selling sex as minors. Here, we aimed to describe associations of initiation of selling sex as a minor in Eswatini.

Methods: In 2011, FSW aged 18+ who exchanged sex for money, favors, or goods in the past 12 months were recruited through respondent-driven sampling in Eswatini, completed a questionnaire, and were tested for HIV and syphilis.

Unadjusted multivariable logistic regression analysis was conducted to compare participants who reported their age of initiation of selling sex was <18 years old to those whose age of initiation was 18+.

	Age at the time of the study [mean]	Education [completed primary school or higher]	Has any living children	Sold sex in multiple geographic regions in the past 12 months	Must share earnings with a person who arranges clients or provides protection	Ever beaten up as a result of selling sex	Can count on sex worker colleagues to help deal with a violent or difficult client	Tested positive for syphilis in the study or reported a previous diagnosis with syphilis in the past 12 months	Tested positive for HIV in the study	Was forced to have sex after age 18
Adjusted odds ratio (95% CI)	0.82 (0.76, 0.88)	0.66 (0.52, 0.87)	0.39 (0.20, 0.79)	1.51 (1.14, 1.99)	2.82 (1.07, 7.41)	1.89 (1.01, 3.54)	0.69 (0.50, 0.96)	3.31 (1.26, 8.71)	N/A	N/A
Started 18+ 74% (237/320)	28	80% (189/237)	84% (199/236)	38% (90/236)	7% (15/229)	35% (81/234)	86% (199/231)	8% (20/236)	74% (171/233)	38% (89/232)
Started <18 26% (83/320)	22	69% (57/83)	52% (43/83)	51% (42/83)	17% (14/82)	48% (40/83)	77% (64/83)	16% (13/83)	60% (48/80)	44% (32/72)
Note: Multivariable logistic regression analysis controlled for all variables listed above except HIV status and experience of forced sex										

PESAD09 Table.

Results: 60% of FSW who started selling sex <18 tested positive for HIV, and this did not significantly differ from those who started as adults after controlling for current age(p=0.953). Participants who started selling sex <18 were younger at the time of the study, less educated, and more likely to be mobile. They had higher odds of testing positive for syphilis or reporting a recent syphilis diagnosis, being forced to share earnings with someone who arranges clients or provides protection, and being beaten up due to selling sex and lower odds of counting on other sex workers to help deal with violent clients.

Conclusions: Selling sex as a minor has potentially lasting effects on social determinants of adverse sexual health outcomes. Strengthening education, economic support and child protective services is necessary to prevent sexual exploitation of children in Eswatini, and health services are needed address the vulnerabilities of those who are selling or previously sold sex as minors.

PESAD10

Challenges to HIV prevention and sexual health promotion among impoverished youth living in slums/favelas of São Paulo, Brazil in the first two years of the COVID-19 pandemic

M. Jardim dos Santos[1], L. Oliveira da Silva[2], V.S. Facciolla Paiva[2]

[1]*University of São Paulo/Medicine School, Preventive Medicine, São Paulo, Brazil,* [2]*University of São Paulo/ Institute of Psychology, Social Psychology, São Paulo, Brazil*

Background: The emergence of the COVID-19 pandemic and its concomitant socio-economic and humanitarian crises magnified youth's vulnerability to HIV/AIDS, which was already high in impoverished suburban territories. Community-based peer education projects had to innovate to guarantee young people's right to health.

Description: The H.I.V-Project (Heliópolis Investindo na Vida) promotes sexual health among young people in Heliópolis, the largest slum in the metropolitan area of São Paulo. Starting in January 2020, the primary local CBO selected a group of 9 young leaders (age 15-19) to be peer-educators in HIV/STI and pregnancy prevention through a Human Rights and Vulnerability perspective and Freire's pedagogy framework. Seventeen of the twenty months of the project were mostly online, respecting COVID prevention measures and included weekly supervision workshops, interventions using livestreams and social media posts, activities focused on afterschool programs aimed at 13-17 yr-olds, and mask+condom distribution to young people at Street-Funk parties and public gatherings.

Lessons learned: A lack of housing infrastructure and internet access hampered participants' engagement during online activities. Participants kept quiet when trying to discuss sexuality, HIV/STI prevention, and especially "sex during a pandemic." In small houses without privacy, participants had little space to talk about their sexual experiences or explore their thinking and feelings about these themes. Furthermore, in times of COVID, as parents became unemployed, nurseries and daycares closed for long periods, and the domestic workload increased, girls had less time to work on the project. Two girls also had unexpected pregnancies. Boys, on the other hand, had to work long hours to support their family income. Black boys in particular experienced increased police violence and were also more absent from the project. Working COVID and mental health into the program was inescapable while inventing methodologies and producing content, mixing online with in-person encounters.

Conclusions/Next steps:
It remains crucial to consider the coalescence of the ongoing COVID-19 pandemic with the HIV/AIDS and mental health epidemics. In order to innovate HIV/STI prevention peer-education, social, structural, psychosocial, interpersonal, and intrapersonal barriers should be considered. The integrality of human rights and the notion of "comprehensive prevention" needs to encompass "combination prevention".

PESAD12

Resilient & empowered, adolescents and young PLHIV (READY++)-a pilot initiative working with adolescent and young PLHIV in India

F. Khan[1], R. Mitra[2], K Pramod[3], S. Kumar[1], R. Sharma[1]
[1]*India HIV/AIDS Alliance, Care & support, Delhi, India,* [2]*India HIV/AIDS Alliance, Director-Care & Support, Delhi, India,* [3]*India HIV/AIDS Alliance, Associate Director-Care & Support, Delhi, India*

Background: Adolescents and young people contribute 40% of the Indian population. The evidence suggested that adolescents and young people engage in sexual experimentation and sexual risk taking, the accessibility of this group to accurate information on SRH and sexuality related services is poor. Such situations expose to adverse SHR outcomes. Nearly 10% of PLHIV in India are adolescents and young people in the age group. AYPLHIVs face unique challenges related to their HIV status and related to their SRH needs such as growing up changes, developing relationships, sexuality, marriage, and love.

Description: a pilot peer lead initiative namely READY++ was rolled out in five states of India by Alliance India, to address the specific unmet SRHR and mental health needs of AYPLHIVs to build a cadre of informed and empowered AYPLHIVs with information and skills on SRHR and HIV, who in turn reached their fellow AYPLHIVs with comprehensive knowledge on a range of SRHR issues, following activities carried out

1. Identification peer champions pre-training assessment.
2. Capacity building through state level consultations and national level training.
3. One2one session with AYPLHIVs by peer champions.
4. Support group meetings by peer champions.
5. Peer champions engaging parents and families.
6. Advocacy meetings by peer champions with prominent state level officials and.
7. Engaging AYPLHIVs and youth affected by HIV through social media.

Lessons learned: The READY++ program employed an intensive process to create powerful, positive and sustainable changes at the level of peer champions. For the first time, they found a platform to discuss issues of guilt about their HIV status and relationship with an HIV negative person, love, sex, marriage, myths, and misconceptions associated with their bodies.

Over time, peer champions reached thousands of their peers (both online and offline) with knowledge on HIV and SRHR and facilitated their linkages to HIV services, social schemes and vocational skills building programs.

Conclusions/Next steps: The peer champion is playing an active role in the states linking young people with HIV related services, the empowered peer are taking lead to ensure the rights, policy development and active as pressure group and raising issues of the unmet needs of AYPLHIV community.

PESAD22

"Delivery of clinical HIV prevention care and treatment services for Key Populations through safe spaces in Harare"

C. Muchemwa[1], P. Moyo[1], E. Molande[1], J. Murungu[1], S. Nyakuwa[1], I. Mahaka[1], P. Manyanga[2], B. Mushangwe[2], H. Bara[3], B. Chingombe[4], G. Gonese[2], T. Mharadze[5], S. Wallach[5], R. Malaba[5], R. Weber[5], B. Makunike[2], S. Witkor[6]
[1]*Pangaea Zimbabwe AIDS Trust, Programmes, Harare, Zimbabwe,* [2]*Zimbabwe Technical Assistance Training and Education Centre for Health, Programmes, Harare, Zimbabwe,* [3]*City of Harare, Health Department, Harare, Zimbabwe,* [4]*Ministry of Health, AIDS and TB Unit, Harare, Zimbabwe,* [5]*CDC Zimbabwe, Harare, Zimbabwe,* [6]*University of Washington, International Training and Education Centre for Health, Washington, United States*

Background: Key Populations (KPs) bear the burden of HIV yet have poorer access to HIV services. Pangaea Zimbabwe AIDS Trust (PZAT) is building the capacity of public health facilities to provide KP-friendly services to improve uptake of HIV prevention, care, and treatment services. KPs experience barriers to care due to stigma, discrimination, criminalization, and socio-economic challenges. COVID-19 worsened access to comprehensive HIV services. PZAT conducted differentiated service delivery services at safe spaces to ensure access for KPs in areas around 18 high-burden public health facilities in Harare.

Description: From October 2020 to September 2021, PZAT supported the delivery of comprehensive HIV services for KPs at safe spaces, including secluded outdoor spots. KPs identified safe spaces based on privacy, convenience, safety, and accessibility to many KPs.

Thirty Community Facilitators (female and male sex workers, men who have sex with men, transgender and people who use drugs) identify and mobilize KPs ahead of the visit, link them to services, and follow-up.

A multidisciplinary team provides services including HIV testing, Pre-Exposure Prophylaxis, Antiretroviral Therapy, condoms and lubricants, intimate partner violence screening and referral, sexually transmitted infections (STI) screening, and management.

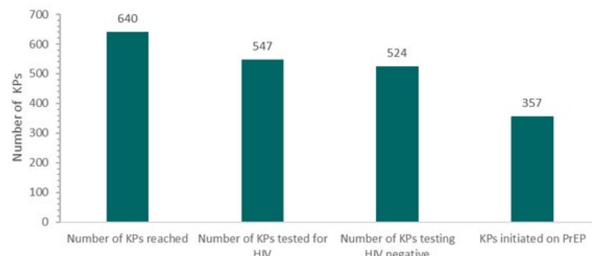

Figure. Number of KPs reached and accessing HTS and PrEP at safe spaces Oct 20 - Sep 21

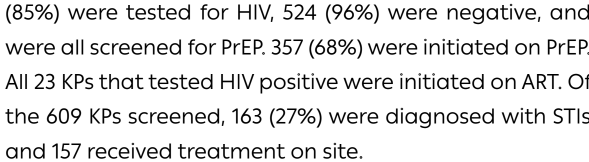
Lessons learned: KPs prefer accessing services where they feel safe and comfortable. A total of 640 KPs were reached with HIV services through safe spaces, among these 547



(85%) were tested for HIV, 524 (96%) were negative, and were all screened for PrEP. 357 (68%) were initiated on PrEP. All 23 KPs that tested HIV positive were initiated on ART. Of the 609 KPs screened, 163 (27%) were diagnosed with STIs and 157 received treatment on site.

Conclusions/Next steps: The involvement of KPs in designing, planning, implementation, and monitoring of HIV services provision is important and can improve uptake and utilization of services. Peer-to-peer support is essential for identifying eligible clients, mobilizing for services, and supporting adherence and retention.

Sex workers

PESAD11

Effectiveness of a multifaceted intervention *(KUJA-KUJA)* to reduce violence and increase condom use in intimate partnerships among female sex workers: a randomized controlled trial in Nakivale Refugee settlement in Uganda

N. Nabulumba[1], J. Ssemanda[2], C. Kamwiine[1]

[1]ALIGHT, Protection, Nsingiro, Uganda, [2]University of Florida, Center for African/Latin American Studies, Gainesville, United States

Background: Intimate Partner Violence (IPV) is among the prevalent problems among sex workers in Nakivale settlement. Evidence suggests that about 41% of sex workers have experienced IPV during Covid-19 lockdown. The high rate of participation in sex work in the settlement is associated with poverty, alcoholism, explore for better shelter and misuse of drugs.

However, the effectiveness of the present interventions to reduce IPV among sex workers isn't well streamlined. "Kuja-kuja" a multifaceted intervention, working with sex workers, their intimate partners (IPs) and communities could help reduce IPV and increase condom use among sex workers and refugees in Nakivale settlement.

Methods: A total of 36 villages (most sex workers) and 2 towns were visited in a two arm cluster randomized control study in Nakivale refugee settlement. 15 villages and 1 town were randomized to Kuja-kuja intervention while the remaining on a wait-list control. Female sex workers above 20 years with IPs in the last 4 months were interviewed and participated in both surveys from Dec 2019 to August 2021. A baseline survey was given 6 months after which an end line surveys was conducted in all villages and towns to assess the effectiveness of "Kuja-kuja" intervention.

Results: With a baseline (n=410) imbalance was observed with reference to age (32.8 vs 34.1) and IPV (32.6% vs 46.1%), study results indicate no differences in physical/sexual IPV (7.1% vs 8.2%), severe physical/sexual IPV (5.8% vs 7.4%) and consistent condom use with IPs (62.5% vs 57.3%) by trial arm at end line (n=257).

Kuja-kuja was connected with reduced acceptance of IPV (adjusted OR (AOR)=0.62, 95% CI 0.40 to 0.94, p=0.025) and solidarity of sex workers around issues of IPV (AOR=1.69, 95% CI=1.02–2.82, p=0.042).

We observed a rise in IPV between baseline (25.9%) and midline (63.5%) among women in Kuja-kuja villages but lower in parallel villages (41.8%–44.3%) and a sharp decrease at end line in both arms (~8%).

Conclusions: The kuja-kuja had a significant effect on both increasing awareness of self-protection strategies and solidarity around IPV among sex workers within the kuja-kuja villages. However, we found insignificant evidence that the proposed intervention increased condom use.

Other populations vulnerable in specific contexts

PESAD13

What are the practices of people attending erotica shows in terms of psychoactive substance use, sexual behavior and HIV testing?

M. Chollier[1], P. Enel[2], M. Bonierbale[3], A. Maquigneau[1], T. Korchia[1], R. De Wever[2]

[1]Aix Marseille University, Psychiatry Dept, CRIR-AVS Paca, Sainte-Marguerite Hospital, Marseille, France, [2]Aix Marseille University, Public Health Dept, COREVIH POC, Marseille, France, [3]Aix Marseille University, Psychiatry Dept, AIUS, Marseille, France

Background: Our action-research aimed to achieve a specific key-population estimated vulnerable to HIV-risk transmission, as people attending Erotic industry shows (ES).

While ES seem appropriate events to raise awareness and survey people potentially with an interest for sex, there is little recent data on screening practices, risk perception and lifestyle behaviors in this population.

Methods: A cross-sectional study was conducted in ES in Dec. 2017 to document substance uses, sexual behaviours, and HIV-screening practices. The intervention was designed as a detached outreach one, with a stand provided information and guidance materials, and an anonymous questionnaire wich investigated knowledge about HIV, HCV and STIs screening history, substance use, sexual behavior and attraction.

Results: Overall,781 respondents, 58% male, mean age 34 years, completed the survey. 18% reported substance use in the last 3 months, 51% with alcohol. Among them, 26% reported sexual purposes to substance use: disinhibition (14%), conditioning (13%) and feeling better (11%).

Main sexual partners were: spouse (68%), regular (21%), unknown (18%) and multi-partners (17%).The 3 main sexual practices were: libertinism (22%), partner-swapping (15%) and threesome (15%). 27% of respondents reported

contactless sexual behaviors: BDSM (13%), voyeurism (10%) and exhibitionism (10%). At last 18% of the respondents reported no previous HIV-test.
In univariate analysis the lack of previous HIV-test was significantly associated ($p<0.05$) with gender, alcohol use, number of drugs, same-sex attraction, sexual partnership with spouse and multiple partner practice. On logistic regression analysis, the independent predictors of the lack of previous HIV-test in men were: alcohol (OR: 1.79), same-sex attraction (OR: 0.13), sexual partnership with spouse (OR: 0.47), and multiple partners practice (OR: 0.60);in women: same-sex attraction (OR: 8.74), sexual context of drug use (OR: 3.07), number of drugs (OR: 0.66).
Conclusions: This innovative intervention explored testing practices, sexual behaviors, substance use and sexual motives for substance use in an audience that was interested in sex but far from perceiving HIV risks.
It highlighted the usefulness of HIV education and testing interventions in fun events context such as ES, and the receptivity of participants to reflect on their risk behaviors. This intervention model is intended to complement existing HIV-testing services.

PESAD14
Perspectives of migrant people living with HIV on multidisciplinary HIV care: a call for greater patient-empowerment and formalized community-engagement

A. Arora[1,2], S. Vicente[2,3], A. Rodriguez-Cruz[1,2], K. Engler[2], N. Kronfli[2,4], J.-P. Routy[4], M. Klein[4], J. Cox[4], A. de Pokomandy[1,4], G. Sebastiani[4], B. Lemire[5], R. Wittmer[6], I. Vedel[1], A. Quesnel-Vallée[7,8], B. Lebouché[1,2,4]
[1]McGill University, Family Medicine, Montréal, Canada, [2]Research Institute of the McGill University Health Centre, Centre for Outcomes Research & Evaluation, Montréal, Canada, [3]Université de Montréal, Mathematics and Statistics, Montréal, Canada, [4]McGill University Health Centre, Chronic Viral Illness Service, Division of Infectious Diseases, Montréal, Canada, [5]McGill University Health Centre, Pharmacy, Montréal, Canada, [6]Université de Montréal, Family Medicine and Emergency Medicine, Montréal, Canada, [7]McGill University, Epidemiology, Biostatistics and Occupational Health, Montréal, Canada, [8]McGill University, Sociology, Montréal, Canada

Background: Multidisciplinary models can facilitate care and treatment engagement for migrants living with HIV (MLWH). However, the perspectives of MLWH around such models have rarely been explored. Our objective was to understand how MLWH experience multidisciplinary HIV care models and their suggestions for improving care.
Methods: In January 2020, we initiated a 96-week prospective longitudinal cohort study with a convergent mixed-method design at a hospital-based clinic serving the largest proportion of MLWH in Montreal, Quebec. Currently, 26 patients have been enrolled. All patients received bictegravir/emtricitabine/tenofovir alafenamide for free and were provided care by a multidisciplinary team composed of physicians, nurses, social workers, and pharmacists. Preliminary qualitative data are presented here. Eighteen interviews were conducted with 10 MLWH at two time-points (10 after 1 week of starting treatment and 8 after 24 weeks) and were analyzed via thematic analysis.
Results: Three themes were identified:
1. *Multidisciplinary care enables holistic, humanizing, and personalized care* – MLWH expressed that their needs extend beyond HIV treatment dispensation and that the different clinicians, together, were able to address their complex bio-psycho-social needs;
2. *Multidisciplinary models need to optimize communication, coordination, and empowerment* – MLWH suggested that multidisciplinary teams are only useful when
a. Consistent and regular contact is maintained between patients and clinicians,
b. All team members are aware of each other's responsibilities, and
c. Clinicians seek to educate MLWH about their HIV and engage them in decision-making; and
3. *HIV care extends beyond multidisciplinary teams and requires a transition to community-engaged models to better address patient needs*– MLWH explained that they navigate various clinics and services across their HIV care trajectory for various reasons (e.g., free and anonymous blood tests from certain clinics and social support from community groups), and that these services should be better integrated to ensure efficient care coordination.
Conclusions: Multidisciplinary care settings can address the needs of MLWH, particularly through the availability of complimentary care. Improved multidisciplinary care for MLWH could result through optimizing communication, coordination, and empowerment. Furthermore, such care models must evolve to incorporate communities and allied services to better meet the needs of this growing and often vulnerable population.

PESAD15
Perceptions of healthcare accessibility and medical mistrust among African American women living with HIV in the United States

L. Small[1], S. Godoy[2], C. Lau[1]
[1]University of California, Social Welfare, Los Angeles, United States, [2]University of North Carolina at Chapel Hill, School of Social Work, Chapel Hill, United States

Background: African American women living with HIV frequently endure structural racism, racial biases, and discrimination in healthcare systems that affect their access to care. The present study sought to explore the lived experiences of these women in healthcare settings as it relates to HIV-treatment accessibility and medical mistrust.
Methods: Four focus groups were conducted with seropositive African American women *(N =20)* residing in a large urban region. Participants were asked about their experiences with healthcare providers including:

a. Their relationship with healthcare providers;
b. Accessibility of community-based medical and mental health services; and
c. Experiences while attending HIV-treatment appointments.
Utilizing Dedoose software, interviews were transcribed and coded for themes using analytic induction techniques.
Results: Analyses revealed four interrelated themes:
1. Multilevel stigma and discrimination;
2. Mmedical mistrust of multiple providers;
3. Mixed responses to stigma, discrimination, and medical mistrust; and
4. Preferences for patient-provider relationship.
Participants expressed that medical providers and staff perpetuated negative treatment that included multiple forms of discrimination and stigmatization based on their HIV/AIDS status and social identities. In particular, our participants perceived that their negative experiences were connected to their HIV/AIDS diagnosis, race, class, and gender. Participants described ways their mistrust moved beyond their primary doctors to include nurses, medical staff, and pharmaceutical staff. The stigma, discrimination and resulting mistrust that they experienced often resulted in hurt feelings and decisions to disengage from treatment or remain with providers while feeling unwelcome. Participants described their desire to feel seen, supported and validated by their entire team of care providers.
Conclusions: This study provides insight about the myriad of challenges Black women living with HIV/AIDS face when navigating the healthcare system. Narratives reveal that feelings of being discriminated against or minimized can cultivate mistrust not only towards primary physicians, but across various healthcare providers and staff.
Findings from this study can inform care models for low-income African American women living with HIV/AIDS. Specifically, medical education and healthcare trainings should include the stories and perspectives of marginalized communities, including seropositive African American women, in an effort to actively work against negative effects due to stigma and discrimination.

PESAD16
Villains to superheroes: supporting adolescents and young people living with HIV through a social media-based psychosocial support intervention

V. Munatsi[1]
[1]*University of Cape Town, Sociology, Cape Town, South Africa*

Background: Sexually transmitted diseases cause shame. Therefore, having HIV is shameful and results in a spoiled identity, vilification, self- loathing and stigma. Although shame can be experienced by all people with HIV, its impact is greater on adolescents, young people and key populations.
For these sub groups, shame and HIV infection are developmental traumas that affect mental health, identity formation, self-esteem, worth and confidence. They cause hiding, isolation, secrecy, poor health seeking behaviour and adherence which is slow suicide.
Description: Positive Konnections (PK) is a mobile application with a mental health intervention for young people with HIV, designed to counter the effects of shame and help them access services privately and anonymously. From October 2020 to December 2021, 100 young people with HIV, 18 -28 years of age, (60% females) signed up to use the intervention. They engaged with 10 chapters of stories designed to help them discover their true identity, value and self -worth. In each chapter, a short video clip was taken from a movie where a super hero was facing a situation.
The video was accompanied by a short story that demonstrated how the situations the super heroes were facing were similar to experiences of having HIV. After watching the videos and reading the stories, participants were asked to reflect on how the stories relate to their lives. This was done in the PK Work Book, a personal reflective space were participants expressed their thoughts or feelings which they discussed with a counsellor. Participants also interacted with others in weekly group sessions.
https://play.google.com/store/apps/details?id=com.health.positive_konnections&hl=nl&gl=US
Lessons learned: Process evaluation suggests that showing young people that their experiences of living with HIV are similar to those of superheroes helped them to reframe negative self or social perceptions and see themselves in a positive light, increasing self-worth, love and acceptance.
Reframing helped them see their true identity, re-write the narrative of their lives mentally shifting from villains to superheroes. A reduction in shame increased openness to disclose, health seeking behaviour, mental health and adherence to medication.
Conclusions/Next steps: Various packages of the intervention are being developed or strengthened to scale up to more people including key populations

Community mobilization and demand creation

PESAD17

Intensifying community testing strategies to achieve improved case identification in the context of COVID-19: lessons from Eastern Uganda

O. Apok[1], C. Cheptoris[1], E. Serioni[1], I. Mirembe[1], J. Nakazzi[1], T. Ijjagason[1], A. Mugabe[1], D. Wamboya[1], D. Ako-Arrey[1]
[1]*IntraHealth International/USAID RHITES-E Activity, Mbale, Uganda*

Background: UNAIDS' Fast-Track strategy focuses on enhanced HIV case finding toward accelerating the end of AIDS by 2030. WHO echoes that without deliberate follow-up interventions, less than 90% of identified positives get linked into care, while retention decreases among those linked to less than 70% in the first six months of care.

In Kapchorwa district in Eastern Uganda, where HIV prevalence is 4.8%, myths and misconceptions surrounding COVID-19, as well as fear of acquiring COVID-19, directly impacted access to and uptake of health services, including HIV testing and treatment. DHIS2 data in March 2021, at the height of the pandemic, indicated that HIV case identification and linkage to care had fallen off significantly compared to pre-pandemic outcomes.

Description: To improve HIV case identification using a community model, the USAID RHITES-E Activity, led by IntraHealth International, engaged HIV ART clinic staff to intensively search for positive clients via targeted testing and linkage to ART.

Approaches included active follow-up of enlisted clients from assisted partner notification/index line lists and targeted community/home testing in known high HIV burden villages. In addition, home-based counseling was provided to address COVID-19 myths/misconceptions that hindered accessibility and utilization of health facility services. Virtual tools were adapted to improve reporting.

Lessons learned: The team quickly adapted to the COVID-19 pandemic to safely deliver quality services using personal protective equipment and virtual tools. DHIS2 data comparison on entry point of all new positives (see figure) shows a steady increase from 56% in the last quarter of 2020 to 88% by September 2021.

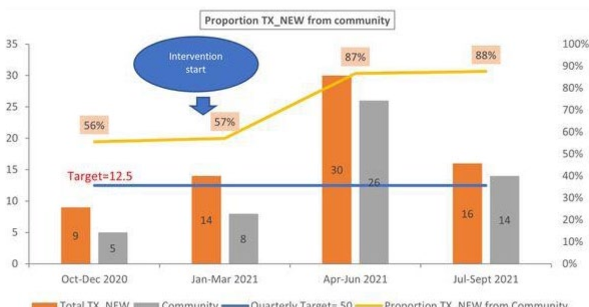


Figure.

Conclusions/Next steps: Deliberate integrated community engagement during the pandemic improved continuity of health services in this setting and can be duplicated in similar settings.

PESAD18

Engaging PrEP Champions to improve uptake and continuation on PrEP among AGYW in the DREAMS Program in Matabeleland North Province, Zimbabwe

P. Moyo[1], E. Molande[1], J. Murungu[1], I. Mahaka[1], S. Nyakuwa[1], J. Ncube[1], P. Ndlovu[1], A. Musonza[1], S. Ruzibe[1], B. Chingombe[2], A. Muchara[3], R. Mundingi[3], R. Mashapa[3], A.K. Korn[4], G. Gonese[3], T. Mharadze[5], S. Wallach[6], R. Malaba[5], B. Makunike[3], S. Wiktor[4]
[1]*Pangaea Zimbabwe AIDS Trust, Harare, Zimbabwe,* [2]*Ministry of Health and Child Care, Harare, Zimbabwe,* [3]*Zimbabwe Technical Assistance, Training & Education Center for Health, Harare, Zimbabwe,* [4]*International Training and Education Center for Health, University of Washington, Seattle, United States,* [5]*Division of Global HIV & TB, U.S. Centers for Disease Control and Prevention, Harare, Zimbabwe,* [6]*Public Health Institute (PHI)/U.S. Centers for Disease Control and Prevention (CDC) Global Health Fellowship, Harare, Zimbabwe*

Background: Oral pre-exposure prophylaxis (PrEP) implemented as part of combination prevention reduces the risk of HIV infection by 99%. The level of protection provided by PrEP depends on adherence. Pangaea Zimbabwe AIDS Trust (PZAT) supports the delivery of PrEP as part of the Determined, Resilient, Empowered, AIDS-Free, Mentored and Safe (DREAMS) program aiming to reduce new HIV infections among adolescent girls and young women (AGYW) aged 15-24 years. PrEP interventions for AGYW include monitoring PrEP uptake, continuation, and psychosocial support.

Description: Starting January 2021, PZAT engaged 16 AGYW (mean age 23 years) as PrEP Champions (PCs) in Matabeleland North province and trained them on effective engagement of AGYW using a standard Ambassador Toolkit developed by the Optimizing Prevention Technology Introduction on Schedule project to provide peer-to-peer support, mobilization, education, and linkage to PrEP. PCs supported effective use and continuation on PrEP through telephone calls, text messages and in-person follow up. Community dialogues with AGYW were conducted around catchment areas of the 16 supported health facilities and PrEP support groups were formed. Feedback from AGYW was used to address gaps and improve programming. Data were captured and reported using DHIS2 through supported facilities.

Lessons learned: The proportion of newly initiated AGYW continuing on PrEP at month 1 increased from 40% in November 2020 to a peak of 91% in July 2021. A temporary PrEP stock-out affected performance in August 2021.

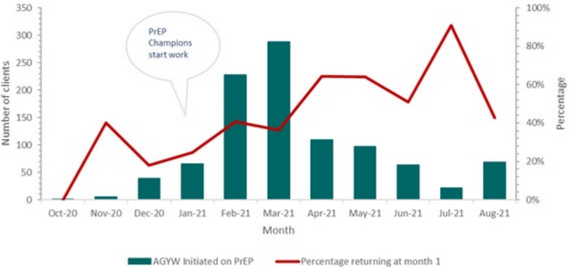

Figure. PrEP initiations and continuation at month 1

Conclusions/Next steps: PCs were cited in community dialogues as sources of accurate information that led to an increase in knowledge and linkage to PrEP services for AGYW. Coordination between the health care workers and PrEP Champions resulted in joint defaulter tracking. Peer-to-peer support through interpersonal and mobile platforms leads to successful awareness raising, improved uptake and continuation on PrEP. Collection of long-term continuation data in future promotes further analysis of the impact of PCs.

PESAD19

The race to end AIDS and COVID-19: how edutainment and a rallying call to run for a cause boosted HIV prevention and COVID-19 vaccination uptake in Zambia

B. Simpasa[1], M.N.J.MN.S.H. M. Chikuba-McLeod,[1], K.P. M. Bwembya,[2], M. Musonda[3]
[1]*JSI Research & Training Institute, Inc., Lusaka, Zambia,* [2]*John Snow Health Zambia (JSH), Lusaka, Zambia,* [3]*United States Agency for International Development (USAID)/ Zambia Mission, Lusaka, Zambia*

Background: In Zambia, Adolescent Girls and Young Women AGYW (15-24 years) and men (20-34 years) are among the most vulnerable groups to HIV infection (ZAMPHIA 2019). In addition, COVID-19 has negatively affected access to HIV testing and treatment services (MOH COVID-19 Media Briefing, Jan 2022).

In response to this, the USAID ZAM-Health and USAID DISCOVER-Health Projects, in collaboration with the Ministry of Health (MOH) and National AIDS Council (NAC), designed a #Run2EndAIDS#Run4COVIDVaccination event to promote COVID-19 and HIV service uptake, primarily targeting these groups.

Description: Over a 14-day period between October and November 2021, the #Run2EndAIDS#Run4COVIDVaccination event attracted 7,457 runners from Zambia and 5 other countries, who collectively covered 74,410 kilometers.

The event far surpassed the target of 2,000 runners. Runners took photos on their routes of health facilities that provide HIV and COVID-19 vaccination services to raise awareness about their location and submitted them with their run data.

During the event, healthcare providers distributed 22,027 condoms, vaccinated 680 against COVID-19, tested 775 for HIV, initiated 193 on PrEP, and distributed 1,500 PrEP factsheets. The Zambia Ending AIDS Facebook page recorded 1,945,425 impressions, and 64,553 people were actively engaged. The event culminated in a live-streamed 'Virtual Fest', bringing music and messaging together; the momentum continued with the artists and other participants continuing to champion COVID-19 vaccination and HIV prevention.

Lessons learned: Targeted edutainment events appeal to both young and old, and effectively rally target audiences around a cause, providing correct HIV prevention and COVID-19 vaccine information and increasing knowledge levels and numbers accessing services. It is, however, crucial to harness the momentum for ongoing activism. A website or mobile app is recommended for ease of registration, to capture run-data in real-time, and to provide targeted messaging/engagement, for events that might attract a similarly overwhelming response.

Conclusions/Next steps: The #Run2EndAIDS #Run4COVID-19Vaccination event empowered primarily young people, but also others, to make smart and safe choices about COVID-19 and take control of their physical, mental and sexual health. It created a group of HIV and COVID-19 prevention champions who continue to champion these causes.

PESAD20

Does normalizing sexual conversations increase HIV prevention demand in young women aged 20-24 years? Lessons from the *Mo'ghel, Get Your Life Pack* campaign in five South African districts

Z. Penzhorn[1], S. Stafford[1], M. Kelly[1], C. Wendler[1], R. Makiwa[1], A. Machinda[1]
[1]*Shout-It-Now, Cape Town, South Africa*

Background: Shout-It-Now (Shout), a PEPFAR/DREAMS partner in South Africa, experienced difficulties mobilizing young women aged 20-24 years to access community-based HIV prevention services during the country's first two COVID-19 waves between May 2020-May 2021. During the third wave, Shout engaged clients, staff and a creative/media partner to develop a demand creation campaign that tapped into young women's desire to move forward in their lives and relationships after feeling stalled by COVID-19 lockdowns.

Description: Using human-centered design principles, Shout engaged clients and staff to provide input on messaging and service journey mapping. Informed by this, Shout's *Mo'ghel, Get Your Life Pack* campaign featured an aspirational value proposition: a free pack of youth-friendly services that improve young women's lives and relationships.

Campaign promotion hinged on sexual conversations in a youthful but trustworthy vernacular using print media, targeted radio broadcasts/podcasts and social media via igniters and Shout's platforms. Shout also improved staff engagements with young women about HIV pre-

vention through a training video and IEC materials that facilitated organic sexual health conversations. The campaign was implemented August 12-October 8, 2021 in five districts.

Lessons learned: Clients and staff valued contributing to the campaign design, and their input was instrumental to the core message. Shout surveyed clients during the 6-week campaign to assess its impact on HIV prevention uptake. A combined 2,854 of the total 3,499 (82%) clients served reported they heard of the campaign, including 2,697 females of whom 1,368 (51%) were aged 20-24 years. A comparison of service data among females aged 20-24 years between the six weeks leading up to the campaign and the six weeks of the campaign found a 668% increase in HIV testing and a 44% increase in PrEP initiations.

Analysis of the engagement channels found the podcasts and one radio promoter were most effective at mobilizing young women.

Conclusions/Next steps: Increased uptake of HIV prevention services among young women during the campaign shows that promoting empowerment and normalizing sexual health conversations can lead to HIV prevention seeking behaviors among a highly vulnerable population. This approach is now used to design all Shout communications and is easily replicable.

PESAD21

Fake porn videos helped save real lives - creative approaches to increase demand in Ukraine in the context of the HIV epidemic

L. Gavrysh[1]

[1]*All-Ukrainian Network of People Living with HIV, HealthLink Project, Kyiv, Ukraine*

Background: Ukraine is the second-fastest HIV-spreading country in Europe and Central Asia. HealthLink project is aimed at HIV case-finding in Ukraine through testing populations at risk of HIV. In Ukraine 257000 people live with HIV, 30% among them don't know their HIV-status and one of the largest key risk groups is MSM (near 179400 people). Almost 90% of HIV testing within the project is implemented in healthcare facilities.

A project's study indicated that men are the priority group for HIV testing and detection, but are less likely to visit the doctors than women. The uptake of HIV testing is especially low among MSM who widely experience stigmatization in the Ukrainian context.

Description: HealthLink project set a goal to inform MSM about the option to order the oral HIV self-tests online completely confidential. Porn sites are those digital places where people seek for anonymity and which are extremely popular at the same time. For the second year in a row, Ukraine is in the top 20 countries in which the PornHub site is used the most.

We created 4 high-quality videos, which had one detail making them different from most porn site content. There was no sex. Different scenes with real actors and dialogues, but always with the same message — a passionate relationship must be followed by a test which is easy to order. The videos have been uploaded on PornHub and more than 20 famous gay category resources.

Lessons learned: For 3 month of campaign in 2020: total reach of 85000 people had a positive effect on the level of knowledge about HIV testing. 9000 clicks were received. The level of clickability reached 3.35%, indicating that the advertising visual was interesting to the audience. More than 700 self-tests were ordered online.

Conclusions/Next steps: Crucial aspect of motivation for HIV testing is meeting the need for protection and staying confidential, therefore it's important to emphasize that testing is confidential, completely safe, fast and easy. The information space is so full of content that it is important to be bold and choose communication channels, messages and visuals that will definitely attract the attention of the target audience.

Comprehensive sexuality education

PESAD23

Awareness and acceptability of undetectable=untransmittable among a national sample of HIV-negative young adults in Nigeria

K. Nworie[1,2], U. Agbom[1,2], E. Duru[1,2], U. Eze[1,2], D. Aluh[3], A. Aliu[2], A. Ezeh[4], S. Abah[2], C. Onyekwum[2], S. David[1]

[1]*University of Nigeria, Pharmaceutical Outcomes Research Group, Nsukka, Nigeria,* [2]*YOUALIVE AIDS, Enugu, Nigeria,* [3]*Nova Medical School, Universidade Nova de Lisboa, Institute of Global Mental Health, Lisbon, Portugal,* [4]*Taraba State Specialist Hospital, Department of Family Medicine, Jalingo, Nigeria*

Background: Despite widespread support for the U=U statement as an empowering initiative aimed at raising awareness about treatment as prevention (TasP) and ending stigma towards PLWH, information about its reach and impact in developing countries is sparse.

In our study, we described the socio-demographic characteristics and sexual behaviors that are associated with awareness of and trusting U=U in a Nigerian national sample of HIV-negative participants.

Methods: Cross-sectional cohort analysis of an internet-based survey of HIV-negative young adults in Nigeria (n = 1,016) between February and September 2021. Measures included socio-demographics, sexual behaviors, and awareness of and trust in U=U. Descriptive statistics and multivariable logistic regression were used to identify the characteristics associated with awareness of and trust in U=U, as well as patterns of willingness to engage in condomless sex based on trust in U=U.

Results: The participants' mean age was 26.94±4.68 years. Of the participants, 52.1% of participants reported having heard of U=U. Among those who were aware of

U=U, 51.0% reported they trusted it, 20.4% did not trust it, and 28.5% were unsure. Gender identity, sexual orientation, and having tested for HIV in the last 6 months were significantly associated with being aware of U=U. Non-gay participants were 2 times more likely to be aware of the U=U message (OR =2.99; 95% CI: 1.08-8.25) than gay participants.

Similarly, gender identity, sexual orientation, and having tested for HIV in the last 6 months were significantly associated with trust in U=U. No significant differences were observed by age, level of education, geographic region, or recent condomless sex in the study.

Overall, participants were more likely to engage in condomless sex with HIV-negative partners than with HIV-positive partners. However, willingness to engage in condomless sex with an HIV-positive but undetectable partner was associated with trust in U=U.

Conclusions: Although we observed moderate U=U awareness and trust in this cohort, crucial populations and minorities are still unaware and distrustful of the U=U message. This study will serve as a basis for further elaborate studies and to develop community-based health education and awareness initiatives regarding U=U in Nigeria.

People who inject drugs

PESAD24

Differences in drug use and HIV stigma among people who inject drugs in Kyrgyzstan

S. Yeager[1], N. Shumskaya[2], A. Kurmanalieva[2], A. Blyum[1], T.L. Patterson[1], D. Werb[3,1], J. Cepeda[4], L.R. Smith[1]
[1]University of California San Diego, San Diego, United States, [2]AIDS Foundation East-West, Bishkek, Kyrgyzstan, [3]University of Toronto, Toronto, Canada, [4]Johns Hopkins, Baltimore, United States

Background: The Eastern Europe and Central Asia (EECA) region has the highest annual rate of HIV infections worldwide, primarily concentrated among people who inject drugs (PWID). In Kyrgyzstan, where stigma appears to be reducing syringe service program (SSP) access, approximately 51% of people living with HIV are PWID. We aimed to characterize differences in drug use and HIV stigma by SSP access.

We hypothesized that PWID who did not report recent (i.e., past 6 month) SSP access would have higher mean levels of structural and internalized drug use (DU) and HIV stigma, but lower mean levels of anticipated DU and HIV stigma compared to those with recent SSP access.

Methods: A cohort of 279 PWID were recruited via community-based HIV service agencies and word of mouth in the Kyrgyzstan capital city of Bishkek and surrounding rural Chuy region. Participants completed DU and HIV stigma measures that included structural, anticipated, and internalized stigma subscales (1=low stigma, 5=high stigma). Anticipated stigma items distinguished between three stigma sources (e.g., healthcare workers, family, other PWID). Internalized HIV stigma was only assessed among PWID who reported living with HIV at baseline (n=57). Chi-square and t-tests were used to assess group differences by SSP utilization.

Results: Participants were primarily male (75.3%) with a median age of 40 years. Compared to PWID that did not recently access SSP, those that did access SSP had a higher prevalence of public injection (16.2% vs. 5.3%, p=.018) and a lower prevalence of sharing syringes and equipment (14.2% vs. 22.7%, p=.092). Compared to PWID that did not access SSP, those that did access SSP had significantly higher internalized DU stigma (M=3.52 vs. M=3.04, p<0.001) and anticipated DU stigma from family (M=3.28 vs. M=2.89, p=0.020). Compared to PWID without SSP access, those that did access SSP had significantly greater anticipated HIV stigma from other PWID (M=3.52 vs. M=3.20, p=0.005) and internalized HIV stigma (M=2.88 vs. M=1.83, p=0.004).

Conclusions: DU and HIV stigma levels are high, but significantly higher among PWID with recent SSP access, whose drug use is more publicly visible, than PWID without recent SSP access who remain at higher risk for HIV transmission.

Implementation science of scaling up prevention (including PrEP)

PESAE01

At risk in the emergency department: can the electronic health record identify patients with indications for PrEP?

L. Walter[1], N. Carlisle[2], J. Rodgers[1], J. Booth[1], S. Heath[2]
[1]University of Alabama at Birmingham, Emergency Medicine, Birmingham, United States, [2]University of Alabama at Birmingham, Internal Medicine, Birmingham, United States

Background: Persons newly diagnosed with HIV often had previous, recent contact with healthcare, including emergency departments (EDs). While EDs have become vital partners in screening and linkage to care for persons living with HIV, ED engagement in HIV prevention efforts, to include risk assessment and pre-exposure prophylaxis (PrEP) referral, are rare. We sought to assess the proportion of patients presenting to the ED with HIV risk factors and PrEP indications.

Methods: In an ED with a preexisting universal HIV screening program, a retrospective electronic health record (EHR) query was performed for all patients who screened negative for HIV in 2019-2020. Objective laboratory evidence of sexually transmitted infection (chlamydia, syphilis, gonorrhea, and/or trichomoniasis) at the time of ED

visit or within six months prior was utilized to assess risk of HIV acquisition through sexual behavior. Urine drug screen positive for commonly injected substances at the time of ED visit or within twelve months prior, was utilized to assess risk of HIV acquisition through injection drug use practices. Descriptive and chi-square analyses were performed.

Results: 26,914 ED patients screened negative for HIV during the study timeframe. Of these, 1,403 (5.2%) were found to have one or more potential HIV risk factors and PrEP indications; 304 (21.7%) had a sexual behavior risk identified and 1,111 (79.2%) had an injection drug use risk identified; of note, 12 (0.9%) had both. Median age was 40; the majority (58.2%) were male and white/non-Hispanic (50.8%), followed by Black/non-Hispanic (43.5%). Injection drug use as a risk factor represented a significant proportion as compared to the general population (79.2% versus 9.3% nationally; $p<.0001$).

In consideration of sexual behavior as a risk factor, women in this study represented a significant proportion as compared to national estimates (62.2% versus 41.9%; $p<.0001$). During the study period, 52 ED patients were newly diagnosed with HIV; retrospective application of 'EHR query' approach successfully identified 29% of this cohort.

Conclusions: In addition to screening, EDs may represent an opportune setting for HIV risk assessment and PrEP referral. Given time constraints and competing demands inherent to EDs, an objective EHR approach represents a low resource option for risk factor identification.

PESAE02

The fidelity of a pharmacy-based PrEP delivery model in Kenya: an unannounced standardized patient actor assessment

V. Omollo[1], M. Asewe[1], P. Mogere[2], G. Maina[2], A. Kuo[3], J. Odoyo[1], J. M. Baeten[4,5,6,7], T. Owens[8], E. Anne Bukusi[9,6,10], K. Ngure[11], K. F. Ortblad[12], P. Kohler[5,13]

[1]Kenya Medical Research Institute, Kisumu, Kenya, [2]Partners in Health and Research Development, Thika, Kenya, [3]University of Washington, Department of Pharmacy, Seatle, United States, [4]Gilead Sciences, Foster City, United States, [5]University of Washington, Department of Global Health, Seattle, United States, [6]University of Washington, Department of Epidemiology, Seattle, United States, [7]University of Washington, Department of Medicine, Seattle, United States, [8]Howard University, Washington, DC, United States, [9]Kenya Medical Research Institute, Centre for Microbiology Research, Nairobi, Kenya, [10]University of Washington, Department of Obstetrics and Gynecology, United States, [11]Jomo Kenyatta University of Agriculture and Technology, Department of Community Health, Nairobi, Kenya, [12]Fred Hutchinson Cancer Research Center, Public Health Sciences Division, Seattle, United States, [13]University of Washington, Department of Nursing, Seattle, United States

Background: The delivery of HIV PrEP at private pharmacies is a promising new model that may address barriers to clinic-based delivery. In Kenya, a pilot study testing this new model found it reached populations at HIV risk and had comparable PrEP continuation to clinic-based PrEP delivery models. We used unannounced standardized patient (USP) visits to measure the fidelity of pharmacy PrEP delivery in a pilot study.

Methods: Five retail pharmacies were purposefully selected to participate in the pilot. Following a two-day training, pharmacy providers delivered counseling on HIV risk and PrEP safety, provider-assisted HIV self-testing, and PrEP to eligible clients as per the Kenya national guidelines. We trained eight USPs and asked them to visit each pharmacy acting the following cases:

1. A young woman seeking emergency contraception,
2. A young woman who fears HIV testing,
3. A young man who has sex with men seeking treatment for a sexually transmitted infection, and;
4. A young man seeking sexual performance enhancement drugs.

After each visit, the USP actors completed a 40-item checklist that assessed PrEP promotion, behavioral risk assessment, counseling, medical safety assessment, HIV testing, PrEP dispensing, and service quality at the pharmacy. We descriptively analyzed our data.

Results: From February 2021 to August 2021, eight USPs completed 15 pharmacy PrEP visits. At these visits, 60% (9/15) of the USP were asked about their interest in PrEP and 80% (12/15) about behaviors associated with HIV risk. All USP actors (100%, 15/15) reported being counseled

on PrEP safety and side effects and most (87%, 13/15) on the PrEP efficacy Almost all USP actors (87%, 13/15) were assessed for a history of kidney or liver disease and all (100%, 15/15) received assisted HIVST and PrEP in a private room during the visits. Of the USPs, 60%(9/15) agreed and 40%(6/15) strongly agreed that the quality of service at their visits was as expected.

Conclusions: The fidelity of PrEP delivery at private pharmacies in the pilot study was high, as assessed by USP actors. This suggests pharmacy providers can deliver high-quality PrEP services supporting possible scale up of pharmacy-based PrEP delivery models in Kenya and similar settings.

PESAE03

Community preparedness to embrace new biomedical HIV prevention technologies. CHEDRA's experience with the Dapivirine vaginal ring and Female Sex Workers (FSWs) amidst a volatile atmosphere in Masaka, Uganda

M. Kigozi[1], N. Georgina[2]
[1]CHEDRA (Community Health Empowerment Development and Relief Agency), Research and Advocacy, Masaka, Uganda, [2]CHEDRA (Community Health Empowerment Development and Relief Agency), Health Education and Community Mobilization, Masaka, Uganda

Background: In Uganda, HIV prevalence is high among FSWs (37%) and their partners (18%). The brutal law against sex work creates institutional obstacles in accessing HIV prevention services for FSWs. Since 2015 todate, the International Partnership for Microbicides supports CHEDRA (Community Health, Empowerment, Development and Relief Agency) introduced the Dapivirine Vaginal Ring among FSWs within fishing communities to assess preparedness towards uptake of new Biomedical HIV prevention technologies.

Description: We popularized the Dapivirine Ring among key populations.'Bar to Bar', 'With the Brothel' and 'Personalized HTS', strategies were developed to intensify advocacy and awareness raising for the Dapivirine Ringas well as assessment for uptake and acceptance preparedness. Permission to operate from within brothels was obtained from owners, Trained front line staff used a snowball approach to penetrate FSWs networks, demonstration on how to use the vaginal ring, personalized HTS, STI management, Counseling, condom and contraceptive distribution was done within brothels. 314 FSWs were secretly mobilized, 154(49%) of them were between 14-22 years, others were above 23 years.283 (90%) of them received HTS, 108 (38%) of them were HIV positive. 65 (60%) enrolled in HIV care, all brothel owners yearned for our services. 100% of FSWs reported that the ring is the best HIV prevention option they had ever heard, those aged 26 and above showed much willingness to use it compared their younger counterparts, 100% of them desired to have a ring that would prevent both HIV and pregnancy.

Lessons learned: New biomedical HIV prevention strategies need to be tailor made to address gender specific imbalances in HIV prevention. 'Within the Brothel' and 'Personalized HCT, strategies proven highly effective in increasing HIV prevention services to FSWs, Communities need to be educated about a new HIV prevention option even before it becomes available for public consumption.

Conclusions/Next steps: HIV prevention programs urgently need to widen HIV prevention options. No one size its all.

PESAE16

Impact of a community health worker intervention on PrEP knowledge and utilization in Rakai, Uganda: a mixed methods assessment

A. Edwards[1], R. Pollard[1], C.E. Kennedy[1,2], G. Nakigozi[2], J. Mulamba[2], I. Mbabali[2], A. Anok[2], X. Kong[3,4,5], N. Nakyanjo[2], W. Ddaaki[2], H. Nishimura[1], M. Wawer[2,3,6], L.W. Chang[1,2,3,6]
[1]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States, [2]Rakai Health Sciences Program, Rakai, Uganda, [3]Johns Hopkins School of Medicine, Division of Infectious Diseases, Baltimore, United States, [4]Wilmer Eye Institute, Johns Hopkins School of Medicine, Baltimore, United States, [5]Johns Hopkins Bloomberg School of Public Health, Biostatistics, Baltimore, United States, [6]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States

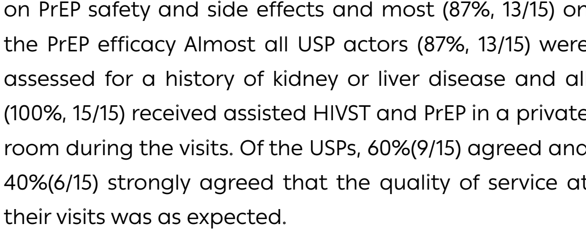
Background: Highly mobile individuals living in Ugandan fishing communities face increased HIV acquisition risk. From 2015-2018, the Rakai Health Sciences Program (RHSP) implemented a novel mHealth, motivational interviewing-informed counseling intervention led by community health workers (CHW) to improve uptake of HIV treatment and prevention services in an HIV hyperendemic fishing village.

Following introduction of PrEP in 2017, a PrEP counseling module was incorporated into the intervention to increase PrEP awareness and uptake. This mixed-methods study evaluated the intervention's impact on PrEP knowledge and utilization.

Methods: Survey data were collected from all available community members aged 15-49 through the Rakai Community Cohort Study. Multivariable logistic regressions with generalized estimating equations were used to estimate the effect of the CHW intervention on PrEP knowledge and use.

We also conducted 74 in-depth interviews with 5 types of informants: clients, CHWs, program staff, community leaders, and health clinic staff. Transcripts were analyzed using a deductive, iterative approach.

Findings were triangulated with programmatic data from an electronic mobile application used by CHWs during counseling visits.



Results: 1848 individuals were surveyed; 46% were female; mean age was 31.8 years (SD: 8.2). In as-treated analyses, individuals exposed to the CHW intervention reported significantly higher PrEP knowledge (N=1848, PRR: 1.10, 95% CI: 1.06-1.14, p= <.0001), lifetime PrEP use ((N=1176 (HIV-negative participants only) PRR: 1.77, 95% CI: 1.33-2.36, p= <.0001)), and current PrEP use (N=1176, PRR: 1.86, 95% CI: 1.22-2.82, p= 0.0039) compared to those unexposed. Qualitative data supported quantitative findings and attributed positive PrEP outcomes to CHW counseling and effective use of motivational interviewing skills by CHWs.

Barriers to PrEP uptake included misinformation about PrEP, HIV-related stigma, and pill burden. Mobile application data demonstrated that the PrEP module was delivered consistently by CHWs throughout the implementation period.

Conclusions: CHWs positively influenced PrEP knowledge, use, and retention among clients of a motivational-interviewing informed counseling intervention in an HIV hyperendemic fishing community. A mixed methods approach provided important insights to inform implementation of future PrEP programs. Findings suggest use of CHWs and motivational interviewing-informed counseling can be effective components of interventions to improve PrEP outcomes.

Implementation science of scaling up HIV testing

PESAE04

Optimising provider-initiated indicator condition guided testing for HIV to identify undiagnosed individuals: preliminary results of a multifaceted, multicentre intervention study

S. Bogers[1], M. Schim van der Loeff[1,2], U. Davidovich[2], A. Boyd[2,3], M. van der Valk[1,3], K. Brinkman[4], K. Sigaloff[1], J. Branger[5], N. Bokhizzou[6], G. de Bree[1], P. Reiss[1,3,7,8], J. van Bergen[9,10], S. Geerlings[1], on behalf of the HIV Transmission Elimination AMsterdam (H-TEAM) Consortium

[1]Amsterdam University Medical Centers, Department of Internal Medicine, Amsterdam, Netherlands, the, [2]Public Health Service of Amsterdam, Department of Infectious Diseases, Amsterdam, Netherlands, the, [3]HIV Monitoring Foundation, Amsterdam, Netherlands, the, [4]Onze Lieve Vrouwe Gasthuis, Department of Internal Medicine, Amsterdam, Netherlands, the, [5]Flevoziekenhuis, Department of Internal Medicine, Almere, Netherlands, the, [6]BovenIJ ziekenhuis, Department of Internal Medicine, Amsterdam, Netherlands, the, [7]Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands, the, [8]Amsterdam University Medical Centers, Department of Global Health, Amsterdam, Netherlands, the, [9]Amsterdam University Medical Centers, Department of General Practice, Amsterdam, Netherlands, the, [10]STI AIDS Netherlands, Amsterdam, Netherlands, the

Background: In the Netherlands, approximately 7% of people with HIV (PWH) remained undiagnosed in 2020. Indicator Condition (IC)-guided HIV testing is a cost-effective strategy to identify such undiagnosed individuals. We implemented a multicentre intervention study in hospitals in the Amsterdam region to increase provider-initiated IC-guided HIV testing.

Methods: Two university hospitals, two teaching hospitals, and one non-teaching hospital participated. Seven ICs were selected (Table 1).

Relevant departments participated in a multifaceted intervention from June-December 2020, including competitive audit and feedback and multimedia materials. Department-specific solutions such as guideline adaptation, implementation of order sets and reflex-testing varied by IC and hospital. HIV testing among patients ≥18 years not known to have HIV and presenting with an IC was assessed using electronic health records during pre-intervention (January 2015-May 2020) and post-intervention (June 2020-December 2021) periods. The primary endpoint was documentation of an HIV test ≤3 months around IC diagnosis. The difference in endpoints between periods was compared using logistic regression.

Results: Data from 8,017 patients were included. During the pre-intervention period, HIV testing varied widely, (range 0.7%-83.7%), and increased significantly in 4/7 ICs post-intervention, but not in the two ICs with the highest-

and the one with the lowest baseline testing (Table 1). Of 3,074 tested patients, 18 (0.6%) were HIV positive [4 (22%) female; median age 45 years (IQR=34-54)], exceeding the consensus cost-effectiveness threshold of 0.1%. Eight (44%) had tuberculosis, 7 (39%) malignant lymphoma, 2 (11%) hepatitis B and 1 (6%) hepatitis C. Median CD4 count at diagnosis was 97 cells/mm3 (IQR=50-130); 94% had CD4 <350 cells/mm3.

Indicator condition	Tested before intervention n/N (%)	Tested after intervention n/N (%)	OR	95% CI	aOR*	95% CI
Tuberculosis	312/373 (83.7%)	57/65 (87.7%)	1.39	0.63 - 3.07	1.61	0.69 - 3.80
cervical carcinoma/ intraepithelial neoplasia grade III	46/1065 (4.3%)	78/295 (26.4%)	7.96	5.38 - 11.79	14.30	9.04 - 22.62
vulvar carcinoma/ intraepithelial neoplasia grade III	2/279 (0.7%)	0/56 (0.0%)	2.06	0.00 - 26.67	0.72	0.00 - 10.76
Malignant lymphoma	993/1580 (62.9%)	316/398 (79.4%)	2.28	1.75 - 2.97	2.27	1.73 - 2.98
Hepatitis B virus	514/798 (64.4%)	84/112 (75.0%)	1.66	1.06 - 2.60	1.64	1.02 - 2.62
Hepatitis C virus	345/491 (70.3%)	54/75 (72.0%)	1.09	0.63 - 1.87	1.07	0.61 - 1.88
Peripheral neuropathy	217/2041 (10.6%)	56/389 (14.4%)	1.41	1.03 - 1.94	1.74	1.24 - 2.45
*Odds ratio adjusted for hospital and patients' sex, age category and socio-economic status						

Table 1: Patients tested for HIV ≤3 months around indicator condition diagnosis, by period before and after intervention

Conclusions: Overall HIV positivity underlined this testing strategy's cost-effectiveness to identify undiagnosed PWH. IC-guided testing improved in some, but not all ICs. Differences in intervention elements and observed effect by IC and hospital must be used for tailored, impactful strategies to optimise IC-guided HIV testing by setting.

PESAE05

Index testing approaches for early diagnosis of PLHIV and treatment initiation for HIV epidemic control

A. Enugu[1], P. Mugundu[1], A.R. Yeruva[1], A. Devanga[1], S. Chintala[1], J. Thakker[1], A. Singh[1], •. Aylur Kailasom[2], S. Ghosh[2], V. Arumugam[2], V.R. Munagala[2], R. Pollard[1], A. McFall[3], J. Bell[1], S. Mehta[3], S. Solomon[1]
[1]Johns Hopkins University, School of Medicine, Baltimore, United States, [2]YR Gaitonde Centre for AIDS Research and Educa, ACCELERATE, Chennai, India, [3]Johns Hopkins University, Bloomberg School of Public Health, Baltimore, United States

Background: Innovative case identification strategies remain critical for countries to achieve the UNAIDS fast track targets. Telangana is one of the Indian states with the highest HIV prevalence. Of the estimated 158,000 PLHIV in Telangana, ~35% remain undiagnosed. We evaluate the impact of index testing as a case identification strategy.

Description: Under the PEPFAR/USAID funded ACCELERATE, index testing was implemented across 50 facilities (38 testing and 12 treatment) in five high prevalence districts of Telangana. Contacts were elicited from newly diagnosed clients at testing centers and PLHIV with either unsuppressed viral load, low CD4, demonstrated poor adherence, or previous loss-to-follow-up at treatment centers. Contacts elicited were contacted and offered testing as per National guidelines.

Lessons learned: From Aug 2020-Dec 2021, from 8,868 index clients, 13,375 contacts were elicited and tested (7,200 sexual partners; 4,155 spouses; 1,973 children; and 47 mothers) of whom 2,634 (20%) were newly diagnosed with HIV infection. Positivity was highest among spouses (23%), followed by sexual partners (21%), parents (11%) and children (7%). There was also heterogeneity in positivity by district (range, 17-24%). Positivity was comparable by type of facility (testing vs, treatment sites = 19% vs 21%). However, within treatment sites, positivity among contacts of virally suppressed index clients, virally unsuppressed index clients and clients with no viral load data but CD4<500 cells/mm^{3}were 17%, 21% and 29%, respectively. 2,433 (92%) of all new cases diagnosed were initiated on treatment.

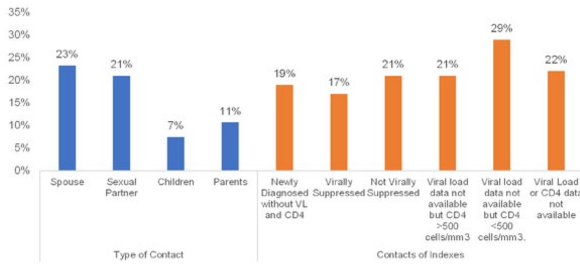


Figure. Case identification (test positivity) by characteristics of the index case.

Conclusions/Next steps: We demonstrated the efficiency of index testing in identifying and linking cases to ART at testing and treatment facilities. It is critical to ensure that all clients at treatment facilities undergo index-testing when initiating ART with regular updating of contacts particularly for clients who are virologically unsuppressed. If scaled, such efforts could significantly support new case identification globally and achieve HIV/AIDS epidemic control.

Implementation science of scaling up HIV treatment

PESAE06

Scale-up of "same-day ART initiation" in South Africa

J. Bor[1,2], N. Jinga[2], K. Shumba[2], W. MacLeod[1,2], M.P. Fox[1,2], S. Rosen[1,2], D. Onoya[2]

[1]Boston University, Boston, United States, [2]Health Economics and Epidemiology Research Office (HE2RO), University of Witwatersrand, Johannesburg, South Africa

Background: Initiation of HIV antiretroviral therapy (ART) on day of diagnosis has been shown to increase treatment uptake and viral suppression in randomized trials. South Africa implemented "same-day ART" in September 2017, a year after expanding ART eligibility to all patients under Universal Test-and-Treat (UTT). We assessed the impact of same-day ART and UTT on time from diagnosis to ART initiation.

Methods: The study included all patients diagnosed with HIV at public-sector health facilities in six South African provinces from 2016-2019 who started ART within 90 days. Data were extracted from the Three Interlinked Electronic Registers (TIER.Net) clinical database, and patients were followed up for 90 days.

For each patient, we computed days from HIV diagnosis (or first clinical presentation with HIV) to ART initiation and defined this duration as same-day (within 24 hours), rapid (≤7 days), or 90-day. We stratified the analysis by province and CD4 count at presentation.

We also assessed trends in the share of facilities that had adopted rapid ART as standard of care, which we defined as initiating at least 80% of patients within 7 days.

Results: Among 1,193,618 ART-initiators who entered care between 2016 and 2019, the proportion starting ART on the same day and ≤7 days increased from 16% and 38% in 2016 to 70% and 87% in 2019, respectively (*Figure 1a*). The increase in same-day and rapid initiation occurred starting during the Universal Test-and-Treat (UTT) in September 2016 and continuing with the formal implementation of same-day ART in 2017. The pace of same-day rollout varied by province (*Figure 1b*). In 2019, the share of patients starting ART within 7 days ranged from 53% in Northern Cape to 90% in KwaZulu-Natal and Mpumalanga.

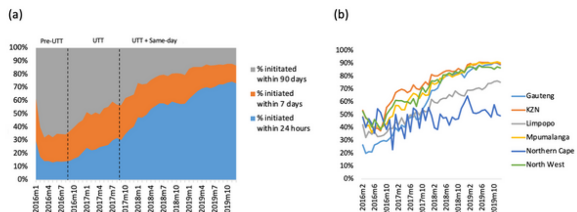

Figure 1. (a) Percent of patients starting ART within 24 hours (blue), 7 days (orange) or 90 days (grey) of HIV diagnosis; and (b) percent starting ART within 7 days by province.

Conclusions: By 2019, over two-thirds of people starting ART did so on the day they were diagnosed with HIV.

PESAE07

Long term effects of donor transition processes and their potential influence on the realization of the country's 90-90-90 targets. Experiences from a subnational level in Uganda

E. Ssegujja[1], M. Mukuru[1], H. Zakumumpa[1], F. Ssengooba[1]

[1]School of Public Health, Makerere University, Health Policy Planning and Management, Kampala, Uganda

Background: Great improvements in the quality of HIV service delivery coupled with performance of some national key HIV/AIDS delivery indicators arising from donor support bestowed hope that realization of the 90-90-90 targets by 2030 were within reach. However, experiences from some districts following implementation of donor transition activities reflected potential threats to the country's ability to achieve some of the set targets.

We explore this phenomenon in-depth to document the long-term effects of donor transition processes on HIV service provision at subnational level and its potential influence on the country's 90-90-90 aspirations over a ten-year period.

Methods: A exploratory qualitative study was conducted between November 2021 and January 2022 in three districts representing three regions of the country that received donor support. Interviews were conducted among a purposively selected sample of 25 health managers and providers. Data was collected using audio recorders with analysis conducted following a thematic content analysis technique.

Results: Results reflected mixed experiences with the first 90 of the population tested being compromised by withdrawal of community linkage facilitators which greatly affected the community HIV counselling and testing (HCT) activities. HIV services to key population were worst affected as they greatly rely on community component and having been set in project mode rendered it challenging to integrate into routine care. Disruptions in medical supplies and human resource for health following scale-down of formally supported activities affected the second 90 of provision of appropriate care.

However, whereas some previously supported health workers were absorbed into the government pay roll, not all were lucky particularly community linkage facilitators. Scale down of service delivery for the community component affected retention in care while disruptions in the hub system caused delayed delivery of test results which impacted clinical decision making.

Conclusions: Despite progress in realizing national 90-90-90 targets, transitional processes presented challenges to maintenance of these achievements. Effective transition calls for orderly and consultative processes beyond focusing more on set outcome targets calling for dedicated efforts to prioritize transition processes as a target for achievement in its self.

High rates of interruptions in HIV treatment in people living with HIV on ART less than three months across the age continuum

M. Williams Sherlock[1], P. Bachanas[1], L. Lee[2], C. Biedron[1], J. Aberle-Grasse[1], P. Agaba[3], L. Bailey[2], D. Connor[4], J. Devine[2], J. Stephens[2], I. Zulu[1], C. Godfrey[5]

[1]U.S. Centers for Disease Control and Prevention, Division of Global HIV/AIDS and TB, Atlanta, United States, [2]US Agency for International Development, Washington DC, United States, [3]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, United States, [4]Department of Defense, Defense Health Agency, DOD HIV/AIDS Prevention Program, San Diego, United States, [5]Department of State, Office of the Global AIDS Coordinator, Washington DC, United States

Background: The importance of retaining people living with HIV (PLHIV) on treatment has been established. Emerging evidence indicates that many newly initiated persons experience treatment interruptions within the critical first few months after antiretroviral (ART) initiation. We analyzed treatment interruption rates among PLHIV on ART less than or more than three months in President's Emergency Plan for AIDS Relief- (PEPFAR) supported ART programs.

Methods: Aggregate routine program data from 45 countries receiving PEPFAR support for HIV services between July and September 2021 were included in this analysis. Interruptions in treatment (IIT) were defined as more than 28 days since a client's last expected clinic appointment or medication pick-up date. Trends in IIT were examined by age, sex and time on ART for PLHIV aged 15 and older.

Results: Overall, 2.7% (292,722/10,790,728) of females and 3.0% (167,934/5,674,008) of males on ART experienced IIT during the last quarter of the fiscal year (July – September, 2021). PLHIV who were on ART less than three months experienced IIT approximately three times more often than PLHIV on ART more than three months (7.8% versus 2.6% p<.0001), respectively. Significant differences in IIT rates for females (8.0% and 2.6%, p<.0001) and males (7.6% and 2.8%, p<.0001) between time on ART disaggregates were also observed. Across all age groups of PLHIV on ART less than 3 months, IIT rates were significantly higher than of those on ART for more than three months (p<.0001 for each age group comparison; Figure 1).

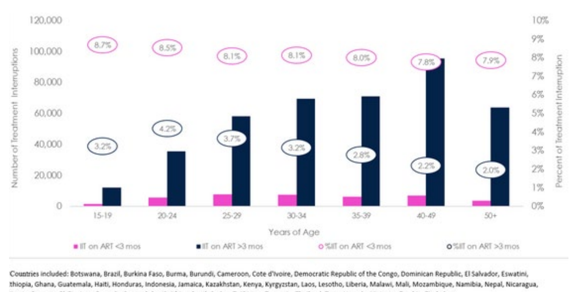

Figure 1. Number and percent of treatment interruptions by time on ART and age group July - September, 2021 across 45 countries*

Conclusions: The overall rate of treatment interruptions across PEPFAR-supported programs was low during this investigation period. However, the risk of interruptions for those on ART less than three months is a critical challenge across sex and age groups. Targeted interventions for PLHIV newly initiating ART should be prioritized to ensure treatment continuity, especially in the era of multi-month dispensing.

Scaling up access to models of integrated services (HIV, hepatitis, STI and other services, such as harm reduction, SRHR, gender affirming care, TB, NCDs and mental health)

PESAE09

Asynchronous prescribing of ART and antihypertensives results in frequent clinic visits despite multi-month dispensing of ART in Malawi

H.S. Whitehead[1], C. Moucheraud[2], K. Phiri[3], B.A. Banda[3], A. Moses[3], J. van Oosterhout[3], S. Phiri[3], R.M. Hoffman[1]

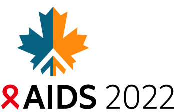
[1]David Geffen School of Medicine at the University of California, Department of Medicine, Division of Infectious Diseases, Los Angeles, United States, [2]Fielding School of Public Health, University of California, Department of Health Policy and Management, Los Angeles, United States, [3]Partners in Hope, Lilongwe, Malawi

Background: While multi-month dispensing (MMD) of antiretroviral therapy (ART) up to 6 months has become routine in Malawi, hypertension care often involves dispensing a 1-2-month supply of medication, diminishing the benefits of MMD for ART.

We assessed the degree of asynchronous dispensing in patients on ART and antihypertensives and estimated visit savings that would result from synchronized three- and six-month prescribing of these medications.

Methods: We performed a cross-sectional study of adults receiving care for both HIV and hypertension at an urban, PEPFAR/USAID-supported clinic in Malawi between June-December 2017. During this timeframe, the clinic provided integrated ART and hypertension care, with free ART and antihypertensives available for purchase. The quantity of ART and antihypertensive medications prescribed at individuals' three most recent clinic visits was abstracted, and the median quantity for each medication was used to estimate the total number of refill visits per year (including visits where both meds were prescribed at the same time and any additional visits where prescribing of ART or antihypertensives would be required for a continuous supply).

We then estimated visit savings that would result from synchronized three-month and six-month dispensing of ART and antihypertensives.



Oral abstracts

Poster exhibition

Late-breaker abstracts

Author Index

Results: We evaluated 193 adults (≥18 years): 65% female, median age 53 years (IQR 44-59), and median of 4 years (IQR 2-7) on antihypertensive medication. Four-month dispensing was most common for ART (64.8%), while one-month dispensing was most common for antihypertensive medications (59.6%). Only 16.6% of individuals received synchronous dispensing for both conditions at all three visits. The majority (62.2%) of participants were estimated to have 12 annual refill visits, 22.8% had 6-8 annual visits, and 15.0% had 3-4 annual visits. Under synchronized six-month dispensing nearly two-thirds of patients (64.8%) would eliminate 6+ visits. Under three-month synchronized dispensing, 85.0% of respondents would eliminate at least 2 visits per year.
Conclusions: We found a high rate of asynchronous dispensing of ART and antihypertensive medication in an integrated care setting, with most individuals requiring monthly clinic visits despite MMD of ART. Expanding integrated care with synchronized MMD for stable individuals with HIV and hypertension has the potential to reduce patient and health system burdens.

PESAE10

Using a robust approach to rapidly scale up integration of cervical cancer screening and treatment of pre-cancerous lesions in HIV clinics

S. Namaganda Aleserwe Hope[1,2], B. Babirye[2], J. Businge[1], T. Nsubuga -Nyombi[3], J. Nakaweesi[1], S. Alger[3], J.N. Kalamya[3], C. Senyimba[1], B. Mukasa[1]
[1]Mildmay Uganda, Health, Kampala, Uganda, [2]Mildmay Uganda, Kampala, Uganda, [3]CDC Uganda, Health, Kampala, Uganda

Background: Cervical cancer (CxCa) is the second most common cancer among women worldwide, causing significant mortality. In 2020, an estimated 604,237 women were diagnosed with CxCa globally. In Uganda, CxCa is the leading cause of cancer death. Women living with HIV (WLHIV) are 4-5 times more likely to develop CxCa. In October 2020, with support from CDC/PEPFAR, Mildmay Uganda (MUg) started implementing CxCa screening and treatment of precancerous lesions among WLHIV in central Uganda. This paper describes MUg's experience and successes in implementing the program.
Description: The CxCa screening program was implemented in 49 health facilities (HFs) in 8 districts of central Uganda. The program implemented from October 2020 to September 2021 targeted to reach 17,464 WLHIV aged 25 to 49 years. A needs assessment conducted to identify hindrances to CxCa screening found that HFs lacked equipment for screening and health workers lacked technical capacity to conduct screening and treatment of precancerous lesions. Mildmay provided the equipment, trained, and mentored the health workers. Two screening approaches used were visual inspection under acetic acid (VIA) at all HFs and Human Papilloma Virus (HPV) testing at 4 HFs with GeneXpert capacity.
Lessons learned: A total of 250 health workers from 49 participating HFs were trained on CxCa screening and treatment of precancerous lesions.
The number of WLHIV screened for CxCa markedly improved from 560 (3.2%) in Jan-March to 14,101 (81%) in July-September 2021. The positivity rate was 7% and treatment rate 83%. Twenty-one women with suspicious lesions were supported to access biopsies. Five had invasive carcinoma and were referred for further management.
The scale up of differentiated service delivery models and multi- month dispensing of ARVs and COVID-19 lockdown restrictions affecting access to HFs by clients and health workers were key challenges. Strategies implemented to mitigate these included pre-appointment reminders, screening at community drug distribution points, cancer camps, mentorship, and flexi -hours for HPV testing and treatment.
Conclusions/Next steps: It is feasible to integrate CxCa screening into HIV care using the screen & treat approach. The roll out was able to achieve 81% of the target despite the challenges from COVID-19.

Strategies to enhance U=U communication and implementation

Community antiretroviral therapy dispensation in Cameroon associated with superior client outcomes: a national evaluation

T. Epie[1], M. Bateganya[2], P. Sadate-Ngatchou[2], L. Nishimoto[2], M. Abass[2], M. Nsoh[1], P.-P. Ewane[1], M. Anastasie[3], N. Kamgaing[3], J.d.D. Anoubissi[3], R. Wilcher[2], H. Mahler[2], V. Nzima[4], L. Bonono[3], S. Billong[3]
[1]FHI 360, Yaounde, Cameroon, [2]FHI 360, Durham, United States, [3]Cameroon National AIDS Control Committee, Yaounde, Cameroon, [4]USAID, Washington D.C, United States

Background: The USAID- and PEPFAR-funded Meeting Targets and Maintaining Epidemic Control (EpiC) project and the Government of Cameroon developed and evaluated a model in which some health facilities providing antiretroviral therapy offered clients the option to receive antiretroviral (ARV) drug refills at community-based organizations (CBOs).
Methods: A mixed-methods evaluation was conducted from October to December 2020 in10 regions of Cameroon to determine the CBO model's impact on client retention and viral suppression.
Retention was compared cross-sectionally at 3, 6, 12, and 24 months between clients receiving ARV refills at 50 CBOs (n=2633, 2549, 2425, 2063 respectively) and clients receiving refills at 38 health facilities offering the CBO option/model (offering facility) (n=2017, 1916, 1805, 1606 respectively).
Additionally, retention at 3, 6, 12, and 24 months was compared between a cohort of clients receiving ARV refills at

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

a subset of 3 health facilities offering the CBO model (offering facility) (n=126) and 3 health facilities that did not (non-offering facility) (n=114).

Lastly, viral suppression was compared each year from 2016-2020 cross-sectionally between clients receiving ARV refills at CBOs (n=91, 217, 550, 664, 964 respectively) and at offering health facilities (n=31, 130, 342, 347, 543 respectively). Program data from August 2014 to October 2020 was used for descriptive and inferential analysis.

Results: Clients receiving ARV refills at CBOs had higher retention than those at offering health facilities at 3 (94% vs. 90%, p-value<0.000), 6 (91% vs. 86.1%, p-value<0.000), 12 (86.6% vs. 81.1%, p-value<0.000), and 24 (86.1% vs. 72.2%, p-value<0.079) months. Clients receiving ARV refills at offering facilities had higher retention than at non-offering facilities, but significantly only at 3 (100% vs. 93.1%, p-value=0.0013) and 24 months (90.5% vs.79.0%, p-value=0.0127).

Similarly, viral suppression was higher among clients receiving ARV refills at CBOs than at offering health facilities each year, but significantly only in 2018 (98.6 vs. 92.4%, p-value<0.00) and 2020 (95.1% vs. 92.3%, p-value=0.02).

Conclusions: Dispensation of ARV through CBOs was associated with higher retention and viral suppression. The model has potential to improve clinical outcomes for clients who receive ARV refills at CBOs and those who continue to receive refills at health facilities offering the CBO option/model.

Awareness of U=U among sexual and gender minorities in Brazil, Mexico and Peru: differences according to self-reported HIV status

K. Konda[1], T.S. Torres[2], H. Vega-Ramirez[3], O. Elorreaga[1], C. Guillén-Díaz-Barriga[3], D. Diaz[3], B. Hoagland[2], J.V. Guanira[4], M. Benedetti[2], C. Pimenta[5], H. Vermandere[6], S. Bautista-Arredondo[6], V.G. Veloso[2], B. Grinsztejn[2], C.F. Caceres[1], for the ImPrEP Study Group

[1]*Universidad Peruana Cayetano Heredia, Centro de Investigación Interdisciplinaria en Sexualidad, Salud, y SIDA, Lima, Peru,* [2]*Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz (INI-Fiocruz), Rio de Janeiro, Brazil,* [3]*Instituto Nacional de Psiquiatria Ramon de la Fuente Muñiz, Mexico City, Mexico,* [4]*Inmensa, Lima, Peru,* [5]*Brazilian Ministry of Health, Departmento de Doenças de Condições Crônicas e Infecções Sexualmente Transmissiveis, Rio de Janeiro, Brazil,* [6]*Instituto de Salud Pública (INSP), Mexico City, Mexico*

Background: The slogan "Undetectable=Untransmittable" (U=U) was created to translate the message that people living with HIV (PLHIV) using antiretroviral treatment (ART) with undetectable viral load will not transmit HIV to sex partners.

We describe U=U awareness among sexual and gender minorities (SGM) in Latin America and investigate differences by self-reported HIV status.

Methods: We conducted an online survey among SGM (≥18 years) living in Brazil, Mexico, and Peru during 2021. We used Poisson regression to calculate prevalence ratios of factors associated with awareness of U=U stratified by self-reported HIV status (PWH, negative and unknown). First, we estimated initial models (Model A), including socio-demographic factors (country, gender, age, race, education, and income) and then subsequent models (Model B), including risk behavior, ever taking PrEP, and HIV risk perception for HIV-negative/unknowns or taking ART for PLHIV.

Results: A total of 21,374 respondents were included (Brazil: 61%, Mexico: 30%, Peru: 8%); median age was 32(IQR:26-39), 96% cisgender man, 57% Black/Mixed-race; 3% <secondary education and 23% <minimum wage.

Among HIV-negative (16338/21374; 76%) and unknown status (2169/21374; 10%) SGM, 9% reported high self-perceived HIV risk, 58% were classified as high-risk for HIV, and 13% ever used PrEP. Among HIV-positive SGM (2867/21374; 10%), 93% were using ART.

Awareness of U=U was 89% in both Brazil and Mexico, higher than Peru 65%. Awareness of U=U was higher among HIV-positive (96%) than negative (88%) and unknown (69%) SGM.

In multivariate models, U=U awareness was lower among lower-income and Black/Mixed-race SGM. Among HIV-negative SGM, trans/non-binary had lower awareness of U=U compared to cisgender men, while those reporting high HIV-risk and ever using PrEP had higher awareness.

Characteristics	PLHIV Model A	PLHIV Model B	HIV Negative Model A	HIV Negative Model B	Unknown HIV Status Model A	Unknown HIV Status Model B

>=10 (ref. <10, MSM risk index)	-	-	-	**1.01 [1.01-1.03]**	-	1.01 [0.95-1.07]

Table.

Conclusions: Awareness of U=U varied according to HIV status, sociodemographic characteristics, and HIV risk behavior. Broad educational strategies, including teaching U=U , focusing on SGM vulnerable to HIV infection are urgent to decrease stigma against PLHIV.

PESAE13

Changes in "Undetectable Equals Untransmittible" (U=U) knowledge and practices by HIV and PrEP status among gay, bisexual, queer and trans men and Two-Spirit and non-binary people across Canada, 2015-2021

N. Lachowsky[1,2], A. Hu[1], C. Draenos[2], B. Klassen[2], K. Card[2,3], R. Higgins[1,2], F. Ibáñez-Carrasco[4]
[1]University of Victoria, Public Health & Social Policy, Victoria, Canada, [2]Community Based Research Centre, Vancouver, Canada, [3]Simon Fraser University, Burnaby, Canada, [4]University of Toronto, Toronto, Canada

Background: Canada officially endorsed "Undetectable equals Untransmittible" (U=U) in 2018, but few longitudinal and nation-wide studies on the impacts exist. We sought to examine population-level trends of U=U-related knowledge and sexual behaviour among gay, bisexual, trans, Two-Spirit, and queer men and non-binary people (GBT2Q) across Canada, by HIV and pre-exposure prophylaxis (PrEP) status.

Methods: Data are from community-based repeated cross-sectional bilingual (English/French) surveys: 2015 (online), 2018 (pride festivals), 2019 (online), 2020 (online), and 2021 (online).

Online recruitment used advertisements on sociosexual websites/apps, and community-based organizations' social media and email lists. Eligible participants were at least 15 years old, lived in Canada, and either identified as non-heterosexual or reported recent sex with a man. Women were ineligible.

Temporal trends were evaluated using separate multivariate logistic regressions by HIV/PrEP status, with survey year (continuous) as the primary explanatory variable, and controlling for age, education, ethnoracial identity, sex/gender identity (cisgender man, transgender man, non-binary), and number of recent sexual partners (for behavioural outcomes). Adjusted odds ratios (AOR) with 95% confidence intervals are shown.

Results: The pooled sample included 24,160 responses: 8.6% from GBT2Q living with HIV, 14.4% HIV-negative PrEP users, and 77.1% HIV-negative non-PrEP users.

Knowledge that HIV medications effectively suppress viral load increased from 2015-2021 for those living with HIV (68.8%-100%, AOR=3.43 [2.69-4.37]), PrEP users (70.3%-97.3%, AOR=1.77 [1.56-1.99]), and non-PrEP users (69.6%-84.1%, AOR=1.26 [1.22-1.27]).

Knowledge of the U=U scientific consensus on sexual transmission increased from 2018-2021 for those living with HIV (95.2%-98.3%, AOR=1.61 [1.04-2.47]), PrEP users (92.3%-95.5%, AOR=1.20 [1.02-1.42]), and non-PrEP users (68.9%-77.7%, AOR=1.25 [1.19-1.30]).

Reporting recent anal sex with an undetectable partner decreased from 2018-2021 for those living with HIV (55.3%-52.7%, AOR=0.78 [0.67-0.90]), PrEP users (46.3%-24.5%, AOR=0.73 [0.68-0.79]), and non-PrEP users (7.2%-6.8%, AOR=0.91 [0.84-0.99]) after additionally controlling for number of recent sex partners.

In 2021, participants living with HIV reported whether U=U impacted stigma (37.9% decreased, 55.6% no change, 6.5% increased) and access to sexual partners (14.2% decreased, 57.9% no change, 28.0% increased).

Conclusions: While U=U knowledge increased over time among GBT2Q, behavioural uptake remains incommensurate. The self-reported impacts of U=U for GBT2Q living with HIV are mixed, and require further investigation.

Implementation of HIV status-neutral approach to enhance HIV testing, HIV prevention and HIV treatment services

PESAE14

U=U awareness promotes engagement in HIV care among HIV negative men who have sex with men in Mississippi and Alabama

T. Mckay[1], J.C. Henne[2], C. Shinners[2], S. Schwartz[2], A. Dyson[3], T. Evans[3], M.C. Penner[4], C. Kinker[5], R.C. Quarles[6]
[1]Vanderbilt University, Department of Medicine, Health, and Society, Nashville, United States, [2]The Henne Group, Inc., San Francisco, United States, [3]ViiV Healthcare, Research Triangle Park, United States, [4]Prevention Access Campaign, Washington, D. C., United States, [5]Prevention Access Campaign, New York, United States, [6]Q Catalytics, Arlington, United States

Background: Expanding public awareness of the "Undetectable=Untransmittable" (U=U) message is central to a status neutral approach prioritizing engagement with health care providers (HCP) to monitor HIV status and viral load.

This study tests the dissemination of a U=U communication campaign on HCP engagement among HIV negative men who have sex with men (MSM) in Alabama and Mississippi, two US states with high rates of new HIV diagnoses and deaths.

Methods: We use a two-group pre/post study design with data from MSM in Alabama and Mississippi. Three interactive social media ads designed by Prevention Access Campaign (PAC) were run in both states from April to June 2021. In Mississippi, PAC ambassadors provided additional peer-to-peer engagement around U=U from February to May 2021. Survey data were collected from December 2020 to April 2021 (N=801; pre) and June to July 2021 (N=504; post) with similar retention across states (62% vs 64%). HIV negative men comprised 72% of the sample. Analyses below are restricted to HIV negative men who completed follow-up (N=368).

Results: Before campaign exposure, 38% of HIV negative men reported having an HCP monitoring their HIV status and 29% were aware of and understood U=U. Campaign exposure significantly increased overall U=U awareness with comprehension (29% to 52%), with larger increases in Mississippi (28% to 41%) than Alabama (30% to 38%).

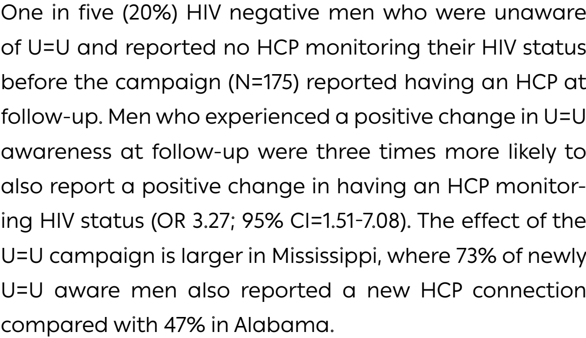
Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index



One in five (20%) HIV negative men who were unaware of U=U and reported no HCP monitoring their HIV status before the campaign (N=175) reported having an HCP at follow-up. Men who experienced a positive change in U=U awareness at follow-up were three times more likely to also report a positive change in having an HCP monitoring HIV status (OR 3.27; 95% CI=1.51-7.08). The effect of the U=U campaign is larger in Mississippi, where 73% of newly U=U aware men also reported a new HCP connection compared with 47% in Alabama.

Conclusions: Engagement with care is an important step for improving timely HIV testing and PrEP uptake for at-risk MSM. The U=U communication campaign increased HCP engagement among HIV negative men, with larger increases in Mississippi where men received the social media campaign with peer-to-peer outreach.

Innovations and lessons for supporting HIV prevention effective use and treatment adherence

PESAE15

Amazon smart locker collaboration as a pick up point preference for medicine distribution programs in Sub-Saharan Africa

S. Hendriksz[1], B. Meyer[1], C. Kraamwinkel[1]
[1]*Right e-Pharmacy, Pretoria, South Africa*

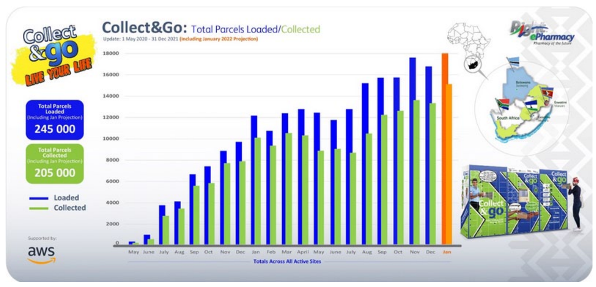
Background: The Collect & Go Smart Locker Solution serves as a Pick-up Point (PuP) for pre-dispensed medicines from Centralised Dispensing Facilities with built in monitoring and reporting capabilities. There are currently 101 Smart Locker sites located in South Africa, Lesotho, Eswatini, Zambia and Botswana. In response to the COVID-19 pandemic, PuPs were required to encourage medication collection outside overburdened facilities.

Right ePharmacy deployed Collect & Go Smart Locker PuPs as an alternative and scalable solution for various distribution programs, including ART refills.

Description: Commodity distribution programs in Africa utilises various PuPs to cater for patient and program needs. Alternative PuPs are a priority to alleviate burden on clinical staff and to reduce patient waiting times and exposure. Collect & Go Smart lockers further reduce waiting times and eliminate interpersonal contact, ultimately improving patient experience.

In May 2020 the 1st smart lockers were deployed and continue to be scaled due to patient preference, positive impact on adherence and accurate supply chain management capabilities.

Lessons learned: Rapid uptake of Collect & Go lockers were observed in Southern Africa with more than 250 000 prescriptions loaded and 220 000 successfully collected by January 2022. Smart lockers addressed critical challenges related to patient and commodity management, decreasing exposure risk and increasing capacity, with the goal to facilitate more convenient and safe collection practices for patients.



Conclusions/Next steps: While alternative PuPs remain a critical solution for convenient access to chronic and HIV medication, the locker solution does provide an additional layer of patient satisfaction in terms of preference for quality, privacy and safety when compared to other PuP options. The integrated temperature control unit, technology and parcel monitoring also allows for accurate commodity and supply change management, and ultimately positive patient adherence management. In addition, this solution proved to be an ideal solution to limit exposure during the COVID-19 pandemic.

PESUE17

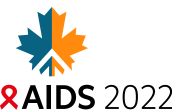
Triangulating orphans and vulnerable children program and health facility data to improve HIV treatment outcomes for children and adolescents living with HIV

B. Sousa[1], H. Bryant[1], T. Medrano[2], S. Chiale[3]
[1]*FHI 360, Programs, Maputo, Mozambique,* [2]*FHI 360, Programs, Durham, United States,* [3]*CARE, Programs, Inhambane, Mozambique*

Background: COVida (2016-2022) is a PEPFAR/USAID-funded orphans and vulnerable children (OVC) project implemented in 30 districts in seven provinces in Mozambique by FHI 360 and local partners. A project priority is to help children and adolescents living with HIV (CALHIV) achieve viral load (VL) suppression, but lack of accurate data on their treatment status prevented COVida from providing appropriate support at the community level. To address this challenge, COVIDA introduced a data-triangulation approach in October 2019.

Description: The data-triangulation approach compares self-reported OVC program data with data in the health facility (HF) patient information system to identify data gaps and discrepancies and inform corrective actions. This approach was piloted during October–December 2019 in 14 HFs in five districts in Inhambane province in collaboration with the PEPFAR HIV clinical partner.

Lessons learned: Of the1,555 CALHIV self-reported as on ART in OVC program data, HFs confirmed only 1,473 as on ART. Among those confirmed, only 767 (52%) had VL data, of whom only 462 (60%) were virally suppressed. These results led to improvement actions such as finding de-



faulters, referring CALHIV to VL testing, and providing enhanced adherence counseling to those with high VL loads. In September 2020, the number of CALHIV on ART had increased to 1,647, those with known VL to 1,183, and those virally suppressed to 552, a 12%, 54%, and 19% increase, respectively. Given these results, data triangulation was scaled up to all 203 HFs in COVida's program sites during the remainder of 2020.

Data triangulation has contributed to improve treatment outcomes among CALHIV in all project sites. The project's overall VL coverage rate increased from 50% in 2020 to 91% in 2021, and VL suppression from 61% to 82%.

Conclusions/Next steps: Data triangulation helps OVC and clinical partners work together to improve treatment outcomes for CALHIV. It also allows OVC programs to access real-time clinical data to meet the needs of CALHIV at the community level.

This approach is critical to reduce the pediatric and adolescent HIV treatment gap and should be used by all OVC and HIV clinical partners working in the same geographic areas.

PESUE18

Take home dose of Methadone: new arena for OST adherence during COVID-19 in Bangladesh

M.S. Farid[1], D.L. Rahman[2], D.S. Islam[1], E.I. Chowdhury[1]
[1]*Save the Children, HIV/AIDS Program, Dhaka, Bangladesh,* [2]*Save the Children, Health, Nutrition and HIV/AIDS, Dhaka, Bangladesh*

Background: Bangladesh has an estimated 33,067 people who inject drugs (PWID) who are the major drive for HIV among the Key population (KP). In 2015-16, HIV prevalence in Dhaka among the male PWID was 22% and among female PWID was 5%. The Global Fund HIV project in Bangladesh, implemented by Save the Children, targets high impact & cost-effective interventions towards 14,035 PWID through 35 centers in 13 districts that was 60% of the national target (23,371).

Description: This project offers differentiated HIV prevention and treatment services to PWID in the 13 districts, contextualized by epidemiological and other factors. Save the Children provides Oral Substitution Therapy (OST) to 2,351 PWIDs in 2021, that was 2,013 in 2020 and 1,257 in 2019. After the outbreak of COVID-19, OST could not be dispensed from some centers due to restricted movement and lockdowns. Many centers also were forced to close. Some PWIDs were shifted to other nearby centers temporarily for OST, and also to the Central Drug Addiction Treatment Center (CTC), Tejgaon.

In addition to the Directly Observed Therapy, a take-home dose (THD) of OST for 3-10 days was introduced to the stable and home-based PWID upon getting approval from DNC. PWID Network members were engaged as volunteers to dispense OST, manage crowds, maintain social distance, and ensure adherence. The proportion of THD in any given location varied with the intensity of lockdown requirements. THD was highest (90%) in April-June 2020 when lockdown was most strict, and gradually dropped to 64% in October 2020 when lockdown became relaxed.

Lessons learned: During July- Dec 2019, the retention rate of OST was 68.1%. In initial months of COVID-19, OST intake reduced to 62-63% due to restriction. After taking different approaches and THD, OST intake increased and the OST retention rate increased to 72.9% during Jan-Jun 2020; 82.73% in Jul-Dec 2020; and 87.33% during Jan-March 2021.

Conclusions/Next steps: Use of THD as an option for OST and use of outreach workers for follow up, had a positive impact on adherence of OST. THD need to continue as alternative options in reasonable scale for better compliance of PWID when COVID will no longer exist.

Laws and policies on HIV transmission, exposure, and non-disclosure

PESAF01

The role of the *Canadian Coalition to Reform HIV Criminalization* in changing Canada's approach to HIV criminalization: 5 years of community-led strategies, advocacy and consensus-building

I. Annamanthadoo[1,2], C. Clarke[2], R. Elliott[1,2], C. Johnson[2], C. Kazatchkine[1,2], A. McClelland[3,2], R. Peck[4,2], L. Pelletier-Marcotte[5,2], S. Rahim[6,2]
[1]*HIV Legal Network, Toronto, Canada,* [2]*Canadian Coalition to Reform HIV Criminalization (CCRHC), Toronto, Canada,* [3]*Carleton University, Ottawa, Canada,* [4]*HIV & AIDS Legal Clinic Ontario (HALCO), Toronto, Canada,* [5]*Coalition des Organismes Communautaires Québécois de Lutte Contre le Sida (COCQ-SIDA), Montréal, Canada,* [6]*Kastner Lam LLP, Toronto, Canada*

Background: Canada has one of the world's highest number of recorded HIV-related criminal cases, resulting from a broad interpretation of the sexual assault provisions in the *Criminal Code*. The most commonly laid charge in cases of alleged non-disclosure is *aggravated sexual assault,* where conviction carries a maximum penalty of life imprisonment and mandatory registration as a sex offender. People living with HIV (PLWH) have been convicted even in cases where no transmission occured, when they used a condom or had an undetectable viral load.

Description: In 2016, a number of organizations and advocates, including people with lived experience of HIV criminalization, created the Canadian Coalition to Reform HIV Criminalization (CCRHC) to change Canada's approach to HIV criminalization. In 2017, CCRHC conducted its first national consultation, leading to a widely endorsed Community Consensus Statement that makes specific demands to the federal and provincial governments to limit HIV criminalization.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Lessons learned: Involving people with lived experience and adapting strategies to shifting (political and social) landscapes are key to the CCRHC's work, and led to positive developments.

In 2017, Justice Canada made recommendations to both federal and provincial officials to limit HIV criminalization. In 2018, following a call for action by the CCRHC, the Attorney General of Canada (AGC) issued a (limited) directive based on Justice Canada's recommendations.

In 2019, CCRHC members testified before the House of Commons Standing Committee on Justice and Human Rights (SCJHR) on the issue of HIV criminalization. The SCJHR majority report concluded that Canada's approach is too broad, too punitive and unscientific. It recommended limiting the use of criminal law in cases of HIV non-disclosure, including through *Criminal Code* reform.

In 2021, the CCRHC launched a second community consultation on *Criminal Code*reform advocacy. Since 2017, some provinces have also adopted policies or directives to limit HIV-related prosecutions.

Conclusions/Next steps: While significant, these developments remain insufficient to end the overbroad criminalization of PLWH in Canada. While results from the ongoing consultation around Criminal Code reform will inform advocacy strategies at the federal level, CCRHC must continue to demand concrete actions from both levels of government to implement recommendations to limit HIV criminalization.

PESAF02

Harms of Sex Offender Registries in Canada among people living with HIV

L. Michaud[1], I. Annamanthadoo[2], S. Ka Hon Chu[2], A. McClelland[3], R. Nobleman[4], R. Peck[4]

[1]*York University, Toronto, Canada,* [2]*HIV Legal Network, Toronto, Canada,* [3]*The Institute of Criminology and Criminal Justice, Carleton University, Toronto, Canada,* [4]*HIV & AIDS Legal Clinic Ontario, Toronto, Canada*

Background: The number of prosecutions of people living with HIV in Canada for alleged HIV non-disclosure is among the highest in the world, and Canada is unique in applying aggravated sexual assault charges in the majority of these cases. Following amendments to Canada's Criminal Code in 2011, all individuals living with HIV convicted of aggravated sexual assault for non-disclosure became subject to mandatory sex offender registration, in many cases for life.

Methods: This research is based on qualitative interviews conducted from 2017 to 2019 with 16 people living with HIV from across Canada who have faced criminalization and incarceration for alleged non-disclosure of their HIV status, and compulsory registration with the National Sex Offender Registry due to their conviction. We combined this qualitative research with a legal analysis of the interplay between federal legislation, correctional policy, and the related regulatory practices of law enforcement.

Results: Mandatory sex offender registration triggers substantial harms among people living with HIV, further exacerbating the harms caused by ongoing criminalization and incarceration of non-disclosure.

These harms include: family estrangement and internalized stigma, negative impacts on re-entry and reintegration, an excessive burden due to onerous registration requirements, as well as psychological harms arising from potential lifetime government and police surveillance.

These impacts also interact with – and are reinforced by – harms resulting from news media reporting of sex offender status to the public and resulting stigma and social violence, as well as psychological harms from inappropriate sex offender treatment stemming from correctional policy.

Conclusions: This study provides an assessment of the complexity of interlocking legal and social harms experienced by people living with HIV as a result of sex offender designation and registration.

The research makes visible and contextualizes these harms, providing important knowledge for individuals supporting and caring for people living with HIV who have been subject to criminalization.

Our analysis also offers critical knowledge related to how sex offender registration laws operate in the daily lives of people living with HIV for individuals engaged in advocacy and law reform regarding the criminalization of HIV non-disclosure.

Laws, policies and practices impacting access to HIV testing, prevention, treatment, care and support

Flawed by Design: Canada's First Prison Needle Exchange Program

S.K.H. Chu[1], R. Elliott[1], S. Simons[2], J. Rowe[3], L. Edmiston[4], T. Stratton[5]

[1]*HIV Legal Network, Toronto, Canada,* [2]*Former Prison Peer Health Worker, Toronto, Canada,* [3]*PASAN, Toronto, Canada,* [4]*CATIE, Toronto, Canada,* [5]*Communities, Alliances and Networks (CAAN), Fort Qu'Appelle, Canada*

Background: Prisoners have long been recognized as a "key population" disproportionately affected by HIV. Yet despite ample evidence demonstrating the effectiveness of needle and syringe programs in reducing the risk of HIV infection and other harms to prisoners' health, for decades Correctional Service Canada (CSC) refused to implement this essential harm reduction measure in prison. This had an especially severe impact on the disproportionate number of Indigenous people in federal prisons, and particularly Indigenous women in prison — 11.7% of whom are reported to be living with HIV.

Description: In 2012, a former prisoner and four HIV organizations challenged CSC's failure to provide prisoners with equivalent access to sterile injection equipment as breaching their constitutional rights to life, liberty, and security of the person and to equal benefit of the law without discrimination.
Eventually, in response, the federal government announced that it would introduce a prison needle exchange program (PNEP) in two prisons in 2018, and gradually extend the program to all federal prisons.
Lessons learned: Serious deficiencies in the PNEP's design have impeded access to the program. Participation involves a four-step assessment process that requires disclosure of one's drug use to the prison warden, among others — without any guarantee of approval of participation.
Those approved to participate are subject to daily "visual inspections" by security staff to verify accountability for the equipment distributed, breaching prisoners' confidentiality regarding their participation.
CSC's own interim evaluation revealed extremely low rates of participation, and as of September 2021, only 9 (out of 43) federal prisons were identified by CSC as having a functioning PNEP, despite CSC's initial pledge to fully implement the program by August 2020.
Of those 9 prisons, CSC identified only 43 people participating in the program across four prisons, and only two participants in one women's prison.
Conclusions/Next steps: CSC's PNEP is seriously compromised by design deficiencies, low uptake and the indefinite suspension of its roll-out during the COVID-19 pandemic. There is an urgent need to continue monitoring the program and address barriers to participation. If the benefits of a PNEP are to be realized, prisoners need easy, confidential access.

PESAF04

Investigating premarital HIV testing in Indonesia and its risks of human rights violations

N. Puspitasari[1], A. Wirya[1], A. Larasati[2]
[1]Community Legal Aid Institute, Jakarta, Indonesia, [2]Harm Reduction International, London, United Kingdom

Background:
HIV programs in Indonesia often place families as the basis of intervention, believing that resilient families will result in HIV prevention. One of such policies is mandatory premarital HIV testing. This study aims to review this intervention, using the lens of human rights.
Methods: This research uses a qualitative method, combining literature reviews and interviews. The literature includes laws, modules, and healthcare guidelines. In total, the researchers collected 218 laws, spanning across different provinces in Indonesia. The data was then complemented by online interviews with stakeholders and civil societies.

Results: Fourteen regions have local regulations imposing premarital HIV testing. There are four forms of the regulation, namely
1. Mandatory premarital HIV testing,
2. Recommendations for testing through the provision of information,
3. Mandatory health check, or
4. Mandatory notification to the partner of HIV status.
Most of them require people who want to get married to provide health certificates detailing their health alongside recommendations from doctors.
Clients are often not free to opt-out of the test since the Office of Religious Affairs or the Civil Registration Service is only willing to marry people when there is a health certificate. This requirement results in marriage cancellations in Gorontalo, Banyuwangi, and Jakarta.
In addition, when the test result is positive, a health certificate will be issued only when the person is willing to undergo ARV therapy. The test also does not guarantee one's right to privacy since the notification of HIV status is conducted together with the partner.
Some displayed a lack of risk mitigation efforts, causing reluctance to undergo the test for fear of being abandoned or experiencing violence, especially when the positive is the bride.
Conclusions: Mandatory premarital HIV testing, which has been implemented in various regions in Indonesia and used different strategies to compel people to take HIV tests poses many human rights issues. It is not based on voluntariness that should be the underlying principle of HIV tests. Without comprehensive risk mitigation strategies, this effort could potentially result in violence, stigma and discrimination from partners—counterproductive to the idea of 'making the family resilient'.

PESAF05

An advocacy campaign to increase access to Post-Exposure Prophylaxis (PEP) through expansion of pharmacist scope of practice in North Carolina

M. Martin[1], D. Ward[2], D. Rowan[3], G. Wilkins[4], L. Storrow[5]
[1]NC AIDS Action Network, Raleigh, United States, [2]Southern AIDS Coalition, Bluffton, United States, [3]University of North Carolina at Charlotte, School of Social Work, Charlotte, United States, [4]East Carolina University, Brody School of Medicine, ECU Adult Specialty Care, Greenville, United States, [5]Community Education Group, Charleston, United States

Background: Since 2010, North Carolina AIDS Action Network (NCAAN) has led HIV/AIDS treatment and prevention advocacy/lobbying efforts in North Carolina (NC), a state in the southern United States. In 2020 & 2021, NCAAN partnered with Southern AIDS Coalition (SAC) to lead an educational advocacy campaign to increase access to Post Exposure Prophylaxis (PEP) through policy change that expands the scope of practice of NC pharmacists to prescribe PEP medications.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Description: In 2020 there were 1,079 reported new cases of HIV in NC, with disproportionate incidence in rural counties. There are five rural counties without a family physician, while licensed community-based pharmacists often serve as the main healthcare contact. There is a negative correlation between the availability of specialized medical services and the rate of incidence of HIV transmission. Therefore, expanding the scope of practice of pharmacists to prescribe PEP promotes public health outcomes in rural and other under-resourced communities.
To build support for pharmacists prescribing PEP, NCAAN hosted virtual advocacy trainings and organized an advocacy day at the NC state capitol. Advocates met with NC legislators to discuss HIV trends and barriers to care in rural communities. Professional lobbyists worked closely with key legislators and medical associations to ensure expansion of pharmacist scope of practice was included in key legislation introduced in 2021.
Lessons learned: Based on interviews with key legislators, lobbyists, and stakeholders, NCAAN and SAC's joint advocacy efforts were critical to the passage of NC State House Bill 96 (2021), which allows NC pharmacists to prescribe PEP and other public health-promoting agents. Framing PEP as medication to be prescribed with urgency and demonstrating support from other medical providers was politically strategic and helped generate support from more conservative, Republican lawmakers.
Conclusions/Next steps: In 2022, NCAAN and SAC will partner with the NC Association of Pharmacists to train pharmacists on their new authority in the expanded scope of practice, with a focus on rural communities that have limited PEP prescribers. This successful advocacy case study serves as a model for other states and communities on advancing policy change to increase access to HIV biomedical prevention tools.

PESAF06
Community-led law making in HIV field as a Ukrainian know-how

V. Rachynska[1]
[1]All-Ukrainian Network of PLWH, Kyiv, Ukraine

Background: Over the last 15 years only 3 laws regulating issues in the field of HIV and key populations were adopted in Ukraine. While the world is moving forward protecting the rights of PLHIV and other KPs legislation of our country slows down this progress being an impediment to innovations in medicine, decreasing retention in treatment and strengthening stigma towards PLWH and KPs.
Description: For acceleration of changes in laws most relevant to the interests of PLWH and other key affected populations a Parliamentary platform „Fight for Health" was established.
Taking into account the fact that key populations should be the final beneficiary and the main drivers of the mentioned changes the structure of the Platform includes:
9 Platform Community representatives collecting the needs of key communities (WHIV, AHIV, ex-prisoners, SW, MSM, TG, PWID; PLHIV, TB) on national level;
Lawyers developing draft bills and recommendations on changes to legal acts for submission to the Parliament, Ministries, CCM and regional Coordinating bodies based on needs ofKPs;
Coordination of activities is conducted by supervisors. Supervisors communicate with Parliamentarians, Ministries, CCM presenting proposals of communities;
27 Community representatives taught to collaboration with Legislative, Executive and Judicial branches of power at the School of Power.
Technical support visits to regions improve communication with communities and regional coordinating bodies at regional level.
Lessons learned: The intervention has had the following outcomes:
5 draft bills for decriminalization of sex work with 1 parliamentarian as a lead;
3 draft bills for decriminalization of HIV with 3 parliamentarians as leads;
A draft bill on HIV and a Parliament Committee with participants representing key communities;
A draft bill on decriminalization of drug use;
A concept and draft bill on civil partnerships for LGBTIQ+;
communities of Trans* people, women and adolescents living with HIV developed and submitted their proposals for changes in the regulatory documents of different relevant Ministries.
Community of ex-prisoners initiated penitentiary system reform on all levels.
Conclusions/Next steps: Further work of the Platform will focus on passing of the draft bills by the Parliament of Ukraine and strengthening capacity of KPs in law making initiatives improving their lives and protecting their rights.

PESAF07
Strengthening youth voices for change: the role of advocacy training in enhancing meaningful engagement of young people in youth-friendly HIV service provision

C. Zinyemba[1], R. Igweta[2], C. Audi[3], H. Paul[4]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Public Policy & Advocacy, Harare, Zimbabwe, [2]Elizabeth Glaser Pediatric AIDS Foundation, Public Policy & Advocacy, Harare, Kenya, [3]Elizabeth Glaser Pediatric AIDS Foundation, Public Policy & Advocacy, Washington DC, United States, [4]Elizabeth Glaser Pediatric AIDS Foundation, Public Policy & Advocacy, Kampala, Uganda

Background: In 2020, 3.3 million young people were living with HIV. To meet the global goal of ending AIDS by 2030, specific attention must be paid to adolescents and youth living with HIV, including provision of youth-responsive programming and meaningful engagement of adolescent and youth voices in decision-making fora.

Description: The Elizabeth Glaser Pediatric AIDS Foundation, supported through ViiV Breakthrough Partnership project, led an advocacy training for 20 adolescent leaders living with HIV in Uganda. The three-day virtual training was designed according to principles of adult learning and adapted to suit participants through adolescent-friendly language, case studies, and real-life scenarios. Digital tools were utilized to adapt to challenges of the COVID-19 pandemic.

Through a range of activities targeting diverse learning styles, the training focused on three key themes:

1. The foundations of advocacy,
2. Planning for advocacy, and;
3. Building advocacy skills.

Lessons learned: All participants noted in a post-training assessment an increase in knowledge about advocacy and the development of new skills relevant to their work as youth leaders living with HIV which includes advocating for other adolescents living with HIV, providing peer psychosocial support and bridging the gap between the health care system and the client.

Additionally, the advocacy training was found to refine participants' strategies and skill for engaging decision makers and stakeholders, including service providers.

Using their new skills, all participants successfully organized World AIDS Day activities, related to community sensitization, increasing psychosocial support visibility, and ending stigma. Furthermore, 25% of participants have since engaged with media programs to advocate for improved HIV service delivery.

Conclusions/Next steps: A virtual advocacy training, tailored specifically to adolescents and youth, was found to be an appropriate and effective method for building youth advocacy capacity, engaging adolescent voices in the HIV response, and enhancing youth-friendly service provision.

Further research is needed to confirm durability of knowledge and skills gained, and investigate the long-term impacts on youth advocacy amongst participants.

Moving forward, a skills-based advocacy training targeted at adolescents and youth should be replicated to increase the substantive participation of this population in HIV policy development and program implementation.

Laws and policies regulating access to drugs and medical devices (including intellectual property and trade regimes, competition law and price regulation)

PESAF08

Community based organizations: the lastest bastion against abusive patent protection on life saving medicines. The experience of Make Medicines Affordable consortium

O. Mellouk[1], S. Kondratyuk[2]

[1]ITPC, Marrakech, Morocco, [2]ITPC, Kyiv, Ukraine

Background: For decades, patent barriers have been identified as key barriers for access to HIV, TB, and HCV treatment and more recently to COVID-19 vaccines and antivirals in several low and middle-income countries (LMICs). The use of the TRIPS flexibilities to remove patent barriers remains important component of ensuring access to affordable medicines. Today, civil society and community based organizations (CBOs) play a major role in challenging patents on medicines by filing patent oppositions.

Description: Since 2015, under Make Medicines Affordable (MMA) campaign, an ITPC-led consortium of 13 CBOs managed to file 69 challenges on patent applications and patents aimed at protecting monopolies on 10 ARVs (31 oppositions), 5 DAAs (10 oppositions), 3 COVID (12 oppositions) and 4 anti-TB medicines (16 oppositions) in 13 countries in Latin America, EECA and SEA regions. Oppositions were prepared by local multidisciplinary teams consisting of community representatives (PLHIV, people affected by TB, HCV and COVID), lawyers and chemists. Targeted medicines were informed by consultation with local community organizations and health officials.

Lessons learned: Although filing patent opposition remains a technical process, it is possible to build local CBOs capacity to file oppositions, as it was done by MMA consortium since 2019 in Belarus, Georgia, Guatemala, Kazakhstan, Kyrgyzstan, Moldova. In order to define most optimal target medicines wide consultation with local CBOs in combination with clinical trials, patent and market intelligence work was beneficial. To develop strong patent oppositions arguments that will succeed it is also important to conduct capacity building of local chemists involved in patent oppositions work.

Conclusions/Next steps: While patent oppositions to succeed take some time to prepare and support - from months to several years, - and not all of oppositions succeed, from 69 oppositions - 17 oppositions (25%) led to positive outcomes generating significant savings for state budgets in relevant countries (estimated $472 million savings in Argentina, Brazil, Thailand, Ukraine), which led to significant increases in HIV and HCV treatment programs coverage. Thus, among TRIPS Flexibilities patent oppositions is one of the most accessible and impactful options that can be used by local community organizations.

PESAF09

Brazilian civil society role in opposing HIV/AIDS patent applications: 15 years of experience defending the Brazilian public health system

P. Villardi[1], F. Fonseca[1], G. Zucoloto[2]

[1]*ABIA, GTPI, Rio de Janeiro, Brazil,* [2]*IPEA, Rio de Janeiro, Brazil*

Background: The Brazilian IP law foresees the possibility of any interested party to fill patent oppositions (PO), i.e., document with technical grounds for a given patent application to be rejected. ABIA/GTPI is a civil society coalition that challenges the impact of pharmaceutical monopolies on public health.

Over the last fifteen years (2006-2021), ABIA/GTPI have filed PO against eight patent applications related to six ARVs, to prevent unfair monopolies.

Methods: We analyze the PO's outcome using: patent application granting or rejection, price reductions: yes or not, entry or not of generic versions. We set three categories:

a. Total success,

b. Partial success, and;

c. Unsuccessful.

Total success means the patent was rejected, and there was a price reduction.

Partial success means when the patent is rejected without the entry of generics or a price reduction.

Unsuccessful means when the patent was granted, there was no entry of generic competitors nor price reduction.

Results:

Drug	Patent #	Rejected or granted?	Price reduction?	Generic entry?
TDF	PI0406760-6	rejected	Yes	Yes
TDF+FTC	PI9811045-2 PI9816239-0	rejected	Yes	Yes
Lopinavir +ritonavir	PI1101190-4 PI0413882-1	rejected rejected	Yes	Yes
Dolutegravir	PI0610030-9	granted	Yes	No
TAF	PI0112646-6	granted	-	No
Atazanavir	PI0509595-6	granted	Yes	No

Table 1

Two drugs were total successes (TDF and TDF+FTC), three were partial success (atazanavir, dolutegravir, and lopinavir/ritonavir) and one was unsuccessful (TAF). Considering TDF and TDF+FTC: rejected patent applications and price reduction with the entry of generics.

Granted patents for atazanavir and dolutegravir without generic entry, but with price reductions after PO. In the Lopinavir/ritonavir case, the patent application was rejected, but there was no price reduction or generic entry. The unsuccessful case was TAF.

The patent was granted, but there was no purchase by the Brazilian government until the date of the data collection.

Conclusions: The study showed total or partial success in five out of six cases. The ABIA/GTPI's POs have helped to decrease prices for five ARVs. We highlight the TDF and TDF+FTC cases. TDF was the backbone of treatment in Brazil for almost a decade. The purchase of generic versions of TDF contributed to the universal access public policies. Generic version of TDF+FTC, used in PrEP, made possible this policy's expansion.

Conceptualizing political drivers and their impacts

PESAF10

Where the world stands on the '10-10-10' social enabler policies: mapping and analyzing progress and gaps

M. Pillinger[1], J.R. Moon[2], J. McHardy[1], S. Light[1], K. Aneja[1], S. Lynch[1], T. Erkola[3], M. Kavanagh[3]

[1]*The O'Neill Institute for National and Global Health Law, Georgetown University, Washington, United States,* [2]*University of Sussex, Brighton, United Kingdom,* [3]*Joint United Nations Programme on HIV/AIDS (UNAIDS), Geneva, Switzerland*

Background: Criminalization and stigma/discrimination against PLHIV and key and marginalized populations create significant barriers to achieving global HIV/AIDS goals. In the 2021 UN Political Declaration on HIV/AIDS, governments committed to address these barriers by adopting the UNAIDS-proposed '10-10-10' societal enabler targets.

We identify seven laws/policies that countries should adopt in order to create a legal/policy environment conducive to achieving these targets. They are: non-criminalization of

1. Same-sex sex,
2. Sex work,
3. Drug use,
4. HIV transmission;
5. Creation of national human rights institutions; and legal protections against
6. Discrimination and
7. Gender-based violence.

Methods: Using data from Georgetown University's HIV Policy Lab on 194 countries, we analyze whether each country has adopted each law/policy. We then map and compare policy adoption globally and across regions and other country groupings to describe the current state of policy progress towards the 10-10-10 goals and pinpoint where policy change is needed.

We then apply network analysis methods to map the co-occurrence, clusters and intersections of different sets of policies to deepen and quantify our "3D" understanding of how policies overlap and interact in practice and pinpoint underlying cross-national patterns in policy adoption.

Finally, we investigate correlations between the adoption of different combinations of social enabler policies and key HIV outcomes (e.g., % of PLHIV who know their status, are on ART, and are virally suppressed).

Results: Preliminary descriptive findings indicate that, on average, countries have adopted three of the seven laws/policies (range: 1-6 policies). The adoption rates for individual policies vary widely; whereas 78% of countries have gender-based violence laws, only 3% and 4% do not criminalize drug use and sex work, respectively.
Regionally, we observe the greatest variation in adoption rates for: same-sex sex non-criminalization, where WCENA and EECA countries have significantly higher rates of policy adoption than other regions; and HIV transmission non-criminalization, where sub-Saharan African countries have significantly higher rates of policy adoption than other regions.
Conclusions: These findings will further deepen our understanding of the patterns and political, economic, and geographic factors that shape policy adoption and the importance of supportive law/policy environments in the fight against HIV. They also inform policy change advocacy around the 10-10-10 targets.

Political violence and armed conflict

PESAF11
Violence against people living with HIV in the context of Colombian armed conflict: findings from a report presented to the Colombian Truth Commission

J.F. Serrano Amaya[1], C. Martinez Quesada[2], H. Mejia Mercado[3], M.S. Luna Siachoque[4]
[1]Universidad de los Andes, Lenguas y Cultura, Bogotá, Colombia, [2]Corporación Red Somos, Bogotá, Colombia, [3]Corporación Caribe Afirmativo, Barranquilla, Colombia, [4]Universidad de los Andes, Bogotá, Colombia

Background: In 2020 a group of scholars and activists with expertise on HIV and LGBTQ rights from *Universidad de los Andes*, *Caribe Afirmativo* and *Red Somos* allied to produce a report on how internal armed conflict affected people living with HIV -PLHIV- in Colombia. It was produced as a research document and as a tool for advocacy.
The report was submitted to the Colombian Truth Commission in 2021. It intended to make visible that PLHIV were victims of internal armed conflict due to stigma, vulnerability and lack of institutional support. They were targeted as individuals and as a specific social group for the benefit of armed actors.
Methods: The report describes the patterns of violence suffered by PLHIV from 1995 up to 2020. It has a focus on the experiences of victims, taking a distance from the more common epidemiological approaches in the analysis of interactions between war and HIV (Elbe, 2000; Whiteside, 2006; McInnes, 2009).
17 in-depth interviews to HIV activists in 11 municipalities and a meta-analysis of newspapers and human rights reports were conducted.
Results: Two main patterns of violence were identified:
i. Direct violence, including threats, forced displacement and selective killings of PLWHIV;
ii. Indirect violence, including threats, persecution of marginalised populations and gendered and sexualised violence against PLHIV or collectives associated with HIV, as sex workers and LGBTQ people.
Those patterns acted against individuals with real or assumed diagnostic of HIV and their organisations; occurred all through the period of analysis and in urban and rural areas; were committed by armed actors from all sides of political spectrum in their disputes for territorial control; affected the fabric of community based activism and leadership that has been pivotal in the response to HIV and its consequences.
Conclusions: Findings suggest that a crime of persecution was committed against PLHIV and their organisations during internal armed conflict.
Results are useful in advocacy for rights of PLHIV and in the implementation of transitional justice measures, particularly for truth telling mechanisms such as truth Commissions; in the prosecution of perpetrators; and in the design of reparatory measures for PLHIV victims of armed conflict.

Sexual- and/or gender-based inequalities, inequities and violence

PESAF12
Benchmarks and beyond: assessing and addressing structural barriers to rights-based HIV programming for LGBTI key populations in six African countries

M. Tabengwa[1], M. Judge[1], J. O'Malley[1], F. Damazio[2], A. Kra[3], B. Loots[1], S. Tamundele[4], I. Yekeye[1]
[1]UNDP, Johannesburg, South Africa, [2]UNDP, Johannesburg, Angola, [3]UNDP, Johannesburg, Congo, Democratic Republic of the, [4]UNDP, Johannesburg, Cote D'Ivoire

Background: There has been significant progress in reducing new HIV infections and related morbidity and mortality in the general population in Africa, but much less among key populations. According to UNAIDS, by 2019, approximately 50% of new infections in Sub-Saharan Africa were among key populations and their sexual partners.
There is considerable evidence that stigma, discrimination, criminalization and social exclusion make key populations more vulnerable to HIV infection and less likely to access and use relevant services.
The UNDP's Inclusive Governance Initiative commissioned baseline research in six African countries to benchmark progress and barriers to the rights and inclusion of LGBTI people in national laws, policies, strategies and programmes, in the health sector and beyond.

Oral abstracts

Poster exhibition

Late-breaker abstracts

Author Index

Methods: One of the aims of this research is to contribute to strengthening the structural conditions for effective and accessible HIV programming for diverse LGBTI populations in Africa. Country baseline studies were undertaken in Namibia, Zimbabwe, Angola, Côte d'Ivoire, Kenya and the Democratic Republic of Congo.

Data was gathered through desktop research, targeted policy analysis, and stakeholder interviews in each country including with state decision-makers (in the judiciary, parliament, the executive, national human rights institutions and government departments) and leaders from development agencies and civil society.

Results: Given the links between regulatory environments and HIV outcomes for key populations, structural interventions are necessary to tackle human rights barriers to HIV related services. Extrapolations from the country-level studies identified key policy and legislative developments where significant progress has been achieved, along with critical entry points for the further reduction of structural impediments to effective HIV programming for key populations. Structural factors that perpetuate the vulnerabilities of LGBTI people are also identified, along with potential strategies to address those.

Conclusions: The findings, which highlight contextual dynamics and explore their implications for structural reform efforts, are highly relevant to understanding LGBTI rights and inclusion as a critical step to reducing structural obstacles facing key populations. This provides contextually relevant knowledge to inform advocacy, law reform, and country and multi-country programming, aimed at challenging the structural dynamics that undermine right-based HIV prevention, care and support for marginalised groups in Africa.

Background: Broadly neutralizing antibodies (bnAbs) are a promising approach for HIV-1 prevention. In the only bnAb HIV prevention efficacy studies to date (the AMP studies), intravenous (IV) administration of a CD4-binding site targeting bnAb (VRC01) prevented infection only against highly susceptible viruses. BnAb combinations, particularly using bnAbs engineered for increased potency, breadth, and half-life, may be more efficacious. Clinical data assessing potential interactions between co-administered antibodies is limited.

We present the first interim clinical data comparing VRC07-523LS pharmacokinetics (PK) when administered alone (HVTN 127/HPTN 087) versus co-administered with other bnAbs that bind non-overlapping HIV Env epitopes, including V2-binding PGDM1400 and V3-binding 10-1074 and PGT121 (HVTN 130/HPTN 089).

Methods: Healthy, HIV-uninfected adults received VRC07-523LS administered IV at four-month intervals alone at five timepoints (n=29; 2.5, 5, or 20 mg/kg), sequentially in dual combination with 10-1074, PGT121, or PGDM1400 at one timepoint (n=18; 20 mg/kg), or in triple combination with PGDM1400 and PGT121 at two timepoints (n=9; 20 mg/kg). VRC07-523LS serum concentration kinetics were measured by anti-idiotype Binding Antibody Multiplex Assay. A two-compartment population PK model was fitted to estimate PK parameters.

Results: Participant demographics and baseline characteristics were similar between the two studies. Predicted VRC07-523LS levels from the fitted model were in excellent agreement with observed levels (see Figure).

Small changes in clearance, intercompartmental clearance, and peripheral volume PK parameters of VRC07-523LS were observed with co-administration of 10-1074, PGT121, and/or PGDM1400. VRC07-523LS alone has an estimated median half-life of ~54.8 days versus ~52.3 days when co-administered with 10-1074, PGT121, and/or PGDM1400 (p=0.55).

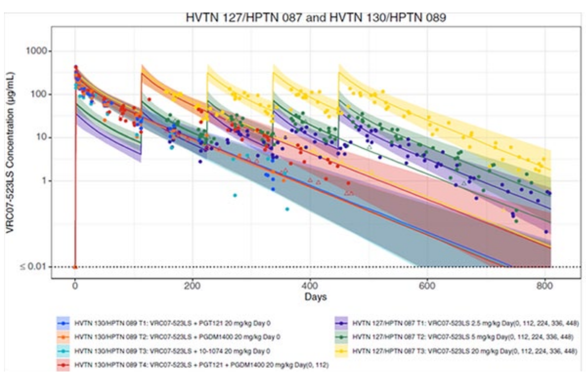

Figure. Observed VRC07-523LS individual binding antibody concentrations with the 90% prediction interval from the population-level model. The shaded area is the 90% prediction interval from the population-level model and the solid line is the median predicted concentration. The points are individual-level observed concentrations. The triangles are participants who missed at least one infusion.

Conclusions: VRC07-523LS appears to be cleared more rapidly with a larger peripheral volume when co-administered with 10-1074, PGT121, and/or PGDM1400 versus administration alone. With an insignificant impact on elimination half-life, these data suggest that the duration of PK coverage for single anti-HIV bnAbs, like VRC07-523LS, is preserved in bnAb combinations.

Depot-medroxyprogeterone acetate use alters immune modulation function of cortisol and thyroid hormones

K. Omollo[1,2], J. Oyugi[1,3], M.M. Kowatsch[3], J. Kimani[2], C. Kaushic[4,5], J. Lajoie[3,1], K.R. Fowke[3,6,2,1]

DeGroote Centre for Learning and Discovery, Hamilton, Ontario, Canada, [5]McMaster University, Department of Pathology and Molecular Medicine, Canada, [6]University of Manitoba, Department of Community Health Science, Winnipeg, Canada

Background: Depot-medroxyprogesterone acetate (DMPA) is a popular contraceptive; however, some studies report an association with increased HIV susceptibility through mechanisms that are not yet fully elucidated.

We investigated the plasma levels of cortisol, free triiodothyronine (T3), and free thyroxine (T4) and the correlation of these hormones with markers of inflammation and CD4+ T cell activation in female sex workers and non-sex workers using DMPA and those not using any hormonal contraception (non-HC).

Methods: From a group of Kenyan female sex workers (FSW (51)) and non-sex workers (60), blood and cervical cytobrush-derived T cells were phenotyped using flow cytometry. Cytokine concentrations were determined in plasma and cervico-vaginal lavages and comparisons were done between the women according to contraception use.

Results: In FSW, we observed that DMPA users (27) had significantly higher levels of Cortisol (p<0.001), T3 (p<0.001), and T4 (p<0.001) while in non-sex workers, only T3 levels were significantly higher in DMPA users (p<0.01). Correlation of the three hormones revealed a direct relationship in the levels of T3 and T4 (r=0.67, p< 0.001), T3 and Cortisol (r=0.54, p=0.002), and T4 and Cortisol (r=0.56, p= 0.001) in DMPA-using non-sex workers.

Increased cortisol levels in DMPA-using FSW inversely correlated with plasma MIP-1β levels but had no effect on genital cytokines. In FSW non-HC users, cortisol and T4 positively correlated with MIP-1α at the genital tract. T3 positively correlated with plasma IL-8 and sCD40L in DMPA-using FSW but had no impact in non-HC users.

Cortisol had an inverse correlation with the proportion of mucosal CD4+CCR5+ T cells in DMPA-using FSW, yet positively correlated with the same cells in non-HC users. Levels of T4 correlated with the per cell expression of CD69, and the proportions of CD4+ T cells expressing CD38, HLADR and CCR5 in DMPA-using FSW.

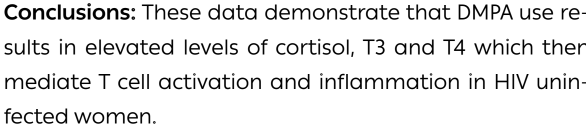
Author Index



Conclusions: These data demonstrate that DMPA use results in elevated levels of cortisol, T3 and T4 which then mediate T cell activation and inflammation in HIV uninfected women.

This effect of DMPA may be an important yet under investigated mechanism by which the contraceptive DMPA may influence susceptibility to HIV in women.

Host cellular factors and viral mechanisms of HIV/SIV persistence and latency

Role of the *pol*gene enhancer in HIV-1 transcription and replication in myeloid infected cells

C. Van Lint[1], O. Hernalsteens[1], R. Verdikt[1], C. Vanhulle[1], A. Dutilleul[1], S. Cristinelli[2], T. Marray[1], L. Nestola[1], V. Monceaux[3], A. David[3], B. Verhasselt[4], H. Galons[5], A. Ciuffi[2], A. Saez-Cirion[3], O. Rohr[6]

Background: There is increasing evidence for the physiological relevance of myeloid HIV-1 reservoirs such as brain microglia and urethral macrophages. However, the molecular mechanisms of HIV-1 expression in myeloid infected cells are still poorly understood. The HIV-1 intragenic *cis*-regulatory region (IRR) located in the *pol* gene exhibits an enhancer activity on the 5'LTR promoter. The IRR possesses multiple binding sites for various cellular transcription factors (TF).

Here, we characterized several of these binding sites and their functional involvement in the IRR-mediated control of HIV-1 gene expression in monocytes/macrophages.

Special emphasis was put on studying several binding sites for the myeloid-specific PU.1 TF, known to be a pioneer factor inducing the opening of heterochromatin in enhancers.

Methods: Electrophoretic Mobility Shift Assays (EMSAs), chromatin immunoprecipitations, infection studies, ATAC-seq (Assay for Transposase-Accessible Chromatin sequencing).

Results: We demonstrated the *in vivo* recruitment of PU.1 to the HIV-1 intragenic enhancer in latently-infected cell lines from myeloid origin. We physically characterized *in vitro* PU.1 binding to the different intragenic PU-boxes by EMSAs and identified mutations abolishing PU.1 binding without altering the underlying amino acid sequence of the *pol*gene. We demonstrated the role of the PU-boxes in the IRR enhancer activity, its chromatin remodeling and HIV-1 epigenetic regulation, in concert with other IRR transcription factor binding sites. We showed the importance of intragenic TF binding sites in HIV-1 replication using mutated viral particles in single-round infection experiments using primary monocytes-derived macrophages isolated from uninfected individuals. To overcome HIV- 1 persistence, targeted approaches for each specific cellular reservoir are needed.

As a proof-of-concept, we revealed the potential therapeutic application of a specific inhibitor interfering with PU.1 binding as a new anti-HIV-1 approach.

Conclusions: The HIV-1 intragenic enhancer brings an additional factor in an already complex network of regulators affecting the level of HIV-1 transcription. Such complexity could allow a finer-tuned regulation that might find its purpose when HIV-1 transcription needs to be moderately or transiently modified within different cellular and chromatin environments. The cell specificity of the IRR in HIV-1 gene expression regulation opens new avenues for HIV cure approaches targeting the heterogeneous cellular and tissue latent reservoirs of virus.

Background: DNA methylation is one of the epigenetic mechanisms involved in HIV-1 latency. The latent 5'LTR methylation profile is heterogeneous in latency model cell lines and in patient cells where it increases with the duration of cART.

We have previously demonstrated that 5-Azadeoxycytidine (decitabine) treatment, an inhibitor of DNA methylation, resulted in variable levels of HIV-1 reactivation

in latently infected T-cell lines and in *ex vivo* patient cell cultures. Nevertheless, the mechanisms mediating HIV-1 latency through DNA methylation remain unclear.

Methods: Sodium bisulfite sequencing, Electrophoretic mobility shift Assay, ChIP-qPCR, RNA interference, GFP fluorescence FACS, p24 ELISA and purification of primary cells from HIV+ patient blood.

Results: Using latently infected J-Lat cell lines, displaying different integration sites, we showed that decitabine-induced reactivation of HIV-1 was accompanied by differential DNA demethylation profiles at the 5'LTR, occurring at specific CpG positions, termed DDMP (*Differentially De-Methylated Positions*).

Interestingly, we showed that UHRF1 (Ubiquitin-like with PHD and Ring Finger domain 1) bound *in vitro*to several of these DDMPs through different binding modalities where DNA methylation was either non-essential, either essential, or enhancing UHRF1 binding.

Moreover, since UHRF1 was originally identified as an CCAAT/enhancer binding protein (C/EBP), we were able to show *in vivo* recruitment of UHRF1 to four C/EBPs motifs localized in the 5'LTR independently of DNA methylation, in both cell line and primary cell models for HIV-1 latency. UHRF1 depletion through RNA interference induced an increase in HIV gene expression accompanied by global DNA and histone demethylation of the 5'LTR .

We showed that UHRF1 repressed HIV-1 in absence and presence of Tat, independently of 5'LTR DNA methylation. Pharmacological inhibition of UHRF1 in PBMCs isolated from aviremic cART-treated HIV+ individuals reactivated expression of HIV-1 RNAs.

Conclusions: We demonstrate an important role in HIV-1 latency of UHRF1 which binds to multiple sites throughout the 5'LTR in a methylation-dependent and -independent manner. As UHRF1 is known to maintain heterochromatic profiles during replication, our results suggest its involvement in HIV-1 latency by maintenance of the 5'LTR methylation and other mechanisms. In this regard, UHRF1 constitutes a new therapeutic target for HIV cure strategies.

Identification, characterisation and Quantification of HIV/SIV reservoirs and rebounding virus

In vivo and *in vitro* evidence for infection of naïve CD4 T cells with CCR5-tropic HIV

C. Kearns[1], M. Pinzone[1], A. Oceguera[1], A. Ginda[1], U. O'Doherty[1]

[1]*University of Pennsylvania, Department of Pathology and Laboratory Medicine, Philadelphia, United States*

Background: Historically, the field of HIV research has largely ignored the viral reservoir in naïve CD4+ T cells, due to lower HIV DNA levels compared to memory subsets. Our analysis reveals unique proviral sequences within naïve CD4 T cells suggesting that the naïve reservoir is distinct from the memory reservoir. The naïvereservoir represents a unique hurdle because it is persistent, diverse, and resistant to immune clearance. It may also serve to replenish the more differentiated memory reservoir.

Curiously, we detected CCR5-tropic HIV in naïve cells in Persons Living with HIV (PLWH) using computer algorithms to determine tropism. Given that naïve T cells appear to lack the CCR5 co-receptor, we first wanted to determine tropism phenotypically *in vivo* and then explore mechanisms of naïve infection *in vitro*.

Methods: We tested the *in vivo* tropism bystimulating sorted naïve CD4 T cells (distinguished as CD95-, CD45RA+, CCR7+, CD27+) to release virus at limiting dilution from PLWH on antiviral therapy. Tropism of HIV RNA+ supernatants were then determined by infecting cells engineered to express CCR5 or CXCR4.

We next investigated *in vitro* conditions that promote naïve infections. We infected mixtures of CD4 subsets, as well as pre-sorted naïve cells alone with a CCR5-tropic HIV utilizing fibroblast reticular stromal cells to preserve the naïve phenotype.

Results: We showed CCR5-tropic HIV can be isolated from naïve CD4 T cells of PLWH by performing infection studies with out-growth virus in the presence and absence of CCR5 inhibitors.

We also found CCR5-tropic infection occurred *in vitro* in phenotypically naïve cells when CD4+ T cells were infected in bulk, but not when naïve cells were pre-sorted and then infected. Thus, memory T cell reversion or transient upregulation of CCR5 expression may provide a mechanism for CCR5-tropic naïve infection which may be promoted by cellular interactions that occur in the lymph node milieu.

Conclusions: We present *in vivo* and *in vitro*data that CCR5-tropic infection occurs in naïve cells.

Additionally, we developed an infection model that promotes naïve infection, potentially by reversion. This model can be utilized to explore mechanisms that underlie naïve infection and for preclinical studies to probe the naïve reservoir.

Background: HIV persistence in the central nervous system (CNS) may be an important barrier to cure/remission strategies and may impact long-term cognitive outcomes in adolescents and young adults with perinatal HIV (AYAPHIV). IMPAACT 2015 systematically examined AYAPHIV with cognitive impairment and receiving effective antiretroviral therapy (ART) to quantify HIV persistence in blood and cerebrospinal fluid (CSF).

Methods: AYAPHIV (13-30 years old) with cognitive impairment and on suppressive ART were consented and enrolled into IMPAACT 2015, an IRB-approved U.S.-based cross-sectional, multi-site, exploratory, observational study. Cognitive impairment was defined as NIH Toolbox Fluid Cognition composite standard score >1 S.D. below the normative group mean.

Participants underwent lumbar puncture (LP), phlebotomy, and hair collection. CSF and blood were measured for HIV-RNA and HIVpol/gag-DNA and 11 biomarkers of inflammation and neuronal injury. Hair was used to quantify ART exposure levels. Exact binomial confidence intervals (CIs) were calculated, and 41 comparisons evaluated with Wilcoxon rank sum tests.

Results: Among 24 enrolled participants, 22 underwent LP, and 20/22 (91%) had successful CSF collection. 18 participants met ART suppression criteria, and had plasma HIV-RNA <20 copies/ml from entry through the day of LP. 9/18 (50%) were cisgender females and 14/18 (78%) were Black. Median (range) age was 20 years (13-27), time on ART 18.3 years (8.0-25.5), CD4 count 701 cells/mm^3 (143-1342), and Fluid Cognition T-score 68 (53-80). HIV-DNA was detected in PBMCs in all participants. In CSF, 2/18 participants had detectable HIV-RNA, one of whom was quantifiable (5.6% 95% CI (0.1%, 27.3%)) and HIVgag and/or pol-DNA was detectable in 13/18 (72% 95% CI (47%, 90%)).

Detectable HIV-DNA in CSF was associated with higher levels of HIVpol-DNA copies in PBMCs (medians 227, 27 per million cells, p=0.04), and trended with lower scores on a Fluid Cognition subtest measuring Inhibitory Control and Attention (medians 49, 65 p=0.09). Measured biomarkers and ART levels were not statistically associated with presence of detectable HIV-DNA in CSF.

Conclusions: Findings from IMPAACT 2015 suggest that the CNS is a site of HIV persistence in the majority of AYAPHIV with cognitive impairment, warranting further evaluation in pediatric HIV treatment and eradication studies.

PESUA20

Subtype A1 and D HIV-1 proviral genome landscape in Rakai, Uganda

[1]Weill Cornell Medical College, Department of Medicine, Division of Infectious Diseases, New York, United States, [2]Simon Fraser University, Burnaby, Canada, [3]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [4]Rakai Health Sciences Program, Kalisizo, Uganda, [5]National Institute of Allergy and Infectious Diseases, Division of Intramural Research, Bethesda, United States, [6]Johns Hopkins University School of Medicine, Department of Medicine, Baltimore, United States, [7]Western University, Department of Microbiology and Immunology, London, Canada

Background: Whether various HIV-1 subtypes have similar reservoir profiles, such as the frequencies of intact proviruses and extent of clonal expansion, remains a major knowledge gap in cure research. Here, we describe and compare near-full-genome DNA sequences of subtype A1 and D HIV-1 and their associated recombinant forms observed in Rakai, Uganda.

Methods: Blood was collected from 7 male and 16 female participants with chronic HIV-1 who were virologically-suppressed for >1-year. Resting CD4+ cells were negatively selected from total PBMC (CD69$^-$/CD25$^-$/HLA-DR$^-$) and extracted for DNA. Total HIV-1 DNA levels were quantified via *gag*-specific droplet digital PCR, followed by limiting dilution, nested near-full-viral-genome PCR (HXB2 638-9632) and Illumina sequencing. Viral genome-intactness was assessed using a previously published software suite HIVSeqinR adapted for non-B HIV subtypes.

Results: We obtained 607 near-full-genome HIV-1 DNA sequences after sampling ~two million cells per individual. Among the 23 donors, subtype distribution was 4 A1, 9 D, 9

A1/D and 1 A1/C/D. Intact genomes were relatively rare and made up <1.6% to 33%, whereas clonal expansion was detected in both intact and defective genomes and made up <2-14% (intact) and <3-70% (defective) of the intrahost viral DNA population. Total HIV-1 DNA load per million CD4 cells, relative proportions of intact genomes, proportions of clonally expanded genomes, and proportions of hypermutated genomes did not differ among subtypes (Kruskal-Wallis all p>=0.1) and did not differ by sex (Mann-Whitney all p>=0.2).

Large deletions were significantly less frequently observed in *gag* relative to reverse transcriptase, RNaseH, integrase, *vif, vpr, vpu,*and *env* (intra-host median 50% *gag-retained* versus 18-35% other genes, Mann-Whitney p=0.0004-0.03). Among all the defective genomes, 85% (A1), 87% (D), 87% (A1/D), 79% (A1/C/D) lacked one or both of the Intact Proviral DNA Assay (IPDA) psi/*env* primer binding sites, whereas 100% of intact genomes in this study contained both regions.

Conclusions: Similar to subtype B reservoirs reported in the literature, persisting HIV DNA pools in subtypes A1, D, A1/D and A1/C/D had high proportions of defective genomes and/or had undergone clonal expansion. Future research should explore whether re-activatability differs across HIV-1 subtypes and utilize these sequence data to validate IPDA for non-B HIV-1.

Strategies to reduce/eliminate viral reservoirs

PESUA21

The LRA HODHBt synergizes with IL-15 to enhance the cytotoxic capacity of HIV-specific CTL

D. Copertino[1], C. Stover[2], T. Zaikos[2], A.B. Macedo[2], A. Bosque[2], R.B. Jones[1]

[1]*Weill Cornell Medicine, Infectious Diseases, New York, United States,* [2]*The George Washington University, Department of Microbiology, Immunology and Tropical Medicine, Washington, United States*

Background: More potent "shock and kill" therapeutics are likely needed to achieve reductions in HIV reservoirs. We previously showed that 3-hydroxy-1,2,3-benzotriazin-4(3H)-one (HODHBt) enhances IL-15-mediated HIV reactivation in cells from people living with HIV (PLWH), by increasing occupancy of STAT5 on the HIV-LTR. Since IL-15 can also enhance CD8+ T-cell effector functions through STAT5 activation, we hypothesized that HODHBt would also synergize with IL-15 to enhance cytotoxic functions of HIV-specific CD8+ T-cells.

Methods: CD8+ T-cells from 9 HIV-negative donors were treated with HODHBt and IL-15, and assessed by flow cytometry for phosphorylation of STAT-1, -3, and -5, and expression of Granzymes A (GZMA) and B (GZMB), Perforin and Granulysin. GZMB ELISpots were performed on PBMCs from 14 PLWH – suppressed on ART for an average of 10.9 years - stimulating with peptide pools spanning Gag, Pol, Nef, Env, or CMVpp65, with or without IL-15 and HODHBt. Secreted cytokines were measured in supernatants using the CorPlex Human Cytokine Panel 10-Plex array.

Results: HODHBt alone increased STAT-1 phosphorylation (p=0.031) but did not increase STAT-3 or STAT-5 phosphorylation, nor expression of GZMB, GZMA, perforin and granulysin. Relative to IL-15 alone, CD8+ T-cells treated with IL-15 and HODHBt showed increases in phosphorylation of STAT-1 and STAT-5 (p=0.031) but not STAT-3, as well as expression of GZMB (p<0.001). HIV-specific GZMB-releasing responses were enhanced by treatment with HODHBt in combination with IL-15, relative to medium only as follows: Gag 6.8-fold (p=0.005), Pol 6.8-fold (p=0.005), Nef 12.8-fold (p<0.001), and Env 3.7-fold (p=0.438, ns). These were substantially increased relative to enhancements with IL-15 alone (IL-15+HODHBt/IL-15+DMSO) Gag 2.4-fold (p<0.001), Pol 1.8-fold, (p<0.001), Nef4.3-fold, (p<0.001), and Env 2.6-fold, (p<0.001). HODHBt alone did not increase background (no peptide) above IL-15 alone.Across all conditions, except CMV stimulation, GZMB was significantly positively correlated with cytokines IFNγ (r=0.89, p<0.001) and IL-22 (r=0.73, p<0.001) by CorPlex.

Conclusions: HODHBt synergizes with IL-15 to significantly enhance HIV-specific cytotoxic T-cell responses in *ex vivo*-PBMCs from ART-treated PLWH.

Our results highlight that pharmacologic enhancement of IL-15 mediated STAT activation can be a therapeutic strategy with the potential to enhance both the 'shock' and the 'kill' components of strategies aimed at depleting HIV reservoirs.

Productively-infected CD4 T cells are resistant to ADCC mediated by non-neutralizing antibodies

J. Richard *[1,2], G. Sannier[1,2], J. Prévost[1,2], H. Medjahed[1], G. Gabrielle Delgado[1], G. Gendron-Lepage[1], M. Dubé[1], D. E.Kaufmann #[1,3], A. Finzi #[1,2], * # Equal Contribution

[1]*Centre de Recherche du CHUM, Montreal, Canada,* [2]*Université de Montreal, Département de Microbiologie, Infectiologie et Immunologie, Montreal, Canada,* [3]*Université de Montreal, Département de Médecine, Montreal, Canada*

Background: The conformation of the HIV-1 envelope glycoprotein (Env) substantially impacts antibody recognition and antibody-dependent cellular cytotoxicity (ADCC) responses. In its unliganded form, the Env samples a "closed" conformation that is preferentially recognized by broadly-neutralizing antibodies (bNAbs). CD4 engagement drives Env into the "open" CD4-bound conformation, preferentially targeted by non-neutralizing Abs (nnAbs). The virus prevents exposure of CD4-induced epitopes by downregulating CD4 via Nef and Vpu. Despite sig-

nificant advances on the understanding of HIV resistance to ADCC, the capacity of nnAbs to mediate ADCC against productively-infected cells remain controversial.

Methods: We used a multiplexed viral RNA detection by flow cytometric fluorescent *in situ*RNA hybridization (RNAflow-FISH) technique to characterize cell populations targeted by bNAbs and nnAbs in the context of primary CD4+ T cells infected with a primary HIV-1 isolate or isolated from HIV-1-infected individuals.

Results: Productively-infected cells are recognized by bNAbs, efficiently downregulate CD4, express high levels of Nef and p24 proteins and are enriched in HIV-1 mRNA ($CD4^{-}p24^{+}Nef^{+}HIV\ mRNA^{+}$).

In contrast, cells targeted by nnAbs are CD4-positive, express little or no p24 and are negative for Nef expression and HIV-1 mRNA ($CD4^{+}p24^{-}/p24^{low}Nef^{-}HIV\ mRNA^{-}$).

Moreover, cells recognized by nnAbs are *env* mRNA negative, suggesting that they represent cells coated with either shed Env and/or non-infectious viral particles. As expected, we observed that CD4 downregulation precedes the expression of HIV-1 late transcripts, thus confirming that the $CD4^{+}p24^{low}Nef^{-}HIV\ mRNA^{-}$cells targeted by nnAbs are not part of the viral replication cycle.

Finally, we found that *ex vivo* expanded CD4+ T cells isolated from HIV-1-infected individuals are sensitive to ADCC mediated by bNAbs but resistant to those mediated by nnAbs.

Conclusions: Our results demonstrate that productively-infected cells are resistant to nnAbs. This information is important for the development of immunotherapy-based strategies aimed at targeting and eliminating productively-infected cells.

Background: Optimal time to administrate COVID-19 vaccines after natural infection is a matter of debate. This study aims to evaluate the humoral immune response elicited against the variants of concern (VOCs) alpha, beta, and delta in convalescent and naïve people vaccinated with SpikeVax (Moderna).

To evaluate the effect of extending the vaccination schedule we compared the impact of immunization 1-3 months versus 4-12 months after the natural infection in recovered patients.

Methods: Sera from 66 health care workers were collected at pre-vaccination, at pre-boost, and at post-boost. A total of 31 out of the 66 participants had a documented prior history of SARS-CoV-2 infection, including 17 (53.1%) lately-infected (LI) within three months before vaccination and 14 (43.7%) with early infection (EI) documented from 4 to 12-months before vaccination.

Antibody-mediated immune responses were assessed by three commercial immunoassays and a SARS-CoV-2 lentiviral-based pseudovirus neutralization assay.

Results: Levels of immunoglobulins (Ig) to SARS-CoV-2 were lower in naive participants at post-boost as compared with convalescents after a single dose of SpikeVax ($p<0.05$). In recovered patients, after two vaccine doses total Ig to RBD were higher in EI (21,618 BAU/ml; 95% CI: 18,092-25,831) as compared to LI (10,219 BAU/ml; 95% CI: 7572-13,792 BAU/ml) ($p<0.001$). These differences were also observed for anti-trimeric spike IgG levels and anti-spike IgA.

The SARS-CoV-2 neutralization titer 50 (NT50) observed in EI was consistently higher than in LI against VOCs alpha, beta, and delta. Specifically, after the second dose of SpikeVax, the geometric mean NT50 against alpha were

6306 (95% CI: 4548-8743) for EI and 2575 (95%CI: 1737-3817) for LI; 2607 (95% CI: 1614-4211) vs 922 (95% CI: 553-1536) for beta, and 4991 (95% CI: 3319-7506) vs 1795 (95% CI: 1135-2838) for delta.

These levels involve fold reductions in NT50 of 2.4-, 2.8-, and 2.8-fold against alpha, beta, and delta respectively in LI in comparison with the EI group.

Conclusions: Increasing more than 4 months the interval between SARS-CoV-2 infection and the immunization with mRNA-based vaccines generates a more efficient humoral immune response against VOCs. This improvement can be related with the time requested to mount a strong recall memory B cell response.

Unvaccinated individuals admitted to the ICU due to fatal COVID-19 showed progressive decay of unresponsive cytotoxic cells

G. Casado[1], M. Corona[2], M. Torres[1], L. Vigón[1], A.J. Saez[2], F. Ramos Martín[1], E. Mateos[1], S. Rodríguez Mora[1], V. García-Gutierrez[2], M. Coiras[1]

[1]*Instituto de Salud Carlos III, AIDS Immunopatology Unit, National Center of Microbiology, Madrid, Spain,* [2]*Hospital Universitario Ramón y Cajal, Hematology Service, Madrid, Spain*

Background: Individuals admitted to the ICU due to critical COVID-19 show an ineffectual cytotoxic activity against SARS-CoV-2. We determined whether this impaired cytotoxic activity could be restored in PBMCs from individuals with critical and fatal COVID-19.

Methods: 23 patients with critical COVID-19 admitted to the ICU were divided in two groups according to the outcome: Exitus (n=13) or Survival (n=10). Blood samples were collected every 10-15 days during 80 days of hospitalization. Cytotoxic activity against SARS-CoV-2-infected Vero E6 cells was analyzed after co-culture (2:1) with PBMCs treated or not with IL-15 (0.13µL/mL) 48h.

Results: 1) Median age was 65.0 (IQR 62.0-69.0) and 63.0 years (IQR 59.0-68.5) in Exitus and Survival groups, respectively. 73.9% individuals were men with dyslipidemia (52.2%), hypertension (40.1%), and/or diabetes mellitus (26.1%).

2) Mean length of hospital stay was 65.3 (SD: 37.1) and 68.1 days (SD: 29.3), respectively, whereas mean length of ICU stay was 53.8 (SD:30.6) and 46.3 days (SD: 23.3). 3) Cytotoxic activity against SARS-CoV-2 of PBMCs in the Exitus group increased 1.9-fold (p=0.0313) after 21-35 days of hospitalization, but this response decayed steadily until the fatal outcome (*Figure 1*).

In the Survival group, cytotoxic activity was 5.6-fold (p=0.0290) higher than the Exitus group at days 21-35 and it increased steadily until days 36-50. 4) Treatment with IL-15 increased cytotoxic activity of PBMCs in both groups but it remained 6.2-fold (p=0.0303) lower in the Exitus group after 21-35 days. 5) CD8 count increased 2.1-fold (p=0.0409) in the Exitus group (t=0) and remained enhanced until the fatal outcome.

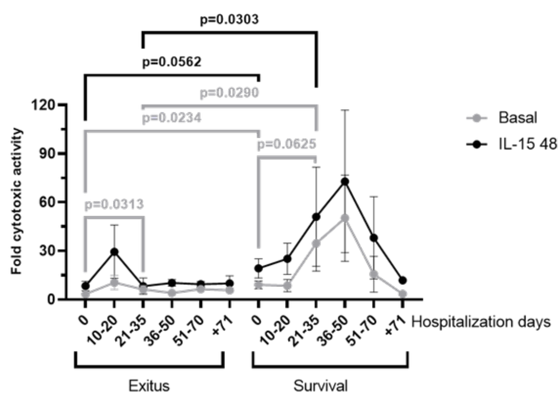

Figure 1. Measurement of cytotoxic activity against SARS-CoV-2 of PBMCs from individuals with critical (Survival) and fatal (Exitus) COVID-19 during 80 days of hospitalization in the ICU, in the presence (black) or the absence (grey) of IL-15.

Conclusions: Individuals with fatal COVID-19 showed increased levels of CD8 with impaired cytotoxic activity that were unresponsive to IL-15-induced proliferation. The reactivation of this impaired cytotoxic response appears to be essential to avoid a fatal outcome and has to be considered to develop new strategies against critical COVID-19.

Background: SARS-CoV-2 induces cytokine response dysregulation and immune dysfunction. What remains unclear is how cytokine signaling shapes immune responses during early SARS-CoV-2 infection when adaptive immunity is developing.

Our goal is to identify immune pathways that shape the early development of adaptive immune responses in COVID-19 patients.

Methods: We performed paired single-cell transcriptomic and epigenomic profiling at two time-points of early SARS-CoV-2 infection to determine immune signatures of acute infection and epigenetic drivers that underpin immune response dynamics. PBMC samples from Yale IMPACT cohort were collected from four moderate to severe COVID-19 patients at two early time-points (n = 3 for Week 1 and n = 3 for Week 2 after symptom onset, including 2 participants having paired blood sampling at both time points) and from two healthy controls (n = 2). Using paired scRNA-Seq and scATAC-Seq, we captured transcriptomic and epigenomic profiles in the same single cells to

identify chromatin accessibility changes as a potential mechanism for the surge and decline of immune responses elicited during acute SARS-CoV-2 infection. Using bioinformatic approaches, we identified heterogeneous immune cell populations, determined dysregulated immune pathways through gene set enrichment analysis, and connected RNA expression profiles with chromatin co-accessible landscapes.

Results: We captured transcriptomic and epigenomic profiles of 34,954 single cells and identified paired transcriptional and epigenetic landscapes. We found that SARS-CoV-2 infection induced an early surge in IL-2, IL-6, IFN-α, IFN-γ, and SMAD-dependent TGF-β responses at Week 1 that declined at Week 2 in adaptive immune cells (CD4+ T, CD8+ T, and B cells).

In contrast, we found steady increase in AP-1-induced immune responses that persisted at Week 1 and 2 in adaptive immune cells despite convalescence. Expression levels of the AP-1 transcription factors *JUN* and *FOS* were upregulated in tandem with increased chromatin accessibility at the AP-1 binding sites and increased expression of host genes epigenetically regulated by AP-1 signaling, such as MAP kinase activation genes (*PPIA* and *ADAP1*), *NFKB1*,and the CXCR5 ligand *CXCL13*.

Conclusions: Our finding suggests that AP-1 signaling shapes early adaptive immune responses during early stages of acute SARS-CoV-2 infection.

Background: HIV dysregulates the B cell compartment affecting the nature and quality of the memory B cell, antibody secreting cell (ASC) and resulting antibody response to infections. Understanding the B cell response to COVID-19 in people living with HIV (PLWH) could explain the increased morbidity, reduced clearance and intra-host evolution of SARS-CoV-2. We compared the B cell response to SARS-CoV-2 infection in PLWH and HIV negative patients.

Methods: Our cohort from Durban, KwaZulu-Natal, South Africa comprised primarily of mild to moderate COVID-19 severity and was recruited during the first wave of the pandemic, in July 2020. Most HIV positive patients were on effective ART (n = 28), of which five were HIV viremic, and 32 were HIV negative. Patient blood samples were collected weekly for five weeks from symptom onset and positive diagnostic swab. Peripheral blood cells (PBMC) were isolated for B cell phenotyping by flow cytometry using three phenotyping panels to assess maturation, homing and regulatory populations.

Results: Using an unbiased tSNE analysis we observed a coordinated B cell homing response after infection. The ASC frequency associating with disease severity; where class switched memory and transitional B cells associated with resolution of disease. PLWH had lower germinal center (GC) homing capacity and class switched memory responses.

In stark contrast to HIV negative patients, the COVID-19 B cell response in PLWH had pronounced EF activity, despite only mild to moderate disease. This included expanded activated double negative (DN2) and activated naïve responses. In turn the higher early plasma blast frequencies also supported an active EF pathway in PLWH. The SARS-CoV-2 specificity of the EF response was confirmed using viral spike and RBD bait proteins.

Conclusions: HIV primes an EF B cell response to COVID-19 even with mild to moderate disease, contrasting with the response in HIV negative patients. This suggests a potentially suboptimal B cell response to infection in PLWH. These results could explain the reduced antibody affinity and B cell memory responses in PLWH and support future studies aimed at monitoring both responses, especially considering new SARS-CoV-2 variants and vaccine dosing for optimal protection in PLWH.

PEMOA32

The impact of delta and omicron variants in the T-cell response to mRNA vaccination in people living with HIV

J.L. Casado[1], P. Vizcarra[1], S. Martín-Colmenarejo[1], J. del Pino[1], M.J. Pérez-Elías[1], A. Moreno[1], M.J. Vivancos[1], A. Martín-Hondarza[2], A. Abad[1], A. Vallejo[1,2]

[1]Ramon y Cajal University Hospital, Infectious Diseases, Madrid, Spain, [2]Ramon y Cajal University Hospital, Laboratory of Immunovirology, Madrid, Spain

Background: SARS-CoV-2 variant-of-concern (VOC) B.1.1.529 (Omicron) presents a surprisingly large number of mutations in its spike protein escaping from antibody neutralization.

Thus, it is important to determine how well T-cell responses perform against different variants including Omicron in people living with HIV (PWH) following SARS-CoV-2 vaccination.

Methods: Pilot study of PWH who underwent blood tests for humoral and cellular immunogenicity testing 30 days after the second dose of a SARS-CoV-2 mRNA vaccine. Humoral (anti-S IgG, CLIA) and IFN-γ producing T-cell responses to spike peptides of the ancestral virus, delta, and omicron variants were performed.

Results: Overall, 24 PWH were included. Median age was 53 (interquartile range, IQR, 33-57) years, 71% were male, 4% were obese, and 42% had at least one comorbidity. Median nadir CD4+ count was 287 cells/mm3, and 13% had a previous AIDS diagnosis. Median current CD4+ count was 746/mm3 and HIV-RNA viral load was ≤ 50 copies/ml in all the individuals.

After the second vaccine dose, humoral and T-cell responses to ancestral SARS-CoV-2 were observed in 96% and 92% of PWH, respectively, and were highly correlated (rho=0.657; p<0.01 between IgG and CD4+).

Additionally, there was a high correlation between T-cell responses to the ancestral strain, delta, and omicron variants. However, the magnitude of CD4+ and CD8+ T-cell responses were significantly lower to delta (-13%, p=0.004; and -32%, p=0.007, respectively), and to omicron variants (-40%, p<0.001; and -27%, p=0.012,respectively) compared to the ancestral strain. In any case, 75% and 87%% of PWH continued to have CD4+ and CD8+ T-cell responses to the omicron variant. As expected, those with the best cellular response to delta or omicron variants were those with the highest humoral response (rho=0.62, p<0.01 for CD4+, rho=0.42, p=0.03 for CD8+).

Conclusions: We report that IFN-γ producing T cell responses against delta and omicron spike peptides, although preserved in an important proportion of PWH, were significantly lower than to the ancestral strain in individuals who received two doses of SARS-CoV-2 mRNA vaccine.

The clinical importance of these findings should be further evaluated, as the presence of T-cell responses could avoid the progression to severe disease in most cases.

PEMOA34

Seroprevalence of cross-reactive anti-SARS-CoV-2 antibodies in pre-COVID-19 samples collected from Cameroonian women during pregnancy and at delivery

[1]University of Yaounde I, The Biotechnology Center, Yaounde, Cameroon, [2]University of Yaounde I, Department of Animal Biology and Physiology, Yaounde, Cameroon, [3]University of Yaounde I, Department of Biochemistry, Yaounde, Cameroon, [4]Stanford Medicine, Stanford Health Care, Palo Alto, United States, [5]Insititute Medical Research and Medicinal Plant Studies, Center For Research on Emerging and Reemerging Diseases, Yaounde, Cameroon, [6]University of Buea, Faculty of Health Sciences, Buea, Cameroon

Background: TheCOVID-19 Pandemic still causes significant morbidity and mortality worldwide. Significantly more cases of COVID-19 and its related deaths are reported in High-Income countries compared to Low- and Middle-Income Countries (LMIC). This might be due to pre-existing cross-reactive antibodies to other human coronaviruses in the LMIC setting. It is also unclear whether these antibodies circulate amongst pregnant women and can be acquired transplacentally.

Our study aimed to determine the seroprevalence of cross-reactive anti-SARS-CoV-2 antibodies in pre-COVID-19 samples collected during pregnancy and at delivery from women in three settlements in Cameroon.

Methods: A total of 1,711 archival plasma from pregnant women and 84 cord blood plasma collected from 2009 to 2019, were tested for COVID-19 using the Abbott Panbio ™- COVID-19 IgG/ IgM rapid diagnostic test that captures antibodies to viral N protein. Samples from 128 (7.5%) women were collected from the rural area, 1115 (65.2%) in the peri-urban area, and 468 (27.3%) in an urban area at different antenatal visits. Samples from the peri-urban area were split into pregnancy (293) and delivery (876) arms. Data was summarized in proportions.

Results: Overall, 13.7% (235/1711) of pregnant women were seropositive for COVID-19, among whom, 27.3% (35/128) were from rural areas, 14.3% (160/1115) from peri-urban areas, and 22.0% (103/468) from urban areas. During pregnancy 22.8% (8/35), 2.2% (1/46), 30.09% (31/103) of the women were IgG positive while 2.8 % (1/35), 2.2% (1/46), 3.9% (4/103) of pregnant women were seropositive for both IgG and IgM in rural areas, peri-urban and urban respectively. At delivery, the seroprevalence of IgG, IgM, and both were 13.1% (15/114), 83.3% (95/114), and 3.5% (4/114) respectively. Transplacental transfer of cross-reactive anti- SARS-CoV-2 IgG was found in 5.9 % (5/84) of these women.

Conclusions: This study provides evidence of existing of cross-reactive anti-SARS-CoV-2 antibodies among pregnant Cameroonian women in the Pre-COVID-19 era and

that these antibodies can be transferred transplacentally. However, the protective nature of these antibodies should be investigated further.

Neuropathogenesis

PESUA24
Chronic CNS inflammation in ART-suppressed SIV-infected rhesus macaques is associated with immune activation and viral persistence in the gut

S. Byrnes[1], T. Angelovich[1], K. Busman-Sahay[2], S. Younger[2], M. Nekorchuk[2], C. Cochrane[1], M. Roche[3], C. Deleage[4], B. Brew[5], J. Estes[2], M. Churchill[1]
[1]RMIT University, School of Health and Biomedical Sciences, Melbourne, Australia, [2]Oregon Health & Science University, Vaccine and Gene Therapy Institute, Oregon National Primate Research Centre, Portland, United States, [3]Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, [4]Leidos Biomedical Research, Inc., Frederick National Laboratory for Cancer Research (FNLCR), AIDS and Cancer Virus Program, Frederick, United States, [5]St Vincent's Hospital, Peter Duncan Neurosciences Unit, Departments of Neurology and Immunology, Sydney, Australia

Background: HIV-associated neurocognitive disorders (HAND) affect ~30% of virally suppressed people with HIV (PWH), suggesting that HAND pathogenesis may be driven by mechanisms other than direct viral replication in the brain including chronic systemic inflammation.
However, to date, the precise viral dependent and independent changes to the brain of virally suppressed PWH remains unclear.
Methods: Here we comprehensively characterised the CNS reservoir and immune environment of SIV-infected (SIV+) rhesus macaques during acute (n=4), chronic (n=16) or ART-suppressed SIV infection (n=11). Multiplex immunofluorescence for markers of SIV infection (vRNA/DNA) and immune activation was performed on frontal lobe and matched gut tissue. CNS and gut inflammation was also measured in an SIV-uninfected model of chronic colitis, validated to mimic SIV-induced gut damage, to determine the effect of gut damage on neuroinflammation independent of SIV infection.
Results: SIV+ animals contained viral DNA+ cells that were not reduced in the brain or gut by ART (P<0.05), supporting the presence of a stable viral reservoir in these compartments. SIV+ animals had heightened levels of activated astrocytes (GFAP+) and microglia (Iba1+) producing antiviral (Mx1 and/or TGF-β1) and oxidative stress markers (SOD1) as well as reduced blood-brain barrier integrity than uninfected animals, and these dysfunctions were not abrogated by ART (P<0.05 for all). Interestingly, measures of CNS immune activation and blood brain barrier integrity correlated with gut, but not CNS, viremia and immune activation in virally suppressed animals, supporting the role of systemic inflammation as a contributor to neuroinflammation.
Furthermore, SIV-uninfected animals with experimentally induced gut damage showed a similar immune activation profile in the brain to animals with SIV, supporting the role of chronic gut damage as an independent source of neuroinflammation.
Conclusions: Collectively, we show that ART-suppressed SIV+ rhesus macaques exhibit impaired blood brain barrier integrity and heightened microglial and astrocyte activation which is associated in part with viral reservoirs and immune activation in the gut.

Neurologic disorders (e.g. CNS malignancies)

PESUB14
Low frequency of activated T cells in people living with HIV, aviremic under treatment, and presenting neurocognitive disorders

L. Kundura[1], R. Cezar[2], M. Pastore[3], L.-A. Gutierrez[4], C. Berr[4], C. Reynes[3], J. Reynes[5,6], A. Makinson[5,6], P. Corbeau[1,6]
[1]Institute of Human Genetics - CNRS, Homing, immune activation and infection, Montpellier, France, [2]Nîmes University Hospital, Immunology Department, Nîmes, France, [3]Institute of Functional Genomics - CNRS, Montpellier, France, [4]Institute for Neurosciences of Montpellier - CNRS, Montpellier, France, [5]Montpellier University Hospital, Infectious and Tropical Diseases Department, Montpellier, France, [6]Montpellier University, Montpellier, France

Background: Prevalence of HIV-associated neurocognitive disorders (HAND), either asymptomatic neurocognitive impairment (ANI), minor neurocognitive disorder (MND), or HIV-associated dementia in people living with HIV (PLWH) under efficient combined antiretroviral therapy is high. Here, we looked for links between immune activation and HAND in an HIV-population over 55 years age with controlled HIV-disease.
Methods: This study is an ancillary study of the French national ANRS EP58 HAND 55-70 project (Clinical trial registration NCT02592174). We recruited 71 PLWH with a mean (±SD) age of 62±2.4 years; CD4 count, 553±249 cells/µL; CD4:CD8 ratio, 1.03±0.58; duration of infection, 20.0±7.7 years under efficient treatment during at least two years (<50 copies/mL and less than 2 viremic blips). We used the Frascati criteria to classify neurocognitive performances. We analyzed 31 peripheral blood soluble and cell surface markers of T cell, NK cell, monocyte, endothelial cell activation and inflammation by ELISA and flow cytometry. We performed two hierarchical clustering analyses, one at a participants' level, and the other one at a markers' level.

Results: We found that 53% of PLWH were classified as HAND (ANI, n=21; MND n= 12). The proportion of CD8+ (44.3±10.3 vs. 52.6±10.4 %, p = 0.002), activated (HLA-DR-positive) CD4+ (19.6±10.3 vs. 28.9±14 %, p = 0.002) and activated (HLA-DR-positive) CD8+ (19.6±10.3 vs. 28.9±14.0 %, p = 0.025) T cells were lower in participants with ANI or MND than in participants without HAND. The double hierarchical clustering identified six different immune activation profiles in participants.

Participants with one of these profiles, also characterized by a low frequency of circulating activated CD4+ T cells, presented more frequently ANI and MND (odds ratio 8.8 [95% CI 1.0-77.0], p = 0.041) than the participants with other profiles.

Conclusions: We did not find a positive correlation between HAND and circulating markers of immune activation in ageing PLWH. Our observation of a low percentage of activated T cells in peripheral blood raises the interesting hypothesis of a recruitment of these lymphocytes into the central nervous system.

Mental health (including depression and psychiatric manifestations) and HIV

PESUB16

The burden of and risk factors for maternal mental health and the impact on parenting by mothers living with HIV in rural Zimbabwe

R.M.S. Chingono[1,2], V. Simms[3], F. Cowan[4], L. Sherr[1]
[1]University College London, Institute of Global Health, London, United Kingdom, [2]Biomedical Research and Training Institute, Social Science, Harare, Zimbabwe, [3]London School of Hygiene and Tropical Medicine, London, United Kingdom, [4]Liverpool School of Tropical Medicine, London, United Kingdom

Background: Mothers in limited-resource settings, especially those living with HIV, are at increased risk of comorbidities, including mental health disorders. In sub-Saharan Africa, mental health disorders are common in the population living with HIV, yet they remain undetected and untreated. We explored the prevalence of, and factors associated with prolonged depression and parenting stress in HIV positive mothers and their association with parenting behaviour. We hypothesised that prolonged depression leads to stress and hostile parenting.

Methods: We conducted a secondary analysis of a cluster-randomised controlled trial in two districts in Zimbabwe between 2016-2017, enrolling 485 HIV positive mothers of infants. Outcomes included prolonged depression, measured using the 14-item Shona Symptom Questionnaire (and defined as depression at baseline and 12 months follow up) and parenting stress using the Parenting Stress Index Short Form.

We assessed mother-child interaction, maternal social interaction, and health. Logistic regression was used to determine the correlates of prolonged depression and parenting stress.

Results: Overall, 26% of mothers experienced prolonged depression with no difference by the trial group. Risk factors for prolonged depression included being the only adult in the household (aOR=2.49); food insecurity (aOR=1.90); domestic violence (aOR=3.45); mobility problems (aOR=3.77); lack of social support (aOR=1.33) and poor postpartum bonding (aOR=2.52). For those in a relationship, prolonged depression was independently associated with impaired postpartum bonding and lower relationship quality. Overall, 73% of mothers with parenting stress were at risk of symptoms suggestive of prolonged depression. Factors associated with parenting stress included symptoms of prolonged depression and having pain or discomfort. 70% of mothers with prolonged depression had slapped, shaken or spanked their child and it was associated with increased parenting stress.

Conclusions: We found a high prevalence of prolonged depression and parenting stress among HIV positive mothers associated with food insecurity, experiencing pain or mobility problems, being less resilient and having poor relationships and low social support. There is a critical need to address depression and parenting stress both for its own sake and to benefit child outcomes.

Weight gain

PESUB17

DTG associated weight gain: real or perceived? Real world experiences from Zimbabwe

T. Shamu[1,2,3], C. Chimbetete[1], T. Mudzviti[1,4], J. Manasa[5], M. Egger[2,6,7], N. Anderegg[2]
[1]Newlands Clinic, Harare, Zimbabwe, [2]University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland, [3]University of Bern, Graduate School of Health Sciences, Bern, Switzerland, [4]University of Zimbabwe, Department of Pharmacy and Pharmaceutical Sciences, Harare, Zimbabwe, [5]University of Zimbabwe, Innovation Hub, Harare, Zimbabwe, [6]University of Cape Town, Centre for Infectious Disease Epidemiology and Research, School of Public Health and Family Medicine, Cape Town, South Africa, [7]University of Bristol, Population Health Sciences, Bristol Medical School, Bristol, United Kingdom

Background: Dolutegravir (DTG) based regimens have been associated with weight gain in clinical trials. We compared real-world weight changes after starting or switching of treatment for DTG, efavirenz (EFV), and atazanavir (ATV/r) based regimens.

Methods: We included adults (≥18 years) starting or switching (defined as baseline) to EFV, ATV/r, or DTG between 2008 and 2021 at Newlands Clinic, Zimbabwe.

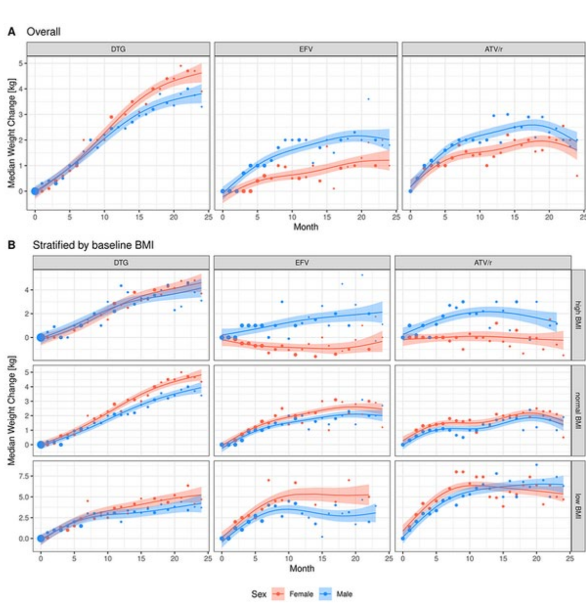
We calculated weight changes for subsequent visits from the baseline weight. We aggregated data by treatment regimen, sex, and month after baseline and calculated median weight change for each data cell.

We analyzed trends in median weight changes after baseline by generalized additive models. We included sex, regimen, and their interaction as fixed effects, and smoothed monthly trends by sex and regimen. We analyzed overall and baseline BMI category (<18.5 "underweight", 18.5-24.9 "normal", ≥25 "overweight/obese") stratified weight gain.

Results: We included 59,564 weight measurements of 7047 adults, with 5342, 1108, and 597 being on DTG, EFV, and ATV/r, respectively. Two years post-baseline, estimated median weight (95% CI) increased by 3.81kg (3.43-4.19), 2.01kg (1.58-2.44), and 1.92kg (1.52-2.31) for DTG, EFV and ATV/r, respectively in males and by 4.63kg (4.24-5.01), 1.21kg (0.81-1.61), and 1.61kg (1.23-2.00) for DTG, EFV and ATV/r, respectively in females (Figure).

Overall, DTG-based regimens showed a strong, almost linear increase in weight over time, with the inflection point towards the end of the two years, while weight gain plateaued with time for ATV/r and EFV-based regimens. For patients underweight at baseline BMI, increases in weight were similar among treatment groups, while normal or overweight/obese patients had substantially larger weight gains with DTG-based regimens.



Conclusions: Patients receiving DTG based regimens had a two- to four-fold weight gain compared to EFV and ATV/r over two years, with little evidence of plateauing of the trend among those in on DTG.

Hepatic complications (e.g., NASH)

PESUB18

Progression of hepatic steatosis in people with HIV on integrase inhibitors

D. Kablawi[1], J. Milic[2], A.S. Al Hinai[1], B. Lebouche[1], M. Klein[1], M. Deschenes[1], G. Guaraldi[2], G. Sebastiani[1]

[1]McGill University, Montreal, Canada, [2]University of Modena and Reggio Emilia, Modena, Italy

Background: Hepatic steatosis (HS) is frequent in people with HIV (PWH), due to viral hepatitis coinfection, overweight and antiretroviral therapy (ART). Recent data suggest weight increase in PWH on integrase inhibitors (INIs)-based ART. The effect of this ART regimen on HS progression is not known.

Methods: Fibroscan with controlled attenuation parameter (CAP) was performed in consecutive PWH from the LIVEHIV Cohort in Montreal. Overweight was defined as body mass index>25Kg/m^2. Any grade and severe HS were defined as CAP>270 and CAP>330dB/m, respectively. HS progression was defined as development of any grade HS, or transition to severe HS if CAP<330 at baseline.

We compared incident overweight and HS progression in PWH with and without INIs-based ART. Covariate adjustments for HS progression were evaluated by multivariable Cox regression analysis.

Results: We included 393 PWH (mean age 50yrs, HIV duration 16yrs, BMI 26Kg/m^2; 76% male, 32% with viral hepatitis coinfection, 29% on INIs). Prevalence of any grade and severe HS at baseline was 25% and 7%, respectively.

During a median follow-up of 2.7yrs, incidence rate of overweight was similar in PWH with (28.8 per 100 person-years [PY], 95% CI 23.8-50.5) or without (36.2 per 100 PY, 95% CI 29-45.1) INIs-based ART (log-rank: p=0.50).

Progression of HS between baseline and last visit was observed in both PWH with and without INIs-based ART (see Figure). Progression rate of HS was 14.3 (95% CI 11.5-17.9) and 11.9 (95% CI 7.1-20.9) per 100 PY, in PWH with or without INIs-based ART (log-rank: p=0.46).

In multivariable analysis and after adjusting for HIV duration, overweight (adjusted hazard ratio 2.91, 95% CI 1.33-6.36) was associated with progression of HS while INIs-based ART was not.

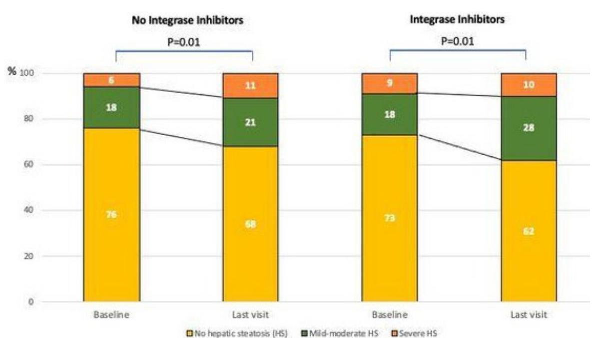


Figure.

Conclusions: PWH on INIs-based ART did not exhibit accelerated progression of HS. Incident overweight was similarly observed in PWH with or without INIs-based ART. Overweight was associated with HS progression.

ART in acute, first- and second-line therapies

PESUB19

Rapid ART initiation: a four-years observational study

R. Pincino[1,2], L. Taramasso[3], M. Berruti[1,2], G. Cenderello[1], M. Bassetti[2,3], A. Di Biagio[2,3]
[1]*Borea Hospital, Infectious Diseases Clinic, Sanremo, Italy,* [2]*University of Genoa, Health and Science Department, Genoa, Italy,* [3]*Policlinico San Martino Hospital, Infectious Diseases Clinic, Genoa, Italy*

Background: Rapid initiation of antiretroviral therapy (ART) benefits both people living with HIV (PLWH) and the community. We assessed predictors of virological suppression and adverse outcome in a cohort of newly diagnosed PLWH, comparing rapid ART initiation with other treatment strategies.

Methods: Observational, single center, retrospective study.

The study population was divided into: "same-day ART" (0-3 days post diagnosis/referral), "rapid ART" (4-14 days post-diagnosis/referral), and "early ART" (more than 14 days after diagnosis).

Predictors of virological suppression (HIV RNA < 50 copies/mL) and of adverse outcome (composite of lack of virological suppression, loss to follow up and death) within 24 weeks were analyzed using a binomial regression model.

Results: 116 PLWH were enrolled from January 2018 to December 2021, 33 (28.4%) in same-day ART, 61 (52.6%) in rapid ART and 22 (19.0%) in early ART group; baseline characteristics are shown in image 1.

	Same day ART	Rapid ART	Standard ART	*p*

Image 1. Difference between the study groups.

ART: antiretroviral therapy; MSM: men who have sex with men; IVDU: intravenous drug users; AIDS: acquired immunodeficiency syndrome; HBsAg: Hepatitis B surface antigen; GRT: genotypic resistance test; RAMs: resistance associated mutations.

Same day and rapid ART strategies became more used, with two (9.1%) people starting ART more than 14 days after HIV diagnosis in 2021 compared with 9 (40.9%) in 2018. PLWH in the same day ART group showed higher rates of virological suppression and lower rates of adverse outcomes.

AIDS diagnosis (p 0.025) and a longer time between HIV diagnosis and ART initiation (p 0.014) were negatively associated with virological suppression; the same variables were predictors of adverse outcome at multivariate analysis (Image 2).

Ibalizumab long-term efficacy is not impacted by partially active antiretrovirals

J. Leider[1], T. McLaughlin[2], A. Lee[2], C. McGary[2], P. Mesquita[2]
[1]*Jacobi Medical Center, Medicine, Bronx, United States,* [2]*Theratechnologies, Inc., Medical Affairs, Montreal, Canada*

Background: Ibalizumab (IBA) is a long-acting post-attachment inhibitor approved for heavily treatment-experienced (HTE) adults with multidrug resistant HIV-1 failing their current antiretroviral (ARV) regimen. We have previously demonstrated IBA's efficacy in the TMB-301/311 clinical trials. Complex resistance profiles in HTE patients limit the number of fully active agents.

Therefore, partially active ARVs are required to build optimized background regimens (OBR) to maintain suppression. As such, we sought to characterize the complexity of OBR in TMB-301/311 and determine its impact on the durability of response to IBA.

Methods: In TMB-301/311, 40 viremic patients received a 2000 mg loading dose of IBA followed by 800 mg doses every 2 weeks up to 96 weeks. OBR was incorporated 7

days after starting IBA. Baseline resistance mutations were entered into the Stanford database to scale the activity of each ARV in the patient's OBR 0-1. Drug activities were summed to generate a continuous genotypic susceptibility score (CGSS), which was averaged when OBRs were adjusted.
The impact of CGSS on virologic outcomes was evaluated by linear or logistic regression, controlling for baseline viral load and CD4 count.
Results: The study population was 85% male with a median age of 53 and 23 years of HIV infection. Baseline median viral load and CD4 count were 35,350 copies/mL and 73 cells/mm^3, respectively. The median number of drugs in participants' OBRs was 4.
Despite this, the median CGSS of OBR was only 1.58, indicating many partially active agents, the most common being tenofovir. Average CGSS was not associated with decrease in viral load at week 96 (p=0.18), maximal decrease in viral load (p=0.59), or viral suppression (p=0.69).
In addition, no CGSS threshold was associated with virologic outcomes, even after weighting boosted PIs and DTG to account for differences in potency and barrier to resistance amongst ARVs.
Conclusions: The high disparity between the number of drugs in patients' OBR and their median CGSS highlights the challenge of building OBR in HTE patients.
Importantly, IBA remained effective across a range of CGSS scores through week 96, demonstrating the durability of IBA in HTE patients despite combination with partially active agents.

Regimen simplification and switch studies

Efficacy and safety of switching to Dolutegravir/Lamivudine (DTG/3TC) in treatment-experienced, virologically suppressed PLHIV aged ≥50 years: pooled results from the TANGO and SALSA Studies

S. Walmsley[1], D.E. Smith[2], M. Górgolas[3], P.E. Cahn[4], T. Lutz[5], K. Lacombe[6], P.N. Kumar[7], B. Wynne[8], R. Grove[9], G. Bontempo[8], R. Moodley[10], F. Spinelli[8], B. Jones[10], C. Okoli[10], M. Ait-Khaled[10]
[1]University Health Network, Toronto, Canada, [2]Albion Centre, Sydney, Australia, [3]Fundación Jiménez Díaz, Universidad Autónoma de Madrid, Madrid, Spain, [4]Fundación Huésped, Buenos Aires, Argentina, [5]Infektiologikum, Frankfurt, Germany, [6]Hôpital Saint-Antoine, Paris, France, [7]Georgetown University Medical Center, Washington DC, United States, [8]ViiV Healthcare, Research Triangle Park, United States, [9]GlaxoSmithKline, Brentford, United Kingdom, [10]ViiV Healthcare, Brentford, United Kingdom

Background: As older adults living with HIV (OALHIV) are one of the fastest growing populations, concerns over managing age-related comorbidities and polypharmacy while maintaining virologic suppression highlight the importance of their inclusion in clinical trials. DTG/3TC is an international guidelines-recommended 2-drug regimen demonstrating high efficacy and barrier to resistance. We present pooled TANGO and SALSA efficacy and safety analyses in participants aged ≥50 years.
Methods: Week 48 data from the phase 3 TANGO and SALSA trials evaluating switch to DTG/3TC vs continuing current antiretroviral regimen (CAR) were pooled. Proportions of participants with HIV-1 RNA ≥50 and <50 c/mL (Snapshot, ITT-E) and safety were analyzed by age.
Adjusted mean change from baseline in CD4+ cell count was assessed using mixed-models repeated-measures analysis.
Results: Of 1234 participants, 29% were aged ≥50 years (9% female; 3% aged ≥65 years). At baseline, participants aged ≥50 vs <50 years had greater concomitant medication use (median (range): 2.0 [0-20] vs 1.0 [0-16], respectively) and more comorbidities (86% vs 71%); baseline characteristics were otherwise similar.
Among those aged ≥50 years, 1 (0.6%) DTG/3TC participant and 3 (1.6%) CAR participants developed HIV-1 RNA ≥50 c/mL; proportions with HIV-1 RNA <50 c/mL were high, consistent with overall efficacy (Table). CD4+ cell count increased from baseline in DTG/3TC participants in both age groups.
No participants in the DTG/3TC group had confirmed virologic withdrawal (CVW); 1 participant in the CAR group had CVW (no resistance detected). Proportions of AEs, AEs leading to withdrawal, and serious AEs in DTG participants were similar between age groups.

Parameter	Overall DTG/3TC (N=615)	Overall CAR (N=619)	Overall Adjusted difference (95% CI)	Age <50 years DTG/3TC (N=438)	Age <50 years CAR (N=432)	Age <50 years Adjusted difference (95% CI)	Age ≥50 years DTG/3TC (N=177)	Age ≥50 years CAR (N=187)	Age ≥50 years Adjusted difference (95% CI)
Key efficacy endpoints									
Snapshot HIV-1 RNA ≥50 c/mL, n (%)	2 (<1)	5 (<1)	−0.5 (−1.3, 0.4)	1 (<1)	2 (<1)	−0.2 (−1.0, 0.5)	1 (<1)	3 (2)	−1.1 (−3.2, 1.0)
Snapshot HIV-1 RNA <50 c/mL, n (%)	576 (94)	575 (93)	0.8 (−2.0, 3.6)	413 (94)	402 (93)	1.3 (−1.9, 4.5)	163 (92)	173 (93)	0.1 (−5.4, 5.5)
Adjusted mean change in CD4+ cell count (SE), cells/mm^{3b}	22.4 (7.2)	−2.0 (6.9)	24.4 (4.9, 43.9)	29.0 (8.5)	7.6 (8.2)	21.4 (−1.8, 44.6)	6.3 (13.6)	−24.7 (12.5)	30.9 (−5.2, 67.1)

Key safety endpoints	Overall DTG/3TC (N=615)	Overall CAR (N=618)	Age <50 years DTG/3TC (N=438)	Age <50 years CAR (N=432)	Age ≥50 years DTG/3TC (N=177)	Age ≥50 years CAR (N=186)
Any AE	475 (77)	464 (75)	333 (76)	330 (76)	142 (80)	134 (72)
AEs leading to withdrawal	18 (3)	5 (<1)	11 (3)	2 (<1)	7 (4)	3 (2)
Drug-related AEs	93 (15)	21 (3)	65 (15)	18 (4)	28 (16)	3 (2)
Serious AEs	28 (5)	32 (5)	18 (4)	16 (4)	10 (6)	16 (9)

Adjusted mean change in CD4+ cell count was analyzed using mixed-models repeated-measures analysis adjusted for treatment, visit, age, sex, race, baseline CD4+ cell count, baseline third agent, baseline BMI, treatment-by-visit interaction, baseline CD4+ cell count-by-visit interaction, and study, with visit as the repeated factor; analysis by age groups also adjusted for visit-by-age interaction, treatment-by-age interaction, and treatment-by-visit-by-age interaction. [a]In TANGO, 1 participant was found to be taking a TDF-based regimen and was excluded from the safety population. [b]Median (range) CD4+ cell count at baseline, DTG/3TC vs CAR: overall analysis, 680.0 (133-2089) vs 684.0 (94-1954) cells/mm^3; <50 years group, 685.0 (154-1904) vs 686.0 (94-1954) cells/mm^3; ≥50 years group, 649.0 (133-2089) vs 671.0 (119-1530) cells/mm^3.

Table. Efficacy and safety results from the pooled analysis of the TANGO and SALSA trials by age: ITT-E and safety populations.

Conclusions: Although participants aged ≥50 years used a higher number of concomitant medications and had a greater prevalence of comorbidities, switching to DTG/3TC maintained virologic suppression, demonstrating robust efficacy, a high barrier to resistance, and good safety and tolerability.

Pharmacokinetics/pharmacodynamics/pharmacogenomics and therapeutic drug monitoring

PESUB22

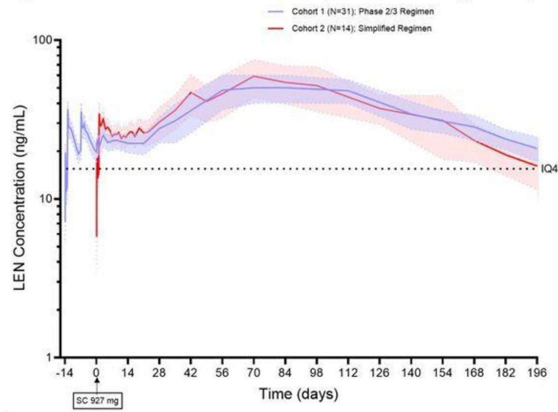
Pharmacokinetics of a simplified subcutaneous lenacapavir regimen versus Phase 2/3 regimen

V. Jogiraju[1], H. Graham[1], S. West[1], J. Ling[1], J. Cuvin[1], M. Rhee[1], R. Palaparthy[1], R. Singh[1]
[1]*Gilead Sciences, Inc., Foster City, United States*

Background: Lenacapavir (LEN) is a potent, first-in-class, HIV-1 capsid inhibitor currently in clinical development for HIV-1 infection treatment and prevention. The ongoing Phase 2/3 studies in people with HIV-1 uses every 6 months subcutaneous (SC) dosing injection with oral loading/lead-in (oral LEN 600 mg on Days 1 and 2, and oral LEN 300 mg on Day 8 followed by SC LEN 927 mg on Day 15 and every 6 months thereafter). While this Phase 2/3 regimen has been shown to be safe and effective, a more simplified regimen (oral LEN 600 mg on Days 1 and 2, with SC LEN 927 mg on Day 1 and every 6 months thereafter) can be more convenient. Our objective was to compare the pharmacokinetics (PK) of the simplified regimen with that of the Phase 2/3 regimen.

Methods: 31 and 14 healthy participants received the Phase 2/3 regimen (Cohort 1) and the simplified regimen (Cohort 2), respectively, in a Phase 1 single subcutaneous dose study. Intensive LEN PK and safety through Day 196 were summarized. PK was evaluated using noncompartmental analysis.

Results: LEN C_{max} (within ±8%) and $AUC_{0\text{-}196\ days}$ (within ±15%) were comparable between regimens. Mean LEN concentrations achieved the efficacy target (inhibitory quotient of 4 [IQ4] =15.5 ng/mL) rapidly and were maintained above IQ4 through the dosing interval. LEN was well tolerated with no Grade 3 or 4 adverse events (AEs), serious AEs or deaths reported. Most common AEs were injection site reactions.



*Blue and pink shaded areas represent 90% confidence interval band for the mean profile for Cohort 1 and Cohort 2, respectively; Horizontal dotted line shows IQ4 of 15.5 ng/mL; Values -14 to 0 on the X-axis represent 14-day oral loading/lead-in period for Cohort 1
#Phase 2/3 regimen (Cohort 1) = oral LEN 600 mg (2x300 mg tablets) on Days 1 and 2, and oral LEN 300 mg (1x300 mg tablet) on Day 8 followed by SC LEN injection (927 mg; 309 mg/mL NaS; 2x1.5 mL) on Day 15
^Simplified regimen (Cohort 2) = SC LEN injection (927 mg; 309 mg/mL NaS; 2x1.5 mL) and 600 mg (2x300 mg tablets) on Day 1, followed by 600 mg (2x300 mg tablets) on Day 2

Figure 1. Mean LEN plasma PK profiles following phase 2/3# and simplified^ Regimens*

Conclusions: LEN concentrations of the simplified regimen were generally comparable to those of the Phase 2/3 regimen. LEN concentrations reached efficacious target rapidly and were maintained through the dosing interval.
These results suggest that the simplified regimen provides similar exposures to the Phase 2/3 regimen and can be utilized as a potential clinical regimen for treatment and prevention of HIV-1 infection.

PESUB23

Simulations for once weekly dosing of oral lenacapavir

N. Shaik[1], H. Zhang[1], S. Girish[1], M. Rhee[1], R. Palaparthy[1], R. Singh[1]
[1]*Gilead Sciences, Clinical Pharmacology, Foster City, United States*

Background: Lenacapavir (LEN), a potent first-in-class inhibitor of HIV-1 capsid function, is in development for thetreatment and prevention of HIV-1 infection. Current data indicates that LEN exhibits near maximal antiviral activity when the lower bound of the 90% confidence interval (CI) of mean C_{trough} are maintained above inhibitory quotient 4 (IQ4) (at least 4-fold greater than the *in vitro* protein adjusted 95% effective concentration).
The objective of this analysis was to utilize a population pharmacokinetic (PopPK) model to simulate various oral weekly dosing regimens of LEN that would rapidly achieve and maintain concentrations above IQ4.

Methods: A 2-compartment PopPK model with first order absorption and linear elimination was previously developed to describe LEN concentration data from multiple clinical studies (384 participants). This model was utilized

to simulate various dosing regimens (loading + maintenance doses) that can achieve efficacious LEN concentrations rapidly and maintain it throughout the dosing interval. Additionally, various scenarios of missed oral doses were simulated to evaluate the forgiveness window.

Results: Simulations showed that an oral loading dose of 600 mg on day 1 and day 2 followed by 300 mg oral once weekly doses maintained the lower bound of the 90% CI of mean C_{trough} above IQ4 (15.5 ng/mL) throughout the dosing interval (Figure 1).

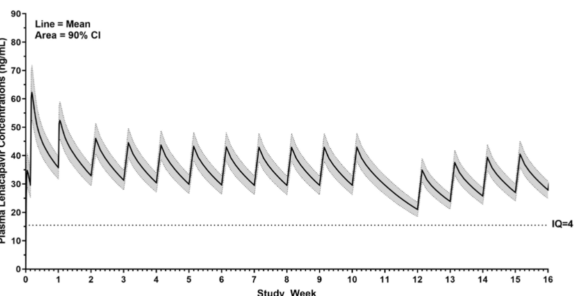


Figure 1. Simulated plasma concentration time profile of oral LEN following once weekly dosing.*

**Profile shows 600mg oral LEN dose on day 1 and day 2 followed by oral LEN 300mg on day 8 and once weekly thereafter with a missed 300mg oral dose at week 11 and continuation of 300mg once weekly from week 12 onwards.*

This dosing regimen reached IQ4 rapidly within 4 hours. In addition, simulations also showed that oral LEN administered once weekly is expected to maintain concentrations above IQ4 with a forgiveness window of up to 7 days after the last missed dose.

Conclusions: Once weekly oral LEN 300 mg is expected to maintain concentrations above IQ4 throughout the dosing interval while allowing for a 7-day forgiveness window after the last missed oral dose. Oral LEN can be developed as part of a complete oral weekly regimen for the treatment of HIV-1 infection.

The first-in-human clinical trial of STP0404, a novel potent HIV-1 allosteric integrase inhibitor

X. Meng[1], U.-I. Kim[1], Y. Donazzolo[2], B. Kim[3,4], K. Kim[1]

[1]ST Pharm Co., Ltd., Seoul, Korea, The Republic of, [2]Eurofins Optimed S.A.S, Grenoble, France, [3]Emory University, School of Medicine, Department of Pediatrics, Atlanta, United States, [4]Children's Healthcare of Atlanta, Center for Drug Discovery, Atlanta, United States

Background: STP0404 is a novel HIV-1 allosteric integrase inhibitor with potent *in vitro* anti-HIV-1 activities, an *in vitro* resistance profile different from those of other catalytic-site integrase inhibitors, and favorable nonclinical safety and PK profiles.

Methods: The safety and PK of STP0404 was evaluated in a double-blinded, placebo-controlled, randomized phase 1 clinical trial in healthy male adult volunteers with once daily regimen. Single and repeated administration with ascending doses (200, 400, 600 and 800 mg for SAD (Single Ascending Doses), 200 and 400 mg for 10 days for MAD (Multiple Ascending Doses)) and food effect (200 mg) were evaluated through this trial.

Results: A total of 65 male subjects were enrolled (aged 18 to 45 years old). Most AEs were mild (75%, 21/28), headache (9/28) and diarrhea (5/28) were most frequently observed. No severe AE, SAE and withdrawn due to AE observed or occurred during the trial.

PK was linear but less-proportional over the dose ranged administered except for SAD 800 mg. C_{max} were reached at 4 to 6 hours throughout the whole study. Accumulation ratio is around 1.3 at steady-state (D10). Food effect factor was around 1.5 to 2, and resulted in a lower variability in drug exposure. $AUC_{0-\tau}$ and C_{max} in plasma ranged from 23.6 h·µg/mL and 2.05 µg/mL at a 200 mg dose (fasted) to 67.7 h·µg/mL and 6.16 µg/mL at a 200 mg dose (fed, steady-state), respectively.

Steady state was reached between Day 3 and Day 6, The mean $C_{ss,24h}$ with a 200 mg dose was 1.37 µg/mL, approximately 600-fold of the protein-adjusted EC_{95} (0.0022 µg/mL).

The elimination half-life were about 18 to 33 hours throughout the study. MAD 400 mg PK data will be ready before presentation.

Conclusions: STP0404 was well tolerated and its PK profile indicated a once-daily regimen at low dose level given after meal will achieve therapeutic concentrations. A Phase 2a clinical trial of STP0404 is planned to start at 3Q, 2022.

Background: Long-acting (LA) injectable cabotegravir (CAB200mg/mL) administered intramuscularly is approved for HIV-1 prevention (every-2-months), and treatment (suppressed switch) with rilpivirine (monthly or every-2-months). A high-concentration (CAB400mg/mL) formulation was developed to support less frequent dosing and/or potential self-administration via subcutaneous or thigh injections.

Methods: The safety and pharmacokinetics of single/repeat administration of CAB400 mg/mL 200–800 mg (Cohorts 1–4, 4b, 4h, 5) intramuscularly (*gluteus medius*, *vastus lateralis*) or subcutaneously (abdominal) in healthy adults was evaluated in this ongoing Phase I study (NCT04484337). CAB200 mg/mL active controls (n=1–2 per cohort) were matched by dose or volume. In Cohort 4h, recombinant human hyaluronidase rHuPH20 will be co-administered subcutaneously.

Pharmacokinetic parameters were estimated via non-compartmental analysis and population pharmacokinetic (PPK) modelling. Simulations were performed using PPK model to assess various CAB400mg/mL regimens. Participant-reported outcome measures (PROMs) were also assessed.

Results: Seventy participants received CAB (oral and/or injection) across Cohorts 1–4; 40% were female (sex), 40% were non-White. Median age, weight, and BMI were 34y, 76.9kg, and 26.1kg/m^2, respectively. Overall, safety profiles, including injection site reaction (ISR) frequency, were similar between formulations. CAB400mg/mL ISRs occurred in 92–100% of injections; most were Grade 1–2 (88–94%, maximum grade) (*Table 1*).

	IM gluteal		IM thigh		SC abdominal	
	600mg [1.5mL] (n=18)	400mg [1mL] (n=34)	600mg [1.5mL] (n=11)	400mg [1mL] (n=12)*	600mg [1.5mL] (n=9)	200mg [0.5mL] (n=24)
Any AE, n (%)	17 (94)	33 (97)	11 (100)	12 (100)	9 (100)	24 (100)
Drug-related AEs, n (%)	17 (94)	33 (97)	11 (100)	12 (100)	9 (100)	24 (100)
Drug-related serious AEs, n (%)	0	0	0	0	0	0
Drug-related AEs leading to withdrawal, n (%)	2 (11)	1 (3)	1 (9)	0	0	0
Any ISR AE, n (% of injections)	17 (94)	33 (97)	11 (100)	11 (92)	9 (100)	24 (100)
Grade 1 events, n (% of ISRs)†	8 (47)	19 (58)	4 (36)	4 (36)	2 (22)	6 (25)
Grade 2 events, n (% of ISRs)†	8 (47)	10 (30)	6 (55)	6 (55)	6 (67)	16 (67)
Grade 3 events, n (% of ISRs)†	1 (6)	4 (12)	1 (9)	1 (9)	1 (11)	2 (8)

Note. Participants receiving CAB400mg/mL across Cohorts 1–4 were pooled by administration route and dose. All participants were scheduled to receive two injections. Each participant received a single injection at one dose/administration route (except the one detailed below), with the other injection being at a different dose/administration route (as seen in Table 2). Therefore, the n numbers are event level and represent the number of participants receiving an injection at each dose/administration route.
*One participant received two injections at the indicated dose/volume for injection 1 and 2 and is therefore counted twice.
†Maximum grade reported following each injection. The denominator is the total number of injections leading to ≥1 ISR. There were no Grade 4 or 5 ISRs.
AE, adverse event; CAB, cabotegravir; gluteal,gluteus medius;IM, intramuscular; ISR, injection site reaction; SC, subcutaneous.

Table 1. Safety Summaryof CAB400mg/mL in Healthy Adult Participants (Cohorts 1–4)

Erythema and induration/swelling occurred more commonly after subcutaneous versus intramuscular injections. CAB400mg/mL pharmacokinetics were similar across administration routes (*Table 2*).

Cohort route	Cohort 1 IM gluteal		Cohort 2 SC abdominal		Cohort 3 IM thigh		Cohort 4 IM gluteal	Cohort 4 SC abdominal
Injection dose	Injection 1 600mg (n=18)	Injection 2 400mg (n=16)	Injection 1 600mg (n=9)	Injection 2 200mg (n=8)	Injection 1 600mg* (n=13)	Injection 2 400mg (n=10)	Injection 1 400mg (n=18)	Injection 2 200mg (n=16)

Concentration at: Week 4 (µg/mL)	2.78 (45.2%)	2.90 (37%)	1.31 (82.4%)	1.29 (65.3%)	0.784 (198.6%)	1.59 (57.2%)	1.22 (31.7%)	1.26 (38.6%)
Week 8 (µg/mL)	NA	0.745 (131.5%)	NA	0.308 (95.8%)	NA	0.24 (215.6%)	NA	0.328 (13.8%)
LA absorption rate constant (h^{-1})	NA	0.00155 (56.2%)	NA	0.00203 (62.8%)	NA	0.00191 (112.3%)	NA	0.00186 (40.8%)
Terminal half-life (weeks)	NA	2.67 (56.2%)	NA	2.03 (62.8%)	NA	2.16 (112.3%)	NA	2.22 (40.8%)

PK parameters were estimated using noncompartmental analysis. Values displayed are geometric mean (CV%).
*Two participants in Cohort 3 received 400mg instead of 600mg for injection 1, and their plasma concentrations were increased by 50% (dose normalized to 600mg) for estimating PK parameters.
CAB, cabotegravir; C_{max}, maximum plasma concentration post IM injection; gluteal,gluteus medius; IM, intramuscular; LA, long-acting; NA, not applicable; PK, pharmacokinetic; SC, subcutaneous (abdominal); thigh, vastus lateralis.

Table 2. Plasma Pharmacokinetic Parameters of CAB400mg/mL in Healthy Adult Participants (Cohorts 1–4)

CAB400mg/mL C_{max} was higher and half-life was 62% shorter than CAB200mg/mL after adjusting for demographics. CAB400mg/mL administered monthly, regardless of route, was predicted to exceed the plasma concentrations of approved CAB200mg/mL regimens. The conference presentation will include Cohort 4b, 4h, and 5 and PROM results.

Conclusions: CAB400mg/mL could potentially expand options for LA injectable ART, and these interim safety and pharmacokinetic data support further clinical evaluation.

Adherence

PESUB25

Bridging the gap between patient perceptions and delivered care among people living with HIV in the Asian region

S. Park[1], Y.-H. Hsiao[2], F. Yu[3], K. Kambara[4], B. Allan[5], G. Brough[6], T.-F. Hwang[7], N. Dang[7], B. Young[8], R. Patel[9], A. Maldonado[10], N. Nwokolo[9], C. Okoli[9]

[1]Love4One, South Korea, Seoul, Korea, The Republic of, [2]Positive Alliance, Taiwan, Taipei, Taiwan, Province of China, [3]Danlan Beijing Media Limited, China, Beijing, China, [4]Japanese Network of People living with HIV/AIDS, Japan, Tokyo, Japan, [5]Australasian Society for HIV, Viral Hepatitis and Sexual Health Medicine, Melbourne, Australia, [6]Positively UK, United Kingdom, London, United Kingdom, [7]ViiV Healthcare, Medical Affairs, Singapore, Singapore, [8]ViiV Healthcare, RTP Durham, United States, [9]ViiV Healthcare, Brentford, United Kingdom, [10]ViiV Healthcare, Wavre, Belgium

Background: Client-centered care is recommended for the care of people living with HIV (PLHIV) to improve client retention and treatment adherence. We assessed how Asian PLHIV perceived their personal healthcare needs/priorities were met, and how these beliefs were associated with health-related outcomes.

Methods: 230 PLHIV aged ≥18 years on anti-retroviral therapy (ART) completed the 2019 Positive Perspectives survey from Taiwan (n=55), Japan (n=75), China (n=50), and South Korea (n=50). Using logistic regression adjusting for age, gender, and HIV duration, we explored how having personal health needs met was associated with ART-related perceptions and self-rated health.

Results: Overall, 57.4% perceived their provider met their personal healthcare needs (South Korea, 38.0%; China, 56.0%; Japan, 62.7%; Taiwan, 69.1%). Prevalence of ART satisfaction was 50.0% (South Korea, 34.0%; China, 40.0%; Japan, 54.7%; Taiwan, 67.3%).

However, 27.0% (China, 38.0%; South Korea, 28.0%; Japan, 24.0%; Taiwan, 20.0%) would not discuss treatment concerns with providers believing, "I don't think my main HIV care provider's priorities are the same as mine". Participants perceiving their personal needs were met had higher odds of reporting ART satisfaction (AOR=5.83, 95%CI=3.19-10.64), optimal overall health (AOR=2.98, 95%CI=1.67-5.31), and greater self-efficacy in managing their daily ART (AOR=2.31, 95%CI=1.32-4.04). Yet, over one-fourth of those wanting more involvement in healthcare decisions indicated their viewpoint was not sought by their provider before prescribing new treatments (overall, 29.1%[46/158]; China, 31.1%[14/45], Japan, 25.0%[10/40]; South Korea, 41.4%[12/29]; Taiwan, 22.7%[10/44]). Regional variations were seen in the extent to which PLHIV's concerns were collaboratively addressed with providers.

For example, while Chinese participants reported the highest overall percentage of those who missed ≥one ART dose in the past month because of concerns over long-term impacts of ART (China, 70.0%; South Korea, 42.0%; Taiwan, 29.1%; Japan, 26.7%), Chinese participants reported the lowest percentage of those whose ART had been changed in the past year by their provider to mitigate their concerns about long-term impacts among those with such concerns (China, 4.4%[2/46]; Taiwan, 9.5%[4/42]; South Korea, 10.5%[4/38]; Japan, 25.9%[14/54]).

Conclusions: Improving client-provider relationships may improve care continuum and treatment satisfaction. ART planning should be done proactively and collaboratively between PLHIV and providers to deliver person-centered care.

PEMOB27

Persistent low-level viremia in the era of dolutegravir in four African countries

J. Cavanaugh[1], N. Dear[2,1], A. Esber[2,1], N. Shah[1], M. Iroezindu[3,1], E. Bahemana[4,1], H. Kibuuka[5], J. Owuoth[6], J. Maswai[7], V. Singoei[8], C. Polyak[1,2], J. Ake[1]

[1]Walter Reed Army Institute of Research, Military HIV Research Program, Silver Spring, United States, [2]Henry Jackson Foundation, Bethesda, United States, [3]Henry Jackson Foundation Medical Research International, Abuja, Nigeria, [4]Henry Jackson Foundation Medical Research International, Mbeya, Tanzania, The United Republic of, [5]Henry Jackson Foundation Medical Research International, Kampala, Uganda, [6]Henry Jackson Foundation Medical Research International, Kericho, Kenya, [7]US Army Medical Research Directorate - Africa, Nairobi, Kenya, [8]Henry Jackson Foundation Medical Research International, Kisumu, Kenya

Background: HIV programs frequently use a viral load (VL) <1000 copies/mL as the threshold for VL suppression (VLS). Consequently, persistent low-level viremia (pLLV), VL between 50-999 copies/mL on at least two consecutive measurements, is often undetected even though it has been associated with worse clinical outcomes.

Methods: The African Cohort Study (AFRICOS) enrolls people living with HIV (PLWH) who are engaged in routine HIV care in Uganda, Kenya, Tanzania and Nigeria. Semiannually, participants come to study sites for more intensive evaluation, including quantified VL testing.

In this analysis, we included participants who were taking tenofovir/lamivudine/dolutegravir (TLD) for at least three months and had two subsequent VL measurements; we used the two most recent VL measurements. We calculated frequencies for VLS using the number of participants

with two VL measurements as the denominator. We documented participants with VL >1000 copies/mL and stratified results for those with VL <1000 copies/mL by: both VL measurements <50 copies/mL, pLLV, one VL 50-999 copies/mL and one VL <50 copies/mL.

We further stratified results by site, age group, and sex. We used Pearson's Chi-squared and Fisher's exact tests to compare frequencies.

Results: Between January 2013 and November 2021, 1439 participants were eligible. Across all sites, 1388 participants had VL <1000 copies/mL on both tests, 28 (2.0%) of whom had pLLV. Three participants were above 1000 copies/mL on both VL tests, 39 had one VL <50 copies/mL and one VL ≥1000 copies/mL, and 9 had one VL 50-999 copies/mL and one VL ≥1000 copies/mL. Prevalence of pLLV, by strata, was highest in Nigeria, among young adults, and among males (Table 1).

	N	Both tests <50 c/mL*	p-value	Persistent low-level viremia*	p-value	One test <50 c/mL and one test 50-999 c/mL*	p-value
Uganda	193	165 (85.5%)	<0.001	3 (1.5%)	<0.001	21 (10.9%)	<0.001
Kenya	777	704 (90.6%)	<0.001	5 (0.6%)	<0.001	48 (6.2%)	<0.001
Tanzania	264	195 (73.9%)	<0.001	7 (2.6%)	<0.001	49 (18.6%)	<0.001
Nigeria	205	130 (63.4%)	<0.001	13 (6.3%)	<0.001	48 (23.4%)	<0.001
15-24 years	64	43 (67.2%)	<0.001	3 (4.7%)	0.091	10 (15.6%)	<0.001
25-49 years	844	679 (80.4%)	<0.001	19 (2.2%)	0.091	119 (14.1%)	<0.001
50+ years	531	472 (88.9%)	<0.001	6 (1.1%)	0.091	37 (7.0%)	<0.001
Male	717	575 (80.2%)	0.005	19 (2.6%)	0.054	94 (13.1%)	0.061
Female	722	619 (85.7%)	0.005	9 (1.2%)	0.054	72 (10.0%)	0.061

Table 1.

Conclusions: Studies to investigate associations with unsuppressed and pLLV are needed in these populations, including documentation of differences in viral genomics (e.g., viral subtypes and drug resistance mutations) and local participant demographic factors associated with adherence.

Surveillance of HIV in key populations

PESUC18
Disproportionate HIV burden among key populations in sub-Saharan Africa: national estimates of population size, HIV prevalence, and ART coverage

O. Stevens[1], K. Sabin[2], S. Arias García[2], R. Anderson[1], K. Willis[3], E. Grard[1], A. Stuart-Brown[1], F. Cowan[4], L. Degenhardt[5], J. Zhao[6], M. Maheu-Giroux[7], L. Platt[8], B. Rice[8], I. Sathane[9], M. Boothe[10], S. Baral[3], M. Mahy[2], J. Eaton[1]

[1]Imperial College London, London, United Kingdom, [2]UNAIDS, Geneva, Switzerland, [3]Johns Hopkins University, Baltimore, United States, [4]Centre for Sexual Health and HIV/AIDS Research, Harare, Zimbabwe, [5]University of New South Wales, Sydney, Australia, [6]The Global Fund to fight AIDS, TB, and Malaria, Geneva, Switzerland, [7]McGill University, Montreal, Canada, [8]London School of Hygiene and Tropical Medicine, London, United Kingdom, [9]Ministry of Health, Maputo, Mozambique, [10]UNAIDS, Maputo, Mozambique

Background: The Global AIDS Strategy 2021-2026 calls for equitable programme access to end HIV/AIDS by 2030. Robust HIV data among key populations (KP) are important for monitoring and reducing inequality in the global HIV/AIDS response.

Methods: We systematically collated population size (PSE), HIV prevalence, and ART coverage data for female sex workers (FSW), men who have sex with men (MSM), people who inject drugs (PWID), and transgender (TG) populations in sub-Saharan Africa (SSA) 2000-2021 from existing databases and primary source review.

We used spatial random-effects regression to pool and extrapolate data relative to age-sex-year-area matched total population estimates.

Results: We extracted 1557 datapoints for PSE [FSW (n=670); MSM (n=522); PWID (n=296); TG (n=69)], 1248 HIV prevalence datapoints, and 212 ART coverage datapoints. Across countries, median 0.65% of women were FSW (interquartile range [IQR] 0.44-1.2%); 0.56% of men were MSM (IQR 0.33-0.72%); and 0.1% of adults injected drugs (IQR 0.08-0.15%) (Figure 1).

In Eastern and Southern Africa, HIV prevalence among FSW, PWID, and TG was correlated with and higher than total population prevalence, but less correlated for MSM.

In Western and Central Africa, KP HIV prevalence was higher than population prevalence with weak correlation. FSW and MSM ART coverage was similar to population ART coverage, and PWID ART coverage was lower (Figure 2). Insufficient data were available to estimate TG PSE or ART coverage.

Conclusions: National-level KP estimates may guide HIV programming to reduce inequality, but highlight insufficient data for many countries. HIV surveillance for PWID and TG should be prioritised to improve programmatic responses.

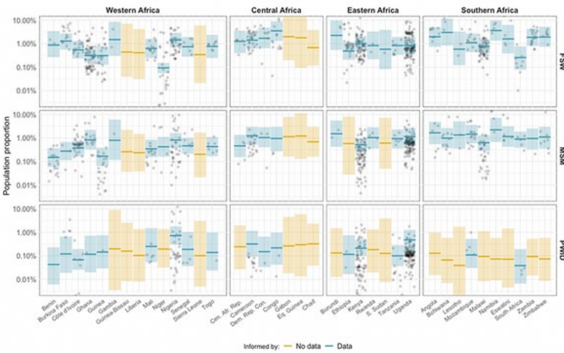

Figure 1. Key population size estimates for female sex workers (FSW, top row), men who have sex with men (MSM, middle row), and people who inject drugs (PWID, bottom row) as a proportion of age-sex-area-year matched total population for four subregions of sub-Saharan Africa. Countries which had empirical key population size data (dots) available are in blue. Countries which had no empirical data are in yellow (estimates are delivered solely from spatial smoothing). Observations are from 2000-2021.

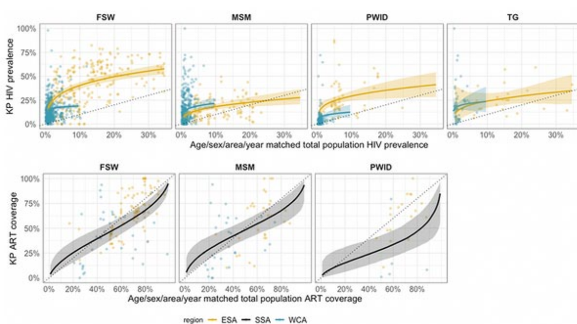

Figure 2. Estimated KP HIV prevalence (top) and ART coverage (bottom) against total population HIV prevalence and ART coverage in the same year and location. Observations are from 2000-2021 for ages 15-49, 15+, <25 or ≥25. Dotted line represents the line of equality.

Monitoring and evaluation of health systems along the HIV cascade

PESUC19

Assessing levels of provincial HIV virological suppression in the public health sector in South Africa during the COVID-19 pandemic

L. Hans[1,2], N. Cassim[1,2], S. Sarang[2], S. Ndlovu[2], P. Da Silva[1,2], W.S. Stevens[1,2]

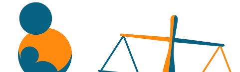
[1]*University of the Witwatersrand, Faculty of Health Sciences, Molecular Medicine and Haematology, Johannesburg, South Africa,* [2]*National Health Laboratory Service, National Priority Programme, Johannesburg, South Africa*

Background: In December 2019, the first reports of a novel coronavirus infection originated from the city of Wuhan, China. The World Health Organization named the new disease COVID-19, which spread globally and was classified as a pandemic in March 2020. Many countries, including South Africa, introduced social distancing and lockdown rules to limit transmission. South Africa has experienced four waves of infection with rises in the number of diagnosed cases. A local study has reported reductions in average weekly HIV viral load (VL) testing due to legislated lockdown levels. This study aims to assess the impact of COVID-19 on provincial HIV viral load (VL) suppression (<50 copies/ml).

Methods: Specimen-level VL data were extracted from the corporate data warehouse (CDW) for the period January 2019 to December 2021. We assessed the provincial percentage of samples with virological suppression (<50 copies/ml) by calendar year. Data without a province indicated in the CDW were excluded. The change in the provincial proportion of samples with virological suppression (VS) in 2019 was compared to the subsequent years where lockdown was implemented (percentage change).

Results: Data was reported for 17,460,264 samples, of which 61,073 did not have a valid province populated (%0.35%) and were excluded. Overall, VS was reported for 67.7%, 70.3% and 70.0% of samples for the 2019, 2020 and 2021 calendar years respectively. In 2019, VS ranged from 58.6% (Limpopo) to 76.3% (KwaZulu-Natal). The provincial percentage change in VS between 2019 and 2020 ranged from -1.3% (Northern Cape) to 8.6% (Eastern Cape). Similarly, between 2019 and 2021, the provincial percentage change in VS ranged from -6.0% (North West) to 1.5% (Western Cape). Between 2019 and 2021, the Limpopo province reported a percentage change decrease in VS of 5.8%.

Conclusions: Our findings indicate that Covid-19 has not had a substantial impact on the percentage of samples with virological suppression when compared with 2019 at the national level. However, at the provincial level decreases in VS have been shown particularly for the 2021 year for the Limpopo and North West provinces. Further analysis is required to understand why VS decreased in these two provinces.



Modelling future healthcare needs

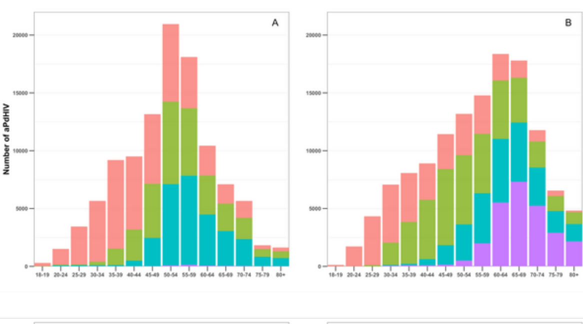
PESUC20

Projection of age of people living with HIV and time since ART initiation in high-income countries in 2030: estimates for France

D. Costagliola[1], M. Lise[1], Y. Diawara[1], A. Rachas[2], S. Grabar[3], V. Supervie[1]
[1]Sorbonne Université, INSERM, Institut Pierre Louis d'Epidémiologie et de Santé Publique, Paris, France, [2]Direction de la Stratégie, des Etudes et des Statistiques, CNAM, Paris, France, [3]Sorbonne Université, INSERM, Institut Pierre Louis d'Epidémiologie et de Santé Publique, AP-HP, Hôpital St Antoine, Paris, France

Background: Thanks to antiretroviral treatment (ART), HIV-infected individuals are aging. This involves increased co-morbidity risks, which also depend on when individuals started ART. These upcoming challenges require knowledge of the future demographic profile of HIV population. Here, we forecast the demographic profile of the adult population diagnosed with HIV (aPDHIV) in France up to 2030, accounting for the impact of ART initiation period on mortality.

Methods: Using national data from the French Hospital Database on HIV (ANRS CO4-FHDH) and a sample of the National Health Data System, we characterized the aPDHIV in 2018 and estimated their mortality rates according to age, sex, and ART initiation period. Using national surveillance data, we defined three scenarios for the numbers of newly-diagnosed HIV cases over 2019-2030: 30% decrease (S1), status quo situation (S2), and epidemic elimination (S3). Combining these data, we projected the age structure of the aPDHIV and time since ART initiation.



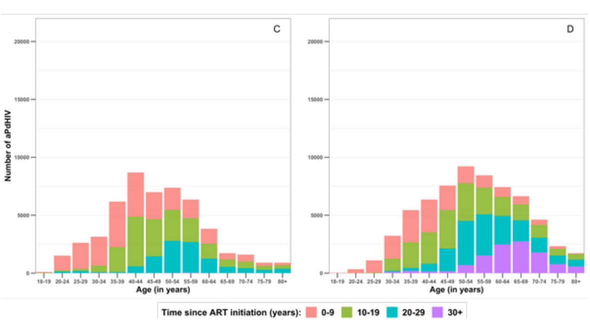


Figure. Numbers and age distribution of adults aged 18 years or older living with diagnosed HIV (aPLdHIV), stratified by time since ART initiation (in years): for men (A & B) and women (C & D) in 2018 (A & C) and in 2030 (B & D) under scenario 1 (i.e. 30% decrease in newly diagnosed HIV cases between 2018 and 2030).

Results: In 2018, there was an estimated 161,125 aPDHIV (67% men), of which 55% were aged 50 or older (50+), 22% 60+ and 8% 70+. In 2030, the aPDHIV would be 192,181 under S1, 204,813 under S2 and 164,224 under S3. Whatever the scenario, the age distribution would shift towards older ages: with in 2030, 64 to 71% aPDHIV aged 50+, 41-47% 60+ and 16-18% 70+. This corresponds to ~80,800 aPDHIV (72% men) aged 60+, among which ~69% started ART ≥20 years ago and ~39% ≥30 years ago, and to ~31,500 aPDHIV (72% men) aged 70+, among which ~72% started ART ≥20 and ~43% ≥30 years ago (Figure).

Conclusions: By 2030, in France, close to 20% of theaPDHIV will be aged 70+, of which >40% would have spent ≥30 years on ART. These estimates are essential to anticipate co-morbidity screening and resource provision in the aged care sector.

Demand creation for PrEP use

PESUC24

Willingness to use PrEP among gay, bisexual, and other men who have sex with men in five Asian countries: results of the Asia Pacific MSM internet survey

B. Bavinton[1], A. Hill[2], N. Amos[2], S.H. Lim[3], T. Guadamuz[4], N. Kaneko[5], M. Holt[6], A. Bourne[2]
[1]University of New South Wales, Kirby Institute, Sydney, Australia, [2]La Trobe University, Australian Research Centre in Sex, Health and Society, Melbourne, Australia, [3]University of Malaya, Kuala Lumpur, Malaysia, [4]Mahidol University, Bangkok, Thailand, [5]Nagoya City University, Nagoya, Japan, [6]University of New South Wales, Centre for Social Research in Health, Sydney, Australia

Background: PrEP is highly effective at preventing HIV infection among gay, bisexual, and other men who have sex with men (GBM). However, across Asia, PrEP programs are limited, and little is known about men's willingness to use PrEP.

Methods: A cross-national online survey targeting GBM in Indonesia, Japan, Malaysia, Thailand, and Vietnam was conducted from May 2020–January 2021. Factors independently associated with willingness to use PrEP among non-PrEP-users were determined by multivariable logistic regression.

Results: We recruited 10,339 HIV-negative/untested GBM who reported ≥1 male sexual partners in the previous year (Japan = 5,660; Vietnam = 2,257; Thailand = 1,076; Indonesia = 803; Malaysia = 543).

Overall, 7.4% were currently using PrEP (Thailand = 14.0%; Vietnam = 11.1%; Malaysia = 7.4%; Japan = 5.4%; Indonesia = 2.0%). After restricting to the 9,578 non-PrEP-users, 54.4% were willing to use PrEP (Malaysia = 73.6%; Thailand = 65.2%; Indonesia = 62.6%; Vietnam = 51.2%; Japan = 50.6%). Among these non-users, 2.0% (n = 194) had previously

Author Index

used it (range = 0.8% in Indonesia/Japan–5.4% in Thailand). Factors independently associated with PrEP willingness among non-users were: younger age (adjusted odds ratio [AOR]=0.98, 95% confidence interval [CI]=0.97-0.98, p<0.001); higher levels of education (diploma: AOR=1.54, 95%CI=1.18-2.01, p=0.001; university: AOR=1.34, 95%CI=1.04-1.72, p=0.022); having more than 10 sexual partners in the previous 12 months (AOR=1.21, 95%CI=1.01-1.44, p=0.041); awareness of the "undetectable = untransmittable (U=U)" message (AOR=1.23, 95%CI=1.12-1.36, p<0.001); condomless anal intercourse with regular (AOR=1.16, 95%CI=1.05-1.28, p=0.003) and casual (AOR=1.29, 1.16-1.43, p<0.001) male partners in the previous 12 months; use of Viagra (AOR=1.33, 95%CI=1.17-1.50, p<0.001); being a former PrEP-user (AOR=1.93, 95%CI=1.34-2.77, p<0.001); and being willing to pay for PrEP (AOR=4.61, 95%CI=4.09-5.20, p<0.001). Of those willing to use PrEP, only 36.1% were willing to pay for it (versus 10.8% of those not willing to use it).

Conclusions: PrEP use was very low overall. However, more than half of non-PrEP-users were willing to use it, indicating that there is a large pool of potential users; these men were younger and at higher risk (having more sexual partners, reporting condomless intercourse).

In some countries, the gap between willingness and use can be explained by the lack of PrEP programs, but other factors may be important. Affordability of PrEP is critical, as most men – even many willing to use it – were not willing to pay for it out-of-pocket.

Scale up of PrEP

PESUC25

Recovery in the uptake of pre-exposure prophylaxis (PrEP) in Australia after COVID-19 restrictions: analysis of national pharmacy dispensing data

D. Fraser[1], H. McManus[1], N. Medland[1], A. Grulich[1], R. Guy[1], B. Bavinton[1]

[1]*Kirby Institute, UNSW, Sydney, Australia*

Background: Initial COVID-19 restrictions in 2020 were accompanied by reductions in HIV pre-exposure prophylaxis (PrEP) prescribing in Australia. We analysed the rate of PrEP uptake nationally before and after COVID-19 restrictions to examine whether PrEP use returned to pre-COVID levels.

Methods: Data were extracted from all publicly-subsidised PrEP prescriptions dispensed in Australia between 01 January 2019 and 30 June 2021. We used interrupted time series analyses of time trends in the weekly number of bottles (30 pills) of PrEP dispensed nationally and by state/territory of residence, age group, and socioeconomic status of residential postcode.

We also report total dispensing in March 2020, the month immediately before COVID-19 restrictions were implemented with June 2021, the final month of follow-up.

Results: Over the 30-month period, 45,147 people (98.4% male) were dispensed 395,707 bottles of PrEP. Before restrictions, PrEP dispensing increased by 17 bottles each week (p<0.001; 95%CI:13.0, 21.6). In the week following implementation of restrictions, 1,023 fewer bottles were dispensed than the previous week (p<0.001; 95%CI:-1,339.8, -707.4). Dispensing then increased at an average of 13.1 bottles per week (p<0.001, 95%CI:6.9, 19.3). The rate of increase was not significantly different to the pre-restrictions rate (p=0.272; 95%CI:-11.8, 3.3). By the end of follow-up there were 15,330 bottles dispensed in June 2021, approaching the 16,635 bottles dispensed in March 2020 (immediately before COVID-19 restrictions were implemented). There were no significant differences between the rate of post-restriction dispensing between subpopulations of state/territory, age groups or socioeconomic status.

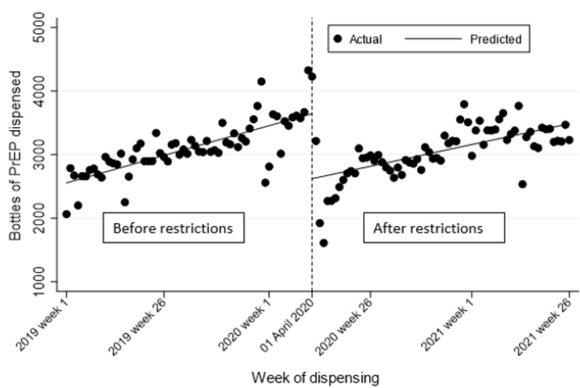

Figure 1. Number of PrEP bottles dispensed each week before and after COVID-19 restrictions were first implemented (dotted vertical line), and the number predicted by interrupted time-series analysis.

Conclusions: PrEP use steadily increased in Australia before COVID-19 restrictions led to a sudden large decrease in dispensing. By June 2021, nationwide PrEP use recovered to pre-pandemic levels. There were no disparities by jurisdiction, age, or socioeconomic status in the rate of recovery. This suggests that, as restrictions were lifted and sex increased, PrEP uptake also recovered.

PESUC26

Fostering access to PrEP among high-risk adolescent girls and young women aged 16 to 24 years through the DREAMS initiative in 4 districts in Zambia

J. Chipukuma[1], P. Olowski[1], B. Lindsay[1,2], L. Mwango[3], K. Tembo[1], C. Bwale[3], P. Makasa[3], M. Muchoka[3], S. Tembo[3], W. Mbokile[3], B. Bwembelo[3], E. Fundulu[3], C. Munsongo[4], K. Watala[4], B. Musonda[4], J. Okuku[5], A. Mwila[5], C. Muleya[5], C.W. Claassen[1,2]

[1]Maryland Global Initiatives Corporation Zambia, Lusaka, Zambia, [2]Center for International Health, Education, and Biosecurity, University of Maryland School of Medicine, Baltimore, United States, [3]Ciheb Zambia, Lusaka, Zambia, [4]Ministry of Health, Zambia, Lusaka, Zambia, [5]U.S. Center for Disease Control and Prevention, Lusaka, Lusaka, Zambia

Background: In Zambia, adolescent girls and young women (AGYW) remain at high risk of HIV infection due to social, cultural, and economic vulnerabilities. Pre-exposure prophylaxis (PrEP) is effective at preventing HIV especially when used as part of a combination prevention approach. However, limited data exists on PrEP eligibility, uptake and persistence among AGYW in sub-Saharan Africa.The University of Maryland Baltimore CIRKUITS and Z-CHECK projects implemented the Determined Resilient Empowered AIDS-free Mentored Safe (DREAMS) initiative aimed at educating young girls, communities and families on HIV prevention using evidence-based interventions, as a holistic HIV prevention intervention, including PrEP provision to AGYW.

Methods: We examined PrEP uptake among AGYW aged 16 to 24 years using a retrospective cohort enrolled in DREAMS between October 2020 and September 2021 in four districts of Zambia. AGYW were screened for substantial HIV risk; those eligible were consented and voluntarily initiated on PrEP at DREAMS centers by health care workers. Follow ups were conducted for refills and laboratory investigations. Multivariable logistic regression was used to examine variables associated with obtaining at least one PrEP refill following initiation.

Results: A total of 1,734 AGYW were assessed for PrEP eligibility, of whom 1,733 (99.9%) were eligible and 1,716 (99.0%) started PrEP. The median age at PrEP initiation was 21 years (IQR: 19, 23). Of those who started, 938 (54.7%) had at least one PrEP refill. Factors associated with obtaining at least one refill included age 20-24 years (aOR 1.88, 95% CI 1.51-2.34), being married (aOR 1.80, 95% CI 1.37-2.36) or sexually active in last six months (aOR 2.82, 95% CI 2.29-3.48), and reporting an STI in the prior six months (aOR 10.13, 95% CI 3.08-33.34). Among AGYW who discontinued PrEP and had at least one follow-up visit (99, 10.0%), reasons for discontinuation included: no longer at risk (56, 57%), relocation (12, 12%), and side effects (7, 7%).

Conclusions: The DREAMS initiative was successful at reaching AGYW with PrEP services. A high proportion at risk of HIV elected to initiate PrEP for at least some time. More evidence is needed to assess reasons for discontinuation and improve persistence for those with sustained risk.

PESUC28

Primary care providers' perspectives regarding PrEP care at primary care settings: a qualitative analysis

C. Zhang[1], S. Przybylek[1], Y. LiU[2]

[1]University of Rochester, School of Nursing, Rochester, United States, [2]University of Rochester, Public Health Science, Rochester, United States

Background: Primary care providers (PCPs) are crucial for preventing HIV and promoting sexual wellbeing for their patients. PCPs are considered the ideal pre-exposure prophylaxis (PrEP) care providers as they usually encounter more HIV-negative patients with indications for PrEP use. Nevertheless, limited data are available to assess PCP's perspectives regarding PrEP care.

This current study will explore their perceived barriers and potential facilitators on providing PrEP care at primary care settings in a cohort of PCPs recruited from a northeastern state in the United States.

Methods: In the current study, we employed a semi-structured in-depth interview to collect information about barriers and facilitators in PrEP care implementation among 18 PCPs who practice in New York State. We coded texts using coding themes related to the central questions in our interview guides and new themes that emerged in the coding process. Mixed methods including content and grounded theory analyses were used to analyze the transcribed narrative data.

Results: The recruited PCPs aged 30-68 years old reported a few specialties, including internal medicine, family medicine, and adolescent health. We identified a few themes related to their perspectives on PrEP care in primary care settings. Perceived barriers included: reluctance for discussion on sexual health-related topics, lack of navigations for patients and providers, the complexity of the regimen for engaging and monitoring patients, patients' low perceived risks, and HIV and PrEP associated stigma. In addition to barriers, a few potential solutions have been proposed by PCPs, such as screening for PrEP eligibility before the doctor visit, increasing self-awareness of HIV risk among patients, the flexible regime being available (e.g., long-term injectable PrEP), providing comprehensive PrEP navigation system to both providers and patients, and providing PCPs with peer education and sufficient training for PrEP care.

Conclusions: Our study is one of the first to explore PrEP care implementation in primary care settings. Findings suggested a navigation system for PrEP care in patients and providers is urgently needed. Future studies should facilitate PrEP discussion, engagement, and monitoring in primary care settings.

Innovative behavioural prevention interventions

PESUC27

Transforming Social and Behaviour Communication (SBC) using digital platforms: the case of USSD HIV self-assessment and PrEP adherence support tools

R.M. Muleya[1]

[1]JSI- USAID DISCOVER - Health, Prevention and Behavioral Interventions, Lusaka, Zambia

Background: In 2018 in Zambia, the USAID DISCOVER-Health Project, implemented by JSI, was one of the first partners to roll out PrEP. In Zambia, PrEP is only provided to individuals at substantial risk of HIV, using a paper-based national eligibility screening tool, administered by healthcare workers (HCWs) during service delivery. This is sometimes challenging to do in busy clinics, from both time-constraints and privacy perspectives.

Description: To help address this, the Project developed an Unstructured Supplementary Service Data (USSD) information management system, available to the public, to support self-risk assessment and improve linkage to services. Using mobile phones, clients access the HIV self-risk assessment platform to ascertain their risk level using the USSD. If an individual is at substantial risk, the USSD links them geographically to their nearest PrEP service provider (SP). TheSP reaches out to the client and makes an in-person appointment to initiate them on PrEP.

Once the client is initiated, the USSD, in combination with Short Message Service (SMS), provides PrEP adherence support, through periodic reminders.

Lessons learned: The Project analysed PrEP USSD/SMS access log to determine the volume of access for this service. 123,388 clients accessed this service between October 2018 and June 2019. Out of the 123,388 clients that accessed the USSD platform and used the HIV self-risk assessment, 16,430 were found to be at risk and requested the system to link them to the next step of in-person PrEP services.

In addition, 916 clients also requested to be linked to PrEP clinics, before full completion of the HIV risk assessment. Through the USSD, 17,346 people were linked to PrEP clinics from January to December 2021. During the same period, 33,776 clients accessed PrEP Adherence support using the USSD.

Conclusions/Next steps: The Project has demonstrated that simple digital solutions, such as USSD platforms, can facilitate health service linkage and adherence support for clients. The USSD platform provides privacy through self-risk assessment and reduces the initial screening burden on busy HCWs, while significantly opening up access to essential HIV prevention services to a wider beneficiary universe.

HIV prevention services for key populations

PrEP use and HIV incidence among young Thai men and transgender women who sell sex in Bangkok and Pattaya, Thailand: results of the COPE effectiveness study

C. Beyrer[1], B.W. Weir[1,2], A.L. Wirtz[1], S.H.H. Mon[1], N. Qaragholi[1], T. Chemnasiri[3,4], A. Warapornmongkholkul[3,4], D. Linjongrat[5], S. Janyam[6], P. Sirivongrangson[7], B. Chua-Intra[7], A.C. Hickey[3,4]

[1]Johns Hopkins Bloomberg School of Public Health, Center for Public Health and Human Rights, Department of Epidemiology, Baltimore, United States, [2]Johns Hopkins Bloomberg School of Public Health, Department of Health, Behavior, and Society, Baltimore, United States, [3]U.S. Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States, [4]Thailand Ministry of Public Health-U.S. Centers for Disease Control and Prevention Collaboration (TUC), Nonthaburi, Thailand, [5]Rainbow Sky Association of Thailand (RSAT), Bangkok, Thailand, [6]Service Workers in Group Foundation (SWING), Bangkok & Pattaya, Thailand, [7]Thailand Ministry of Public Health, Department of Disease Control, Nonthaburi, Thailand

Background: Young men who have sex with men (MSM) and transgender women (TGW) who exchange sex in Thailand have high HIV incidence. Access to PrEP for combination HIV prevention is imperative.

Methods: The COPE study recruited HIV-negative Thai MSM and TGW aged 18-26 years, who exchanged sex in the last year through online and community outreach. Participants were offered oral PrEP and could start and stop PrEP as desired. Participants were followed for 1 year, with some extending up to 2 years, and completed quarterly assessments, weekly SMS surveys and HIV and STI testing. The primary outcome was HIV seroconversions per 100 person-years (PY) on PrEP and not on PrEP, based on monthly pill pickups.

Results: Among 846 participants at 4 community clinics (October 2017-August 2019), 531 (62.8%) initiated PrEP at baseline, 104 (12.3%) subsequently initiated PrEP, and 211 (24.9%) never initiated PrEP. Participants contributed 598.4 PY on PrEP and 335.5 PY not on PrEP. Sufficient adherence was self-reported during 96.2% of SMS surveys while on PrEP. In a sub-sample of 66 dried blood spots with high self-reported adherence (≥4 pills per week), 53 (80%) had protective levels of intracellular tenofovir diphosphate.

Of the 10 participants diagnosed with HIV during study participation, none were using PrEP at the time of diagnosis (Figure 1), corresponding to an on-PrEP incidence rate of 0.0 per 100 PY (95% CI = 0.0, 0.62), an off-PrEP incidence rate of 2.98 per 100 PY (95% CI = 1.43, 5.48), and an IRR of 0.0 (95% CI = 0.0, 0.25; p <.0001). Sensitivity analyses accounting for uncertainty in time of seroconversion provided an IRR of 0.041 (95% CI = .006, .311; p = .001).

Conclusions: Combination HIV prevention with PrEP for young Thai MSM and TGW who exchange sex can achieve high PrEP uptake, high adherence, and reduced HIV incidence.

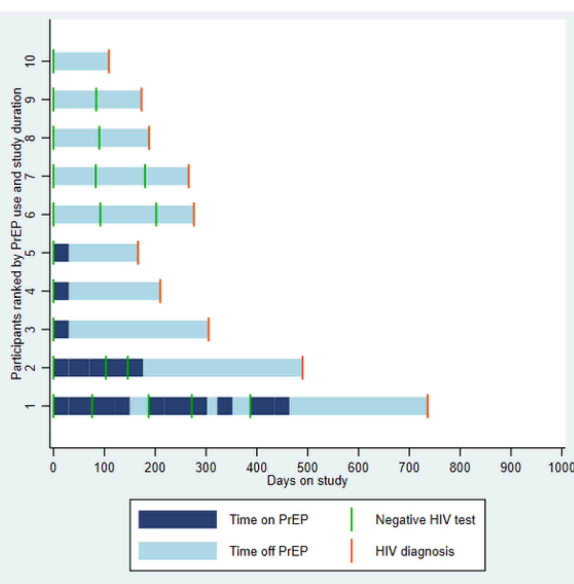

Figure 1. Patterns of PrEP use and HIV testing among participants with HIV seroconversion in the COPE study for young men who have sex with men and transgender women who exchange sex, Thailand (2018 - 2020).

PESUC30

Preferences for potential long-acting pre-exposure prophylaxis (PrEP) dosing regimens among gay, bisexual and other men who have sex with men (GBMSM) in Taiwan: 2021 HEART Survey

S.W.-W. Ku[1,2], T.-W. Chen[3], C.-W. Li[4], P. Huang[5], H.-J. Wu[6], T.-H. Wu[2], A. Bourne[6,7], C. Strong[3]

[1]*Taipei City Hospital Renai Branch, Division of Medicine, Department of Infectious Diseases, Taipei City, Taiwan, Province of China,* [2]*HIV Education And Research Taiwan (HEART) Association, Taipei City, Taiwan, Province of China,* [3]*National Cheng Kung University, College of Medicine, Department of Public Health, Tainan City, Taiwan, Province of China,* [4]*National Cheng Kung University, College of Medicine, National Cheng Kung University Hospital, Center for Infection Control and Department of Internal Medicine, Tainan City, Taiwan, Province of China,* [5]*National Taiwan University, Institute of Health Behavior and Community Sciences, Taipei City, Taiwan, Province of China,* [6]*Kirby Institute, University of New South Wales, Sydney, Australia,* [7]*Australian Research Centre in Sex, Health and Society, La Trobe University, Melbourne, Australia*

Background: Various antiretrovirals have been examined as potential candidates for long-acting PrEP. While event-driven (ED) PrEP is currently the most prevalent dosing regimen among GBMSM in Taiwan, there is a need to determine preferences for other possible regimes and what factors might inform such preferences, in order to support future PrEP uptake.

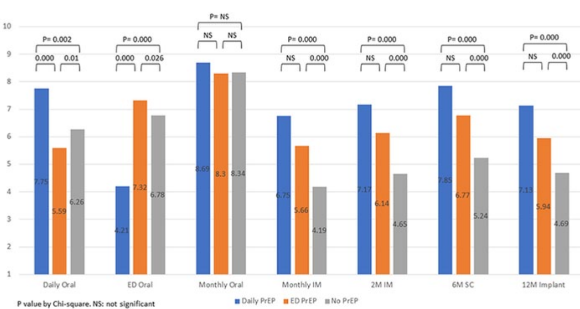
Methods: Between November 28th-December 28th 2021, a survey comprising 67 questions was administered online to GBMSM using social networking applications in Taiwan. Beyond demographics, HIV serostatus and HIV risk behaviors, respondents were asked to indicate their preference for different PrEP formulations on a 10-point Likert scale (1=least preferred; 10=most preferred).

Options included: daily oral, ED oral, monthly oral, monthly or bimonthly intramuscular injectable (2M IM), 6-month subcutaneous injectable (6M SC), and 12-month implant.

Results: In total, 1,880 survey responses were included in this analysis. Among 1,728 respondents who reported HIV-negative or unknown serostatus, 52 took PrEP daily and 198 event-driven.

Regardless of cost, current daily PrEP users were most likely to prefer monthly oral, followed by 6M SC, daily oral, and 2M IM. Current ED PrEP users preferred monthly oral form the most, followed by ED oral, 6M SC, and 2M IM.

Overall, the majority (67.7%) were only willing to pay less than 150 USD per injection to receive 2M IM PrEP. Multivariable logistic regression revealed current daily PrEP users (AOR 2.19 vs. ED user), those willing to take PrEP (AOR 1.45), those with more sex partners (AOR 1.39), and those not feeling happy about their sex life (AOR 1.60) had significant correlation with preference of 2M IM over ED oral PrEP.



Conclusions: Monthly oral was the most preferred dosing regimen. Bimonthly intramuscular injectable PrEP could be an alternative to ED PrEP for certain populations. Cost and means of administration could affect new regimen uptake and should be further investigated.

Real-world utilization of HIV Pre-Exposure Prophylaxis (PREP) by cisgender and transgender individuals in the United States

J. Thorburn[1], J. Paone[1], A. Kong[1], C. Bush[1], D. Patel[1], C. Carter[2], M. Das[2], L. Tao[2]

[1]*Aetion, New York, United States,* [2]*Gilead Sciences, Foster City, United States*

Background: This study describes real-world utilization of daily oral PrEP regimens emtricitabine (F)/tenofovir disoproxil fumarate (TDF) and F/tenofovir alafenamide (TAF) by gender.

Methods: HIV-1 negative individuals receiving PrEP (F/TDF or F/TAF) were identified from a pharmacy claims database linked with medical claims from physicians' offices across the US. Transgender men (TGM) and women (TGW) were identified using an algorithm which incorporated claims for gender dysphoria, gender-affirming surgery, and gender-affirming hormone therapy. Individuals not identified as TGM or TGW were classified as cisgender men (CGM) or women (CGW).

Results: Most people receiving PrEP were CGM while the proportions of individuals classified as CGW, TGM, and TGW increased from 2015 to 2020 (CGW: 8.1% to 11.9%; TGM: 0.3% to 0.6%; TGW: 0.4% to 1.4%).

Among 104,354 people receiving PrEP from 10/3/2019 (approval date of F/TAF) to 3/31/2021, 90.2%, 7.9%, 0.6%, and 1.2% were CGM, CGW, TGM, and TGW, respectively, and 37% were from the South (Table). The proportion of people receiving PrEP of each state ranged from 79.2% (Louisiana) to 95.4% (Utah) for CGM, from 2.7% (Vermont) to 19.6% (Florida) for CGW, and from 0.0% (North Dakota) to 3.7% (Ohio) for TGM/TGW (Figure).

Higher proportion of people on F/TAF received prescriptions from an infectious disease physician compared with F/TDF (9.2% vs. 6.7%); this difference was greatest among CGW (13.7% vs. 7.1%).

	Total N=104,354	CGM N=94,159 (90.2%)	CGW N=8,291 (7.9%)	TGM N=605 (0.6%)	TGW N=1,299 (1.2%)
F/TAF Users	28,372	27,211 (95.9%)	725 (2.6%)	114 (0.4%)	322 (1.1%)
F/TDF Users	75,982	66,948 (88.1%)	7,566 (10.0%)	491 (0.6%)	977 (1.3%)
Median Age at Initiation (IQR)	36 (28, 48)	36 (28, 48)	36 (27, 47)	32 (25, 44)	29 (23, 37)
Region: Northeast	24,143	21,703 (89.9%)	1,913 (7.9%)	154 (0.6%)	373 (1.5%)
Region: Midwest	17,253	15,787 (91.5%)	1,077 (6.2%)	106 (0.6%)	283 (1.6%)
Region: South	38,177	33,597 (88.0%)	4,078 (10.7%)	175 (0.5%)	327 (0.9%)
Region: West	24,287	22,631 (93.2%)	1,182 (4.9%)	167 (0.7%)	307 (1.3%)

Table.

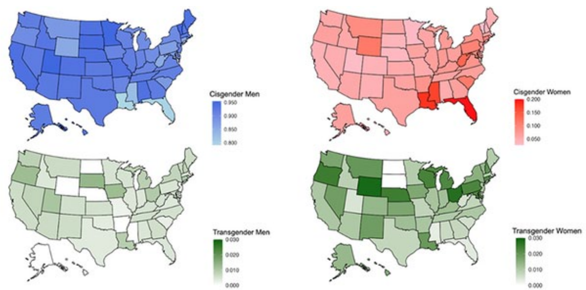

Figure. The proportions of CGM, CGW, TGM and TGW among people receiving F/TAF and F/TDF for oral PrEP by state in the US, 2019/10/3 - 2021/3/31

Conclusions: This study describes the changing gender composition of people on PrEP, with CGW, TGM, and TGW accounting for increased proportions over time in the real-world. Demographic and geographic variation across genders highlights the importance of improving access for people who would benefit from PrEP.

Community-based HIV testing strategies

Contact tracing - an innovative approach to fight the HIV epidemic in Haiti

G.E. Thermidor[1], J. Ukwishaka[1], J.F. Gakindi[1], J. Deas Van Onacker[2], N. Duval[2], E.G. Robin[2]

[1]*Universite Libre de Bruxelles, School of Public Health, Bruxelles, Belgium,* [2]*MSPP/PNLS, Port-au-Prince, Haiti*

Background: Significant progress has been made in controlling the HIV epidemic in the past 20 years. In 2020, 84% of people living with HIV (PLHIV) knew their status in Worldwide. During the last decade, the Haitian Ministry Health (MSPP) through the National program against STIs and HIV/AIDS (PNLS) has concentrated on discovering creative techniques to expanding HIV testing in line with WHO, CDC and USAID strategies. One of implemented strategy was contact tracing which was adapted to the Haitian settings to be more effective. This study's objectives were to identify the percentage of PLHIV (People Living with HIV) who accepted to participate in contact notification services, to determine the prevalence of HIV in tested contacts and to determine the number and profile of new cases enrolled in HIV-care and treatment services.

Methods: It was a retrospective cross-sectional descriptive study conducted between July 2018 to July 2021. The data were collected from the MESI (monitoring evaluation surveillance integree) national database. The search included (149) health facilities involved in providing care and treatment to PLHIV in the whole country with available data on partner services platform viamesi.ht. The data were collected on the platform from Index patient and their contact information forms.

Results: Among the Index cases contacted, 94% accepted the contact notification services. From July 2018 to July 2021, the contact tracing unveiled 52742 contacts. Among them (85.9%) 45324 were contacted. Among those contacted only (92.7%) were found. Among the interviewed people, 31806 persons were not aware of their HIV status. Among those who were not aware of their status (95.5%) 30393 were tested and (33.7%) 10252 of them were positive. (94%) 9636 of new cases were enrolled in the service of care and treatment. The analysis per index cases priority group revealed that 52% of MSM contacts and 43% of FSW contacts tested positive for HIV.

Conclusions: Contact tracing approach adapted to local settings is an effective targeted method of identifying and enrolling to treatment many patients. It helps finding the high number of contacts including the key population.

PESUC32

Potential use of pooled point-of-care HIV-1 viral load to detect HIV infection at PrEP initiation and follow-up visits in key population-led PrEP clinics in Thailand

N. Thammajaruk[1], S. Thongsuksangcharoen[1], R. Trichavaroj[1], P. Thapwong[2], S. Saiwaew[3], S. Sangtong[4], M. Avery[5], S. Mills[5], P. Phanuphak[1], R.A. Ramautarsing[1], N. Phanuphak[1]

[1]Institute of HIV Research and Innovation (IHRI), Bangkok, Thailand, [2]The Service Workers In Group Foundation, Bangkok, Thailand, [3]Rainbow Sky Association of Thailand, Bangkok, Thailand, [4]Mplus Foundation, Chiang Mai, Thailand, [5]FHI 360, Bangkok, Thailand

Background: Use of HIV-1 viral load (VL) assay can improve detection of HIV infection before pre-exposure prophylaxis (PrEP) initiation and during follow-up, as PrEP can delay detection by fourth- and third- generation immunoassays. We studied potential use of individual and pooled point-of-care VL assays to detect acute/early HIV infection in key population (KP)-led PrEP clinics in Thailand.

Methods: From August 2019 to September 2021, men who have sex with men and transgender women PrEP clients were enrolled from four KP-led clinics in Bangkok, Chiang Mai, and Pattaya. EDTA plasma was collected at entry and quarterly visits and tested for HIV VL (Xpert HIV-1 VL) and conventional HIV rapid testing algorithm (Alere Determine HIV-1/2, if reactive, then followed by Wantai Colloidal Gold Device and SD Bioline HIV-1/2 3.0).

Participants with detectable VL had their leftover plasma tested by Wantai and SD Bioline (regardless of Alere Determine result) and Alere HIV COMBO (fourth-generation rapid test). Their samples and those from other PrEP clients who came on the same day were pooled for VL testing by Xpert.

Results: Of 3,828 visits (390 PrEP initiation and 3,438 PrEP follow-up), VL was detected in three participants; one at PrEP initiation (>10,000,000 copies/mL) and two at PrEP follow-up visits (810 and 5,940,000 copies/mL). Pooled VL showed detectable VL at 3,670,000 (11 samples/pool), 43 (12 samples/pool), and 670,000 (7 samples/pool) copies/mL, respectively (see Table 1). Alere HIV COMBO showed antigen positivity for the participant with detectable VL at initiation, and antibody positivity for the follow-up participants. All tested HIV negative by conventional algorithm.

Participants	HIV testing algorithm at KP-led clinics				Individual HIV-1 VL result (copies/mL)	Alere HIV COMBO (4th generation rapid HIV test) Individual HIV-1 VL result (copies/mL) Alere HIV COMBO (4th generation rapid HIV test)	Pooled HIV-1 VL	
PrEP users	Conventional HIV test result	A1: Alere Determine HIV-1/2	A2: Wantai Colloidal Gold Device	A3: SD Bioline HIV-1/2 3.0			Number of samples per pool	HIV-1 VL result (copies/mL)
PrEP initiation	negative	negative	negative	negative	> 10,000,000	positive (Ag band)	11	3,670,000
PrEP follow-up	negative	negative	negative	positive	810	positive (Ab band)	12	43
PrEP follow-up	negative	negative	positive	positive	5,940,000	positive (Ab band)	7	670,000

Table 1: Results of individual and pooled virological and immunological response to HIV-1 infection among PrEP users.

Conclusions: Pooled point-of-care HIV VL testing and fourth-generation rapid test detected HIV infections at PrEP initiation and follow-up visits that were missed by conventional third-generation rapid testing algorithm. Both assays have high potential and affordability to be integrated into KP-led PrEP clinics in resource-limited settings.

PEMOC40

Leveraging faith communities to test and treat men living with HIV in Uganda

L.J. Nelson[1], A.G. Fitzmaurice[1], R. Kamara[2], L. Sekimpi[2], H. Mwesezi[2]

[1]US Centers for Disease Control and Prevention (CDC), Division of Global HIV & TB, Kampala, Uganda, [2]Uganda Episcopal Conference, Uganda Catholic Medical Bureau, Kampala, Uganda

Background: In Uganda, disproportionately fewer men living with HIV (MLHIV) than women are aware they have HIV. This is partly due to not seeking out healthcare, so providing testing services where men frequent might help MLHIV get tested and treated for HIV. Uganda's population comprises 84.4% Christians and 13.7% Muslims, so faith communities are effective venues for reaching many Ugandans.

Here, we describe how national faith-based medical organizations introduced HIV testing to faith communities in Uganda; we compare results from Catholic churches with those from regional HIV testing programs to demonstrate the potential of faith community HIV programs.

Description: In April—September 2021, Uganda's Catholic, Protestant, Muslim, and Orthodox medical bureaux conducted two-day trainings of 794 faith leaders in three regions using curriculum endorsed by the Ministry of Health. Faith leaders used sermons, free/subsidized Christian radio and television, and social media to mobilize 53,826 community members for counseling and HIV test screening. Some men came to HIV testing events when COVID-19 vaccination and hypertension screening were offered concurrently. Faith leaders administered 15,578 HIV tests, including 9,101 rapid test kits.

We used a two-sample proportion test to compare results from a subset (5,449 rapid tests administered by Catholic faith leaders) with HIV test data in Uganda's Electronic Health Information System (eHMIS) from the same time period and regions.

Lessons learned: Catholic churches tested more men than women (62%; 3,378/5,449), while traditional testing programs tested fewer men (31%; 168,649/546,956). Tests in Catholic churches were more seropositive than in traditional testing programs (4.6% vs. 3.7%; OR=1.25; P=0.0005). Churches needed fewer tests than traditional programs to identify each person living with HIV. Of the 138 men and 114 women with positive results in Catholic churches, 111 men (80%) and 106 women (93%) went to facilities and had confirmatory positive tests; 109 men (98%) and 98 women (92%) initiated treatment.

Conclusions/Next steps: Faith communities can be leveraged to test and treat those who do not typically seek HIV services. We spent only 2 USD per person for one-on-one counseling and screening. Further implementation will help reveal whether faith communities can identify MLHIV at an impactful and cost-effective scale.

PEMOC41

A geospatially targeted field-based approach is more efficient than a network-driven approach for reaching PWID living with HIV in Punjab, India

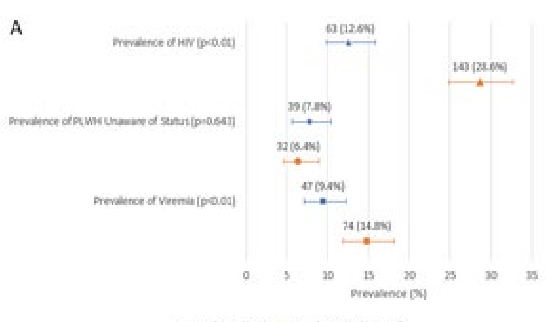
T. Loeb[1], A.M. McFall[1], A.K. Srikrishnan[2], L.R. Sangma[2], P. Narayan[3], P. Nandagopal[2], S. Anand[2], V. Swaminathan[2], S.H. Mehta[1], S.S. Solomon[3]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [2]YR Gaitonde Center for AIDS Research and Education, Chennai, India, [3]The Johns Hopkins University School of Medicine, Baltimore, United States

Background: Respondent-driven sampling (RDS) - network referral/recruitment - is an effective approach to reach people who inject drugs (PWID) at risk for or living with HIV. Yet, in most RDS samples, ~30-60% of recruitment coupons remain unreturned. We explored the impact of integrating a geospatially targeted field-based HIV testing strategy with an RDS survey.

Methods: PWID were first recruited in the town of Patti, Punjab near the India-Pakistan border using RDS (Nov 2019-Feb 2020) in which they reported on injection venues. HIV prevalence by venue informed field-based testing (Feb-May 2021; paused Mar 2020-Feb 2021 for COVID-19). Biometric data ensured individuals could only enroll in one of the two approaches. All participants completed a survey and underwent rapid onsite HIV testing. HIV RNA was quantified for positive participants. For each sampling approach, we calculated the number of: 1) HIV+; 2) undiagnosed (HIV+ but unaware of status [self-report]), and 3) viremia (≥150 copies/mL). We compared the prevalence and identification rate (average number identified per day) by each approach for each outcome.

Results: 501 PWID were recruited using RDS in 81 days; median age was 29 years, <1% were female, and 94% reported active injection. In the geospatially targeted field-based testing, 500 PWID were recruited in 81 days; median age was 31 years, 4% were female and 99.8% reported active injection. The prevalence of HIV in the RDS vs. field-based testing was 12.6% vs. 28.6% (p<0.01); and prevalence of viremia were 9.4% vs 14.8% (p<0.01; Figure). The field-based approach was significantly faster than RDS at identifying both PWID with HIV (1.77/day vs. 0.78/day; p<0.01) and PWID with viremia (0.91/day vs. 0.58/day; p=0.014).



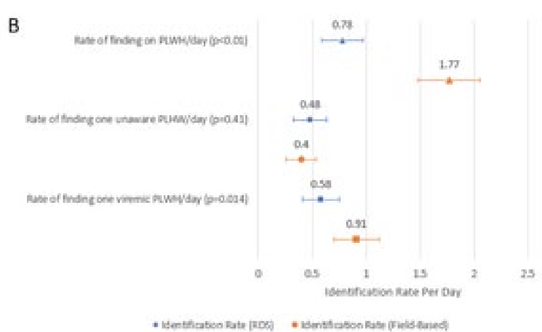


Figure A) Prevalence and B) identification rate of people who inject drugs living with HIV (PLWH) using repsondent-driven sampling (RDS) and a geospatially targeted field-based approach in India.

Conclusions: A geospatially targeted field-based testing approach was faster than a network-driven approach at identifying PWID with transmission potential. Surveillance programs should consider capturing injection venues to facilitate such field-based HIV testing approaches.

Community-based approaches (including empowerment, outreach and service delivery)

Burnout among service providers for people living with HIV: factors related to coping and resilience

S. Dale[1], R. Reid[1], A. Madhu[1], S. Gonzalez[1], H. Crosby[1], M. Stjuste[1]

[1]*University of Miami, Miami, United States*

Background: Individuals who provide services for people living with HIV (PLWH) face numerous challenges at work, including psychosocial and structural factors, which affect quality of care and service delivery. Little is known about the factors that relate to burnout among case managers/ workers, peer counselors, group facilitators, social workers, and HIV testers who may share overlapping identities with their clients, which may increase their effectiveness in their roles, yet also exacerbate burnout.

The current study seeks to examine the factors associated with burnout, as well as the role of resilience and coping among service providers for PLWH.

Methods: Data was collected from 28 service providers for PLWH (67.9% Black/African American, 53.6% HIV negative and 57.1% HIV testers) in the United States from January to October 2021 using a mixed methods research design. Participants completed quantitative measures on sociodemographics, organizational factors, discrimination, trauma, depression and burnout.

A sub-sample of 19 participants also provided in-depth qualitative data via semi-structured interviews, which explored the aforementioned factors as well as the impact of COVID-19, coping, and resilience on burnout.

Results: Thematic content analysis revealed important themes on the factors related to burnout (e.g. discrimination, microaggressions, shared identities, limited financial and housing resources, and COVID-19), rejuvenating factors (e.g. finding purpose in one's work), coping with burnout (e.g. psychotherapy and spirituality), and intervention strategies that are individually tailored.

Results of Pearson correlations were consistent with the stories and insights shared by participants and revealed significant associations between mental health variables (i.e. depressive and posttraumatic stress disorder symptomology), discrimination and microaggressions, and burnout.

Conclusions: Our findings highlight structural barriers within organizations and discrimination that are impacting professionals in this sample who share identities (e.g. LGBTQ+, living with HIV, race) with the PLWH whom they serve.

This research also highlights the relationship between discrimination and the mental health and well-being of key professionals who serve PLWH. These findings may inform the development of an intervention targeting burnout among individuals providing services to PLWH as well as incite change to remove structural barriers that may improve the work environments for providers and ultimately the quality of care for PLWH.

PESUD26

Using technology to increase STI/HIV case finding through pharmacies in Cambodia

J. Neukom[1], S. Suon[2], J.M. Lailo[3], E.G. Ramoran[4], M.A. Tripon-Manguiat[5], O. Vichea[6]

[1]*mClinica Pharmacy Solutions, Public Sector, Ho Chi Minh City, Viet Nam,* [2]*mClinica Pharmacy Solutions, Public Sector, Phnom Penh, Cambodia,* [3]*mClinica Pharmacy Solutions, Public Sector, Taguig City, Philippines, the,* [4]*mClinica Pharmacy Solutions, Data, Taguig City, Philippines, the,* [5]*mClinica Pharmacy Solutions, Technology, Taguig City, Philippines, the,* [6]*National Center for HIV/AIDS, Dermatology and Sexually Transmitted Diseases, Phnom Penh, Cambodia*

Background: Pharmacies serve as an initial source of health care for key populations at risk of HIV and sexually transmitted infections (STIs) in Cambodia and other low and middle income countries. Despite this, public health programs have struggled to engage pharmacies at scale given the fragmented nature of the pharmacy channel in Southeast Asia.

In this context, the National Center for HIV/AIDS, Dermatology and Sexually Transmitted Diseases (NCHADS) collaborated with mClinica to leverage the SwipeRx network to facilitate HIV/STIs e-referral practices in Cambodia.

Description: With support from the Global Fund and technical assistance from USAID EpiC, Linkages, and Enhancing Quality Health Activity (EQHA), NCHADS and mClinica tested an e-Referral system. The system was built using an e-Referral tool within the SwipeRx app with linkages to three referral facilities (1 private and 2 public) in Phnom Penh. Clients who consent to be referred through SwipeRx provide a mobile phone contact through which they receive automated SMS messages to encourage them to seek referral care. Pharmacies invited to join the program were identified based on their pre-existing key population client volume, technology capacity, and willingness to participate in the program.

Lessons learned: Data from June-December 2021 suggest that 252 clients were referred through SwipeRx by 39 pharmacies trained to use e-Referral system.

Among the clients referred, 93 were referred for STI/HIV diagnosis, the average number of STI/HIV clients referred through e-Referral system increase by 130% based on comparison of 3-month averages.

Close to 3 out of 4 clients (73%) referred for STI/HIV services chose Chouk Sar (private, non-governmental) referral site while 27% chose one of the two (public) referral sites accessible through the system. During the initial 6.5 months of e-Referral, 17 STI cases and 4 HIV cases were diagnosed and treated.

Conclusions/Next steps: These findings highlight the potential for pharmacies linked to e-Referral system to contribute to national STI/HIV program goals. Future efforts to expand e-Referral system coverage to include additional pharmacies serving key populations and to include pharmacy access to HIV self-testing are sustainable strategies to increase coverage of key populations and link with the full cascade of care available at referral health facilities.

PESUD27

Integrated HIV testing service delivery: an innovative approach to reaching female head porters and high risk men in Ghana amid COVID-19

R. Afriyie[1], P. Ayamah[2], N.A. Acheampong[1], C. Adobea Asante[2], S. Oppong[3], D.K. Atuahene[4], F.N. Poku[1], B. Amankwa[5]

[1]Ghana AIDS Commission, Technical Services, Accra, Ghana, [2]Ghana AIDS Commssion, Accraa, Ghana, [3]NHS, UK, United Kingdom, [4]Ghana AIDS Commssion, Director General, Accraa, Ghana, [5]UNDP, Accra, Ghana

Background: In Ghana, head porterage is an urban phenomenon dominated by young women who have migrated from other parts of the country. These young migrants live in deplorable conditions in the city and engage in risky sexual behaviours. UNDP and GAC collaborated on an integrated outreach programme to reach them and other vulnerable populations with an integrated HIV service in the COVID-19 era.

Description: To ensure sufficient coverage of the target population, leaders of the Female Head Porters (FHP) were engaged in mapping their sites with support of Peer-Educators in the nine communities (located in the Accra Metropolis and GA Central Municipality) targeted for the intervention.

Other vulnerable groups including seafarers, truck drivers and mates, HRM were reached and served. Event-based and mobile based testing was adopted to reach the target population with integrated health outreach services namely HTS, Malaria and Hepatitis B test, BMI checking, Blood Glucose Testing, TB Sputum collection and COVID-19 vaccination.

The participants benefited health education on HIV, nutrition, sexual and gender-based violence and substance abuse.Condom demonstration and BCC leaflets were also distributed.

Lessons learned: With the integrated services approach to HTS, 3,580 FHP and other vulnerable groups were reached in 9 days as against 821 and 488 reached in the whole of 2020 and 2021 respectively at the same catchment area.

Moreover, the integrated HTS approach yielded HIV positivity of 2.2% as against 0.01% for each of 2020 and 2021. Over 90% of positive clients were linked to care and treatment. 1,680 were screened for Blood Pressure and Body Mass Index Screening and 1,172 blood Sugar were checked with 104 receiving COVID-19 vaccines. Mobile testing strategy helped to overcome some barriers to HTS for persons who would otherwise not seek it. Ghetto clients had opportunity to interact with health care staff and the nutritionist and discuss matters of concern to them.

Conclusions/Next steps: Integrated services approach as against standalone HTS encourages more vulnerable people to test and removes stigma relating to HIV service uptake. GAC is therefore encouraged to pursue more such collaborations to reach hidden populations with the services they need.

PESUD28

High linkage to treatment among key populations who self-test through a peer HIV self-test distribution and community-based ART program among key populations in Lagos, Nigeria

A. Fernandez[1], W. Tun[2], E. Shoyemi[3], J. Pulerwitz[4], A. Adedimeji[4]

[1]Population Council, HIV/AIDS, Lagos, Nigeria, [2]Population Council, Washington, United States, [3]Centre for Population Health Initiative, Lagos, Nigeria, [4]Population Council, Washington DC, United States

Background: HIV self-testing (HIVST) presents an opportunity to increase HIV testing uptake. It offers a confidential alternative particularly for highly stigmatized and criminalized populations such as men who have sex with men (MSM), transgender persons (TG), and female sex workers (FSW). However, follow-up of HIVST recipients is often a challenge, thus hindering appropriate referral to prevention and treatment services.

We report on implementation outcomes and lessons learned from community-based HIVST distribution and linkage to community-based ART and PrEP for key populations (KPs) in Lagos, Nigeria.

Description: In 2020, as part of outreach services of a community-based health clinic (CBHC) serving KPs, HIVST kits were distributed to 1,174 MSM, 224 FSWs, and 102 TG persons (TG men: 12; TG Women: 90) by peer educators (PEs). PEs (N=10) reached their peers at physical hotspots and through social media (WhatsApp followed by in-person distribution) and provided HIV education and shared an HIVST demonstration video and brochure on post-test services (e.g., confirmatory testing, ART, PrEP). Contact information was obtained from clients for follow-up (e.g., referral to the CBHC or linked with a community health extension worker for ART or PrEP enrollment).

Lessons learned: 17% of recipients were first-time testers. PEs reached 100% of kit recipients within five days of distribution (majority by phone call); all reported having unassisted self-testing.

The self-reported positivity rates were 3.1% in MSM, 0.4% in FSWs, and 4.9% in TG persons. All KPs who self-tested positive initiated ART; 10 of 1,458 who self-tested negative initiated PrEP (all MSM).

Employing trusted peers was an effective way of reaching KPs with HIVST. Follow-up calls were successful due to:
i. verifying the number at the time of kit distribution,
ii. following-up soon after distribution by the PEs themselves.
Successful linkage to treatment was likely due to referral to a KP-friendly community-based clinic supplemented by community-based ART initiation.
Conclusions/Next steps: The high uptake of HIVST and ART was facilitated by strategies led by PEs and post-test services being offered in KP-friendly clinics and in the community. HIVST is especially essential given that the COVID-19 pandemic has limited numbers of in-person testing at clinic and outreach.

Sexual- and/or gender-based violence and exploitation (including in conflict settings)

PESUD29
"Coming out or not": sexual orientation disclosure, HIV testing, and homoprejudiced violence for MSM in China

X. Yan[1,2], Y. Ni[1,2], Y. Lu[1,2], Q. Wang[1,2], R.K.J. Tan[1,2], G. Marley[1,2], Y. Zhou[3], W. Tang[4,2,1], D. Wu[5,2]
[1]University of North Carolina at Chapel Hill Project-China, Guangzhou, China, [2]Social Entrepreneurship for Sexual Health (SESH) Global, Guangzhou, China, [3]Zhuhai Center for Disease Control and Prevention, Department of HIV/AIDS Prevention and Control, Zhuhai, China, [4]Dermatology Hospital of Southern Medical University, Guangzhou, China, [5]London School of Hygiene and Tropical Medicine, International Diagnostics Centre, London, United Kingdom

Background: Disclosure of sexual orientation to health professionals has been advocated in clinical settings because it could be an entry point to providing HIV testing and optimal care for men who have sex with men (MSM). Yet, sexual orientation disclosure is stigmatized or even criminalized in certain societies.
This study aimed to test the association between disclosure of sexual orientation and the uptake of HIV testing services, and explore whether disclosing one's sexual orientation would increase the risk of experiencing homoprejudiced violence (i.e., violence against individuals based on their actual or perceived sexual orientation) for Chinese MSM.
Methods: We obtained the data from a cross-sectional survey among Chinese MSM in January 2021. Participants were recruited online through a popular gay dating app called BlueD. The measurements 'ever disclosed sexual orientation', 'ever tested for HIV', and 'ever self-tested for HIV' were all dichotomous variables. Ever experiencing homoprejudiced violence was measured on a 12-item scale and recoded as a dichotomous variable (i.e., ever experienced any one of the twelve items). Multivariable logistic regressions were used to explore the relationships, adjusted for sociodemographic characteristics.
Results: A total of 1828 MSM were enrolled in the survey, of whom 73% (1334) identified as gay, 56% (1023) had ever disclosed their sexual orientation to others, 77.5% (1417) have ever tested for HIV, and 68% (1244) have ever self-tested for HIV. 46.3% (847) reported ever experiencing homoprejudiced violence. Ever disclosing one's sexual orientation was associated with greater odds of HIV testing (aOR=1.90, 95%CI: 1.50~2.41) and HIV self-testing (aOR=1.39, 95%CI: 1.13~1.71). However, sexual orientation disclosure was also positively associated with ever experiencing homoprejudiced violence (aOR=1.70, 95%CI: 1.48~2.07).
Conclusions: Sexual orientation disclosure is a double-edged sword for the MSM population in China. While it showed public health benefits in improving HIV prevention by increasing the uptake of HIV testing/self-testing services, we need to be cautious about encouraging disclosure in high-stigma settings as it may subject MSM to greater exposure of homoprejudiced violence.
Future researches should verify the causal relationship between these factors, and our findings call for an inclusive social environment that safeguards disclosure of sexual orientations.

Harm reduction

PESUD30
Marijuana use goals, patterns, and perceptions of health impact among persons with HIV in care in the era of state-level legalization

R. Fredericksen[1], E. Fitzsimmons[1], M. Sigal[2], S. Dougherty[3], J. Pearce[1], M. Powell[1], J. Nguyen[1], S. Ruderman[1], B. Whitney[1], L. Drumright[1], J. Ma[1], R. Nance[1], J. Delaney[4], K. Mayer[2], A. Willig[3], H. Crane[1], A. Hahn[1]
[1]University of Washington, Seattle, United States, [2]Fenway Institute, Boston, United States, [3]University of Alabama-Birmingham, Birmingham, United States, [4]University of Manitoba, Winnipeg, Canada

Background: We sought to determine whether state-level marijuana policy changes were associated with marijuana use behaviors and perceptions among people with HIV (PWH), including access to marijuana, goals for use, patterns of use (e.g., frequency, modality), use of other substances, and perceived health impacts.
Methods: We recruited PWH aged ≥18 for 1:1 interviews at three U.S.-based HIV clinics within the Centers for AIDS Research Network of Integrated Clinical Systems (CNICS) between 2019-2020.
Two clinics were in states that legalized marijuana use. PWH reporting weekly or more frequent marijuana use on routinely administered, clinic-based, electronic assess-

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

ments of patient reported outcomes (PROs) were eligible for inclusion. We transcribed and coded interviews based on sub-topic areas of interest.

Results: We interviewed 29 PWH who reported weekly-or-greater marijuana use [80% cisgender male; mean age=50; 48% Black, 34% White, 17% Hispanic, 10% multiracial, 7% Asian-American]. One-quarter of participants reported increased marijuana use since legalization in their state, primarily due to increased accessibility and a desire to explore products and varieties for therapeutic needs.

The most cited therapeutic goals included relaxation/sleep (66%), increased appetite (41%), stress/anxiety relief (31%), pain relief (28%), fun/recreation (28%), to reduce cravings for another substance (17%), and to alleviate physical symptoms other than pain (10%); overall, 69% of interviewees reported they used marijuana for more than one purpose.

Reasons for use were not reported to be influenced by legalization. In legalized settings, increased product diversity and attribute labeling (e.g., cannabinoid type and strength) facilitated decision-making, allowing PWH to tailor to their specific goals.

Several PWH reported marijuana's role in helping maintain sobriety from other substances. Edible marijuana products were regarded as a healthier alternative to smoking and very few reported concerns with over-use or addiction. PWH reported stopping use once a goal was met (e.g., being pain-free). Short-term therapeutic benefits were prioritized over what were believed to be ambiguous, potential long-term negative health consequences.

Conclusions: Among a sample of PWH who used marijuana, the broad availability of products following legalization offered a means for facilitating decision-making for targeted therapeutic use, including stress reduction and minimization of craving alcohol and 'harder' substances.

PESUD31

HIV remission trials with treatment interruption of fixed duration:Trial investigators' perceptions of strategies to mitigate HIV transmission risk

C. Golin[1,2], E.A. Okumu[2], G.E. Henderson[3], K.J. Kuczynski[3], N. Ormsby[3], H.L. Peay[4]

[1]UNC Gillings Global School of Public Health, Health Behavior, Chapel Hill, United States, [2]UNC Center for AIDS Research, Chapel Hill, United States, [3]University of North Carolina at Chapel Hill, Social Medicine, Chapel Hill, United States, [4]RTI International, Durham, United States

Background: Early phase HIV remission („cure") trials aim to develop interventions to eradicate HIV from the body, or to sustainably control HIV without antiretroviral treatment (ART). Controversy over analytic treatment interruption (ATI) has been generated by trials with longer duration before re-starting ART, which involves greater risk for individuals and partners.

Methods: In a 2021 online survey of international HIV remission trial investigators and study team members registered on clinicaltrials.gov, we assessed perceptions of feasibility, acceptability, and efficaciousness of six HIV transmission risk mitigation strategies during trials with ATI of fixed duration, using 7-point semantic differential scales (-3; 0; +3).

Results: Of 170 recruited, 52 participated. Respondents were diverse in demographic characteristics, current geographical location, and clinical trial/professional role. Mean scores indicate respondent concerned about risk of HIV transmission during ATI (M=1.11). The mean scores for feasibility, acceptability, and efficacy for each of the transmission mitigation strategies are reported in Table 1. Requiring counseling for potential participants was judged feasible, acceptable, and efficacious. Respondents were, overall, neutral on the feasibility, acceptability, and efficacy of requiring that participants' sexual partner(s) participate in risk counseling. Limiting participation to those who commit to abstaining from sex during the entire ATI period was judged as not feasible and acceptable, but respondents were more neutral on its efficacy. Providing referrals so that all HIV negative partners of participants can obtain PrEP, providing PrEP directly to all HIV negative partners of participants without cost, and monitoring participants for new STD acquisition as an effort to assess sexual activity were all judged as feasible, acceptable, and efficacious.

Conclusions: Our study demonstrates that HIV remission trial investigators are concerned about the risk of transmission. Their assessment of risk mitigation strategies for transmission risk demonstrates the importance of examining feasibility, acceptability, and efficacy when designing risk reduction programs.

Anticipate how feasible, acceptable, and efficacious you anticipate the following actions would be to reduce transmission risk during trials with ATI of fixed duration. *(-3: Not at all; 3: Extremely)* Anticipate how feasible, acceptable, and efficacious you anticipate the following actions would be to reduce transmission risk during trials with ATI of fixed duration. *(-3: Not at all; 3: Extremely)*	Mean (n)

Addressing the unique needs of learners living with HIV in the education setting

J. Ouma[1], T. Rufurwadzo[2], M. Katekwe[1], G. Caswell[3], A. Stahmer[4]

[1]Global Network of Young People Living with HIV (Y+ Global), Capetown, South Africa, [2]Global Network of Young People Living with HIV (Y+ Global), Amsterdam, Netherlands, the, [3]Global Network of People Living with HIV, Capetown, South Africa, [4]UNESCO, Paris, France

Background: In 2012,UNESCO collaborated with the Global Network of People living with HIV(GNP+) to produce the publication "positive Learning: Meeting the needs of young people living with HIV(YPLHIV) in the education sector". The tool identified key issues faced by YPLHIV in education settings and recommendations for the education sector on areas including confidentiality and disclosure.
In 2021 UNESCO commissioned the Global Network of Young People Living with HIV(Y+ Global) with support from GNP+ to revise the tool to reflect the current needs of YPLHIV in schools and to develop recommendations for stakeholders.

Description: The positive Learning revision process capitalized on youth leadership and leveraged on the experiences of the YPLHIV in schools engaging 145 young people from Asia (21),Middle East and North Africa (19), Anglophone and Francophone Africa (43),Eastern Europe and Central Asia (20) and Latin America and Hispanic Caribbean (17) and Global (25).
The revised tool highlights recommendations in seven thematic areas; comprehensive sexuality education, confidentiality and sharing information about HIV status, end HIV related stigma, discrimination, bullying and violence, HIV treatment and care, sexual reproductive health and rights, mental health and psychosocial well being and creating an inclusive and health promoting learning environment.

Lessons learned: YPLHIV globally are facing a compendium of cross cutting challenges such as stigma and discrimination, mental health issues and adherence to medication in the school settings. As YPLHIV we are aware of the issues and we have the solutions to these issues. YPLHIV leadership is critical as we are the agents of change in addressing these challenges and holding stakeholders accountable.

Conclusions/Next steps: The Positive Learning tool provides YPLHIV in schools with safe and conducive learning environments to improve treatment, education and mental wellbeing outcomes. The tool will be disseminated on a rolling basis through all platforms to ensure that relevant stakeholders in countries are reached.

Pathways from multiple stigmas to ART adherence among transgender women and men who have sex with men newly diagnosed with HIV in India: a prospective cohort study

V.V. Patel[1], V. Chakrapani[2], A. Gupta[3], F. Gulfam[3], J. Kaur[4], N. Chopra[1], J. Ross[1], J. Rendina[5], A. Ahalawat[3], S. Reddy[3], S.A. Safren[6], S.A. Golub[7]

[1]Albert Einstein College of Medicine, Montefiore Health System, General Internal Medicine, Bronx, United States, [2]Centre for Sexuality and Health Research and Policy (C-SHaRP), Chennai, India, [3]Alliance India (India HIV/AIDS Alliance), New Delhi, India, [4]Post Graduate Institute of Medical Education & Research, Chandigarh, India, [5]Whitman-Walker Institute, Washington D.C., United States, [6]University of Miami, Psychology, Coral Gables, United States, [7]Hunter College, City University of New York, Hunter HIV/AIDS Research Team, Department of Psychology, New York, United States

Background: Stigma remains a major barrier to ART adherence among persons newly diagnosed with HIV. However, little research exists on the impact of multiple stigmas on treatment outcomes for transgender women (TGW) or men who have sex with men (MSM) living with HIV in South Asia.
Guided by the Health Stigma Discrimination Framework, we conducted a longitudinal study among Indian TGW/MSM to understand how multiple stigmas (enacted, anticipated, and internalized) related to HIV and either gender (for TGW) or sexuality (for MSM) may influence ART adherence.

Methods: Between 2020-2021, 140 TGW and 227 MSM from 11 Indian states (≥18 years, diagnosed with HIV in past six-months) completed interviews at baseline, three- and six-months.
Using mediational analyses, we tested the associations of baseline stigma scores (HIV- and gender-identity for TGW, or sexual-identity for MSM) stigmas with past 30-day self-reported ART adherence (0-100) at six-months, and the indirect effects of stigma on ART adherence through three-month depression, anxiety, and alcohol use scores.

Results: Among TGW, mean age was 31.1 years and 23% were illiterate. At six-months, 92% of TGW had been prescribed ART; mean (sd) adherence was 77.9±17.1. Mediational analysis (Fig.1a) revealed a significant direct-effect of anticipated HIV-stigma in healthcare on adherence and indirect-effect of enacted HIV-stigma via alcohol use.
Among MSM, mean age was 33.3 years and 18.5% were illiterate.
At six-months, 98% of MSM were prescribed ART; mean (sd) adherence was 74.9±20.1. Mediational analysis (Fig.1b) revealed significant direct-effects from internalized MSM-stigma and enacted community HIV-stigma on adherence and indirect-effects of enacted HIV-stigma in healthcare via alcohol use.

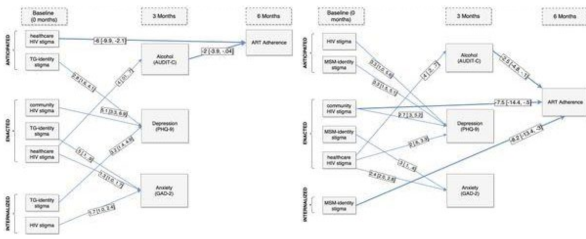

Figure 1. a) Significant pathways from stigmas to ART adherence for transgender women, b) Significant pathways from stigmas to ART adherence for MSM

Conclusions: Adherence was suboptimal and distinct forms of stigmas, either directly or indirectly differentially influenced ART-adherence among TGW and MSM. For both TGW and MSM, interventions to reduce stigma faced in healthcare settings and beyond and by addressing alcohol use could improve ART adherence.

Conceptualizing social and structural factors and their impacts

PESUD35

Racial residential segregation as a structural barrier to viral suppression among people living with HIV in Southern United States from 2013 to 2018: a county-level longitudinal study

F. Shi[1], J. Zhang[2], X. Yang[1], Z. Li[2], X. Sun[2], C. Zeng[2], H. Ning[2], B. Olatosi[2], S. Weissman[3], X. Li[1]
[1]University of South Carolina, Health Promotion, Education, and Behavior, Columbia, United States, [2]University of South Carolina, Columbia, United States, [3]University of South Carolina, School of Medicine, Columbia, United States

Background: Achieving viral suppression (VS) is one of the crucial goals of HIV care cascade. Residential segregation by race has long been framed as a potential structural barrier to successful VS at the individual level, but evidence is scarce at the population level, which has strong implication for healthcare policymaking and resources allocation.
This study aims to examine the longitudinal relationship between county-level racial segregation and VS rate among people living with HIV (PLWH) in 46 counties of South Carolina (SC) from 2013 to 2018.
Methods: De-identified laboratory reports of all PLWH in SC were extracted from the electronic HIV/AIDS reporting system in the SC Department of Health and Environment Control from January 2013 to December 2018. Based on CDC's definition, county-level VS rate was calculated as the percentage of PLWH who have viral load (VL) less than 200 copies/ml in the last VL report at each calendar year (excluding those newly diagnosed in that year).
Racial residential segregation was calculated using Massy and Denton's formula of isolation index for Black residents. The association between racial segregation and VS rate was tested by generalized linear mixed model, adjusting for potential confounders (e.g., sociodemographic characteristics, social capital, HIV care resources) and time.
Results: From 2013 to 2018, the average VS rate in SC increased from 64.3% to 65.4% among all PLWH. Counties in Upstate (Spartanburg and Cherokee) and Lowcountry (Orangeburg) reported low VS rate. Final model revealed that counties with higher residential isolation experienced lower VS rate (b = -0.354, 95%CI: -0.614 ~ -0.095). However, stronger county-level social capital, which was indicated by community health index, was related to higher VS rate in SC (b = 0.757, 95%CI: 0.277~1.237).
Conclusions: This study described the temporal and spatial distribution of VS rate in SC. Structural influence of residential segregation on viral suppression was found.
It is also suggested that more social cohesion at the county level was a protective factor of VS. These findings emphasize the need to address racial disparities in social capital based on racial residential segregation as part of a comprehensive strategy to curb the HIV epidemic.

PESUD36

Improving our understanding of how structural determinants impact HIV epidemics: a scoping review of dynamic models to guide future research

J. Stannah[1], J.L. Flores Anato[1], K.M. Mitchell[2], J. Larmarange[3], M. Maheu-Giroux[1], M.-C. Boily[2]
[1]McGill University, Department of Epidemiology, Biostatistics, and Occupational Health, Montreal, Canada, [2]Imperial College London, Department of Infectious Disease Epidemiology, London, United Kingdom, [3]Université Paris Descartes, Institut de Recherche pour le Développement, Paris, France

Background: Dynamic models of HIV transmission have proven valuable tools for informing HIV prevention strategies. Including structural determinants in models is crucial to estimate their population-level impacts on HIV transmission and inform efforts towards HIV elimination. However, this is challenging due to a lack of coherent conceptual frameworks, limited understanding of their specific causal pathways, and few empirical estimates of their impacts on downstream mediators.
Methods: With the overarching aim to improve models, we conducted a scoping review of studies that used dynamic HIV transmission models to evaluate the impact of structural determinants. From included studies, we extracted information on the types of structural determinants and methods used to model their impacts on HIV transmission. We appraised studies on how they conceptualized structural exposures and represented their causal relationships over time within models.
Results: We identified 9 dynamic transmission modelling studies that incorporated structural determinants of HIV, including violence (N=3), incarceration (N=2), stigma (N=2), housing instability (N=2), migration (N=1), and education (N=1). Only one study modelled multiple determinants

simultaneously. In most models, structural determinants were conceptualized using current, recent, non-recent and/or lifetime exposure categories. Modelled structural determinants largely impacted HIV transmission through mediated effects on one or more proximate risk factors, including sharing injection equipment, condom use, number of partners, and access to treatment.

However, causal pathways were simplistic, with few mediators and/or lack of clear empirical justification. To measure impact, most studies simply assumed the elimination of structural determinants in counterfactual comparison scenarios. Few models included long-term and/or delayed effects of past, recurrent, or acute exposure, potentially overestimating impacts of determinants.

Conclusions: Despite the importance of structural determinants for HIV prevention, methods for including them in dynamic HIV transmission models remain insufficient. Few studies have attempted to incorporate structural determinants in HIV models, and methods vary considerably. To improve inferences, models should adopt precise exposure definitions, deconstruct and estimate their complex causal pathways, and translate them into their mechanistic components.

The need for development of coherent frameworks to conceptualize the synergistic interplay between strengthened empirical data analysis and the inclusion of structural determinants in dynamic models is pressing.

PEMOD56

Risk, vulnerability, and protective factors for HIV and STI infection among adolescent girls and young women in West and Central Africa: pooled analysis of available Demographic and Health survey data

S.K. Brar[1], J.G. Rosen[2], P.T. Yeh[2], L. Dongmo Tsague[3], D. Walker[4], C. Lwamba[1], J. Harris Requejo[1], C.E. Kennedy[2]
[1]UNICEF, Data & Analytics Section, Division of Data, Analytics, Planning, and Monitoring (DAPM), New York, United States, [2]Johns Hopkins Bloomberg School of Public Health, Department of International Health, Social and Behavioral Interventions Program, Baltimore, United States, [3]UNICEF, West and Central Africa Regional Office, Dakar, Senegal, [4]UNICEF, HIV/AIDS, Health Programme Group, New York, United States

Background: Adolescent girls and young women (AGYW) are considered at heightened risk for HIV in sub-Saharan Africa, but most data on risk and vulnerability factors for this group comes from Eastern and Southern Africa, where HIV prevalence is highest. We assessed risk and vulnerability factors across nationally representative household surveys in West and Central Africa to better understand relationships and inform policy and programmatic decision-making in this region.

Methods: We used cross-sectional data from sexually-active AGYW participating in Demographic and Health Surveys from 17 West and Central African countries. Sexually transmitted infection (STI) symptomatology was used as a proxy for HIV risk. Modified Poisson regression models (for binomial outcomes) estimated prevalence ratios for associations between risk and vulnerability factors and past-year STI symptomatology among AGYW.

Models were stratified by five-year age bands (15-19, 20-24, 25-29 years) as well as current marital status to identify stratum-specific risk and vulnerability factors associated with STI symptomatology.

Results: Almost three-fourths of AGYW were married/cohabiting and 40% had completed secondary or higher education. Prevalence of past-year symptomatology was 20.7%. Consistent and strong associations existed between several risk and vulnerability factors and STI symptomatology.

Older age (25-29-year-olds) and secondary or higher education were associated with increased prevalence of past-year STI symptomatology in the pooled AGYW sample and among married AGYW, specifically.

Urbanicity and secondary or higher education were associated with increased prevalence of past-year STI symptomatology across five-year age bands.

Employment, migration and accepting spousal violence were strongly associated with past-year STI symptomatology among all three age groups, with adjusted prevalence ratios (aPR) ranging from 1.13–1.33 ($p<0.0001$).

Multiple sexual partners and unprotected last sex were also strongly associated among all three age groups, with aPR ranging from 1.35–1.64 ($p<0.0001$).

Conclusions: These findings indicate heterogeneities in STI symptomatology by key sociodemographic characteristics and corresponding sources of risk and vulnerability among AGYW, highlighting the need to develop effective policies to address increased risk and vulnerability of AGYW to HIV and STI infection.

HIV/STI prevention interventions should focus on supporting individual agency to engage in safer sexual practices and addressing harmful gender norms and practices, including acceptance of spousal violence.

PEMOD57

How can text-messaging change the context of living with HIV and engaging with treatment in Iran: building a realist programme theory

V. Ameli[1], G. Wong[2], J. Barlow[3], F. Meinck[4]
[1]Vira Ameli, Social Policy and Intervention, Oxford, United Kingdom, [2]University of Oxford, Primary Healthcare Sciences, Oxford, United Kingdom, [3]University of Oxford, Social Policy and Intervention, Oxford, United Kingdom, [4]University of Edinburgh, School of Social and Political Sciences, Edinburgh, United Kingdom

Background: Text-messaging interventions are increasingly used to address the complex challenges of lifetime antiretroviral therapy (ART). A wealth of evidence supports the efficacy of text-messaging in improving treatment adherence, yet there is a dearth of evidence on

how text-messaging is improving outcomes and *why* it works in a particular context. This study uses stakeholder views to theorise *how*and *why* text-messaging could change the context of living with HIV and engaging with ART in Iran.

Methods: The study is part of an ongoing research project on ART engagement among Iranians living with HIV. We draw on the perspectives of recently-diagnosed and treatment-experienced patients and their providers, using purposive sampling, conducting 17 individual interviews and 9 focus group discussions. A realist framework of inquiry is utilised to conceptualise how interventions alter the context of people's lives by providing new paths for individual reasoning and [re]action, thereby producing altered outcomes.

Results: Our findings build on the previously identified socio-ecological pathways that disrupt ART in Iran (Figure 1).

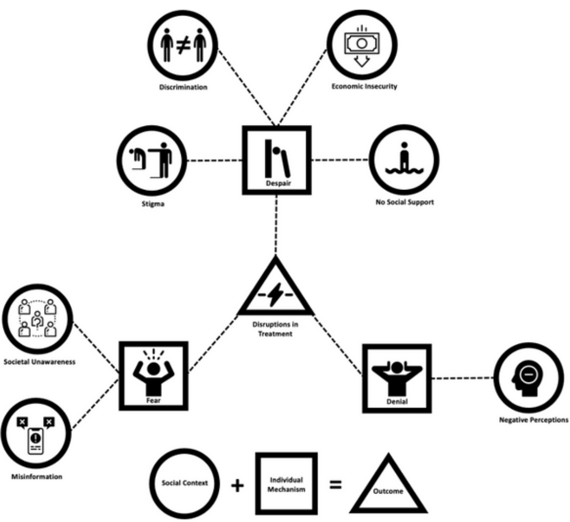

Figure 1.

We found that participants perceive text-messaging can improve adherence by changing socio-ecological pathways and the relation between the health-system and patients in terms of support, motivation, initiative, and information (Figure 2).

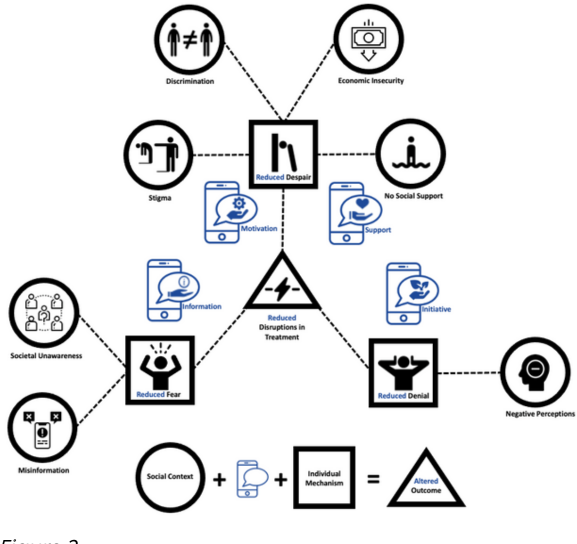

Figure 2.

Conclusions: We believe this is the first study to explain how and why text messaging works to reduce disruption in ART treatment. It identifies the important contexts that interventions need to address for desired outcomes to occur. The realist programme theory developed here can inform future design and evaluation of interventions and trials.

Dynamics of social status and power: Sex, gender, age, race/ethnicity, sexual orientation and disability

"Guys are different": young women's views on heterosexual relationship dynamics and how they influence women's potential PrEP uptake and disclosure in Durban, South Africa

L. Miller[1], A. Harrison[2], N. Bhengu[3], N. Tesfay[3], S. Magutshwa[3], S. Khumalo[3], S. Bergam[4], T. Exner[5], J. Hanass-Hancock[3], S. Hoffman[5,6]

[1]Columbia University, ICAP, Mailman School of Public Health, New York, United States, [2]Brown University, Behavioral and Social Sciences, International Health Institute, Providence, United States, [3]South African Medical Research Council, Gender and Health Research Unit, Durban, South Africa, [4]Brown University, Providence, United States, [5]NYS Psychiatric Institute and Columbia University Irving Medical Center, HIV Center for Clinical and Behavioral Studies, New York, United States, [6]Columbia University, Department of Epidemiology, Mailman School of Public Health, New York, United States

Background: Considerable evidence demonstrates that heterosexual relationship dynamics influence women's decisions around HIV prevention methods, but little research has been conducted among educated South African women.

In the context of oral pre-exposure-prophylaxis (PrEP) becoming publicly available in South Africa (2019), we explored urban, educated young women's views on relationship dynamics with male partners, how these dynamics might impact women's use of PrEP, and how women might navigate those dynamics if they chose to use PrEP. Understanding and taking into account the realities of the lives of women is key to designing successful PrEP programs.

Methods: This analysis utilized qualitative data from a study to develop a gender-focused PrEP information-motivation workshop to introduce young women to PrEP, in Durban, South Africa. Participants were aged 18-25, educated, and recruited from urban clinic and community settings. Six focus group discussions and eight in-depth interviews were conducted with 46 women. Data were analyzed thematically.

Results: Women described men as having a different culture and set of behaviors than women and as experiencing different societal gender norms, which leads to women being at a greater risk for HIV. These differences bring complexity to women's relationships and influence their choices around PrEP use and disclosure. While acknowledging the potential benefits of PrEP, women stated that risks included: potential for anger and loss of trust in relationships, breakup, physical violence, pregnancy or other sexually transmitted infections.

Despite these concerns, woman expressed desire for mutuality in relationships and shared suggestions to manage choices around PrEP use and disclosure, including willingness to end relationships.

Conclusions: These results document the challenges that even urban, educated women experience in heterosexual relationships with respect to gender dynamics and HIV prevention and add to the growing body of evidence that women's use and adherence to PrEP in Africa is shaped by male partners and women's perceptions of their male partners' reactions.

For PrEP to be rolled out successfully, implementation programs need to provide women with concrete methods to improve self-agency and communication skills that address conflict. Women need these skills to navigate the complex power dynamics they experience in heterosexual relationships.

Humanitarian crises and HIV

PESUD38

HIV testing experiences and priorities among refugee youth in a humanitarian setting in Uganda

K. Malama[1], C. Logie[2], M. Okumu[3], M. Loutet[1], M. Coelho[1], S. Odong[4], N. Kisubi[4], R. Lash[2], P. Kyambadde[5]

[1]University of Toronto, Toronto, Canada, [2]University of Toronto, Social Work, Toronto, Canada, [3]University of Illinois Urbana-Champaign, Urbana, United States, [4]Uganda Refugee and Disaster Management Council, Yumbe, Uganda, [5]Uganda Ministry of Health, Kampala, Uganda

Background: Refugee youth experience social drivers of HIV, including violence, poverty, and constrained access to HIV prevention services. Scant research has focused on youth-centred HIV testing strategies—including HIV self-testing (HIV-ST)—in humanitarian crises.

We explored HIV testing experiences and preferences among refugee youth in Bidi Bidi refugee settlement, Uganda to inform development of an HIV self-testing intervention.

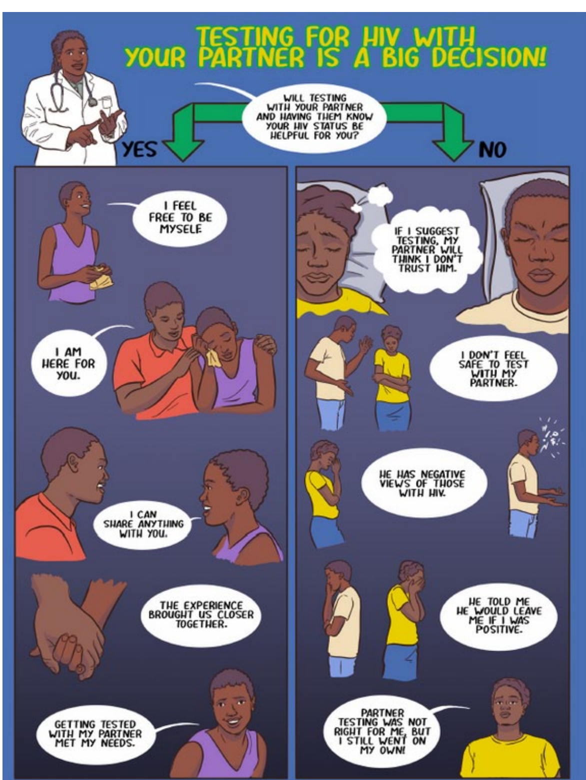
Methods: We implemented a multi-method community-based study in Bidi Bidi. We conducted four focus groups (FG) with refugee youth, 2 with ages 16-19 (women: n=1 FG; men; n=1 FG) and 2 with ages 20-24 (women: n=1 FG; men; n=1 FG). We developed a 9-page comic series illustrating FG findings and then conducted a 3-day human-centred design (HCD) workshop with refugee peer navigators (n=8). We conducted thematic analyses across methods.

Results: Focus group participants (n=40; n=16 ages 16-19, n=24 ages 20-24; 20 men, 20 women) were largely from South Sudan (83%). Most had a lifetime HIV test (83%) yet three-quarters (78%) had not tested in the past year. FG narratives revealed HIV testing decision-making considerations of:

a. positive outcomes (self-care, post-rape awareness, protecting others from infection, self-knowledge) and;

b. negative outcomes (HIV-related stigma, relationship mistrust/violence, healthcare mistreatment).

Participants expressed enthusiasm regarding HIV-ST (e.g., confidentiality, convenience) yet women detailed concerns of relationship violence with HIV-positive results. Comics detailed these HIV testing decision-making processes, including risk-assessment for partner testing. HCD findings identified ways to create youth-friendly HIV testing spaces, address HIV-ST misinformation, and reduce community and health-care stigma.



Conclusions: Findings provide unique insight into refugee youth HIV testing experiences and priorities. This research highlights the salience of the disclosure process model to understand antecedent goals (approach goals for positive outcomes, avoidance goals for negative outcomes) for HIV testing, including HIV-ST. Refugee youths' experiences of cumulative violence signal the need for trauma-informed, youth-centred HIV testing strategies in humanitarian crises.

Societal stigma towards people living with HIV and key populations

PESUD39
Partner social support and sexual satisfaction buffer the effects of stigma on ART adherencein Malawian couples

S.A. Gutin[1], A. Ruark[2], L.A. Darbes[3], T.B. Neilands[1], J. Mkandawire[4], A.A. Conroy[1]
[1]UCSF Center for AIDS Prevention Studies, Division of Prevention Science, San Francisco, United States, [2]Wheaton College, Wheaton, United States, [3]University of Michigan, Ann Arbor, United States, [4]Invest in Knowledge, Zomba, Malawi

Background: For couples affected by HIV, relationship dynamics can have a positive impact on adherence to antiretroviral therapy (ART) via social support and coping. While research suggests that general partner support can enhance ART adherence and that stigma may exert its influence dyadically, few if any studies in sub-Saharan Africa have explored whether relationship dynamics can buffer the experience of anticipated stigma from family members and healthcare providers on ART adherence. We examined this question among a sample of couples living with HIV in Malawi.

Methods: Married couples (N = 211) with at least one partner on ART were recruited from HIV clinic waiting rooms in Zomba, Malawi. Partners completed separate surveys on anticipated HIV stigma from family members of health-care providers, relationship dynamics (e.g., intimacy, trust, sexual satisfaction, general partner social support, communication), and ART adherence.

Using generalized estimating equation (GEE) regression models, we tested for associations between anticipated stigma and ART adherence at the individual level, and whether this association was moderated by relationship dynamics at the couple level, after controlling for socio-demographics and relationship duration.

Results: Couples had been together for a mean of 12.5 years (SD=9.0), 66% were sero-concordant, and 95.6% of participants reported 90-100% adherence. The mean anticipated stigma score was 1.6 (SD=0.74, scale range 1-5), with higher scores indicating higher stigma. In multivariable models, the odds of having 90-100% adherence were 45% lower for each one-unit increase in anticipated HIV stigma (aOR=0.55, 95%CI=0.34; 0.89).

There were significant interactions between partner social support and anticipated stigma from family members and healthcare providers (p=0.032) and between sexual satisfaction and anticipated stigma (p=0.039), showing that the association between higher stigma and non-adherence was moderated in couples with higher social support and sexual satisfaction.

Conclusions: Increased anticipated HIV stigma is associated with higher non-adherence to ART. Supportive and fulfilling relationships, particularly those with greater partner support and sexual satisfaction, may buffer the experience of stigma on ART adherence. Couple-based interventions that intervene on these important aspects of relationships may help lessen the negative impact of HIV stigma on HIV treatment engagement such as ART adherence.

PESUD40
Anticipated stigma among recently diagnosed HIV clients in the UTT era in Johannesburg, South Africa

I. Mokhele[1], T. Sineke[1], J. Bor[1,2], D. Onoya[1]
[1]Health Economics and Epidemiology Research Office, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [2]Boston University School of Public Health, Department of Global Health, Boston, United States

Background: Anticipated stigma – the fear that HIV diagnosis and status disclosure could have negative social implications – may adversely affect engagement with HIV care and treatment, despite universal eligibility for treatment under universal-test-and-treat (UTT).

We aimed to determine prevalence and predictors of anticipated stigma among newly HIV-diagnosed individuals under the UTT policy in Johannesburg, South Africa.

Methods: We analyzed a cross-sectional survey of 652 newly HIV-diagnosed adults (≥18 years) (64.1% female, median age was 33 years, interquartile range [IQR]: 28–39) enrolled in a cohort study from October 2017 to August 2018 from four primary clinics in Johannesburg. Participants were interviewed immediately after receiving their HIV test results. We used an adapted five-item, four-point scale measuring agreement with statements regarding HIV disclosure concerns and HIV status concealment (Cronbach's alpha =0.82). Mean scores were categorized as "low-to-medium" (score<=2.5), or "high" (score>2.5).

We used Modified Poisson regression to assess for predictors of high anticipated stigma and report adjusted risk ratios (aRR) with 95% confidence intervals (CIs).

Results: Overall, 55% of study participants had high anticipated stigma; 55.8% for males, 61.1% for 18–29-year-olds, and 43% for those married. Unmarried individuals who were in a relationship had a higher risk of high anticipated stigma than those married (aRR 1.10, 95% CI: 1.01-1.18). Risk of high anticipated stigma was lower among: older individuals (aRR 0.94 for being 30-39 vs 18-29 years, 95% CI: 0.88-0.99), those having a primary house in another province/rural (aRR 0.82 for primary house in another country vs current house, 95% CI: 0.78-0.87), (aRR 0.83 for primary house in another country vs current house, 95% CI: 0.78-0.88), those living in current homes for ≥5 years (aRR 0.93 for >5 years vs <1 year, 95% CI: 0.88-0.99), those with low ART concerns (aRR 0.86, 95 % CI: 0.82-0.90), and those with low perceived social-support (aRR 0.79 for low vs high, 95 % CI: 0.70-0.88).

Author Index

Conclusions: Over 50% of adults diagnosed with HIV in the UTT era experienced high anticipated stigma. Findings highlight the need to address factors that continue to drive anticipated stigma, to mitigate the potential impact on engagement in HIV care.

PESUD41

Experiences of viral detectability, undetectability, and stigma among recently diagnosed people living with HIV in Australia

N. Wells[1], S. Philpott[1], D. Murphy[1], J. Ellard[2], G. Prestage[1]
[1]The Kirby Institute, Sydney, Australia, [2]Australian Research Centre in Sex, Health and Society, Melbourne, Australia

Background: HIV treatments can improve the health and wellbeing of people living with HIV (PLHIV) and eliminate the risk of sexual transmission for those who can maintain undetectable viral load (UVL). This has been accompanied by a promise of reducing HIV-related stigma. We explored how detectable and undetectable viral loads were experienced by PLHIV, including how these experiences interplayed with experiences of self- and anticipated stigma.
Methods: The RISE study is an ongoing qualitative cohort study of 34 PLHIV diagnosed from 2016 onward in Australia. Of these, 25 had participated in follow up interviews, providing 59 interviews for analysis. Interviews were conducted between January 2019 and November 2021.
Results: Median age was 41; 32 were male and 2 were female; 21 were gay, 8 were bisexual, and 5 were heterosexual. All participants except 1 were on treatment and had UVL when first interviewed.
Participants frequently associated the period in which they were detectable with feeling "dirty," "viral," and "a risk" to sexual partners. During this period, most participants limited or ceased sex, even when in an ongoing romantic relationship. Participants commonly framed reaching UVL as an important goal in their HIV care, with UVL acting as a marker of good health and as reenabling sexual and/or romantic relationships. This helped reduce experiences of self-stigma and enabled participants to envision living a "normal" life, something they could not imagine while detectable. However, some participants described that despite having UVL, and their belief in its preventative efficacy, they remained hesitant to reengage with sex.
This was mainly due to a perceived lack of awareness among the broader, HIV-negative population around UVL, concerns of sexual rejection, and anticipated stigma.
Conclusions: UVL can improve the physical and emotional wellbeing of PLHIV. However, these experiences occur in a context of persistent HIV-related social stigma and a lack of awareness around UVL more broadly. While UVL can reduce experiences of self-stigma, many PLHIV continue to anticipate HIV-related stigma and sexual rejection.
This highlights the limits of biomedicine alone as a stigma-reduction strategy and the need for strategies, programs, and interventions that aim to reduce HIV-related stigma in the broader community.

PESUD42

"Fear really comes from the unknowns": navigating 'unknowable' stigma and discrimination among people living with HIV in Singapore

J. Dewaele[1], S. Hyder[1], R.K.J. Tan[2,3], C.S. Wong[4], B.C. Ng[1], E. Cambria[1], S. Banerjee[5], R. Chan[5], R. Jain[1]
[1]Nanyang Technological University, Singapore, Singapore, [2]University of North Carolina Project-China, Guangzhou, China, [3]National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore, [4]National Centre for Infectious Diseases, Singapore, Singapore, [5]Action for AIDS Singapore, Singapore, Singapore

Background: Structural stigma and institutionalised forms of discrimination towards people living with HIV (PLHIV), especially in the areas of health insurance, immigration, and employment remain pervasive in many settings.
However, no study in Singapore has qualitatively explored how PLHIV navigate such forms of discrimination, its impact on health/social service seeking behaviour and quality of life, and interventions required to address such inequities.
Methods: Semi-structured qualitative interviews were conducted with 73 participants. These included 56 PLHIV (30 men who have sex with men, 23 heterosexual men, 3 women) and 17 stakeholders including healthcare professionals and other allied workers.
Interviews focused on participant perspectives or experiences of HIV diagnosis, navigating healthcare, attitudes towards and impact of HIV on relationships. Data were analysed through inductive thematic analysis.
Results: Participants highlighted that they were aware of institutionalised discrimination towards PLHIV (or experienced it, for participants who were PLHIV) across various aspects of their lives. These included experiences – overt and covert -- of discrimination in education, workplace, and healthcare settings.
However, participants disclosed a greater discriminatory impact due to the manifold unknowns; that is, experiences resulting from 'unknowable' discrimination. We interpreted this as participants' fear of potential legal and/or social repercussions resulting from the disclosure of their HIV status that they may not be able to anticipate. Even though employers may not overtly discriminate, the fear of such ‚unknowable' discrimination influenced decisions to conceal HIV status in job applications and workplaces.
This shroud of fear restricted agency for PLHIV, and impacted their regular medical follow-ups, socialising behaviours, and overall quality of life. Consequently, many participants felt that concealment of their status, and bypassing potential educational, employment, and even health opportunities were the only ways of protecting themselves from such 'unknowable' stigma. Both PLHIV and stakeholders articulated that an anti-discrimination framework is urgently needed to address such uncertainties in their lives.

Conclusions: An anti-discrimination framework, enforceable by law, on the institutional treatment of PLHIV would remove unpredictability and address the manifold unknowns surrounding discriminatory experiences and improve their quality of life. Subsequent elimination of fear for unknown discrimination may also greatly facilitate timely testing, linkage to care and treatment.

PESUD43

Engagement in HIV care and on-going substance use: a qualitative sub-study of BASE participants

L. Heerten-Rodriguez[1], J. Coleman[2], J. Havens[3]
[1]University of Nebraska at Omaha, Grace Abbott School of Social Work, Omaha, United States, [2]University of Nebraska at Omaha, School of Health and Kinesiology, Omaha, United States, [3]University of Nebraska Medical Center, College of Pharmacy, Omaha, United States

Background: Of the 1.2 million people living with HIV (PWH) in the United States, an estimated 48% are also experiencing a substance use disorder (SUD). Inconsistencies in treatment adherence and retention in HIV care have been reported among PWH that use illicit drugs, often leading to poor treatment outcomes and increased HIV transmission. This qualitative sub-study explored factors that influence engagement in HIV care among PWH and ongoing SUD.

Methods: In-depth, semi-structured interviews were conducted in 2021 with 15 PWH/SUD and were enrolled in a pilot study assessing the efficacy and safety of bictegravir/emtricitabine/tenofovir alafenamide (BASE study; NCT03998176) in Omaha, NE, USA. Interviews addressed participants' experiences living with HIV, substance use, and engagement in HIV care. Transcripts were analyzed using the methods of constructivist grounded theory, including initial coding, focused coding and categorization.

Participant Sex	80% Male, 20% Female
Race/Ethnicity	73% White Non-Hispanic, 13% White Hispanic, 13% Black/African-American
Age	Average 43, Range 30-62
Risk factors	53% MSM, 40% IVDU
Reported Substance Use	100% Methamphetamine, 7% Cocaine, 7% Opiate, 7% Sedative

Table.

Results: Participants described complex, interconnected, and mutually reinforcing barriers to engagement in HIV care. For example, experiences of homelessness often disrupted HIV care and medication adherence. At the same time, participants experiencing homelessness also experienced stigma from social service providers related to drug use, HIV status, sexual orientation, and participation in sex work.

Many participants internalized responsibility for these experiences, viewing themselves as unworthy of HIV care which would improve their health or extend their lifespan. In the absence of strong intrapersonal motivation to engage in HIV care, many participants relied heavily on interpersonal motivation, including caring for themselves in order to support loved ones, honoring the efforts of clinic staff, or attempting to prove others wrong.

Engagement in HIV care in respectful and supportive environments increased some participants' sense of self-worth and their own intrapersonal motivation to continue engaging in HIV care.

Conclusions: The development of this mid-range explanatory theory of engagement in HIV care for PWH/SUD highlights the significant role of layered stigma, as well as the importance of recognizing and utilizing interpersonal motivation to help overcome barriers to engagement in HIV care. Results have implications for clinical care and intervention development.

PESUD44

A longitudinal examination of anticipated HIV stigma as a mediator of the relationship between enacted and internalized stigma and self-rated health

J.M. Lo Hog Tian[1,2], J. Watson[1], R.G. Maunder[3,4], J.A. Parsons[5], S.B. Rourke[1,4], The Ontario HIV Stigma Index Team
[1]Unity Health Toronto, MAP Centre for Urban Health Solutions, Toronto, Canada, [2]University of Toronto, Institute of Medical Science, Toronto, Canada, [3]Mount Sinai Hospital, Department of Psychiatry, Toronto, Canada, [4]University of Toronto, Department of Psychiatry, Toronto, Canada, [5]Unity Health Toronto, Applied Health Research Centre, Toronto, Canada

Background: HIV stigma remains high in Canada, causing significant impact on the health and wellbeing of people living with HIV. There is a limited understanding, however, around how different types of stigma act interact to impact overall health.

This study examines how enacted and internalized stigma may lead to worse self-rated physical, mental, and overall health through anticipated stigma as a mediator.

Methods: We recruited 724 participants in Ontario from September 2018 – August 2019 to complete the People Living with HIV Stigma Index at baseline (t_1) using validated measures for stigma and quality of life. Approximately two years later we resurveyed participants (n=407) with the same instruments (t_2).

Five separate mediation models were created with enacted and internalized stigma at t_1 as the antecedents and physical health, mental health, and overall health at t_2 as the outcomes.

Anticipated stigma at t_2 was entered as the mediator in all models. Age, years since HIV diagnosis, gender, ethnicity, sexual orientation, geographic region, education, employment, and anticipated stigma at t_1 were entered into the models as covariates.

Results: With internalized stigma (t_1) as the antecedent, anticipated stigma (t_2) was a significant mediator leading to both decreased mental health (indirect effect =

-0.48, 95% CI = -1.05, -0.01) and overall health (indirect effect = 0.04, 95% CI = 0.00, 0.08). The model with physical health as the outcome was not significant, nor were any of the models with enacted stigma (t_1) as the antecedent.

Conclusions: We found that higher internalized stigma can lead to an increase in anticipated stigma which resulted in worse mental health and overall health.

These findings show how internalizing negative thoughts and feelings about living with HIV can lead to anticipating experiences of discrimination and stereotyping with consequences for health and wellbeing. This highlights potential points for intervention to reduce the negative impacts of stigma.

PESUD45

Influence of multiple stigmas on psychosocial problems and condom use among MSM and transgender women in India: findings from a longitudinal S3 (stigma, syndemics and sex) cohort study

V. Chakrapani[1], J. Kaur[2], A. Sebastian[3], S. Rawat[4], R. Nelson[1], D. Baruah[4], M. Shunmugam[1], A Jaya[5], P.A. Newman[6]

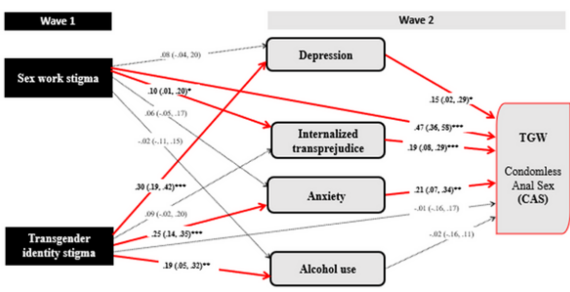
[1]Centre for Sexuality and Health Research and Policy (C-SHaRP), Chennai, India, [2]Post Graduate Institute of Medical Education and Research (PGIMER), Chandigarh, India, [3]National Institute of Advanced Sciences (NIAS), Bangalore, India, [4]Humsafar Trust, Mumbai, India, [5]Sahodaran, Chennai, India, [6]University of Toronto, Toronto, Canada

Background: The disproportionate HIV burden among MSM and transgender women (TGW) in India persists along with multiple forms of stigma and psychosocial problems such as depression and problematic alcohol use. Amid limited research in India on the associations between multiple stigmas, psychosocial problems and condomless anal sex (CAS), we explored these associations, informed by minority stress and syndemic theories.

Methods: We used two-wave data (November 2020 to Jan 2022) from an ongoing cohort study with 500 MSM and 500 TGW recruited through community-based organisations that conduct HIV preventive interventions in Chennai/Mumbai. Path analyses were conducted (Mplus-8) to predict CAS with male non-primary partners (wave-2) from stigma scores (wave-1 sexual stigma, transgender identity stigma, sex work stigma) and psychosocial variables (wave-2 depression, anxiety, internalized homonegativity, internalized transprejudice and alcohol use).

Results: Among MSM (mean age=28.2 years; HIV=4.2%)) and TGW (mean age=27.6 years; HIV=4.8%), CAS (wave-2) was 23.2% and 72.3%, respectively. Compared to MSM, TGW had higher prevalence of moderate depression (MSM-4.3%; TGW-21.1%) and anxiety (MSM-16.2%; TGW-45.9%), but lower prevalence of problematic alcohol use (MSM-13.4%; TGW-12.1%).

Among TGW, sex work stigma, internalized transprejudice, depression and anxiety had significant direct effects on CAS (Figure-1). Transgender identity stigma had significant direct effects on depression, anxiety and alcohol use, and significant indirect effect on CAS through anxiety. Among MSM, sexual stigma had significant direct effects on CAS, depression and anxiety, and sex work stigma had significant direct effects on internalized homonegativity and alcohol use (Figure 1).



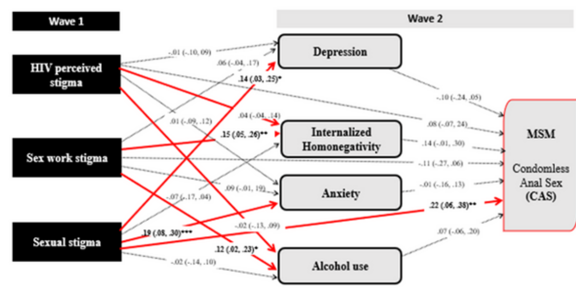


Figure 1. Associations between multiple stigmas, psychosocial problems and condomless anal sex (with male non-primary partners) among MSM (n=500) and TGW (n=500)
*Effects are standardized estimates (95% CI). Bold red arrows indicate significant effects: *p<.05, **p<.01, ***p<.001.*

Conclusions: Stigmas faced by MSM (sexual, sex work) and TGW (transgender identity) contributed directly and indirectly to HIV risk through multiple psychosocial problems. Expanded efforts to reduce societal stigma against transgender people, MSM and those involved in sex work, and to address population-specific psychosocial problems, are needed to promote safer sex and mental health among TGW and MSM in India.

Impacts of intersecting stigma towards Gay, Bisexual men and other Men Who have Sex with Men (GBMSM) on HIV care in a clinical setting: breaking the vicious cycle in Zambia

S. Qiao[1], O. Adeagbo[2], G.S. Mohammad[2], L. Ngosa[3], M. Kabwe[4], A. Sharma[5], A. Menon[6], X. Li[2], G. Harper[7], C. Lwatula[8]

[1]Shan Qiao, Health Promotion Education and Behavior, Columbia, United States, [2]University of South Carolina, Health Promotion Education and Behavior, Columbia, United States, [3]DZL, Lusaka, Zambia, [4]The Lotus Identity, Lusaka, Zambia, [5]CIDRZ, Lusaka, Zambia, [6]University of Zambia, Department of Psychology, Lusaka, Zambia, [7]University of Michigan, Department of Health Behavior and Health Education, Ann Arbor, United States, [8]University of Zambia, Lusaka, Zambia

Background: GBMSM in Zambia face tremendous challenges in accessing HIV care services due to cultural, legal and religious context. A prominent barrier for GBMSM is intersecting stigma in HIV/STI clinic setting. However, few studies have examined impacts of stigma at various ecological levels based on GBMSM's lived experience in Zambia from a holistic perspective.

We aim to explore how the impacts of stigma at different ecological levels (intrapersonal, interpersonal and institutional level) interact with each other as a vicious cycle of impeding GBMSM from HIV-related care and services.

Methods: In-depth interviews were conducted with 19 GBMSM participants aged 18 to 35 purposively recruited from Lusaka in 2021. Interviews were conducted in English in private rooms, lasted 30-80 minutes and were audio-recorded with participant consent. The audio files were transcribed verbatim and then managed and iteratively coded with Nvivo. Inductive approach was applied to conduct thematic analysis.

Results: The impacts of intersecting stigma at different ecological levels interacted with each other as a vicious cycle preventing GBMSM from the linkage, engagement and retention in HIV prevention and treatment cascade. Mental health and substance abuse issues negatively affected their relationship with family/friends, causing social isolation which increased their stress, and reduced social support.

Confidentiality breaches in clinical setting caused unintentional disclosure of sexual orientation or HIV/STI status to family, friends, and communities, exaggerating the tensions between GBMSM and their social environment. Detention and harassment by law enforcement increased the distrust in institutes including some public/government facilities, which drove many GBMSM to select NGOs/private clinics.

However, not all GBMSM could access affordable and sustainable HIV care clinics/programs. GBMSM with negative self-images and mental health and substance abuse issues gave up self-care and self-management, which influenced their health seeking behaviors and medicine adherence (e.g., PrEP use). The negative experiences in health facilities further reinforced the existing social stigma against GBMSM and threatened their self-image.

Conclusions: To increase GBMSM's HIV care access and improve their psychosocial wellbeing in Zambia, integrated intervention strategies are needed to break the vicious cycle of the impacts of intersecting stigma at intrapersonal, interpersonal and institutional levels.

Adaptation to living with HIV for individuals, families and communities

Motivations behind seeking religious and spiritual support and their impact on health and social outcomes for PLHIV in Singapore

S. Hyder[1], R.K.J. Tan[2,3], J. Dewaele[1], C.S. Wong[4], B.C. Ng[1], E. Cambria[1], R. Chan[5], S. Banerjee[5], R. Jain[1]

[1]Nanyang Technological University, Singapore, Singapore, [2]University of North Carolina Project-China, Guangzhou, China, [3]National University of Singapore, Saw Swee Hock School of Public Health, Singapore, Singapore, [4]National Centre for Infectious Diseases, Singapore, Singapore, [5]Action for AIDS, Singapore, Singapore

Background: Existing literature on religion and HIV identified that people living with HIV (PLHIV) who have a religious or spiritual affiliation believe faith helps with coping with illness and finding a renewed sense of purpose in life. However, there is no existing study on religion and HIV in Singapore, much less a study on religion as a resource for treatment or support in clinical interventions for PLHIV.

Methods: Semi-structured qualitative interviews were conducted with a total of 73 participants. These included 56 PLHIV (30 men who have sex with men, 23 heterosexual men, 3 women) and 17 stakeholders including healthcare workers, contact tracers, religious leaders, social workers, and volunteers. Interviews focused on PLHIV and stakeholders' perspectives or experiences of HIV diagnosis, navigating healthcare, attitudes towards HIV, and impact of HIV on relationships. Data were analysed through inductive thematic analysis.

Results: Most PLHIV reported having a religious or spiritual affiliation with varying degrees of practice. Participants report that their faith communities are not directly involved with HIV/AIDS treatment, support, or resource provision. Instead, participants turn to religion to cope with their illness through practice (prayer, reflection) and support-seeking.

Our analysis revealed that those who practice Abrahamic religions (Islam, Christianity, Catholicism) are more inclined to seek support from their community members, while those of non-Abrahamic faiths (Buddhism, Taoism, Hinduism) seek spiritual support from their practice. PLHIV from both groups are reluctant to disclose their HIV-

status to members from their faiths, not because their religions, religious leaders, or fellow practitioners condemn HIV/AIDS, but because of existing prejudices against homosexuality, promiscuity, and infidelity in their religions.
This indicates that cultural stigmas are being reproduced in religious groups in Singapore, as well as conflated with HIV/AIDS by our religious participants.

Conclusions: This paper delineates the motivations of religious/spiritual practice in PLHIV. Understanding the differences between Abrahamic and non-Abrahamic faiths is paramount to conceiving of religion or spirituality as a resource for treatment/support in clinical interventions.
Further, understanding how cultural stigmas are reproduced in religious settings illuminates barriers to health and social outcomes for PLHIV, including a reluctance to seek support from social groups due to a fear of discrimination.

PESUD49

Photovoicing social ecological resilience and resources for youths living with HIV/AIDS in Western Uganda: towards empowering representations

E. Kimera[1,2], S. Vindevogel[2]
[1]*Mountains of the Moon University, Public Health, Fort Portal, Uganda,* [2]*University of Applied Sciences and Arts Gent (HOGENT), Social Educational Carework & EQUALITY Research Collective, Gent, Belgium*

Background: The adversities and challenges faced by youths living with HIV/AIDS (YLWHA) are manifold, but their disproportional documentation results in overly disempowering representations of YLWHA as weak, suffering and vulnerable. What enables resilience has received subpar attention.
This study sought to explore YLWHA's perceptions and representations of social ecological resources that drive resilience. Through stimulating self-representation, the study further pursued critical consciousness and affirmation of voice and agency to challenge dominant disempowering representations and social injustices around YLWHA.

Methods: The study was conducted at a regional referral hospital in Kabarole district, western Uganda. Eleven YLWHA, aged 14-21 years, were recruited from an existing peer support group in the hospital. Drawing on photovoice methodology, seven consecutive sessions were organized to guide participants in producing and discussing their photos and associated narratives. These were subjected to preliminary inductive content analysis by participants, and then analyzed and interpreted by the researchers against the theoretical framework of social ecological resilience.

Results: Through their photos and narratives, participants portray tensions in resilience and document an array of multisystemic resources that are both informal and institutionalized.
Yet, these resources appear rather incidental and not structurally available to YLWHA. Six overarching themes emerged:
1. Availability of structural provisions,
2. Personal and collective senses of purpose,
3. Self-appraisal of strengths,
4. Achieving what society does not expect of them,
5. Expression of appreciation for supportive relationships,
6. Being of value to others and getting recognition.

Conclusions: The representations shared by participants challenge the trope of the weak, suffering, and vulnerable YLWHA and contribute to an understanding of the multisystemic resources that foster resilience and empower YLWHA. Yet, the study also shows that resources need to become more structurally available for these youths.

Confronting stigma: Lessons learned

PESUD50

Frameworks and measures for HIV-related internalized stigma, stigma and discrimination in healthcare and in laws and policies: a systematic review

L. Ferguson[1], S. Gruskin[1], M. Bolshakova[2], S. Yagyu[2], N. Fu[3], N. Cabrera[2], M. Rozelle[2], K. Kasoka[4], T. Oraro-Lawrence[4], L. Stackpool-Moore[5], A. Motala[2], S. Hempel[2]
[1]*University of Southern California, Institute on Inequalities in Global Health, Los Angeles, United States,* [2]*University of Southern California, Southern California Evidence-Based Practice Center, Los Angeles, United States,* [3]*Shanghai University of Finance and Economics, School of Economics, Shanghai, China,* [4]*International AIDS Society, Geneva, Switzerland,* [5]*Watipa, Sydney, Australia*

Background: While global progress towards eliminating HIV-related stigma and discrimination remains of key importance, there is wide variation in efforts to measure and assess existing interventions.

Methods: Given this variability, we carried out a systematic review to address two questions: What conceptual frameworks exist to assess internalized stigma, stigma and discrimination experienced in healthcare settings, and stigma and discrimination entrenched in national laws and policies? Which measures of different types of stigma and discrimination have been proposed and what are their descriptive properties? Searches, completed on 05/06/21, cover publications from 2008 onwards. The review is registered in PROSPERO (CRD42021249348), the protocol incorporated stakeholder input, and the data are available in the Systematic Review Data Repository.

Results: Sixty-nine frameworks and fifty measures met the inclusion criteria. While frameworks generally seek to highlight the complex web of factors affecting different types of stigma and their impacts, their scope varies tremendously as do outcomes of interest.

Measures are equally diverse with substantial differences even between those purporting to measure the same dimension of stigma. Overall, there was disproportionately little attention to stigma and discrimination in laws and policies.

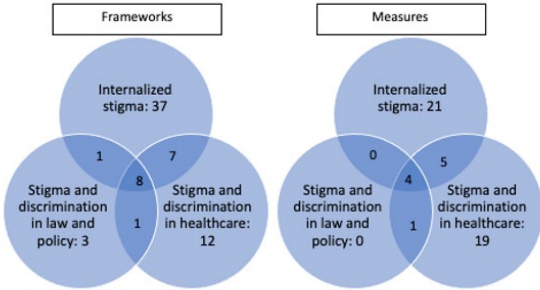

Figure. Number of frameworks and measures included in the review by the dimension(s) of stigma and discrimination covered.

Conclusions: To achieve global targets will require rigorous measurement of stigma and discrimination across different spheres, including those studied here. The challenge remains how to do this with frameworks and measures that are both locally appropriate and globally comparable. Frameworks and measures must be fit to help direct investment, prioritize appropriate actions, and strengthen learning about effectiveness.

Most importantly, the goal must be to understand, measure and help mitigate and alleviate the impact of different types of stigma on people's health and quality of life. This review provides a basis to seek consensus about appropriate concepts and measures to understand the experiences and drivers of stigma for different people in diverse contexts around the world.

PEMOD52

It's time to think positive about HIV – a strengths-based campaign to end HIV stigma from New South Wales, Australia

M. Vaughan[1], K. Johnson[1], L. Rabie[1]
[1]*ACON, Surry Hills, Australia*

Background: Campaigns to address HIV stigma often aim to raise awareness by communicating the experiences of people living with HIV (PLHIV) with stigma. In a new approach, ACON's innovative anti-stigma campaign *It's Time to Think Positive About HIV*reorientates how campaigns address HIV stigma. Rather than focus on the harms of HIV stigma, *Think Positive* celebrates HIV allyship and calls on the broader community, with a focus on those who are HIV negative, to confront HIV stigma together. Featuring Australian community members, *Think Positive*providesa blueprint to challenge HIV stigma through an uplifting, strengths-based message that celebrates allyship.

Description: Aligned with best practice and linked to the Greater Involvement and more Meaningful Engagement of PLHIV (GIPA/MIPA) principals, staff living with HIV led the conceptualisation, development, and delivery of the campaign. *Think Positive* launched on 1 September 2021 and ended promotions on 31 October 2021. Hosted on YouTube and embedded on ACON's Ending HIV campaign platform, the *Think Positive* landing page achieved 12,640 page views, suggesting robust engagement with the message. Beyond ACON web channels, *Think Positive* video content achieved 395,533 views across Facebook, Instagram, and YouTube.

Lessons learned: In an internal evaluation, 97% of survey respondents considered the main campaign video messaging to be extremely, very, or moderately effective. *Think Positive* demonstrates that anti-stigma campaigns can be constructed as uplifting messages that are empowering and optimistic for PLHIV.

Anti-stigma messaging does not need to shame behaviour or showcase harms, but rather can encourage better allyship and collective community care. This new approach relieves the burden on PLHIV around stigma.

Conclusions/Next steps: Addressing HIV stigma and improving quality of life for PLHIV should be prioritised in the global HIV response with equal importance to testing, treatment, and prevention. Reducing HIV stigma is much more than building resilience in PLHIV, who have carried this burden through the history of the epidemic.

Instead, positive examples that engage all of community and provide people with both a blueprint and vocabulary to end HIV stigma should be developed. Guiding people towards high quality HIV allyship should be core to these efforts.

PEMOD53

"My attitude towards my own journey changed the way others see me and treat me": insights from male peers living with HIV on challenging and changing stigma

L. Rambally Greener[1], S. Malone[1], S. Shabalala[2], P. Pitsillides[2], T. Grenville - Grey[2], N. Hasen[1]
[1]*Population Services International, HIV / TB, Johannesburg, South Africa,* [2]*Matchboxology, Johannesburg, South Africa*

Background: HIV-related stigma and discrimination remain significant barriers to achieving the UNAIDS 95-95-95 targets and realizing optimal outcomes for people living with HIV (PLHIV). Among healthcare workers (HCW) living with HIV, there is a complex and multi-layered intersection of both externalized and internalized stigma particularly among peer navigators who work closely with communities.

Efforts are needed to directly address stigma reduction in HIV programs and create a safe and supportive working environment for HCWs.

Description: Programmes that engage with stigma at both inter-personal and community support environments in which stigma and discrimination are no longer accepted or practiced. We explored the experiences and perceptions of male peer navigators living with HIV- re-

ferred to as coaches-, with the aim of understanding how they have addressed stigma in their personal and work lives. We used a qualitative design involving individual semi-structured in-depth discussions with 45 coaches in 5 provinces in South Africa.

Lessons learned: By embracing their HIV status publicly and countering outdated notions of what it means to live with HIV coaches reported being able to overcome internal stigma by reframing their experience of HIV as a resource for advising and supporting other men living with HIV.

"Self-acceptance is the first step to healing and setting the tone on how others will treat you." – Coach, Free State

"Stigma will always be there from lack of information, but we move on, and now we are comfortable in our own skin." – Coach, Gauteng

"People do not believe when I disclose my status during campaigns because I am healthy and confident." – Coach, Free State

The social and professional standing that they hold as healthcare workers and the purpose and meaning that they find in their work appear to serve as protective factors.

Conclusions/Next steps: The Coach intervention has demonstrated that empathy and disclosure from a healthcare worker can reduce stigma and encourage others to seek care.

These approaches are interdependent and mutually reinforcing and have consequences for the way in which people react to others in their community as well as within healthcare facilities. This suggests that greater visibility of PLHIV could be a significant element of stigma reduction strategies.

PEMOD54

"I am a rural woman and living with HIV, how bad can it get?" Exploring the challenges of women living with HIV and AIDS on rural Ghana

N.A. Acheampong[1], T. Nyarko[1,2], R. Afriyie[1], O. Graham[3]

[1]Ghana AIDS Commission, Accra, Ghana, [2]Cocoa Research Institute of Ghana, Rural Sociologist, Akyem New Tafo, Ghana, [3]Ghana AIDS Commission, Kumasi, Ghana

Background: The stigma and discrimination against Persons Living with HIV and AIDS (PLHIV) in Ghana is nothing short of abominable and for PLHIV in rural Ghana where traditional cultures are entrenched, it is virtually abusive. Women living in rural Ghana and having HIV therefore, face unique vulnerabilities that need to be explored in order to appreciate their distinct challenges and make programmatic interventions more effective.

Description: Qualitative data collection method of Focus Group Discussions was employed in the study in 2021. 5 FGD made up of 7 participants each were organized in 5 rural districts in the Ashanti Region of Ghana. The 35 respondents of rural women living with HIV were purposely selected.

The discussions were audio recorded after getting the informed consent of participants. The recorded data was transcribed and the transcripts were thematically analyzed.

Lessons learned: It was revealed during the interactions that the participants face the triple burden of being women, living in a rural area, and living with HIV. Negotiating how to lessen the effects of these burdens is both problematic and extremely difficult.

The perception that HIV is the curse of the gods, and hence has a spiritual aetiology makes these women ultimately responsible for their condition. The women living with HIV are considered to be prostitutes or have caused a sacrilege. Their male counterparts are treated differently and more positively.

It was further observed that women living with HIV and AIDS have limited economic opportunities, as those selling food see their businesses folding up because their customers after knowing their status stop buying from them.

Conclusions/Next steps: There is a need to increase facility lead community outreach services for both HIV sensitization and education and testing. The majority of the residents will be reached through outreach led by a health facility.

Differentiated service delivery for HIV testing, prevention and treatment

PESUE19

What are the 12-month retention and viral suppression outcomes for South African ART clients enrolled in DSD models compared to conventional care?

A.N. Huber[1], N. Jinga[1], L. Jamieson[1,2], B. Nichols[2,3], S. Rosen[1,3], S. Pascoe[1]

[1]Health Economics and Epidemiology Research Office, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [2]Amsterdam University Medical Center, Department of Medical Microbiology, Amsterdam, Netherlands, the, [3]Boston University School of Public Health, Department of Global Health, Boston, United States

Background: South Africa has implemented several differentiated service delivery (DSD) models for HIV treatment. Few comparisons of treatment outcomes between the country's DSD models and conventional care are available. We analyzed routine data to determine one-year retention and viral suppression of clients enrolled in DSD models.

Methods: We analyzed individual data from South Africa's electronic patient record (TIER.Net) for 24 clinics across 4 districts. We followed clients alive and in care on 01/02/2019 and estimated outcomes of retained at 12

months after follow-up start and virally suppressed(<400 copies/ml^3) ≥3-18 months. We classified clients as eligible for DSD models if they were ≥18 years old, on ART ≥12 months and had two suppressed viral load (VL) measurements, per national guidelines at the time. We compared outcomes for those enrolled in a DSD model to those eligible but not enrolled and for those ineligible, compared outcomes by reason ineligible for DSD.

Results: Among 12,120 clients enrolled in DSD and 22,551 ART clients eligible but not enrolled in DSD, retention was 95% and 93%, respectively (risk ratio [95% confidence interval] 1.02[1.02-1.03])(Table). Viral suppression for those with a VL measure was 95% for both groups, but 29% of those in DSD models and 16% in conventional care had no VL measurement recorded. Of the 3,298 recently enrolled into a DSD model (≤6 months), 35% (n=1,153) did not meet the eligibility criteria (0.5% <18yrs, 3% on ART <12 months, 99% missing two suppressed VLs). Retention and VL suppression were higher for those with a known suppressed VL prior to DSD enrollment (93%, n=498) than for those with a known unsuppressed VL prior to DSD enrolment (87%, n=46).

Outcomes (N=59,226)	Total	DSD model enrollment status (n, %)					
		Enrolled in DSD		Eligible for but not enrolled in DSD		Not eligible for and not enrolled in DSD	
N	**59,226**	**12,120**	**20%**	**22,551**	**38%**	**24,555**	**41%**
Retained in care at 12 months							
Alive and in care at 12 months	52,830	11,554	95%	20,930	93%	20,346	83%
Transferred to another facility	3,002	341	3%	874	4%	1,785	7%
Lost to follow up	3,016	168	1%	635	3%	2,213	9%
Died	378	58	0%	108	0%	212	1%
Viral suppression in months 3-18							
VL suppressed	38,745	8,164	67%	17,943	80%	12,638	51%
VL unsuppressed	4,587	431	4%	926	4%	3,230	13%
No VL within 3-18 m	15,894	3,525	29%	3,682	16%	8,687	35%

Table. 12-month retention and viral suppression outcomes by DSD model enrolment status.

Conclusions: DSD model enrolment conferred a minor benefit to retention and equivalent viral suppression over one year of follow-up compared to conventional care for clients eligible for DSD enrolment.

PESUE20

The effect of multi-month dispensing of ART on viral load suppression rates in 18 PEPFAR-supported countries

L. Bailey[1], T. Essam[1], L. Lee[1], P. Agaba[2,3], I. Zulu[4], G. Alemnji[5], D. Patel[1], C. Godfrey[5]

[1]U.S. Agency for International Development, Washington, DC, United States, [2]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, United States, [3]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [4]U.S. Centers for Disease Control and Prevention, Atlanta, United States, [5]U.S. Department of State, Office of the Global AIDS Coordinator, Washington, DC, United States

Background: Research studies demonstrate that people living with HIV (PLHIV) receiving multi-month dispensing (MMD) of antiretroviral therapy (ART) can maintain high rates of viral load suppression (VLS), but little is known about the programmatic effect of MMD on VLS rates rolled out at scale in global HIV programs. The President's Emergency Plan for AIDS Relief (PEPFAR) recommends three to six-month MMD of ART and collects data on ART dispensing and viral load testing at PEPFAR-supported ART sites.

This multi-country analysis aims to describe the effect of MMD scale-up on VLS rates across multiple countries under real world conditions.

Methods: We analyzed quarterly PEPFAR program data from Oct 2018 to Sept 2021 in 18 PEPFAR-supported countries with an average MMD reporting completeness rate > 80%. We compared the proportion of ART patients receiving at least three-month dispensing of ART to VLS rates (proportion of viral load results <1,000 copies/ml) using descriptive statistics, correlations, and a parsimonious fixed-effects regression model.

The analysis incorporated a six-month lag between quarterly MMD coverage and VLS data points to account for time between MMD initiation and subsequent VL testing.

Results: In the 18 countries and 1,472 subnational units analyzed, the scale-up of MMD was moderately positively correlated [r= 0.275] with improved viral load suppression. A fixed-effect regression on VLS and MMD using robust standard errors, suggests a positive correlation between lagged MMD and VLS (beta = 0.032; SE = 0.017, p-value = 0.087, CI = -0.006 to 0.069). Graphical summaries of the data show similar results and point towards a narrowing of the distribution of VLS outcomes with time [Figure 1].

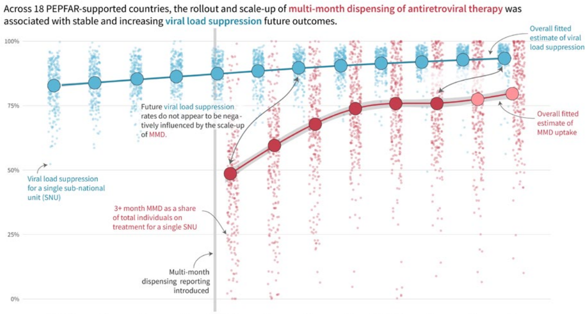

Figure 1. Correlation between changes in MMD and aggregate VLS rates by sub-national unit in 18 PEPFAR-supported countries (Angola, Burundi, Cameroon, Cote d'Ivoire, Democratic Republic of the Congo, Eswatini, Ethiopia, Kenya, Lesotho, Malawi, Mozambique, Nigeria, Rwanda, South Sudan, Tanzania, Uganda, Zambia and Zimbabwe).

Conclusions: Large HIV programs have successfully scaled-up MMD to patients while sustaining and increasing VLS rates in real-world settings, supporting data from clinical trials. Limitations include the use of aggregate program data rather than patient-level data.

National financing analyses and financing mechanisms for HIV, hepatitis and STI programmes and services

PESUE21

Domestic public spending in low-and-middle-income countries 2006-2020: levels and trends

D. Mattur R[1], S. Javadekar[2]
[1]UNAIDS, Geneva, Switzerland, [2]University of Bath, Bath, United Kingdom

Background: Domestic public investments in HIV/AIDS have been the main driver of increase in HIV resources in LMICs during the last decade. For the first time, there is a sign of flattening for last two years and a 2% annual decrease of domestic resources in 2020. Understanding the correlates and predictors of domestic public spending on HIV can inform sustainability plans.

Methods: A panel data regression using reports to UNAIDS for 2006-2020 from 114 low-and-middle-income countries was used for the analysis resulting in 1452 country year data points. All the regression estimates are based on panel data random effects models.

Results: There are significant positive associations between the Gross Domestic Product(GDP) per capita (coefficient 0.2%, p value <0.01) of a country and its level of domestic public spending on HIV. The HIV Prevalence (8.61, <0.001), the non-GDP residuals of the Human Development Index (HDI) (0.25, <0.001) and share of health in total government expenditures (0.05, <0.01) were also significant predictors.

No significant effect was found for ODA for HIV or other independent variables. The domestic public resources per person living with HIV in 2020 were estimated at US$174 in East and Southern Africa, US$36 in West and Central Africa, US$369 in Asia and the Pacific, US$196 in the Caribbean, US$859 in Eastern Europe and Central Asia, US$1699 in Latin America, and US$320 in Middle East and North Africa.

Domestic public spending has increased 70% between 2010 and 2020. In 2020, domestic public resources constituted 50.4 % of all resources in LMICs. [1]

There are large differences in donor dependency across geographies, for example while 98% of AIDS resources in Latin America come from domestic resources, they constitute 35% and 31% in West Central Africa and the Caribbean respectively.

Conclusions: The main determinants of domestic public spending for HIV are ability to pay (GDP percapita), burden of disease (HIV prevalence), non-GDP residuals of HDI and the national prioritization of health within government spending.

With the observed flat lining of international resources, sustained and efficient domestic public spending will be key in achieving resource mobilization targets set by 2021 Political Declaration.

Approaches to achieving sustainability, including sustainable financing for civil society

PESUE22

Stakeholders' perspectives on the financial sustainability of HIV response in Nigeria

D. Ogbuabor[1], O. Onwujekwe[1]
[1]University of Nigeria, Health Administration and Management, Enugu, Nigeria

Background: Transitioning from donors to government requires an understanding of the contextual factors shaping financial sustainability in low-resource settings. As this evidence is scarce in Nigeria, we assessed the perspectives of HIV response stakeholders to understand how domestic funds can be mobilised, pooled, and strategically used to pay for HIV services.

Methods: The study adopted the framework of health financing functions including revenue mobilization, pooling, and purchasing. We conducted document reviews and semi-structured interviews with stakeholders at national and sub-national levels (n = 32) between December 2021 and January 2022. We adopted maximum variation sampling to purposively select individuals whose roles included financing in the HIV response. Data were analysed thematically using NVivo software (version 11).

Results: Public spending is low nationally and sub-nationally due to low resource allocation and low budget execution. Few state governments implemented the policy earmarking 0.5-1% of states' federal allocation to the HIV response.

Decision-makers and budgeting staff perceive the HIV response as getting substantial external assistance. Although private sector investment is low, the establishment of an HIV trust fund might increase its contribution to the HIV response. On pooling and fund management, appropriations are need-based, but releases do not reflect needs. In contrast, external assistance reflects geographic variations in the HIV burden.

Notwithstanding a national strategy for integrating HIV into social health insurance schemes, HIV services have not been prioritised by the schemes. Coverage of some HIV services in the Basic Health Care Provision Fund has not translated into practice. Users pay for some HIV services previously supported by donors.

Regarding purchasing, a parallel procurement system between donors and government, and high supply-side spending undermine the financial sustainability of the HIV response.

Purchasing of services for the key populations is limited by a lack of reliable estimates due to demographic shifts and stigma.

Dysfunctional inter-agency relationships hinder scaling up HIV testing and treatment in primary health facilities despite its efficiency gains. Civil society organisations can be financed through partnerships with the government.

Conclusions: This study highlights the financing and governance factors that can inform the development of a financial sustainability plan for the HIV programme in Nigeria.

Costing of HIV, hepatitis and STI services

PESUE23

Do differentiated models of care for HIV treatment result in lower costs for recipients of care in Zambia?

C. Hendrickson[1,2], B. Phiri[3], N. Lekodeba[1], I. Mokhele[1], A. Huber[1], V. Ntjikelane[1], P. Haimbe[3], H. Shakwelele[3], P. Mulenga[4], B. Nichols[1,2,5], S. Pascoe[1], S. Rosen[1,5]

[1]Health Economics and Epidemiology Research Office, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [2]Amsterdam University Medical Center, Department of Medical Microbiology, Amsterdam, Netherlands, the, [3]Clinton Health Access Initiative, Lusaka, Zambia, [4]Ministry of Health, Lusaka, Zambia, [5]Boston University School of Public Health, Department of Global Health, Boston, United States

Background: One of the benefits that differentiated service delivery (DSD) models for HIV treatment are assumed to generate is a reduction in direct and indirect costs to recipients of care (RoC), but the savings that come with reduced costs must vary among the widely diverse DSD models. We estimated the costs to RoC of nine discrete models currently in routine use in Zambia, compared to conventional care.

Methods: From May to November 2021 we surveyed RoC at 12 clinics in two provinces of Zambia. Participants were selected consecutively on their arrival for routine visits, with stratification by DSD model participation, and asked about time spent and transport costs incurred when accessing care.

We calculated the cost/health system interaction (clinic and out-of-facility) and multiplied by the participant-reported number of interactions per year to estimate an opportunity cost (using the country-specific minimum wage of $1.99/day) and transport cost/RoC/year by model of care.

Results: We surveyed 558 RoC (median age 38, 72% female). Conventional care required four facility visits year, while most (but not all) DSD models reduced facility visits to two per year, with or without additional external interactions such as adherence club meetings or community medication pickups (Figure).

Depending on the model, opportunity costs to RoC ranged from roughly 1 to 3 days' minimum wage. Fewer than half of RoC incurred any transport costs; for those who did, the cost averaged 1-1.5 days' minimum wage. Variation in transport costs among models may reflect RoC choices about paying for transport based on how many interactions will be required and the locations of the interactions.

Model of care	N	Average number of health system interactions/RoC/year			Average opportunity cost/RoC/year†		Average transport costs/RoC/year	
		Facility visits*	Out-of-facility interactions	Total	Time spent (hours)	Cost	% RoC incurring any transport costs**	Travel costs/RoC incurring any transport costs
All facility conventional care	168	4 (4,6)	-	4 (3,5)	17.6 (8.0,33.7)	$4.37 (1.99,8.37)	43.5%	$1.49 (0.50,2.98)
Ineligible for DSD	102	4 (4,6)	-	4 (4,6)	16.0 (7.7,32.0)	$3.98 (1.91,7.95)	38.2%	$1.49 (0.50,2.49)
Eligible for DSD	66	4 (4,6)	-	4 (4,6)	20.5 (10.7,38.0)	$5.10 (2.65,9.44)	51.5%	$1.74 (0.70,4.97)
DSD models	390	2 (2,4)	0 (0,1)	4 (2,4)	3.4 (2.2,5.2)	$3.38 (2.17,5.17)	37.4%	$1.49 (0.60,2.49)
Facility 6-month refills	118	2 (2,2)	0 (0,0)	2 (2,2)	2.2 (1.9,3.3)	$2.17 (1.92,3.23)	35.6%	$1.74 (0.70,2.98)
Facility 3-month refills	68	4 (4,4)	0 (0,0)	4 (4,4)	4.3 (3.5,6.0)	$4.28 (3.55,6.02)	41.2%	$1.38 (0.50,2.49)
Scholar/adolescent groups	51	3 (2,4)	0 (0,2)	4 (3,12)	3.8 (2.4,14.5)	$3.84 (2.39,14.51)	25.5%	$0.99 (0.75,1.99)
Community adherence access points‡	38	2 (2,4)	2 (1,4)	6 (4,7)	4.2 (2.8,6.6)	$4.20 (2.79,6.58)	50.0%	$1.49 (0.50,2.49)
Fast track pickup at facility	33	3 (2,4)	0 (0,0)	3 (2,6)	3.4 (2.4,4.8)	$3.41 (2.42,4.84)	39.4%	$0.99 (0.50,1.49)
Community adherence groups	31	2 (2,2)	5 (2,15)	7 (4,21)	6.3 (4.2,19.5)	$6.33 (4.16,19.48)	38.7%	$0.99 (0.85,5.72)
Home ART delivery	27	2 (1,3)	0 (0,2)	3 (2,4)	2.5 (1.7,3.4)	$2.46 (1.71,3.41)	44.4%	$1.99 (0.99,4.10)
Extended clinic hours	15	2 (2,3)	0 (0,0)	2 (2,3)	2.1 (1.7,2.9)	$2.09 (1.67,2.88)	46.7%	$0.99 (0.60,3.48)
Mobile ART	9	0 (0,4)	4 (0,4)	4 (4,4)	3.4 (2.4,4.0)	$3.35 (2.36,3.98)	0.0%	-

*Includes both clinical consult visits and ART medication pick up visits at the facility.
**Remainder likely walked, incurred no cash costs.
†Calculated opportunity cost based on the cost of time spent travelling and time at clinic visits or out-of-facility events. The minimum wage for Zambia of $1.99/day (adjusted to an hourly minimum wage using 8 working hours/day) as used to assign a monetary value to the time spent.
‡Community adherence access points are equivalent to external medication pickup points.

Figure. Average costs to recipients of care per year in care, by model (2021 USD) (median (IQR))

Conclusions: DSD models generally minimise costs and time for RoC as compared to conventional care, but this depends entirely on model design (number of interactions required/year). Implementing models that minimize RoC interactions with the healthcare system and model events may improve outcomes.

Strategies to increase retention and re-engagement in HIV services

PESUE24

PLHIV refill booklet: an innovative way to reduce interruption in treatment among highly mobile PLHIV in Ghana

A. Dambasea[1], M. Owusu[1], S. Wosornu[1], E. Adiibokah[2], E. Owusu[1], H. Tagoe[2]

[1]Maritime Life Precious Foundation, Sekondi-Takoradi, Ghana, [2]JSI Research & Training Institute, Inc, Takoradi, Ghana

Background: PLHIV who experience interrupted HIV care usually have poor clinical outcomes, and they also contribute to further HIV transmission. HIV-related mortality and morbidity significantly increases when there is interruption in treatment (IIT). Follow-up calls made to PLHIV who interrupted treatment revealed that high mobility from the nature of their jobs or circumstances was a major casual factor. Such clients find it difficult to get their refill when they are due. In October 2019, Maritime Life Precious Foundation (MLPF) a key population focus Civil society organization (CSO), collaborated with Tarkwa Municipal Hospital (TMH) in Western Region, Ghana to find an innovative way to mitigate this situation. We deployed a portable refill booklet system that is easy to use, convenient and ensures that refills are documented.

Description: In October 2019,MLPF and the ART team designed a pocket-sized booklet that enables PLHIV to conveniently get ARV refill from other ART sites. The phone numbers of the ART nurses and data officers were printed

in the booklet. 85% of all clients diagnosed HIV-positive (316 PLHIV) at the Tarkwa Municipal Government Hospital accepted the booklet. 68% (214) of them were female whereas 32% (102) were male. Health facility data officers documented refills on the e-tracker network.

Lessons learned: 91% (212) of all newly diagnosed PLHIV accepted the booklet. After 24 months, 48% (102) of the clients who accepted the booklet visited TMH for their refills and so, did not use their booklet, while 52% (110) used their booklets successfully. 65% (72) of the PLHIV who used the booklet got refills from facilities outside the municipality and 35% (38) got refills from outside the Western region.

The booklet was helpful to PLHIV might interrupt treatment as a result of their high mobility. It also reduced the need for client transfers in-between ART facilities. Data officers verified refill on the e-tracker network. Clients experienced difficulties ART sites that did not have prior information about the pilot.

Conclusions/Next steps: The PLHIV refill booklet is effective and has the potential to improve ART retention and records keeping. Therefore it is recommended that this refill booklet system be supported and scaled up nationwide.

Assessments of cost effectiveness: Provider and community perspectives

PESUE25

Optimal treatment and prevention mix for South Africa's UTT program

S. Nyamhuno[1]
[1]Ashley Nyamhuno, Durban North, South Africa

Background: South Africa has over 8 million people living with HIV/AIDS. In 2016, it adopted the UTT program in a bid to control, the epidemic. There is room to fine-tune the current UTT program to get high impact, less costly programs that give the country a great value for its money.

Methods: We used Goals Model which is a dynamic compartmental model to project the results for the period, 2020-2030 for South Africa's entire population, including PLWHA. We fitted the epidemic model to South Africa's epidemic using current data. For the program components under consideration (PrEP coverage, ART coverage and retention on care), we subjected them to a 3% discount for costs and infections averted.

We further used a scenario analysis in which we varied the program components for different coverage levels to assess each impact on the HIV investment case for South Africa.

Results: Increased ART coverage is more cost-effective than any option with less coverage. The 95% scenario yielded better health benefits than both90% and the current coverage (72%). It records fewer AIDS deaths, gain more life years and averts more new HIV infections than the scenarios with less coverage. It also has an ICER of R13,111/QALY gained which was cost-effective.

A lower migration rate was much beneficial to South Africa. It showed the least amount of deaths recorded, lower costs, the highest number of new HIV infections averted than all scenarios with higher migration rates. It further had the lowest ICER which proved that it was the most cost-effective option. Increased PrEP coverage is associated with more health benefits however at a higher cost at a high cost.

However, the PrEP average to all-risk categories was quite phenomenally high and unsustainable.PrEP coverage was highly beneficial when given to high-risk populations.

Conclusions: The best investment option for South Africa is high ART coverage, low migration to second regimens as well as PrEP average to high-risk groups. With this, South Africa can save costs and redirect savings to other equally important areas. UTT costs are manly driven by ART costs. South Africa must consider local production of drugs to reduce imported inflation costs.

Community participation in systems for health, including community-led and key population-led health systems

PESUE26

Mapping opportunities for CSO financial sustainability through domestic funding access to ensure the continuation of HIV community-led response in Indonesia

A. Nugroho[1], M. Lubis[2], Y. Nurhidayat[2], S. Sarwitri[2], M. Maryono[2], F. Riyadi[2]
[1]UNAIDS Indonesia, Jakarta, Indonesia, [2]Konsil LSM, Jakarta, Indonesia

Background: To support the sustainability of HIV community-led response, Indonesia has launched a pilot project with the support of the Global Fund to strengthen the sustainability of HIV-CSO financing in ten cities through capacity building for CSOs and local governments in developing social contracting initiatives.

The objectives of this mapping were:

1. To evaluate the legality and competence of HIV-CSOs engaged in lobbying, advocacy, and social contracting in ten cities; and,
2. To identify policy and financial opportunities for HIV-CSOs at the national level and in ten pilot cities.

Description: This mapping applied the civic and fiscal space analysis approach and involved 84 HIV-CSOs and 35 local government officials as respondents/participants. The civic space analysis employed both quantitative and qualitative methods and gathered data via literature reviews, online surveys, in-depth interviews, and

FGDs. While the fiscal space approach gathered data through literature reviews and examination of relevant government papers.

Lessons learned: Local governments continue to be unsure about how to interpret the division of responsibilities in dealing with HIV-AIDS. Fiscal capacity is not a big driver, but commitment is. Accountability of HIV CSOs, particularly upward accountability, remains a challenge in comparison to internal and downward accountability. 26 organizations met the eligibility criteria for social contracting.

According to the Organizational Performance Index's score, 20 CSOs (51%) are in a nascent state, which means they are improving their effectiveness, internal efficiency, and human resource strength. And 49% are at an emergent state, which means that practice and skills at the fledgling stage have been achieved.

Conclusions/Next steps: General recommendations include:

1. To determine the area that will serve as the locus of advocacy for the social contract, the most critical factor to map, aside from fiscal capacity, is the commitment of local government, as well as the capacity of local CSOs.
2. Need to identify champions who come from local government leaders as primary partners in social contracting;
3. Invest in raising awareness and understanding of the HIV-AIDS issue as part of local governments' work mandate;
4. Strengthening CSOs' organizational capacity and accountability in order to build public trust in CSOs as strategic partners, particularly among local governments.

Approaches to effective paediatric HIV services

PESUE27

Optimizing diagnostic technologies for pediatric HIV - function or location? Modelling analysis of point of care technologies in Matabeleland South, Zimbabwe

A.K. Amick[1], M. Yildrim[1,2], K.A. Webb[3,4], A. Mushavi[5], C. Flanagan[1], A. Chimwaza[5], N.C. McCann[1], T. Murape[3], A. Claypool[1], K.A. Freedberg[1,6], A. Ciaranello[1,6], M.S. Jalali[2]

[1]Medical Practice Evaluation Center, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, [2]Institute for Technology Assessment, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States, [3]Organization for Public Health Interventions and Development, Harare, Zimbabwe, [4]London School of Hygiene and Tropical Medicine, Epidemiology and Population Health, London, United Kingdom, [5]Ministry of Health and Child Care, National PMTCT Program, Harare, Zimbabwe, [6]Division of Infectious Diseases, Massachusetts General Hospital, Harvard Medical School, Boston, MA, United States

Background: Novel point-of-care (POC) devices for infant HIV testing provide prompt receipt of results and increase ART initiation, improving survival among HIV-exposed infants with HIV. POC device functionality (proportion of days devices are operational) varies with power supply, machine maintenance and testing commodities supply. Program planners must decide in which health facilities to locate a limited supply of POC devices.

Methods: We developed a location-optimization model to identify the placement of 11 currently available POC devices in Matabeleland South Province, Zimbabwe, that would maximize the number of infants with HIV initiating ART within 30 days of testing.

We first examined the current and optimal placement of the currently available devices, then determined the number of new POC machines that would need to be added and optimally located to achieve 50% 30-day ART initiation. We modelled 4724 infants who received HIV testing from Jan2019-Jan2020 using routine program data from 122 health facilities.

Results: With current placement of 11 existing POC machines, 37% of all tested infants with HIV would receive their results and 35% would initiate ART within 30 days.

With optimal placement of existing machines, 46% would receive their HIV test results and 44% would initiate ART within 30 days; retaining 2 machines in their current locations and moving 9 machines to new facilities. Requiring >/=1 machine/district reduced 30-day ART initiation to 42%.

The number of optimally placed POC devices required to achieve 50% 30-day ART initiation depended on device functionality: 38 devices would be needed with low (51%) functionality, 25 with current (63%) functionality, and 15 with high (75%) functionality.

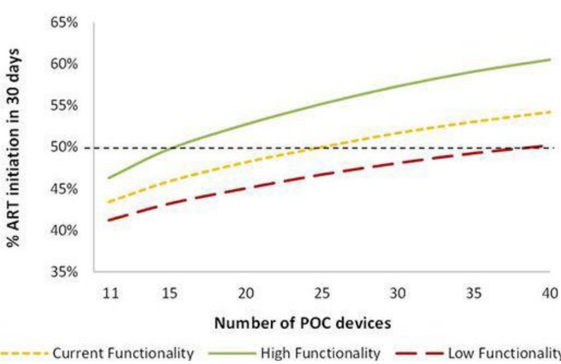

Figure. Percentage of ART initiation due to total number of POC machines across different functionality rates.
Functionality rates are district-specific; with the average of 51% low, 63% current and 76% high utilization.

Conclusions: We demonstrate substantial increases in 30-day result return and ART initiation among infants with HIV through optimization-based location of available POC machines for infant testing.
The benefits of optimal location and/or adding new POC machines are dramatically influenced by machine functionality.

Systems serving underserved populations

PESUE28
Digital Interventions through an online community portal to engage historically hard-to-reach populations of same-sex attracted men living in a heterosexual relationship or lifestyle

C. Hawk[1], S. Ruth[2], C. Batrouney[1]
[1]Thorne Harbour Health, Health Promotion, Policy, & Communications, Melbourne, Australia, [2]Thorne Harbour Health, Melbourne, Australia

Background: Same-sex attracted men living in a heterosexual relationship or lifestyle (often referred to 'gay and married men') have been historically difficult to connect with HIV prevention and sexual health education, peer support, and sexual health services due to a range of factors including structural, social, and self stigma associated with their same-sex attraction.
With limited success achieved through previous face-to-face interventions, this multidisciplinary project sought to realise the potential of digital interventions in engaging this population in Australia.
Description: Originally a two-year research partnership, the development of the DALE project was informed by preliminary qualitative interviews with same-sex attracted men living in a heterosexual relationship or lifestyle to develop a digital wireframe for the delivery of a dual education and contact approach through an online community. The community website included a feed of articles integrated with health promotion messaging alongside peer-moderated discussion boards and live chat sessions. The website also connected site visitors with an online survey about their mental health, sexual behaviours, sexual health, disclosure of same-sex attraction, substance use, and experiences of stigma.
Lessons learned: The online community at DALE has had more than 20,000 visitors and connected with men who have sex with other men identify as identified as gay, bisexual, and heterosexual. These men have reported to experience greater levels of anxiety, depression, stress, and stigma.
Survey participants also showed higher rates of condomless anal intercourse with casual and regular partners alongside lower rates of testing for HIV and other sexually transmitted infections. As the time of the original study period's completion, the findings from the survey combined with the quantitative data from site analytics represented the largest quantitative research to be conducted among this cohort of men.
Conclusions/Next steps: The original research partnership developed an online intervention to address compound forms of stigma and the resulting online community created a valuable connection with a historically hard-to-reach population of men who have sex with other men to disseminate health promotion messaging, peer support, and referrals to additional resources. The developed digital wireframe also has the potential to be adapted for other hard-to-reach communities.

PESUE29
Finding local models for comprehensive HIV/AIDS management in closed settings: documenting the experience of the Bureau of Jail Management and Penology (BJMP) in Cebu City, Philippines

M.J. Villaester[1], E. Bagasol[1], J.O. Corciega[1], R. Rizarri[2], M. Encarnacion[3], I. Tac-an[3], F. Rubio[4], V.P. Baton[4], M.L. Averilla[5]
[1]LoveYourself Inc., Mandaluyong, Philippines, the, [2]Bureau of Jail Management and Penology, Cebu City, Philippines, the, [3]Social Hygiene Clinic, Cebu City Health Department, Cebu City, Philippines, the, [4]Department of Health, Central Visayas Center for Health Development, Cebu City, Philippines, the, [5]Australian Federation of AIDS Organisations, Bangkok, Thailand

Background: HIV prevalence in Philippine jails, compounded by congestion and inadequate health services, pose challenges in treating PLHIV and preventing transmission among persons deprived of liberty (PDL). Acknowledging the public health imperative and opportunity to address HIV-related risks and deaths among PDL, BJMP issued a memorandum circular (MC) to guide jails in establishing HIV/AIDS programs.
Methods: LoveYourself, through the Global Fund SKPA program, helped document and analyze Cebu City Jail's HIV/AIDS program implementation to provide a model for other jails in the country to operationalize the BJMP

Oral abstracts

MC. The process documentation involved policy reviews, stakeholder meetings, and key informant interviews with jail personnel, health officials, and select PDL.

Interventions and challenges throughout the PDL confinement stages (commitment, detention, transfer and release), as well as opportunities to extend HIV interventions for PDL's family members were explored.

Results: Despite PDL's access to condoms, knowledge retention on safer sex practices and HIV/STI prevention remains a challenge. Voluntary testing, offered upon commitment and during detention, is hampered by peer-driven stigma. PDL who test reactive are immediately enrolled to treatment assisted by peer health aides. Health aide accounts, however, reveal PLHIV hesitancy in accessing/maintaining treatment caused by fear of ARV side effects, ARV access issues, and perceived effects of family disclosure. PLHIV-PDL's continued access to treatment, care and support, following transfer or release, is also unsecured due to the lack of standardized procedure for referral and monitoring.

Local government social hygiene clinic and community-based organization collaborations help address these gaps, including through periodic mass HIV screening, conduct of PDL/PLHIV learning group sessions, treatment monitoring, and ARV refill.

Conclusions: Documenting Cebu City Jail's experience surfaced gaps on the BJMP MC and how it can be operationalized at facility level.

The study recommends addressing jails' health human resource limitations; mobilizing and enhancing health-related capacity of PDL aides and jail personnel; improving access of PDL and family members to HIV information and prevention commodities; better documenting PDL/PLHIV learning group sessions to inform service enhancements; firming-up case monitoring, reporting and referral mechanisms; integrating mental health interventions; and ensuring better access to food, water and medicine in-facility.

Public-private partnerships

PESUE30

Expedited development and registration resulting in successful uptake of generic, pediatric dolutegravir products for low- and middle-income countries through an innovative public-private partnership

M. Watkins[1], H. McDowell[2], L. Lewis[1], K. Hayward[1,2], M. Louey[1], A. Djemai[2], S. Ghelani[1], K. Grainger[2], C. Amole[1]
[1]*Clinton Health Access Initiative (CHAI), Boston, United States,* [2]*ViiV Healthcare UK Ltd, London, United Kingdom*

Background: There are 1.7M children living with HIV (CLHIV) globally, with only 54% on treatment and 100,000 deaths each year. Poor viral suppression is observed in CLHIV due to lack of accessible, effective child-friendly formulations. A significant contributor is the time delay between adult and pediatric formulation development, followed by generic development via voluntary licensing mechanisms. Dolutegravir (DTG) was originally approved in 2013 by the US FDA for HIV treatment in adults and children (≥12 years, ≥40kg). In 2018, WHO guidelines recommended DTG, in combination with NRTI backbone, as the preferred first-line treatment for adults and children.

However, ViiV Healthcare's child-friendly formulation (≥4 weeks, ≥3kg), under development, was not yet available and generic development had not yet commenced.

Description: A public-private partnership, consisting of CHAI (funded by Unitaid), ViiV, Mylan and Macleods, was initiated to expedite the development and registration of generic, pediatric DTG dispersible tablets for use in low- and middle-income countries (LMICs) within ViiV's pediatric licensing territory. CHAI/Unitaid provided a financial incentive for product development. ViiV provided a comprehensive technical package. CHAI and ViiV provided ongoing technical and regulatory support.

A novel regulatory strategy enabled generic filing to the US FDA under the PEPFAR program during ViiV's review period. FDA tentative approvals for pediatric DTG were obtained by Mylan and Macleods within 5 and 9 months of ViiV's approval, respectively. The financial incentive enabled a global price agreement (75% price reduction from the existing standard of care).

Lessons learned: Technical support throughout the generic development process was critical to reducing timelines. Early engagement with the US FDA prior to generic filing was key to gain alignment on the proposed novel regulatory strategy and timing.

Conclusions/Next steps: The collaborative partnership between CHAI, ViiV, Mylan and Macleods significantly accelerated development and registration of generic, pediatric DTG products. The gap between innovator and generic US FDA product approvals was reduced to months. The generic products launched at an affordable and sustainable price improving pediatric patient access in LMICs.

Delivering gender-transformative programmes and tackling violence against women and girls: Programmatic lessons

PESUE31

Sexual, physical, economic and emotional violence faced by women and adolescent girls living with HIV and at high risk of HIV in South Africa and Nigeria in time of COVID-19

Okiwu[10], P. Sibisi[11], A. Sunday[12], H. Yunusa Nyako[13], M. Oluwatoyin Folayan[4,14], Q. Abdool Karim[3,15]

[1]UNAIDS, Strategic Information, Geneva, Switzerland, [2]Aix-Marseille University, School of Economics, Marseille, France, [3]CAPRISA, Durban, South Africa, [4]Obafemi Awolowo University, College of Health Sciences, Ile-Ife, Nigeria, [5]Nigeria Sex Workers Association, Kubwa, Nigeria, [6]African Alliance, Johannesburg, South Africa, [7]National Association of Persons with Physical Disability, Abuja, Nigeria, [8]Northern Nigerian Transgender Initiative, Abuja, Nigeria, [9]Youth Health Africa, Johannesburg, South Africa, [10]YouthRise, Abuja, Nigeria, [11]AIDS Foundation of South Africa, Berea, South Africa, [12]African Network of Adolescent and Young Persons Development, Barnawa, Nigeria, [13]Jami Al Hakeem Foundation, Jimeta-Yola, Nigeria, [14]Nigeria Institute of Medical Research, Lagos, Nigeria, [15]Columbia University, Department of Epidemiology, New York, United States

Background: The COVID-19 crisis is associated with a global surge in reports of gender-based violence (GBV). Little is known of its impact on adolescent girls and women living with HIV (W&GLHIV) or at high risk of HIV.
This study aimed to determine the risk factors for physical, sexual, emotional and economic violence during the COVID-19 crisis.
Methods: National cross-sectional surveys were conducted among W&GLHIV or at high risk of HIV ≥15 years in South Africa and Nigeria from July to December 2021. Participants were recruited using a combination of venue-based and snowball convenience sampling methods. The questionnaires were completed online or with assistance from a data collector for those with reading/writing impairment or in the absence of an internet-connected device. Multivariable logistic regression was used for identifying risk factors for GBV and controlled for age, education and working status.
Results: A third (30%) of the 6,689 participants reported experiencing physical or sexual gender-based violence , with 7% facing less violence, 10% facing the same level of violence and 13% facing more violence than before the COVID-19 crisis. W&GLHIV were more likely (adjusted odds ratio (AOR) 1.27, 95%CI 1.09-1.49) to experience violence compared to those HIV-negative. There was a monotonic relationship between violence and mental health with those experiencing violence more than twice likely to report severe symptoms of depression and anxiety (AOR 2.33, 95%CI 1.82-2.99). Violence was also strongly associated with housing insecurity (AOR 1.59, 95%CI 1.27-2.02). Participants engaging in sex work (AOR 2.74, 95%CI 1.62-4.61) or transactional sex (AOR 1.86, 95%CI 1.40-2.46) were more likely to face sexual and physical violence compared to those not engaging in transactional or sex work.
Furthermore, using validated instruments, 35% of all participants reported emotional as well as economic abuse with W&GLHIV reporting higher rates of emotional (AOR 1.19, 95%CI 1.04-1.37) and economic abuse (AOR 1.19, 95%CI 1.04-1.37) respectively.
Conclusions: The COVID-19 crisis resulted in an increase in already high rates of gender-based violence faced by W&GLHIV or at risk of HIV with substantial mental health and economic consequences. COVID-19 and HIV policy and programmes need to pay more attention to the multi-faceted manifestations of GBV.

Access to education

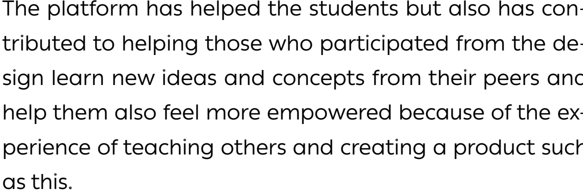
PESUF13

Sex workers educating sex workers, www.plaperts.org and its online school: LXS expertXS

K. Bravo[1], J. Campi-Portaluppi[2]

[1]Plaperts, Machala, Ecuador, [2]Universidad Casa Grande, Applied Research Projects, Guayaquil, Ecuador

Background: Strengthen the capabilities of people who exercise sex work in order to grant them the abilities to better advocate for their access to basic rights, including access to integral health.
Description: Design and creation of an online learning ecosystem. Designed as a MOOC and with courses conceived through an inclusive and constructivist approach where sex workers use backwards design to create courses that help other sex workers strengthen their capabilities around advocacy, project design and human rights. As of now one course has been launched and has started to be applied in 12 countries in Latin America where Plaperts' allies are working every day to better the conditions of sex workers and their access to healthcare and other basic rights.
Lessons learned: Online tools have become a viable alternative in LATAM because of the exponential growth in internet penetration during the covid pandemic.
An online learning ecosystem created by sex workers for sex workers is a space that can potentially grow to become a tool that allows to better educate more women and men, cis or trans, H or LGBTQI+ in matters related to HIV, politics, human rights, gender diversity and other topics connected to the possibility of improving the conditions of the lives of people in a position of vulnerability.



The platform has helped the students but also has contributed to helping those who participated from the design learn new ideas and concepts from their peers and help them also feel more empowered because of the experience of teaching others and creating a product such as this.

Conclusions/Next steps: This initiative is an ongoing project that aims at the creation of 4 more courses in the next 4 years and that is looking to formally evaluate its results within the region, in order to better tune its resources to be able to achieve its goals. We believe that sharing this initiative in this space will allow for others to be motivated by our efforts and that the input obtained will also allow it to evolve and grow.

Criminalization, incarceration and living in closed settings

PESUF14

Community-based assessment on criminalization costs in the Central and Eastern Europe, and Central Asia region

E. Kurcevič[1], G. Dovbakh[1]

[1]*Eurasian Harm Reduction Association, Vilnius, Lithuania*

Background: Criminalization of people who use drugs in the Central and Eastern Europe, and Central Asia (CEECA) region, instead of maintenance of public health increases the financial and social burden on the states. This community-based assessment aimed to evaluate and compare costs of incarceration versus costs of health and social services for people who use drugs; as well, to analyze how incarceration and health costs changed in two years (same assessment was conducted in 2019).

Methods: Assessment was done in 2021, in 29 countries of CEECA region. It was conducted in two stages:

1. Desk research, and;
2. Verifying data with national partners, working in the harm reduction field.

The cost of incarceration was calculated by multiplying 365 days to the cost of maintenance of one prisoner/per day. This sum doesn't include law enforcement work, court proceedings and lost taxes, which person cannot pay, because of the incarceration. The costs of health and social services included cost of needle and syringe exchange services, opioid substitution therapy and unemployment benefit for one person per year.

Results: In most of countries of CEECA region, incarceration costs are 1,5 to even 17 times more than health and social services. The biggest difference of costs is assessed in Georgia (17 times), Hungary (17 times), North Macedonia (13 times), Romania (8 times).

Meanwhile the lowest difference of costs is assessed in countries, which has numerous and gross human rights violations in prisons - Belarus, Bulgaria, Azerbaijan and Kyrgyzstan. In comparison with 2019, few countries made improvements in increasing unit costs for health and social support: Azerbaijan (5,5 time), Croatia (1,6 time) and Czechia (1,5 time). In some countries both - costs of health and social services and incarceration increased on the equal level, in average - Lithuania (1,7 time), Estonia (1,4 time), Moldova (1,1 time).

Conclusions: Assessment shows that there are opportunities for governments to invest into the health and social services for people who use drugs. Governments should take evidence-based health and human rights approaches and reallocate money from policing, prosecuting, and incarceration of people who use drugs to community harm reduction and health services.

Law enforcement and public health

PESUF15

Experiences with criminal justice system and HIV/Hepatitis C testing among people who inject drugs (PWID) in Selangor, Malaysia

J. Pang[1], W.H. Siew[1], A.M. Jailani[2], A. Ahmad[3], N.A. Mohd Salleh[4,5], A. Kamarulzaman[5,1]

[1]*University of Malaya, Department of Medicine, Kuala Lumpur, Malaysia,* [2]*Persatuan Insaf Murni, Kajang, Malaysia,* [3]*Yale University, Department of Medicine, Section of Infectious Diseases, AIDS Program at the Yale School of Medicine, New Haven, United States,* [4]*University of Malaya, Department of Social and Preventive Medicine, Faculty of Medicine, Kuala Lumpur, Malaysia,* [5]*Centre of Excellence for Research in AIDS (CERiA), Faculty of Medicine, Kuala Lumpur, Malaysia*

Background: Early screening of people who inject drugs (PWID) co-infected with HIV and Hepatitis C (HCV) facilitates timely treatment and better management of these co-morbidities. However, the scale-up of HIV and HCV testing can be hampered by punitive criminal justice approaches for this key population. This study aims to describe the characteristics of PWID, experiences with police and incarcerated settings and HIV/Hepatitis C testing status.

Description: Using a cross-sectional, respondent-driven sampling (RDS) survey, a total of 367 PWID were recruited in Selangor, Malaysia between September 2021 to January 2022. The survey assessed the current situation of sociodemographic factors; drug use patterns; experiences with the criminal justice system; health status and access to social support or healthcare services, including HIV/HCV testing.

Lessons learned: Overall, the study recruited 345 (94%) male and 22 (6%) female, with 297 (81%) participants used Methamphetamine and 318 (87%) used Heroin in the past month. A total of 34 (94%) participants had ever been in lock up, 314 (85%) in prisons and 174 (47%) in compulsory

drug detention centers. Among these participants, 163 (44%) reported that they had a rushed injection for fear of police, 129 (35%) experienced confiscation of injecting equipment by the police; 182 (50%) have been beaten up or tortured by police, and 191(52%) avoided carrying injecting equipment for fear of the police. Only 283 (77%) participants and 186 (51%) ever had HIV and HCV screening, respectively. At the study visit, a number of 22 (6%) individuals were detected HIV positive, and 157(43%) were detected HCV positive.

Conclusions/Next steps: Results showed high Hepatitis C prevalence among PWID, in the context of high levels of negative experiences with the criminal justice system which may affect safer injecting practices. A change towards a more health-based policy will lead to a more enabling environment for PWID to access health services and implementation of a more effective harm reduction services for PWID.

Access to appropriate healthcare services (including for co-infections and co-morbidities)

PESUF16

Does travel time matter? Transportation vulnerability and access to HIV care among people living with HIV in South Carolina

P. Hung[1,2], S. Harrison[2,3], K. Green[4], S.J. Miller[3], M. Paton[3], D. Ahuja[4], S. Weissman[4], C.A. Rudisill[5], T. Evans[6]

[1]*University of South Carolina Arnold School of Public Health, Health Services Policy and Management, Columbia, United States,* [2]*University of South Carolina Arnold School of Public Health, South Carolina SmartState Center for Healthcare Quality, Columbia, United States,* [3]*University of South Carolina College of Arts and Sciences, Department of Psychology, Columbia, United States,* [4]*University of South Carolina School of Medicine, Department of Internal Medicine, Columbia, United States,* [5]*University of South Carolina Arnold School of Public Health, Health Promotion, Education and Behavior, Columbia, United States,* [6]*ViiV Healthcare, Research Triangle Park, Columbia, United States*

Background: Access to safe and reliable transportation is necessary for people living with HIV (PLHIV), particularly in areas where public transportation is limited. Transportation barriers and long travel times might result in delayed linkage to care and missed appointments, leading to disease progression for PLHIV. This study examined travel burdens, transportation barriers, and the associated HIV care outcomes among PLHIV in South Carolina—a rural southern state in the United States (US).

Methods: A total of 160 PLHIV from a large immunology center – who were re-engaging with HIV care after a prolonged absence or were in care but not virally suppressed – were enrolled in a randomized clinical trial from January 2020 to June 2021. During the enrollment, each participant completed an intake survey reporting their sociodemographic characteristics, barriers to HIV care, and transportation vulnerability.

Using Kruskal–Wallis tests, sociodemographic characteristics, transportation vulnerability, and negative care outcomes (e.g., missed or delayed appointments) were compared across residential proximity to HIV care, measured by number of minutes needed to travel to the immunology center.

Multivariable logistic regressions were employed to identify the likelihoods of negative outcomes for PLHIV living <15 minutes, 15-30 minutes and >30 minutes from the center.

Results: A majority of participants were male (63.8%), aged 45-64 years (54.4%), never married (77.0%), Black or African-American (77.5%), and non-Hispanic (82.5%). Many were unemployed (40.6%), receiving public insurance (50.6%), and reported transportation barriers (59.4%). Nearly 20% of participants lived <15-minutes from the clinic, 59.1% lived 15-30-minutes, and 21.4% lived >30-minutes from the clinic. Compared to participants living <15-minutes away, those living >30-minutes from the center were more likely to be late for appointments (aOR=5.25, 95% CI, 1.06-25.92), miss appointments (aOR=3.85, 95% CI, 1.04-15.89), and have difficulties seeing doctors (aOR=7.06, 95% CI, 1.61-30.99).

Conclusions: Long travel time is a barrier to care for PLHIV in South Carolina and is associated with negative care outcomes including missed HIV appointments. Lack of transportation is likely to further aggravate HIV disparities in the southern US. Local and statewide efforts such as expanding public infrastructure and developing ride-sharing approaches should be prioritized for underserved and low-resource communities.

PESUF17
Digital health and rights of young adults living with HIV and young key populations in Ghana, Kenya and Vietnam: a participatory action research study

C. Nininahazwe[1], S.L.M. Davis[2], E. Ayeh[3], G. Caswell[4], D.D. Dong[5], T. Ha[6], T. Imalingat[7], I.E. Kpodo[8], N. Mjwana[4], A. Muthui[7], T. Pham[5], M. Podmore[6], T.J. Sandset[9], N. Were[7], A. Maleche[7]
[1]Global Network of People Living with HIV (GNP+), Amsterdam, Netherlands, the, [2]Graduate Institute of International and Development Studies, Global Health Centre, Geneva, Switzerland, [3]Ghana National Association of People Living with HIV (NAP+ Ghana), Kumasi, Ghana, [4]Global Network of People Living with HIV (GNP+), Cape Town, South Africa, [5]Vietnam Network of People Living with HIV (VNP+), Hanoi, Viet Nam, [6]STOPAIDS, London, United Kingdom, [7]KELIN, Nairobi, Kenya, [8]Ghana National Association of People Living with HIV (NAP+ Ghana), Accra, Ghana, [9]University of Oslo, Centre for Sustainable Healthcare Education, Oslo, Norway

Background: Digital health is rapidly scaling up in low- and middle-income countries, transforming access to health services for young people living with HIV and key populations.
However, human rights experts have highlighted related threats to privacy, autonomy and equity, given weak governance of digital platforms.
Methods: To understand the experience of young adults with digital health and how they see their human rights, we conducted a qualitative study in Ghana, Kenya and Vietnam using a participatory action research approach. We combined a legal and policy review of digital health governance and access in each country, with digital ethnography, focus group discussions, and key informant interviews.
Global and national networks of people living with HIV, AIDS advocates, youth activists and human rights lawyers collaborated with anthropologists in design, data-gathering, analysis, and drafting of policy recommendations.
Results: During the Covid-19 pandemic, the 200 respondents described a major shift onto mobile apps and social media platforms to gain information and advice on sexual and reproductive health, which would otherwise be inaccessible to them due to stigma and confidentiality concerns.
In an ungoverned environment of conflicting health advice, many reported relying on social media influencers as trusted sources. Young adults shared positive experiences of empowerment and peer support online, and a growing interest in cybersex as "safe sex". They also reported online and offline harm, including data breaches, extortion, cyberbullying and censorship.
Most respondents lacked basic understanding of online security or data management. They expressed an interest to learn more, and to have a greater voice as youth in design and governance of digital technologies.
Conclusions: To achieve the aim of ending AIDS as a public health threat, more robust rights-based digital policy and governance are critically needed, complemented by digital literacy training for young people. Young people should be fully empowered and engaged in design, planning and governance of digital technologies used for health.

Human rights of people living with HIV and key populations

PESUF18
Understanding intersectional oppressions experienced by Immigrants and Refugees Living with HIV: Equity and social determinants of health lenses

R. Dhungel[1], K. Karki[2], J. Wang[3]
[1]The University of the Fraser Valley, School of Social Work and Health and Community Studies, Abbotsford, Canada, [2]University of the Fraser Valley, School of Social Work and Health Services, Abbotsford, Canada, [3]University of Calgary, Phychology, Calgary, Canada

Background: This presentation examines the intersectional oppression experienced by Immigrants and Refugees Lining with HIV (IRLWH) in Alberta, Canada with a focus on COVID-19 pandemic.
The pandemic has had an unprecedented impact on IRLWH. In response, the Public Health Agency of Canada has expanded its list of risk factors to include occupational, socio-economic, and other life circumstances that increase risk for COVID-19 infection and severe outcomes. This is certainly an advance; however, gaps continue to exist. By recognizing the limited extant knowledge in relationship to the COVID-19 in particular in Alberta, a community-based study was designed.
The primary goal of the collaboration was to critically examine the challenges faced by IRLWH with a particular focus on the mental health and psychosocial wellbeing of IRLWH during the pandemic.
Methods: We employed the concurrent parallel mixed-methods approach. Quantitative data were collected using a self-developed survey (n=124), and qualitative data were collected through three photovoice sessions (n=13) among IRLH across Alberta between May 2021 and December 2021. The survey and the photovoice sessions assessed/captured the experiences of the IRLH on social determinants of health and its impacts on mental health and social wellbeing, both prior to and during the COVID-19.
Results: This study claimed that national HIV policies, programs and services do not address their issues, including affordable housing, food security/ employment opportunities, health plan, and racism, impacted on their mental health.

These results corroborated the findings from the surveys, for instance 51.5% reported having issues accessing healthcare services during COVID-19 compared to 38.4% before the COVID-19 pandemic. Similarly, 45.4% reported having difficulty accessing an HIV organization during the COVID-19 pandemic compared to 35.3% before the pandemic.

We also found that about 58% reported having problems finding housing services during COVID-19 compared to 47.5% before COVID-19.

Conclusions: This study found that COVID-19 had escalated their vulnerabilities to mental health and socio-economic marginalization. Based on the findings of the results, we developed the "Emerging community-led transformative HIV post COVID-19 Model" which speaks to the need of the active involvement of border communities including policy makers, health professionals, practitioners, educators and communities at large with IRLWH in addressing the challenges experienced.

PESUF19

Association between LGBTI+ health equity and achieving UNAIDS 2030 targets: findings from a global study of fast-track cities

C. Prachniak-Rincón[1], J.M. Zuniga[1,2]

[1]International Association of Providers of AIDS Care (IAPAC), Washington, United States, [2]Fast-Track Cities Institute, Washington, United States

Background: Lesbian, gay, bisexual, transgender, and intersex (LGBTI+) individuals face inequities with respect to HIV prevalence, syndemic and comorbid conditions, and accessing services. Progress on LGBTI+ equity is essential to meeting the UNAIDS goals that at least 95% of people living with HIV know their status, 95% of those individuals are on treatment, and 95% of those individuals are virally suppressed.

Methods: Relevant laws and policies for LGBTI+ equity were assessed in 32 Fast-Track Cities. Key informants (131) from these cities were surveyed on LGBTI+ issues using a Likert scale. These responses were averaged and trends were assessed at regional and global levels.

The results were then compared to the cities' average percentage across the three 95 targets. Cities were divided into those with 95-95-95 averages below 85% ("limited progress group"), between 86% and 90% ("mid-progress group"), and at or above 91% ("high progress group").

Results: Cities in the limited progress group had lower LGBTI+ policy scores (2.27, wherein 0 was least inclusive and 4 was most inclusive) than did the mid-progress (2.33) or high progress (3.08) groups of cities.

Similarly, the limited progress group had the lowest-rated LGBTI+ primary care and HIV care, and the most serious problems with respect discrimination, according to key informants. In contrast, the high progress group of cities had the highest levels of LGBTI+ inclusive care and lower levels of discrimination.

Group	Primary care	HIV care
Limited progress	3.08	3.75
Mid-progress	3.24	3.89
High progress	3.64	4.10

Table. Quality of LGBTI+ care (1 = "poor," 5 = "excellent")

Group	Sexual orientation discrimination	Gender identity discrimination
Limited progress	2.85	3.12
Mid-progress	2.73	3.08
High progress	2.19	2.69

Table. LGBTI+ discrimination (1 = "not a problem," 4 = "serious problem")

Conclusions: While this study did not explore causality, an association was found between progress on the 95-95-95 targets and inclusive LGBTI+ policies, better LGBTI+ care, and less discrimination.

Additional research, including surveying LGBTI+ communities directly and using larger sample sizes, could further contribute to knowledge of LGBTI+ health at the local level and aid cities in ending HIV.

PESUF20

Human rights violations against key populations in South Africa Public health facilities: findings from the Ritshidze Community-led Monitoring Programme

N. Mavasa[1,2], N. Rambau[1], M. Sebotsa[1], S. Sibisi[1], L. Rutter[3], J. Sherwood[4]

[1]Ritshidze Community-Led Monitoring Project, Johannesburg, South Africa, [2]Treatment Action Campaign, Johannesburg, South Africa, [3]Health GAP, Johannesburg, South Africa, [4]amfAR, The Foundation for AIDS Research, Washington DC, United States

Background: Members of key populations (KPs), including men who have sex with men (MSM), sex workers (SW), trans* people, and people who use drugs (PWUD), have increased vulnerability to HIV and experience legal and social barriers to healthcare. The HIV response is dependent on the healthcare system's ability to serve these populations, yet they are often the most excluded from care.

Through the Ritshidze Community-led Monitoring Programme we track the quality of healthcare for KPs in South Africa with implications for improving services and rectifying abuses.

Methods: Key populations were recruited for a cross-sectional survey via community-based snowball sampling in 18 PEPFAR-supported districts across seven provinces from August to October 2021. Initial participants were community-recruited and had previously engaged in Ritshidze qualitative data collection. Survey data on KP healthcare experiences were collected electronically by trained KP data collectors. Data were analysed using descriptive statistics for key service quality and human rights indicators by population and province.

Results: A total of 5,979 KP members, including MSM (n=1,476), PWUD (n=2,397), SW (n=1,344) and trans* people (n=762) were surveyed. Over the past year, 14% of MSM (n=207), 13% of SW (n=175), 12% of PWUD (n=288), and 11% of trans* people (n=84) reported being denied health services at a public health facility (PHF) because they are a member of a key population. Denial of services was highest in Limpopo (30% n=218) and KwaZulu-Natal province (20% n= 81). Overall, 24% (n=849) of KPs reported experiencing privacy violations at a facility, including disclosure of their HIV and KP member status.

Among those who were not receiving services at a PHF, the primary reasons were lack of friendly services (66%, n=114), lack of privacy (49% n=84) and unsafe conditions (26%, n=45).

Conclusions: Human rights violations and unfriendly services at PHFs were frequently reported by KP members in South Africa. These violations are a likely detriment to the health of KP members as well as to the broader HIV and public health outcomes in South Africa. Denial of healthcare to KPs in South Africa violates their Constitutional right to access health and requires immediate attention by the National Department of Health.

PESUF21

If not now, when? A unique opportunity to reduce HIV-related stigma & discrimination, criminalization & other human rights-related barriers

R. Jurgens[1], A. Iovita[1], H. Lim[1], A. Shaw[1], N. Avani[1]
[1]*Global Fund to Fight AIDS, TB and Malaria, Community, Rights and Gender, Geneva, Switzerland*

Background: Stigma and discrimination (S&D), criminalization, gender inequality and other human rights (HR) barriers have impeded access to HIV services and attainment of global HIV goals. Despite UN Member States´ commitments to support programs that reduce such barriers, until recently these programs had nowhere been sufficiently scaled up. To address this, the Global Fund's "Breaking Down Barriers" (BDB) initiative has been supporting and evaluating the scale-up of seven key HR programs and undertaken sustained efforts to increase country ownership of HR problems and solutions.

Description: 20 countries are part of BDB: Benin, Botswana, Cameroon, Côte d'Ivoire, DRC, Ghana, Honduras, Indonesia, Jamaica, Kenya, Kyrgyzstan, Mozambique, Nepal, Philippines, Senegal, Sierra Leone, South Africa, Tunisia, Uganda, Ukraine. In these countries, GF investment in HR programs increased more than 12-fold, to levels never seen before, from $10.57 million in 2014-16 to 130 million in 2020-22. Scale, scope and quality of programs, as assessed by independent researchers, also significantly increased. All countries developed country-owned, costed strategies to address HR barriers and established HR working groups to oversee and coordinate implementation.

Lessons learned: Elevating HR to one of four strategic objectives in the 2017-22 GF Strategy enabled the BDB initiative. Providing financial incentives, establishing programmatic conditions, making available long-term TA to assist development of national strategies and scale up of HR programs, and closely monitoring and evaluating the initiative, have been critical.

The initiative itself has evolved, integrating lessons learned and expanding partnerships in countries and at the global level.

Conclusions/Next steps: The experience of this initiative is providing unprecedented, well-evaluated and soundly costed models for rights-based approaches to HIV services. Already, the new GF Strategy (2023-2028) is integrating lessons learned, with an even greater focus on HR, equity and gender inequality and commitment to even greater action against S&D and criminalization and greater support for community-led efforts.

There is also unprecedented commitment to addressing these issues in the Global AIDS Strategy (2021-2026) and there are new and promising initiatives specifically to eliminate S&D. This provides for a unique opportunity we cannot afford to miss to make a real difference, with great expected benefits for health and human rights.

PESUF24

Capacity strengthening of local civil society organizations offering HIV services: learning experiences from Liberia

P. Gobah[1], G. Kamanga[1], C. Kerbay[1], L. Harris[1], N. Fosua Clement[1], D. Darrow de Mora[2], H. Rodriguez Sherman[2]
[1]*FHI 360, Monrovia, Liberia,* [2]*FHI 360, Washington DC, United States*

Background: With support from PEPFAR and USAID, the FHI 360-led LINKAGES project and subsequent EpiC project implemented a comprehensive package of HIV prevention, care, and treatment services among 10 civil society organizations (CSOs) serving key populations (KPs) in Montserrado County, Liberia. When LINKAGES began, the technical and management capacity of these CSOs was limited. LINKAGES, in collaboration with Pact and EpiC, implemented capacity-building innovations to enhance technical delivery of HIV Services and improve organizational management systems.

Description: The project conducted baseline capacity-building assessments with all 10 CSO partners using two standardized toolkits: the integrated technical and organizational capacity assessment and the Organization Performance Index (OPI). Institutional strengthening plans were then developed and implemented to address the issues identified and monitor progress.

Project engagement with the 10 CSO partners around internal control systems, operational management, and governance helped foster ownership of HIV service delivery in Montserrado County.

Lessons learned: From April 2019 through September 2021, EpiC Liberia trained all 10 CSOs in HIV community interventions to empower peer outreach workers, people living with HIV (PLHIV), and KPs, including the members of 23 HIV support groups, to understand and manage their needs, risks, and rights regarding HIV services.

The project also trained CSO leadership in organizational system development, which focused on organizational management and operations policies, resource mobilization, sustainability, partnership, and networking to enable delivery of optimal HIV services.

At the first OPI assessment conducted to measure performance and impact, two out of four performance measurements — "efficiency" and "effectiveness" — achieved the maximum score of 4.0. "Relevance in meeting the needs of beneficiaries" scored 2.5 and "sustainability" scored 1.0.

Measures to improve relevance and sustainability are being implemented, and some CSOs already have won new grants and developed successful small business enterprises. These efforts contributed to reaching 15,000 individuals with a comprehensive HIV service package, testing 12,000 individuals for HIV, and identifying 850 individuals as living with HIV, 94% of whom were linked to treatment.

Conclusions/Next steps: Ongoing Support for CSO capacity building in technical and management operations facilitated the building of a strong KP HIV program and network of KPs and PLHIV.

Availability and access to harm reduction (including OST and NSP)

PESUF22

Evaluating legal obstacles to provider-assisted injection in Ontario's Supervised Consumption Services

M.F. Sana Ullah[1], I. Annamanthadoo[1], S. Ka Hon Chu[1]
[1]*HIV Legal Network, Toronto, Canada*

Background: Approximately 14% of new HIV infections in Canada were acquired through injection drug use,[1] and research indicates significantly higher HIV prevalence among people who require assistance injecting than those who do not. Provider-assisted injection within supervised consumptions services (SCS) could reduce this risk, particularly for people with disabilities, women, and youth.

However, concerns about providers' legal liability impede the provision of this critical service within SCS. We interviewed SCS providers in Ontario to identify key questions and concerns raised by SCS nurses and other SCS staff about potential criminal liability, civil liability, and professional discipline associated with providing assisted injection.

[1] "The epidemiology of HIV in people who inject drugs in Canada" (2018) at 2, online (pdf): *CATIE* <www.catie.ca/sites/default/files/fs-epi-idu-EN-2018-08-15.pdf>.

Methods: SCS providers (n = 11) were interviewed via videoconference in the fall of 2021. Nine respondents identified as nursing staff, one as management staff and one as a peer worker. SCS were selected from across the province to ensure geographical representation.

Interviews were transcribed and consolidated. Respondents were asked to share their experience with assisted injection in SCS, including whether they observed a need for assisted injection, the consequences of refusing assistance, and the perceived legal barriers to providing assisted injection.

Results: All respondents observed a significant need for provider-assisted injection and believed that it should be permitted. However, respondents identified several barriers that impede their ability to provide this service, including the threat of professional discipline (by the nursing regulatory body, for nurses) and a lack of clear guidelines condoning the practice from regulatory bodies and/or employers.

Few respondents expressed serious concern about civil or criminal liability. Respondents reported that clients seeking provider-assisted injection most often turn to peer-assisted injection to meet this need – although such assistance is not always accessible or safe.

Conclusions: There is a significant unmet need for provider-assisted injection within Ontario SCS. Although SCS staff are willing and competent to provide this support, legal and non-legal barriers mean that provider-assisted injection is unavailable to people who use drugs in Ontario, hampering the ability of staff to engage in vital HIV and overdose prevention work.

The impact of scaling up human rights interventions on reducing inequality and increasing access to care and treatment for HIV and TB: mid-term results from the Breaking Down Barriers initiative

J. Amon[1], N. Sun[2], S.K.H. Chu[3], J. Csete[4], R. Elliott[3], M. Golichenko[3], C. Kazatchkine[3], D. Lohman[5], J. Mabilat[3], M. McLemore[6], K. Hinman[2], A. Iovita[7], H. Lim[7], A. Shaw[7], R. Jurgens[7]
[1]*Drexel University Dornsife School of Public Health, Philadelphia, United States,* [2]*Drexel University, Philadelphia, United States,* [3]*HIV Legal Network, Toronto, Canada,* [4]*Columbia University, New York, United States,* [5]*Consultant, New York, United States,* [6]*Consultant, Philadelphia, United States,* [7]*Global Fund, Geneva, Switzerland*

Background: The Global Fund's *Breaking Down Barriers* (BDB) initiative provides support for countries to scale-up to comprehensive programs to remove human rights-related barriers to HIV and tuberculosis (TB) services, with the aim to increase the effectiveness of Global Fund grants and ensure that health services reach those most affected.

Description: A mid-term evaluation, conducted in 2020-21, examined progress in scaling up programs identified as effective in reducing human rights-related barriers to health services for HIV and TB in 20 BDB countries (Benin, Botswana, Cameroon, Cote d'Ivoire, Democratic Republic of Congo, Ghana, Honduras, Jamaica, Indonesia, Kenya, Kyrgyzstan, Mozambique, Nepal, Philippines, Senegal, Sierra Leone, South Africa, Tunisia, Uganda, Ukraine).

These included programs to: reduce HIV-related stigma and discrimination; train health care workers on human rights and ethics; sensitize lawmakers and law enforcement; provide legal literacy; provide HIV-related legal services; monitor and reform laws, regulations and policies; and reduce discrimination against women and girls. For tuberculosis, in addition to these programs, it also included programs that: protect confidentiality and privacy in TB services; mobilize and empower TB patient and community groups; and improve TB services in prisons and other closed settings.

The evaluation included both qualitative and semi-quantitative assessment, focusing upon measuring scale up of programs to ensure nationwide coverage and identifying emerging evidence of impact.

Lessons learned: All countries saw progress in removing human rights-related barriers to HIV and TB services. For HIV, Ukraine had the highest coverage of programs to reduce barriers, and Sierra Leone had the greatest increase compared to baseline, followed by Jamaica, Senegal, Cameroon, and Mozambique. For TB, program coverage was highest in Ghana, and increases in coverage were greatest in Ukraine and Côte d'Ivoire. Evidence of impact was found in relation to success in challenging rights violations in the courts, countering the criminalization of key populations, addressing discrimination and stigma, advancing harm reduction programs, working with police and responding to gender-based violence.

Conclusions/Next steps: Across a diverse set of countries, the scale up of human rights-based programs is possible and effective in reducing barriers and increasing access to HIV and TB services.

Immunotherapy (including broadly neutralizing antibodies)

PEMOA26

Developing a novel HIV cure strategy: retargeting potent cytotoxic T cells to kill HIV-infected cells

E.F. Iversen[1,2], C.V. Konrad[1,2], J.D. Gunst[2], I.M. Johannsen[1,2], L.J. Østergaard[1,2], O.S. Søgaard[1,2], M.H. Schleimann[2], M. Tolstrup[1,2]
[1]*Aarhus University, Institute of Clinical Medicine, Aarhus, Denmark,* [2]*Aarhus University Hospital, Department of Infectious Diseases, Aarhus, Denmark*

Background: Cytotoxic T lymphocytes (CTL) are potent killers of virus infected cells. In most HIV-1-positive people, HIV-specific CTLs are exhausted with limited capacity to control or eliminate HIV-1 infection. Therefore, we developed a novel immunotherapy concept in which potent *de novo* vaccine-induced effector CTLs can be redirected to target and eliminate HIV-1-infected cells.

Methods: We developed a bispecific molecule (RoVER: **Re**director **of** **V**accine-induced cytotoxic T **E**ffector **R**esponses) comprising two functionally distinct domains:
1. A scFv-domain targeting HIV Env, and
2. An HLA-I molecule carrying a yellow fever vaccine epitope.

Following Yellow Fever (YF-17D Stamaril, Novartis) vaccination of 52 healthy volunteers, YF epitope-specific CTL responses were quantified by tetramer staining and multicolour flow cytometry. The ability of RoVER to mediate killing of HIV-infected cells by linking YF vaccine-induced CTLs was assessed in a series of killing assays. As target cells, Raji-Env and autologous CD4+ cells infected *in vitro* with a full-length HIV-1-egfp were used. Moreover, extracellular release of IFN-γ, Granzyme B and TNF-α were analysed by mesoscale multiplex assays.

Results: YF-17D vaccination induced strong epitope-specific CTL responses in all study participants. In HLA*A2 individuals, a mean of 2.8% of CTLs (range 0.1-10.3%) targeted the immunodominant $NS4B_{214-222}$ epitope. RoVER-mediated redirection of NS4B-specific effector CTLs to Raji-Env cells resulted in killing of target cells regardless of whether the two domains of RoVER were linked through streptavidin or recombinantly expressed. Redirection to HIV-egfp-infected autologous CD4 target cells resulted in 65% killing at E:T ratio 3:1. In contrast, no target killing was observed us-

ing autologous CTLs obtained prior to YF-17D vaccination or without exposure to RoVER. Moreover, RoVER-mediated target cell killing could be achieved using different HLA-molecules and YF epitopes. Lastly, target cell killing was associated with pronounced secretion of IFN-γ.

Conclusions: We have developed a novel immunotherapy concept in which epitope-specific CTLs induced by vaccination can be redirected towards HIV-infected cells. This novel technology is highly specific and easily adaptable to recognize any target of interest while obviating the need for *ex vivo* modification and expansion, thus holding great potential for various diseases.

PEMOA27

Clinical and immunometabolic patterns determining efficacy of DC-treatment reinvigorating HIV-1-specific CD8+ T cells in PLWH

M. Calvet-Mirabent[1,2], I. Sánchez-Cerrillo[1,2], N. Martín-Cófreces[1,2,3], H. de la Fuente[1,3], I. Tsukalov[2], C. Delgado-Arévalo[1,2], M.J. Calzada[2], I. de los Santos[4,5], J. Sanz[4,5], L. Background: Heterogeneous dysfunctional states of CD8+ T cells in people living with HIV-1 (PWLH) has limited the efficacy of dendritic cell (DC)-based immunotherapies. Here, we studied associations between improved functional response to Gag-loaded adjuvant-primed DCs of CD8 T cells from PLWH with ART duration, memory subset distribution and exhaustion and metabolic profiles in these cells.

Methods: A cohort of n=49 PLWH on ART with undetectable plasma viremia and CD4+ T counts above 400cells/ml were recruited. Monocyte-derived DC were activated with Poly I:C and 2´3´c-diAM(PS)2 adjuvants in the presence of a pool of HIV-1 Gag peptides and co-cultured with autologous CD8+

T cells. Induction and polyfunctionality of HIV-1 specific CD8+ T responses was evaluated by IFNg and CD107a expression by FACS. Functionality of DC-stimulated CD8+ T cells was evaluated by co-culture with autologous CD4+ T cells and the ability to reduce proportions of p24+ CD4+ T cells. Individual or combined anti-PD1, TIGIT, TIM3 antibodies and Metformin were used in some functional assays. Characterization of CD8+ T cell memory subset and exhaustion markers was analyzed by FACS. Metabolic profiles of CD8+ T cells were analyzed by Seahorse.

Results: Polyfunctionality and functional capacities to eliminate p24+ CD4+ T cells of HIV-1 specific CD8+ T cell responses from PLWH on ART for more than 10 years (LT-ARTp) significantly improved after activation with adjuvant-engineered DC *in vitro* (p=0.001 and p=0.0039; respectively).

In contrast, CD8+ T cells from PLWH on ART for less than a decade (ST-ARTp) were less responsive to DC (p=0.0024) and unable to increase cytotoxic function (p=0.0156). This was associated with lower frequencies of central memory CD8+ T cells, increased co-expression of PD1 and TIGIT (p=0.0362) and reduced mitochondrial respiration and glycolytic induction after TCR activation (p=0.002).

In contrast, enrichment on TIM3+ PD1- cells (p=0.001) and preserved glycolytic induction (p=0.0005) was observed in CD8+ T cells from LT-ARTp.

Finally, combined treatment of anti-PD1, anti-TIGIT antibodies and metformin restored cytotoxic properties of dysfunctional CD8+ T cells from ST-ARTp (p=0.0156).

Conclusions: We identified new immunometabolic parameters potentially useful to personalize DC-based HIV-1 vaccines and improve specific CD8+ T cell response in different PLWH populations.

Pharmacologic intervention to reduce chronic inflammation in people with HIV

S. Rodriguez-Mora[1], G. Casado-Fernandez[1], M. Manzanares[1], J. Canton[2], L. Vigon[1], F. Ramos-Martin[1], M. Torres[1], C. Hoffmann[3], C. Wyen[4], M. Cervero[2], M.A. Murciano-Anton[5], V. Planelles[6], M. Coiras[1]

[1]Instituto de Salud Carlos III, Madrid, Spain, [2]Severo Ochoa University Hospital, Madrid, Spain, [3]ICH Study Center, Hamburg, Germany, [4]University Hospital of Cologne, Cologne, Germany, [5]Laín Entralgo Health Center, Madrid, Spain, [6]University of Utah School of Medicine, Utah, United States

Background: Chronic inflammation and persistent immune activation are critical for HIV-1 disease pathogenesis and progression. HIV-infected monocyte-derived macrophages (MDMs) contribute to long-lived reservoirs and chronic inflammation in people with HIV (PWH) due to persistent release of proinflammatory mediators. Tyrosine kinase inhibitor dasatinib, which is used to treat chronic myeloid leukemia (CML), inhibits HIV-1 infection in CD4+ T cells by preserving SAMHD1 antiviral activity. SAMHD1 also downregulates interferon (IFN) and other inflammatory responses to viral infections.

Our objective was to evaluate if dasatinib may control both infection and proinflammatory effects of HIV-1 on MDMs from PWH, as well as reduce the levels of proinflammatory cytokines in plasma of PWH on ART and dasatinib.

Oral abstracts

Poster exhibition

Late-breaker abstracts

Author Index

Methods: 15 ART-treated PWH, 3 PWH with CML on ART and dasatinib, and 11 healthy donors were recruited. CD14+ cells from PBMCs were differentiated to MDMs and then infected with JR_FL_Renilla strain for 48h with or without dasatinib. HIV-1 infection was analyzed by flow cytometry. SAMHD1 phosphorylation and synthesis of IFNγ and TNFα were analyzed by flow cytometry after stimulation with lipopolysaccharide (LPS). Plasma cytokines were quantified by Luminex.

Results:

1. Dasatinib reduced 3.0-(p=0.0104) and 2.1-fold the LPS-induced synthesis of IFNγ from MDMs of PWH and healthy donors, respectively. TNFα synthesis remained unchanged.
2. Plasma levels of proinflammatory cytokines IL-15, IL-18, IL-21, and IL-23 were reduced 2.17-, 1.55-, 1.61-, and 4.86-fold in PWH on ART+dasatinib, in comparison with ART-treated PWH. IFNβ was undetectable in plasma of PWH on ART+dasatinib.
3. Dasatinib reduced 1.8-(p=0.0420) and 2.6-(p=0.0459) fold SAMHD1 phosphorylation in MDMs from PWH and healthy donors, respectively.
4. Dasatinib interfered with proinflammatory NF-κB-dependent transcriptional activity (p<0.0001).
5. HIV-1 infection was reduced 2.4-(p=0.0006) and 5.9-fold in MDMs from PWH and healthy donors, respectively, after treatment with dasatinib.

Conclusions: New therapeutic interventions are needed to reverse chronic inflammation caused by HIV-1 persistence. Dasatinib reduced the levels of proinflammatory cytokines in plasma of ART-treated PWH and reverted SAMHD1 constitutive phosphorylation of MDMs, protecting them from HIV-1 infection and reducing their inflammatory potential.

The use of dasatinib as adjuvant of ART would decrease the inflammatory environment characteristic of chronic infection, thereby improving health of PWH.

ARVs, small molecules and immunomodulating agents - pharmacodynamics and pharmacokinetics

In vitro release and in vivo pharmacokinetics of antiretroviral drugs from ultra-long-acting polymeric implants: towards better outcomes for HIV prevention and treatment

P. Maturavongsadit[1], R. Shrivastava[1], A. Prasher[1], S.A. Howard[2], C. Sykes[2], M. Cottrell[2], A. Kashuba[2], S.R. Benhabbour[1]

[1]University of North Carolina at Chapel Hill, UNC_NCSU Joint Department of Biomedical Engineering, Chapel Hill, United States, [2]University of North Carolina at Chapel Hill, Eshelman School of Pharmacy, Chapel Hill, United States

Background: Long-acting pre-exposure prophylaxis or treatment formulations that can provide sustained drug release over weeks or months can potentially reduce the incidence of new HIV infections and improve adherence.

Methods: Ultra-long-acting (ULA) biodegradable, removable in-situ forming implants (ISFIs) and polymeric solid implants (PSIs) were generated via phase inversion upon injection (ISFIs) or using a simple process combining phase inversion and compression (PSIs; **Fig. 1A**). These formulations can accommodate one or more antiretrovirals (ARVs) in a single injection or implant. ISFIs and PSIs of Cabotegravir (CAB) and Lamivudine (3TC) were tested for in vitro release (n=3) by HPLC, and in vivo pharmacokinetics in BALB/c mice (n=7) to establish correlations of CAB and 3TC, which have distinct physicochemical properties (**Fig. 1B**). Plasma CAB and 3TC concentrations were quantified by HPLC-MS/MS with a lower limit of quantification (LLOQ) of 25 and 0.1ng/ml, respectively.

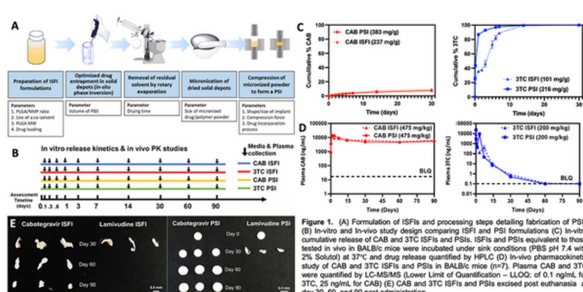

Figure 1. (A) Formulation of ISFIs and processing steps detailing fabrication of PSIs (B) In-vitro and In-vivo study design comparing ISFI and PSI formulations (C) In-vitro cumulative release of CAB and 3TC ISFIs and PSIs. ISFIs and PSIs equivalent to those tested in vivo in BALB/c mice were incubated under sink conditions (PBS pH 7.4 with 2% Solutol) at 37°C and drug release quantified by HPLC (D) In-vivo pharmacokinetic study of CAB and 3TC ISFIs and PSIs in BALB/c mice (n=7). Plasma CAB and 3TC were quantified by LC-MS/MS (Lower Limit of Quantification – LLOQ: of 0.1 ng/mL for 3TC, 25 ng/mL for CAB) (E) CAB and 3TC ISFIs and PSIs excised post euthanasia at day 30, 60, and 90 post administration.

Results: CAB ISFIs and PSIs exhibited minimal burst release (~1%) followed by sustained zero order release both in vitro and in vivo (**Fig. 1C-D**). PSIs and ISFIs (475 mg/kg CAB) resulted in nearly identical plasma CAB levels with sustained zero order kinetics over 90 days (**Fig. 1D**). 3TC ISFIs and PSIs exhibited high burst (38% and 68% respectively) and reached complete release within 14 days (**Fig. 1C**). PSIs and ISFIs (200 mg/kg 3TC) demonstrated nearly identical 3TC plasma concentrations; however, plasma 3TC rapidly declined to below LLOQ at day 60 (**Fig. 1D**). Drug physicochemical properties also influenced in vivo implant degradation rate. 3TC (log P -1.5, pKa 1.09) ISFIs

and PSIs exhibited faster degradation in vivo compared to CAB (log P 1.04, pKa 10.04) and reached complete degradation by day 60 (**Fig. 1E**).

Conclusions: ULA tunable, biodegradable ISFIs and PSIs can accommodate ARVs of distinct physicochemical properties and exhibited near identical plasma drug concentrations for both CAB and 3TC when administered at equivalent doses.

SARS-Cov2 vaccines

Serological responses to SARS-CoV2 vaccination in people with HIV: the SCAPE-HIV study

T.J. Barber[1,2], D. Peppa[3,1], F. Burns[2,1], J.R.G. Brown[4], C. Smith[4], N. Hemat[1], S. Madge[1], A. Hunter[1], M. Lipman[1], S. Bhagani[1], T. Mahungu[1], M.A. Johnson[1]

[1]Royal Free London NHS Foundation Trust, Ian Charleson Day Centre, London, United Kingdom, [2]University College London, Institute for Global Health, London, United Kingdom, [3]University College London, Institute of Immunity & Transplantation, London, United Kingdom, [4]University College London, London, United Kingdom

Background: People with HIV (PWH), despite efficient virological suppression on antiretroviral therapy (ART) often display blunted responses to vaccination. There is a need to establish correlates of vaccine efficacy in PWH to tailor vaccine strategies to maximise protection against disease and new emerging variants.

The SCAPE-HIV Study (SARS-CoV-2 antibody prevalence in an HIV cohort) was established to determine antibody responses in PWH following SARS-CoV2 infection and vaccination and evaluate parameters/clinical variables relating to antibody seropositivity.

Methods: SCAPE-HIV is an ongoing cross-sectional study in our adult PWH cohort. This interim analysis is restricted to 384 participants recruited between July-September 2020 reporting 2 doses of SARS-CoV2 vaccines. Participants completed questionnaires about sociodemographics, medical history, prior COVID19, and SARS-COV2 vaccine uptake. Anti SARS-CoV2 spike and nucleocapsid antibodies were quantified using commercial Roche assays at least 2 weeks after the last vaccine dose.

Results: 73.69% white; 82.55% male; 96.35% virally suppressed. 382/384 (99.47%) generated SARS-CoV2 anti-spike antibodies. 2/384 (organ transplant recipients) failed to seroconvert post two vaccines. Antibodies to nucleocapsid detected in 80/384 (20.8%) consistent with prior infection. 91/384 (23.69%) had an anti-spike titre that fell below the lowest level reported in a health care workers study (<400 after second dose vaccine). Low titre was associated with age ^{3}60y (p=0.018). No clear associations were observed with current CD4 count or CD4 nadir. Participants with history of SARS-CoV2 infection had higher anti-spike antibody titres (p<0.001). 7.8% of participants had an anti-spike titre of <100. These were more likely to be on immunosuppressants (p=0.016), have CD4:CD8 ratio <0.5 (p=0.009) and/or have other medical conditions (p=0.018).

Conclusions: SCAPE-HIV is ongoing. This preliminary analysis shows high levels of seroconversion in our study population (majority of whom are well controlled on ART) and highlights an inverse relationship between age and antibody responses. Immunosuppressants, receipt of a solid organ transplant, and a low CD4:CD8 ratio may all be indicators of poor/no response to SARS CoV2 vaccination. It remains to be determined how antibody titres correlate with functional protection against reinfection and cross protection against variants of concern, especially in people with suboptimal serological responses.

PEMOA35

Side-by-side comparison of SARS-CoV-2 neutralizing antibody responses after various COVID-19 vaccine regimens

Background: Waning immunity and emergence of SARS-CoV-2 variants impact COVID-19 vaccine efficacy. Here, we studied longitudinally the humoral response induced by Pfizer, AstraZeneca, Janssen, Coronavac and Sputnik Vaccines, with or without booster doses. We also asked how breakthrough Omicron infection in Pfizer-vaccinated individuals enhances antibody levels and cross-reactivity.

Methods: We analyzed 349 sera from individuals immunized with five vaccines, Pfizer/BioNTech (BNT162b2), AstraZeneca (ChAdOx1 nCoV-19), Janssen (Ad26COV2.S), Sinovac biotech (Coronavac) or Sputnik (Gam-COVID-Vac). We also examined in 92 sera the impact of a Pfizer booster dose in individuals immunized with Pfizer, Janssen or Sinovac regimens. Samples were collected up to 13 months after the first injection, and 5 months after the boost. We measured anti-S antibodies by flow cytometry with the S-Flow assay, and neutralization titers against infectious D614G, Alpha, Beta, Delta and Omicron isolates.

Results: Administration of two doses of Pfizer, AstraZeneca, Sputnik vaccines, or an heterologous AstraZeneca/Pfizer regimen, induced seroconversion of 95% of individuals and neutralization activity against D614G, Alpha, Beta and Delta, but not Omicron. Janssen and Sinovac

vaccines elicited lower levels of anti-S antibodies, and no detectable neutralization of Delta and Omicron. During the first 8 months, the antibody levels and neutralization activity progressively declined with all vaccines. A booster dose of Pfizer strongly increased antibody response and elicited neutralizing antibodies against Omicron.
However, titers were 8- to 36- fold lower against Omicron relative to Delta. We observed a waning of the humoral response after the boost and estimated that neutralizing antibodies against Omicron will no longer be detectable in the sera after 6 months. Breakthrough Omicron infections strongly increased the levels of cross-reactive antibodies with titers only 2.5-fold lower against Omicron compared to Delta.
Conclusions: Our results highlight differences between vaccines and support the use of an mRNA-based vaccine as a booster regardless of prior regimens. The duration of the neutralizing humoral response after the boost is estimated to be about 6 months. A high level of cross-reactivity is observed in Omicron breakthrough cases. Our data suggest that an Omicron-specific booster may improve cross-immunity.

PEMOA36

Immunogenicity of the BNT 162b2 mRNA vaccine against COVID-19 variants in people living with HIV on antiretroviral therapy in Malaysia

R. Rajasuriar[1], A. Kukreja[1], N.S. Zulhaimi[2], C.Y. Loh[2], C.S. Lee[2], W.Y. Ho[1], S. Shaharuddin[1], W.M.H. Wan Alias[1], J. I-Ching[3], S. Hisham[1], A. Ahsan[1], S.F. Syed Omar[1], A. Kamarulzaman[1]
[1]Centre of Excellence for Research in AIDS, University of Malaya, Kuala Lumpur, Malaysia, [2]Immunotherapeutics Laboratory, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia, [3]University of Malaya, Department of Medical Microbiology, Kuala Lumpur, Malaysia

Background: Few studies have explored the immunogenicity of COVID-19 vaccines in people living with HIV (PLWH) from low-middle income settings where late presentation to care may lead to persistent immune deficiencies despite antiretroviral therapy (ART).
In this study, we compared humoral immune responses following BNT162b2 mRNA primary vaccination in PLWH on ART to age-matched controls and explored the clinical correlates of immunogenicity.
Methods: This prospective study recruited PLWH on ART and HIV uninfected controls (≥18 years) attending vaccination appointments at University Malaya Medical Centre, Malaysia. All participants received two doses of the BNT162b2 vaccine 21 days apart and had serum collected at D0 and D35 after dose 1.
Immunogenicity was assessed by anti-S1 antibody levels (Elecsys Anti-SARS-CoV-2 S assay, Roche) and percent inhibition of neutralization against wild-type D614G, beta and delta variants using cPass SARS-CoV-2 Surrogate Virus Neutralization Test (GenScript). Participant characteristics were extracted from medical records. Clinical factors associated with immunogenicity markers were assessed using univariate non-parametric analyses.
Results: A total of 68 PLWH and 52 HIV-negative controls were recruited with a median age of 37 years. The majority were males (PLWH=96%, controls=64%).94% of PLWH had HIV RNA<50 copies/ml. Median nadir and current CD4 T-cell counts were 182 (44-351) cells/ul and 554 (361-790) cells/ul, respectively. All participants were seropositive (>0.8IU/ml) following vaccination and no difference in median anti-S1 antibody levels were observed at D35 in both groups (p=0.871).
Neutralising activity was lower in PLWH compared to controls for the beta (73.1% vs 83.1%, p<0.001) and delta variants (92.7% vs 95.1%, p=0.008) but not significantly different for the D614G variant. Older PLWH (≥45 years), CD4 T-cell counts <800 cells/ul and CD4:CD8 ratio <0.8 were associated with significantly lower inhibition activity against the beta and delta variants compared to controls (p<0.05). These factors however, had no impact on anti-S1 levels and inhibition activity against the wild-type D614G variant.
Conclusions: Older PLWH with suboptimal immune recovery on ART had lower immunogenicity compared to age-matched controls against variants of concern and should be prioritized for SARS-CoV-2 vaccine boosters. Larger studies are needed to examine clinical correlates of vaccine effectiveness among PLWH on ART.

PEMOA37

Vaccine scheme, age and previous COVID-19 predict humoral response to SARS-CoV-2 vaccination in HIV-infected indivudals

P. Gantner[1], A. Ursenbach[2], C. Cheneau[3], Y. Ruch[2], C. Melounou[3], P. Fischer[3], F. Danion[2], C. Bernard-Henry[3], N. Lefebvre[2], E. Rougier[2], C. Kaeuffer[2], Y. Hansmann[2], M.-J. Wendling[1], N. Meyer[4], S. Fafi-Kremer[1], D. Rey[3]
[1]Université de Strasbourg / Faculté de Médecine, Medical Virology, Strasbourg, France, [2]Hôpitaux Universitaires de Strasbourg, Infectious Diseases, Strasbourg, France, [3]Hôpitaux Universitaires de Strasbourg, HIV-Infection Care Center, Strasbourg, France, [4]Hôpitaux Universitaires de Strasbourg, GMRC, Strasbourg, France

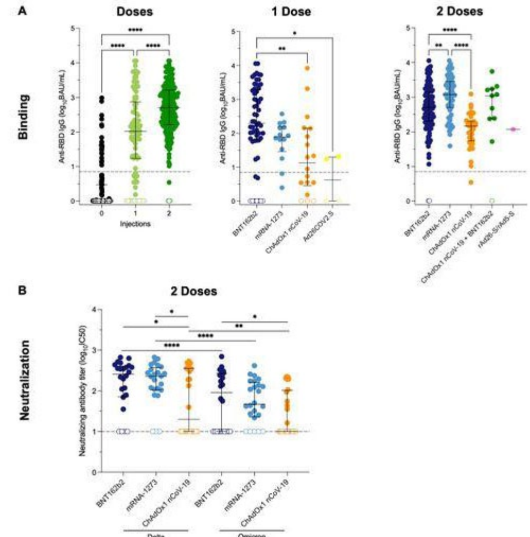
Background: Humoral response to SARS-CoV-2 vaccination in HIV-infected individuals on successful antiretroviral therapy (ART) remain undercharacterized. Here, we obtained anti-SARS-CoV-2 Receptor binding domain (anti-RBD) and neutralization titers detected after vaccination.
Methods: We collected longitudinal serum samples (pre- [D0] and post-vaccination era [M6]) from 447 participants (>200 CD4/mm^3) enrolled in the SECOVIHA study (NCT04515225, Strasbourg, France). We measured anti-RBD and neutralizing antibody titers (Delta and Omicron variants pseudoparticle-based assay), and analyzed predictors of humoral response.

Results: At D0 8.9% of individuals had developed COVID-19 and an additional 9.7% were subsequently infected at M6. Women were at higher risk of COVID-19 (logistic regression, p<0,01). At M6, 132, 93 and 222 participants had received 0, 1 or 2 doses of vaccine, respectively **(Fig1A)**. Median anti-RBD titers were of 2.0 and 3.2 log_{10}binding antibody unit [BAU]/mL after 1 and 2 doses.

Adjusting for time since last vaccine dose, a multivariate analysis showed that an older age was associated to lower anti-RBD titers (-0.09 log_{10}BAU/mL per 10-year increase) and COVID-19 prior to vaccination was associated with higher titers (+0.98 log_{10}BAU/mL).

Decreased titers were associated to an incomplete vaccine scheme (-1.06, -0.81 and -1.87 log_{10}BAU/mL for 1 dose of BNT162b2, mRNA-1273 and ChAdOx1nCov19, respectively) and 2 doses of ChAdOx1nCov19 vaccination (-0.27 log_{10}BAU/mL) but not with 2 doses of mRNA-1273 or heterologous ChAdOx1nCov19/ BNT162b2 compared to 2 doses of BNT162b2.

No HIV-related parameters were associated to humoral response. Delta and Omicron-neutralizing antibody titers from paired participants receiving 2 doses of BNT162b2, mRNA-1273 or ChAdOx1nCov19 (n=24 each) showed a higher neutralizing ability after mRNA-based vaccination and a weaker Omicron-neutralizing ability compared to Delta **(Fig 1 B)**.



Conclusions: Collectively, these data indicate that determinants of anti-SARS-CoV-2 humoral response in HIV-infected individuals on succesfull ART seem similar to those observed in the general population.

PEMOA38

People living with HIV who are receiving suppressive antiretroviral therapy mount strong humoral responses to two and three doses of COVID-19 vaccine

Background: Immune responses to COVID-19 vaccines, particularly to third doses, remain incompletely characterized in people living with HIV (PLWH).

Methods: We are monitoring immune responses to COVID-19 vaccination in a cohort of 99 adult PLWH and 152 controls, aged 22-88 years, in British Columbia, Canada. All PLWH were receiving suppressive ART, with median CD4+ T-cell counts of 715 (Q1-Q3 545-943) cells/mm^3at cohort entry. In samples collected one month after the second and third COVID-19 vaccine doses, we quantified serum antibodies against the SARS-CoV-2 spike protein receptor-binding domain (RBD) using the Roche Elecsys anti-SARS-CoV-2 assay, and measured viral neutralization activity in plasma against the original (USA-WA1/2020) and Omicron (BA.1) SARS-CoV-2 strains.

Results: We previously reported that, at one month following the second COVID-19 vaccine dose, and after adjustment for sociodemographic, health, and vaccine-related variables, HIV infection was not associated with a difference in either anti-RBD antibody concentration nor live virus neutralization activity compared to responses observed in controls.

In PLWH, there was no significant correlation between the most recent (or nadir) CD4+ T-cell count and vaccine responses after two doses. Rather, at this timepoint, older age, a higher burden of chronic health conditions, and having received two ChAdOx1 doses (as opposed to mRNA or heterologous regimens) were associated with lower responses.

One month following the third dose, anti-RBD serum antibodies increased by 0.4 $\log_{10}$ higher on average, and viral neutralization by four-fold higher on average, than values observed one month after the second dose, in both PLWH and controls (Wilcoxon paired test p<0.0001 for all within-group comparisons between time-points). Importantly, there was no significant difference between PLWH and controls in terms of the magnitudes of post-3rd-dose responses. In a subset of 24 participants assessed to date, the ability to neutralize Omicron after three doses was on average 8-fold lower than the pandemic founder strain (p<0.0001).

Conclusions: In PLWH with well-controlled viral loads on therapy and CD4+ T-cell counts in a healthy range, humoral responses to two and three COVID-19 vaccine doses are comparable to individuals without HIV. Third COVID-19 vaccine doses induce responses capable of neutralizing Omicron to some extent.

Safety outcomes among HIV-1 positive Zambian adults receiving Tenofovir Alafenamide combined with Dolutegravir: results from the VISEND clinical trial

D. Engamba[1,2], A. Kumar[1], N. Mbewe[1,2], S. Fwoloshi[3,2,4], G. Phiri[1], A. Mweemba[5,4], S. Sivile[1,4,2], M. Siwingwa[1,6], D. Kampamba[1,4], B. Simons[7], A. Hill[8], L. Chirwa[1], C.W. Wester[9,10], L. Mulenga[1,2,4,10]

[1]*University Teaching Hospital, Adult Infectious Diseases Center, Lusaka, Zambia,* [2]*University of Zambia, Internal Medicine, Division of Infectious Diseases, Lusaka, Zambia,* [3]*University Teaching Hospital, Infectious Diseases, Lusaka, Zambia,* [4]*Ministry of Health, Lusaka, Zambia,* [5]*Levy Mwanawasa Medical University Teaching Hospital, Internal Medicine, Lusaka, Zambia,* [6]*University of Zambia, Department of Medicine, Lusaka, Zambia,* [7]*Imperial College, Faculty of Medicine, London, United Kingdom,* [8]*Liverpool University, Department of Translational Medicine, Liverpool, United Kingdom,* [9]*Vanderbilt University Medical Center (VUMC), Department of Medicine, Division of Infectious Diseases, Nashville, United States,* [10]*Vanderbilt Institute for Global Health (VIGH), Nashville, United States*

Background: Tenofovir disoproxil fumarate (TDF), isassociated with higher risks of renal and bone adverse events, a reason why the WHO had recommended the use of Tenofovir alafenamide (TAF) as a favorable option especially in those with preexisting renal or bone comorbidities.However, there has been limited use of TAF in resource limited settings with scanty data on its safety especially among pregnant women.

We thus evaluated the ARVsafety among HIV-positive, Zambian adults receiving TDF/lamivudine(3TC)/dolutegravir (DTG) or TAF/emtricitabine (FTC)/DTG after being switched from non-nucleoside reverse transcriptase inhibitors (NNRTI)-based ART.

Methods: The VISEND trial is a 144 week, randomized, open label, phase 3 noninferiority study in which weenrolled HIV-1 positive Zambian adults individuals who were receiving TDF/lamivudine (3TC) /efavirenz (EFV) or nevirapine (NVP) ART.

Individuals receiving TDF/3TC/EFV400 or TDF/3TC/NVP with baselineHIV-1 RNA<1,000 copies/mL (arm A) and those with baseline HIV-1 RNA≥1,000 copies/mL (Arm B) were randomized to either TDF/3TC/DTG or TAF/FTC/DTG. Participants who became pregnant after study enrollment were maintained on the study medicines.

Safety was monitored using various biomarkers including serum creatinine with creatinine clearance (CrCl) calculated using the cock-croft gault equation. Creatinine clearance < 50mLs/min and<30 mL/min warranted TDF and TAF discontinuations respectively.

Results: 837 were randomized toTDF/3TC/DTG or TAF/FTC/DTG. At Week 48, eight (8) individuals receiving TLD were discontinued due to kidney events and 2 due to bone related events. Individuals receiving TAFED had a slightly higher mean weight gain (BMI change +1.84) compared to those on TDF/3TC/DTG (BMI change +1.54) although higher among the female.Twenty-four (24) participants (from both arms) became pregnant with 19 (79%) viable babies delivered. There were 4 miscarriages (2 on TDF/3TC/DTG and 2 on TAF/FTC/DTG). 1 whose mother was on TDF/3TC/DTG had congenital cardiac anomaly.

Conclusions: Individuals on TAF/FTC/DTG had better renal and bone safety profiles whereas pregnancy outcomes were comparable in both groups. TAFED was associated with increased weight gain. Tenofovir alafenamide offers a choice for an ARV with balancedoptimal efficacy and potential for improved long-term safety among HIV positive individuals on ART. However, long term follow up is needed to ascertain metabolic complications in women.

Pharmacokinetics/pharmacodynamics/pharmacogenomics and therapeutic drug monitoring in paediatric and adolescent populations

Selection of cabotegravir dosing regimens for HIV treatment and pre-exposure prophylaxis (PrEP) in adolescents by Leveraging adult data

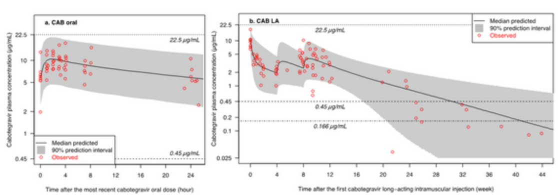
K. Han[1], N. Goyal[1], S. Ford[2], S.Y.A. Cheung[1], L. Tan[3], C. McCoig[4], P. Patel[5], E. Capparelli[6], B. Best[6], M. Marzinke[7], C. Bolton Moore[8,9], A.H. Gaur[10], C. Harrington[5], D. Izard[1], J. Huang[1], M. Baker[11]

[1]*GlaxoSmithKline, Collegeville, United States,* [2]*GlaxoSmithKline, Research Triangle Park, United States,* [3]*ViiV Healthcare, Brentford, United Kingdom,* [4]*ViiV Healthcare, Madrid, Spain,* [5]*ViiV Healthcare, Research Triangle Park, United States,* [6]*University of California San Diego, La Jolla, United States,* [7]*Johns Hopkins University, Baltimore, United States,* [8]*Centre for Infectious Disease Research in Zambia, Lusaka, Zambia,* [9]*University of Alabama at Birmingham, Birmingham, United States,* [10]*St. Jude Children's Research Hospital, Memphis, United States,* [11]*ViiV Healthcare, Nyon, Switzerland*

Background: Cabotegravir (CAB) is the first complete long-acting (LA) regimen for HIV treatment (with rilpivirine) in adults and PrEP in adults and adolescents (≥35kg). CAB LA is an important alternative to daily oral regimens for adolescents. Oral and LA CAB pharmacokinetics (PK) and safety were characterized in virologically-suppressed adolescents (≥35kg) on stable combination antiretroviral therapy in the ongoing MOCHA study. Population PK (PPK) modelling was used to support extrapolation from adults to adolescents and bridge dose regimens and therapeutic use.

Methods: Interim PK from MOCHA (8 adolescents) was compared to adult PK to establish PK similarity and determine feasibility of extrapolation. Adolescent PK profiles following monthly and every-2-months regimens were simulated by incorporating adolescent weight and BMI in a previously developed adult PPK model, and compared to adult PK targets.

Results: Observed and predicted adolescent PK were similar to that in adults receiving treatment or PrEP regimens (Figure 1).



Oral and LA dosing regimens were same as adult monthly regimen. CAB = cabotegravir; LA = long-acting; PK = pharmacokinetics. Reference line of 0.45 µg/mL = 5th percentile of the observed CAB trough concentration following the initiation injection in adult Phase 3 Studies 201584 (FLAIR) and 201585 (ATLAS). Reference line of 22.5 µg/mL = geometric mean of maximum concentration (C_{max}) observed at the supratherapeutic dose of oral CAB 150 mg (3 doses in total, twice daily) in the adult thorough QT/QTc (TQT) study, which is not associated with any toxicity but is the highest exposure observed in clinical studies. Reference line of 0.166 µg/mL = in vitro protein-adjusted concentration resulting in 90% of the maximum inhibition (PA-IC90) of viral growth.

Figure 1. Comparison between observed (interim data from MOCHA study) and simulated (using adult population PK model) cabotegravir pharmacokinetics in adolescents following oral (a) and long-acting (b) dosing.

Adult regimens in adolescents had resulting PK most similar to adults with similar weight range. PPK model accurately predicted PK from adolescents ≥35kg and bridged dose frequency and HIV-infection status. The observed and simulated data demonstrated that adolescents, receiving adult CAB regimens, remained above PK targets observed in adults and below safety thresholds (Figure 2).

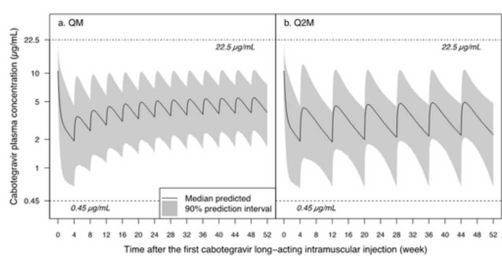


Figure 2. Simulated cabotegravir concentration-versus-time profiles follwing QM (a) and Q2M (b) regimens in adolescents aged 12 - <18 years with body weight of ≥35 kg. QM = once every month; Q2M = once every 2 months. See Figure 1 for interpretation of reference lines 0.45 µg/mL and 22.5 µg/mL.

Conclusions: Robust modelling and simulation approaches, combined with adolescent PK data from MOCHA, allowed bridging and extrapolation across several factors, and inform future study design. The consistency of adolescent and adult PK supports the use of adult CAB regimens in adolescents ≥12 years and ≥35 kg.

ARV management strategies in paediatric and adolescent populations

PEMOB30

Optimizing DTG uptake amongst children living with HIV in Ikom rural communities attending ART clinic at Comprehensive Health Center (CHC) Ikom, Cross River State

E. Chukwu[1], L. Buzaalirwa[2], V. Poopola[3], E. Nwabueze[3], I. Udenkwo[4], C. Michael[5], P.F. Lumenze[6], J.U. Okey[6], R. Okon[6], S. Akanbi[6], I. Ubi[6], N. Oto-Obong[6], I. Igbebor[6], S. Usang[4], A. Ene[4], I. Essien[4], E. Agada[4], P. Ochinokwu[6]

[1]AIDS Healthcare Foundation, Medical Laboratory Science, Ikom, Nigeria, [2]AIDS Healthcare Foundation, Kampala, Uganda, [3]AIDS Healthcare Foundation, Abuja, Nigeria, [4]AIDS Healthcare Foundation, Calabar, Nigeria, [5]AIDS Healthcare Foundation, Medical Laboratory Science, Abuja, Nigeria, [6]AIDS Healthcare Foundation, Ikom, Nigeria

Background: Treatment of HIV infection among children remains very challenging due to several reasons, including difficulties surrounding the availability of effective, palatable, dosage and storage friendly Antiretroviral medications. The introduction of pediatric friendly dolutegravir (DTG) based regimen addressed some of the challenges with previous regimens and this project worked on optimizing its uptake among children living with HIV in rural communities in Ikom Cross River State.

Description: Most of the rural communities in Cross river state are hard to reach making it difficult for children in these communities to have access to effective treatment. Also, due to experience with previous unpalatable regimen, adherence among them was not optimal. To address this challenge, this project was commissioned in one of the rural clinics, CHC Ikom supported by AIDS Healthcare Foundation.

Uptake of the newly introduced DTG was found to be low (25%) amongst children attending ART clinics in CHC Ikom despite being available on site for more than 3 months. Viral suppression among the children was about 35%. Strategies employed include capacity building on DTG administration for healthcare workers, weekly facility-based treatment literacy sessions for caregivers, geographical mapping of the children in care, followed by intensive follow-up through home visits.

Lessons learned: After 6months of this project, DTG uptake among the children increased to 100% and the clinical scores among the children improved significantly. Adherence increased to over 85%, viral load suppression among the children increased to 90% and there was no report of any adverse drug reactions.

There was no record of missed appointment within the period and most of their care givers understand better how ART treatment works. Access to treatment also improved among the children due to the geographical mapping and availability of differentiated services for them.

Conclusions/Next steps: Uptake of key interventions like Pediatric DTG is critical for improved treatment outcome for children living with HIV and should be offered in a comprehensive manner. A tripartite strategy of health-care worker capacity building, Treatment literacy sessions for caregivers and geographical mapping followed by intensive follow up is recommended to improve DTG uptake among Children living with HIV in rural communities.

Mental health and neurocognition in paediatric and adolescent populations

PEMOB31

The cognitive development of children born to adolescent mothers - does child HIV status matter?

K. Roberts[1], L. Sherr[1], K. Haag[1], C. Smith[1], J. Jochim[2], E. Toska[3], M. Marlow[4], L. Cluver[2,3]

[1]University College London, Institute for Global Health, London, United Kingdom, [2]University of Oxford, Oxford, United Kingdom, [3]University of Cape Town, Cape Town, South Africa, [4]Stellenbosch University, Stellenbosch, South Africa

Background: HIV, both directly and indirectly, impacts child development outcomes. The most severe impacts are for children infected with HIV, and those exposed but uninfected are also shown to have challenges - though less severe. However, little is known regarding the development of children born to adolescent mothers affected by HIV.

This study aims to examine cognitive development for children born to adolescent mothers, comparing those children living with HIV, those HIV exposed and uninfected (HEU) and those HIV unexposed (HU).

Methods: Analyses utilise cross-sectional data from 920 adolescent mother (10-19 years)-first born child dyads residing in the Eastern Cape Province, South Africa. Participants completed detailed study questionnaires relating to sociodemographic characteristics, HIV, and maternal and child health. Trained assessors administered standardised child development assessments (Mullen Scales of Early Learning). Chi-square tests and ANOVA tests were used to explore maternal and child characteristics according to child HIV status on cognitive development. Linear regression models were used to explore associations between child HIV status and child cognitive development.

Results: 1.2% of children were living with HIV, 20.5% were classified as being HEU and, 78.3% were classified as HU. Overall, children living with HIV were found to perform lower across developmental domains compared to both HEU and HU groups (composite score of early learning: 73.0 vs 91.2 vs. 94.1, respectively: F=6.45, p=0.001). HEU children on average scored lower on all developmental do-

mains compared to HU children, reaching significance on the gross motor domain ($p<0.05$). Exploratory analyses identified maternal education interruption as a potential risk factor for lower child cognitive development scores and, higher maternal age to be protective of child cognitive development scores.

Conclusions: Analyses identify stepwise differences in the average child cognitive development scores according to child HIV status among children born to adolescent mothers affected by HIV; with children living with HIV performing worse overall. Young mothers and their children may benefit from adapted interventions aimed at bolstering child development outcomes.

Targeted programming particularly among younger adolescent mothers and those experiencing education interruption may identify those families, particularly in need.

HIV-exposed uninfected children

PEMOB32

No difference in prevalence of TB infection among infants in two Southern African cohorts by *in utero* HIV exposure status

Lurie Children's Hospital of Chicago, Department of Pediatrics, Division of Infectious Diseases, Chicago, United States, [13]Northwestern University Feinberg School of Medicine, Department of Pediatrics, Department of Medicine, Chicago, United States, [14]University of Ottawa at the Ottawa Hospital, Divisions of Infectious Diseases and Respirology, Ottawa, Canada, [15]Stellenbosch University, Division of Molecular Biology and Human Genetics, Biomedical Research Institute, Cape Town, South Africa, [16]Seattle Children's Hospital, Seattle, United States, [17]Massachusetts General Hospital, Departments of Internal Medicine and Pediatrics, Boston, United States

Background: Children under 5 years old are at risk for tuberculous (TB) disease. Bacillus Calmette-Guérin (BCG) mitigates this risk and may also improve all-cause mortality. However, whether this is the same for infants exposed *in utero* to HIV yet uninfected (iHEU) is unknown.

Methods: Leveraging mother-child health studies conducted in Botswana and South Africa, women living with HIV and without were enrolled during pregnancy. Mother-child pairs were followed prospectively, and samples collected at 9-12months and/or 18-month of life in Botswana and 9-month or 12-month of life in South Africa were used.

All infants were BCG vaccinated at birth. T-SPOT.TB assays were performed on cryopreserved peripheral mononuclear cells. Cells were stimulated with phytohaemagglutinin (PHA), ESAT-6, CFP-10, and medium.

Results were interpreted as positive, negative, borderline, or invalid, according to the manufacturer's instruction. For invalid or borderline results, re-testing was performed using another aliquot collected at the same visit or in follow-up, if available.

Valid re-tested results from later time points were considered reflective of the initial testing date, acknowledging the potential TB exposure between the tests. Proportions of T-SPOT.TB positive tests were compared by infant HIV exposure status using Fisher's exact test. Median PHA stimulated spot forming cells were compared using Wilcoxon rank sum test.

Results: Overall, 418 infants were tested; 293 (70%) iHEU and 125 (30%) HIV-unexposed infants (iHUU). Women with HIV were older with higher gravidity compared to women without HIV. No infant presented with TB disease. TB infection prevalence did not differ by infant HIV exposure overall or in either cohort. In Botswana, 6 iHEU (4.4%) and 1 iHUU (3.0%) tested positive (p=1.0). In South Africa, 4 iHEU (2.5%) and 3 iHUU (3.3%) tested positive (p=0.71).

Two seroreversions occurred in iHEU. South African iHEU showed a significantly higher PHA stimulation response compared to iHUU (median 575 vs. 409 spots; p=0.004). This was not observed in Botswana (median 289 vs. 426 spots; p=0.059).

Conclusions: TB infection prevalence was similar between two Southern African infant cohorts regardless of fetal HIV exposure status, contrary to previous reports where overall prevalence was higher in infants. Studies with larger cohorts are needed to confirm these findings.

Clinical issues in sex workers

PEMOB33

Causes of death and hospitalisations in a cohort of sex workers in South Africa

H. Hausler[1,2], S. Schwartz[3], C. Comins[3], L. Shipp[3], M. Mcingana[1], N. Mulumba[1], S. Makama[1], S. Baral[3]
[1]TB HIV Care, Cape Town, South Africa, [2]Univeristy of Pretoria, Family Medicine, Pretoria, South Africa, [3]Johns Hopkins University, Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

Background: In South Africa, 60% of female sex workers (FSW) are living with HIV, and many face structural and individual-level barriers to initiating, accessing and adhering to antiretroviral therapy (ART). FSW are criminalized, stigmatized and marginalized. The Siyaphambili (we are moving forward) study enrolled 777 FSW with sustained viremia into an 18 month sequential multistage adaptive randomized trial (SMART) to compare the effectiveness and durability of a nurse-led decentralized treatment program (DTP) and individualized case management (ICM) in isolation or in combination to achieve sustained viral suppression. This study reports on morbidity and mortality in the cohort.

Methods: Non-virally suppressed FSW 18+ years living with HIV in Durban, South Africa were enrolled into the Siyaphambili trial from June 2018-March 2020; follow-up ended January 2022. Attempted contact was made with women every 1 to 2 months dependent on intervention arm and 6-monthly for study visits/blood draws.

We describe morbidity and mortality over 18-months of follow-up; mortality rates were estimated per 1000 person-years of follow-up.

Results: Average age of FSW was 31 years. Sixteen deaths were reported among 777 trial participants during follow-up at a rate of 18.7/1000 PY. Causes of death included TB (n=5), unspecified illness (n=5), murder (n=3), COVID-19 (n=1), suicide (n=1) and hypothermia (n=1). A further 6 women were known to have been incarcerated during study follow-up.

Adverse events outside of death were commonly reported in the study visits at 6, 12 and 18 months: A range of 10.1-15.7% of FSW reported hospitalization in the past 6 months across these each of these visits; 19.4-32.2% reported physical violence in the past 6 months; and 10.6-14.8% reported sexual violence (rape) across the past 6 months. No adverse events were determined to be due to the study.

Conclusions: FSW have high morbidity and mortality relative to their age group in the general population with TB being the major cause of mortality. Hospitalization, physical and sexual violence are also highly prevalent among FSW. Interventions to prevent and treat TB and violence need to be integrated into care for FSW.

Malignancies (AIDS and non-AIDS)

PEMOB34

Prevalence and risk factors for anal dysplasia among men who have sex with men living with HIV: the HPV Screening and Vaccine Evaluation (HPV-SAVE) Study

A.K. Gupta[1,2], T. Tattersall[1,3], A. Ablona[1], R. Azmin[1], A.N. Burchell[4,5], J. Edward[1], M. Gaspar[5], D. Grace[5], J. Gillis[6], B. Lyons[1], P. MacPherson[7], B. Okocha[1], R. Rosenes[8], D.H.S. Tan[4,5], I. Salit[9,5], T. Grennan[1,10]

[1]BC Centre for Disease Control, Vancouver, Canada, [2]University of British Columbia, Faculty of Pharmaceutical Sciences, Vancouver, Canada, [3]University College London, London, United Kingdom, [4]St. Michael's Hospital, Toronto, Canada, [5]University of Toronto, Toronto, Canada, [6]Vaccine Evaluation Centre, BC Children's Hospital Research Institute, Vancouver, Canada, [7]The Ottawa Hospital, Vancouver, Canada, [8]Progressive Consultants Network of Toronto, Toronto, Canada, [9]Toronto General Hospital, Toronto, Canada, [10]University of British Columbia, Faculty of Medicine, Division of Infectious Diseases, Vancouver, Canada

Background: HPV-associated anal cancer is a common malignancy in men who have sex with men living with HIV (MSMLWH). Despite recent indications that screening reduces the incidence of anal cancer, access is limited to urban centres and is coupled with substantial waitlists requiring the need for triaging care. We assessed the prevalence of and risk factors for anal dysplasia among MSMLWH.

Methods: The HPV-SAVE study examines anal cancer screening in MSMLWH in Vancouver, Ottawa and Toronto, Canada. Between 01/2016 and 05/2021, participants were recruited from HIV clinics and completed a questionnaire pertaining to demographics and medical history. We screened participants for anal dysplasia via anal pap, defined as any non-normal result on cytology using the Bethesda classification.

We completed descriptive statistics to report the prevalence of anal dysplasia and binomial logistic regression to identify risk factors for dysplasia.

Results: Among 720 participants screened, most were white (70.0%), over 50 years-old (52.1%) and unpartnered (53.8%). Most had dysplasia (344/663; 51.9%): ASCUS (223/663; 33.6%), LSIL (77/663; 11.6%), HSIL (18/663; 2.7%); and ASC-H (16/663; 2.4%).

Many participants reported past anogenital warts (269/699; 38.5%) however, this did not increase the odds of dysplasia (odds ratio [OR] 1.03 95% confidence interval [CI] 0.75, 1.41).

Black participants were less likely to have dysplasia than non-Black participants (OR 0.47, 95% CI 0.23, 0.96), as were individuals who acquired HIV between 2000-2010 relative to those who were diagnosed after 2010 (OR 0.63 95% CI 0.42, 0.94). Elevated odds of dysplasia were observed for current smokers and individuals who quit within the past 5-years (OR 1.42; 95% CI 1.01, 2.01) and individuals with quarterly physician visitation compared to individuals with biannual visitation (OR 1.61, 95% CI 1.00, 1.93). There was no association between dysplasia and low self-reported CD4+ count (OR 1.10 95% CI 0.75, 1.62) or elevated age (OR 1.10 95% CI 0.80, 1.50).

Conclusions: Anal dysplasia is common among MSMLWH. Smoking, frequent physician visitation, recent HIV acquisition and non-Black ethnicity were associated with dysplasia. These interim results highlight the importance of further research addressing mediators and confounders of engagement in anal cancer screening to support treatment and care for MSMLWH.

Clinical issues in transgender people

PEMOB35

Addressing sexual health in trans masculinities: lessons learned from TransCITAR transgender cohort study in Argentina

N.K. Panis[1], L. Spadaccini[1], N. Cabrera[1], C.F. Perez[1], M.V. Iannantuono[1], M.M. Sandoval[1], N. Doudtchitzky[1], M.I. Figueroa[1], C. Cesar[1], V. Fink[1], C. Frola[1], O. Sued[2], I. Aristegui[1], TransCITAR Study Group

[1]Fundación Huésped, Research Department, Capital Federal, Argentina, [2]OPS, Washington, United States

Background: Trans masculinities (TM) are usually underrepresented in clinical settings, and data involving HIV and other sexually transmitted infections (STIs) are scarce, highlighting health disparities among this community.

This study aimed to describe sexual health status of TM attending a transgender cohort at Buenos Aires, Argentina.

Methods: We conducted a retrospective review of TransCITAR cohort study TM medical records (September 2019-December 2021). Gathered data included age, sexual orientation, sex work history, age of sexual initiation, history of pregnancy, and use of gender-affirming hormone therapy (GHT). STI screening included: HIV (by rapid test), syphilis (by nontreponemal test-VDRL-), hepatitis A (HAV), B (HBV) and C (HCV) serologies, rectal chlamydia and gonorrhea and cervical cytology. Diagnosis of gonorrhea and chlamydia were made by in-house PCR on rectal swabs performed by a healthcare professional.

Results: Thirty-six TM were included, median age 25 years (IQR 21-30). Only two participants reported history of sex work. Regarding sexual orientation a great variation was reported: 15(42%) heterosexual, 9(25%) bisexual, 6(17%) pansexual, 1(3%) gay and 1(3%) asexual. Most participants 69%(n=25) were receiving GHT. Four participants had not initiated sexual activity.

All participants were tested for HIV and syphilis with negative results. Five (14%) had rectal gonorrhea and chlamydia screening, with negative results. Among TM

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

who had initiated sexual activity, only 10/32 (31%) performed the cervical cytology, among these, 2 had low-grade intraepithelial lesions. At baseline visit, all participants consented to hepatitis serology, and all had IgG HAV positive, IgG HCV and HBsAg negative. Ten TM had HBsAb< 10 IU/ml. One person had pregnancy history with miscarriage.

Conclusions: Despite facilitated access to a trans competent facility, only few TM completed STI and genital cancer screening, and almost one third had HBV serology compatible with missing or incomplete vaccination.

These results highlight the urgent need for more formative research to understand how to offer adapted and acceptable genital evaluation and screening of STIs and cancer to this population.

Clinical issues in people who use drugs

PEMOB36

Connecting vulnerable people with opioid use disorder to care: expanding accessibility and building trust through a community-based telemedicine partnership in Montreal, Canada

C. de Montigny[1], S. Hoj[2], R. Leandre[2], M.-E. Beauchemin Nadeau[1], G. Boyer-Legault[3], S. Chougar[1], A. Goyette[3], S.-K. Lamont[1], J. Bruneau[2]
[1]CHUM, Addiction Medicine, Montreal, Canada, [2]CR CHUM, Montreal, Canada, [3]CACTUS Montréal, Montréal, Canada

Background: The COVID-19 pandemic has greatly impacted health service delivery, with unprecedented expansion of telemedicine. To address the needs of people with opioid use disorder (PWOUD), the Centre hospitalier de l'Université de Montréal Addiction Medicine service (CHUM-A) began to initiate new patients on opioid agonist treatment (OAT) – a key intervention for reducing HIV transmission and overdose risk – via telemedicine.

However, PWOUD often lack access to the technological resources necessary for telemedicine. Likewise they often have complex needs while being disengaged from mainstream health services. The CHUM-A and CACTUS Montreal (a community-based harm reduction organisation) therefore co-constructed a unique telemedicine program aiming to provide evidence-based treatment and health care for PWOUD.

Description: Procedures were developed jointly to enable flexible and rapid appointment schedules. CACTUS Montreal workers, known and trusted by their clientele, inform PWOUD of the program, facilitate telemedicine connection in a private room located within their facilities, introduce the CHUM-A team and can accompany the patient throughout the appointment if requested.

Treatments offered by the CHUM-A team include a long-acting opioid, often combined with a short-acting opioid to increase comfort and reduce risk of illicit use and overdose, and other services including HIV and HCV prevention and treatment as needed. CACTUS Montreal workers maintain follow up and support to the participants following an holistic approach.

Lessons learned: Between April 2020 and October 2021, 66 people initiated OAT through the program and 83% currently remain engaged in care, much higher than reported 1-year OAT retention rates of 30-70%. Five participants commenced HIV treatment and 16 were treated for hepatitis C. Qualitative interviews with 20 participants suggest an enthusiastic response; the initiative was perceived to be convenient and protective in the pandemic context, and the implication of CACTUS Montreal was highly valued. Several participants reported having reduced their drug consumption and experiencing greater stability in other areas of their lives.

Conclusions/Next steps: Our telemedicine program provides a flexible approach with alternative treatment options for PWOUD disengaged from traditional care, integrated within a local organisation. It represents an affordable solution to reduce the gap between patients and health providers, and is promising to increase access in remote settings.

Impact of COVID-19 on HIV care

PEMOB37

COVID-related barriers associated with suboptimal adherence during India's second „delta" wave: results from a South India HIV cohort

M.L. Ekstrand[1], S. Chandy[2], M. Pereira[3], E. Heylen[1], K. Srinivasan[4]
[1]University of California, San Francisco, Medicine, San Francisco, United States, [2]Wayanad Institute of Medical Sciences, Department of Medicine, Wayanad, India, [3]St John's National Academy of Health Sciences, SJRI, Bangalore, India, [4]St John's National Academy of Health Sciences, Psychiatry, St John's Medical College, Bangalore, India

Background: Successful management of HIV requires excellent adherence and timely prescription refills to avoid treatment interruptions. The COVID-19 pandemic restrictions have resulted in unintended treatment barriers for people living with HIV (PWH). It is important to document the impact that these barriers had on ability to visit ART clinics, obtain prescription refills, and adhere to medical regimens during different phases of the pandemic.

Methods: The "Tel-Me-Box" study was designed to validate novel measures of medication adherence by enrolling and following a cohort of 526 PWH in South India for 24 months. During COVID-19-related government restrictions on travel and face-to-face visits, we conducted telephone surveys, adding questions on pandemic-related adherence barriers.

This abstract includes data collected in 1) Jan-Feb (n=442) 2) May-June (n=451) and 3) Aug-Sept (449) 2021, i.e. pre-, during, and post- India's "second wave," which occurred during the surge of the delta variant. We assessed past month HIV adherence and >48hr treatment interruptions, combined into a measure of "suboptimal adherence," as well as individual and structural adherence barriers.

Results: In 2021, <95% past month adherence was reported by 7% in Jan-Feb, 8% in May-June, and 4% in Aug-Sept of cohort participants. While these differences were not statistically significant, perceived pandemic-related barriers to clinic visits and medication adherence were significantly more common during the May-June surge of the delta variant than they were pre- or post-surge. These barriers were associated with suboptimal adherence during the surge (see table), but not before or afterwards.

Perceived pandemic-related adherence barriers	% who agreed with each statement (*p<0.05) Pre-surge (Jan-Feb) During surge (May-June) Post-surge (Aug-Sept)	% who reported suboptimal adherence during surge among those who agreed with barriers at that time	% who reported suboptimal adherence during surge among those who disagreed with barriers at that time	p (chi-square test bivariate)	Multivariate model aOR (95% CI)
"I worry that I will run out of my medication and not be able to get refills during the pandemic"	Pre: 13.3% (n=59/442) During: 34.8%* (n=157/451) Post: 8.2% (n=37/449)	16.6% (n=26/157)	7.8% (n=23/294)	p≤0.005	1.13 (0.53, 2.39)
"I don't have transportation to get me to the clinic"	Pre: 10.4% (n=46/442) During: 40.6%* (n=183/451) Post 7.8% (n=35/449)	16.4% (n=30/183)	7.1% (n=19/268)	p≤0.002	1.96 (0.98, 3.91)
"I'm afraid that taking my HIV meds will make me more vulnerable to COVID infection or complications."	Pre: 13.8% (n= 61/442) During: 20.6%* (n=93/451) Post: 6.2% (n=28/449)	20.4% (n=19/93)	8.4% (n=30/358)	p≤0.001	2.13 (1.01, 4.48)
"I'm afraid that doctors won't be available or will treat me differently if I seek care at the hospital"	Pre: 19.7% (n=87/442) During: 31.7%* (n=143/451) Post: 12.0% (n=54/449)	15.4% (n=22/143)	8.8% (n=27/308)	p≤0.036	1.13 (0.55, 2.30)

Table.

Conclusions: Although self-reported adherence levels in this cohort were similar throughout 2021, pandemic-related concerns were significantly greater during India's devastating "second wave" in May-June, during the surge of the delta variant. During this time, COVID-related worries and lack of transportation were significantly associated with suboptimal HIV medication adherence.

These findings have implications for policy and clinical care during future surges and suggest that PWH could benefit from additional counseling to reduce worries together with transportation assistance or medication deliveries to ensure consistent medication access.

Sexuality, gender and prevention technologies (including condoms, treatment as prevention, medical male circumcision, pre-exposure prophylaxis)

Considerations for the delivery of long-acting HIV prevention methods in South Africa: provider perspectives on uptake and facilitating choice and informed decision-making

N. Vundamina[1], C.M. Wong[2], M. Pleaner[1], E. Briedenhann[1], N. Naidoo[1], S. Mullick[1]

[1]*Wits Reproductive Health and HIV Institute (Wits RHI), University of Witwatersrand, Implementation Science, Johannesburg, South Africa,* [2]*FHI 360, Global Health, Population and Nutrition, Durham, United States*

Background: Clinical trials of the dapivirine vaginal ring (PrEP ring or ring) and long-acting injectable cabotegravir (CAB-LA) have shown promising results, with both products exhibiting efficacy in preventing HIV acquisition.

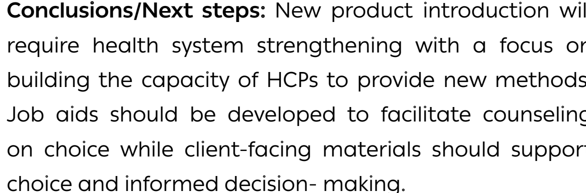
Successful product introduction and scale-up will require in-depth understanding of the knowledge, perceptions, and attitudes of healthcare providers (HCPs) related to these new products.

Description: Through the USAID-funded PROMISE collaboration, we used semi-structured discussion guides to conduct conversations with family planning (FP) and HIV prevention HCPs from public health facilities and project sites in South Africa from May to June 2021.

These conversations explored perceptions of the ring and CAB-LA; experiences with oral PrEP and FP provision; counseling on multiple methods; and strategies to enable informed choice and decision-making among potential clients. Conversations were audio-recorded and thematic analysis was conducted using a two-step rapid analysis process.

Lessons learned: A total of 59 (53 female and four male) HCPs providing integrated FP-HIV prevention services participated in the conversations. 57 HCPs had heard about the ring; about half had heard about CAB-LA. Perceived advantages of the ring included fewer side effects compared to oral PrEP and ease of insertion and removal. HCP concerns included low ring uptake due to low efficacy compared to oral PrEP; incorrect use with clients removing the ring before 28 days; or potential intimate partner violence. For CAB-LA, HCPs mentioned its discreet use and long-acting qualities as advantages. Concerns about CAB-LA included the risk of developing HIV drug resistance and lasting side effects.

Overall, HCPs said the introduction of new PrEP products would be beneficial to clients, allowing them to choose methods based on their lifestyles. They expected uptake of CAB-LA to be higher among women who already use injectable contraceptives. HCPs worried that introducing new products would lead to increased workloads, inadequate counseling, and improper stock control and storage measures, particularly for CAB-LA.



Conclusions/Next steps: New product introduction will require health system strengthening with a focus on building the capacity of HCPs to provide new methods. Job aids should be developed to facilitate counseling on choice while client-facing materials should support choice and informed decision- making.

Access to harm reduction interventions

Effect of combination Needle and Syringe Program and Opioid Agonist Therapy on HIV and hepatitis C virus acquisition among people who inject drugs: a comparison between Amsterdam, Melbourne and Vancouver

A. Boyd[1,2], D.K. van Santen[1,3,4], S. Lodi[5], W. van den Boom[3], P. Dietze[3], K. Hayashi[6,7], H. Dong[6], Z. Cui[6], L. Maher[8], M. Hickman[9], M. Prins[1,10]

[1]Public Health Service of Amsterdam, Infectious Diseases, Amsterdam, Netherlands, the, [2]Stichting HIV Monitoring, Amsterdam, Netherlands, the, [3]Burnet Institute, Disease Elimination, Melbourne, Australia, [4]Monash University, Department of Epidemiology and Preventive Medicine, Melbourne, Australia, [5]Boston University School of Public Health, Department of Biostatistics, Boston, United States, [6]British Columbia Centre on Substance Use, Vancouver, Canada, [7]Simon Fraser University, British Columbia Centre on Substance Use, Burnaby, Canada, [8]The Kirby Institute for Infection and Immunity, Faculty of Medicine, Sydney, Australia, [9]University of Bristol, Population Health Sciences, Bristol Medical School, Bristol, United Kingdom, [10]Amsterdam UMC, University of Amsterdam, Department of Infectious Diseases, Amsterdam Infection and Immunity Institute (AI&II), Amsterdam, Netherlands, the

Background: Harm reduction programs for people who inject drugs (PWID) have been available in Amsterdam, Vancouver, and Melbourne since the 1980s. Compared to the current situation in Vancouver and Melbourne, coverage of harm reduction programs is higher in Amsterdam, fewer individuals initiate injection drugs, and HIV and HCV transmission has been largely stopped among PWID. We aimed to assess whether the effect of needle and syringe program (NSP) and opioid agonist therapy (OAT) participation on HIV and HCV incidence differs in these three settings.

Methods: We emulated the design of a target randomized trial using observational data from the Amsterdam Cohort Studies (ACS, 1985–2014), Vancouver Injection Drug Users Study (VIDUS, 1997-2009), and Melbourne Injecting Drug User Cohort Study (SuperMix, 2008-2021).

We included PWID with a recent history of injecting drug use and opioid use, and who tested negative for HIV or HCV. We compared the effect of complete NSP/OAT participation (current OAT and 100% NSP coverage, or current OAT if no recent injection drug use) versus no or partial NSP/OAT participation combined (no OAT and/or <100% NSP coverage) on HIV and HCV risk, per cohort (only HCV in SuperMix as transmission of HIV is rare among PWID in Australia). Marginal structural models were used to analyze data.

Results: During follow-up among participants included in analysis, there were 61/624 HIV seroconversions in ACS and 37/1,399 in VIDUS, and 34/129 HCV seroconversions in ACS, 30/216 in VIDUS, and 21/122 in SuperMIX.

Compared with no/partial NSP/OAT participation, complete participation led to lower risk of HIV and HCV acquisition, with the strongest effect on HIV observed in the ACS (Hazard ratio (HR)=0.38, 95%CI= 0.23-0.66) compared to VIDUS (HR= 0.45, 95%CI= 0.11-1.84), while its effect on HCV was strongest in VIDUS (HR= 0.11, 95%CI= 0.01-0.85) and ACS (HR= 0.29, 95%CI= 0.12-0.67) compared to SuperMix (HR= 0.49, 95%CI= 0.14–1.71).

Conclusions: Complete NSP and OAT participation led to a reduction of HIV and HCV acquisition compared to no/partial participation in regions from two and three continents, respectively.

Findings reinforce the crucial role of combined NSP and OAT in infection prevention and the need for comprehensive access to both interventions.

Combination prevention strategies

Background: HIV treatment has clear Health-Related Quality-of-Life (HRQoL) benefits. However, little is known about how Universal Testing and Treatment (UTT) for HIV affects HRQoL. We examined the effect of a combination prevention intervention, including UTT, on HRQoL among PLHIV.

Methods: Data were from HPTN 071 (PopART), a three-arm cluster randomised controlled trial in 21 urban and peri-urban communities in Zambia and South Africa (2013-2018). Arm A received the full UTT intervention of door-to-door HIV testing plus access to antiretroviral therapy regardless of CD4 count, Arm B received the intervention but followed national treatment guidelines (universal ART from 2016) and Arm C received standard care.

The intervention effect was measured in an open cohort of randomly selected adults (18-44 years) in randomly selected households, using data from baseline and 36-months. HRQoL scores (range:0-1), and the prevalence of problems in five dimensions of HRQoL (mobility, self-care, performing daily activities, pain/discomfort, anxiety/depression) were assessed among all participants using the EuroQol-5-dimensions-5-levels questionnaire (EQ-5D-5L). HRQoL among PLHIV with laboratory confirmed HIV status was compared between arms.

This was achieved using two-stage cluster-level analyses, controlling for baseline imbalances in language(s) used to complete the survey, wealth and HRQoL, as well as age and gender.

Results: Data from 10,900 PLHIV (women, n=9,205, 84.4%; men, n=1,695, 15.6%) were examined. At 36-months, the mean HRQoL score was 0.893 (95% confidence interval:0.891-0.894) in Arm A, 0.888 (0.886-0.890) in Arm B and 0.891 (0.889-0.892) in Arm C. There was no evidence of a difference in HRQoL scores between arms (adjusted mean difference, A vs C:0.003, -0.001-0.006; B vs C:-0.004, -0.014-0.005).

However, the geometric mean prevalence of problems with pain/discomfort was 2.4% in Arm A, 7.5% in Arm B and 7.8% in Arm C, with prevalence lower in Arm A than C (adjusted prevalence ratio:0.37, 0.14-0.97). There was no evidence of a difference in effect between men and women.

Conclusions: The PopART UTT intervention did not change overall HRQoL, suggesting that improving HRQoL among PLHIV might require more than access to testing and treatment. However, PLHIV had fewer problems with pain/discomfort under the full intervention; this benefit of UTT should be maximised in further roll-out.

PEMOC45

A latent class analysis of combination HIV prevention strategies enacted by a prospective cohort of midlife and older men who have sex with men in the United States

S. Meanley[1], J.E. Egan[2], D. Ware[3], M. Brennan-Ing[4], S. Haberlen[5], R. Detels[6], A.L. Brown[2], S. Wolinsky[7], M.R. Friedman[8], M.W. Plankey[3]

[1]University of Pennsylvania School of Nursing, Family and Community Health, Philadelphia, United States, [2]University of Pittsburgh Graduate School of Public Health, Behavioral and Community Health Sciences, Pittsburgh, United States, [3]Georgetown University Medical Center, Washington, D.C., United States, [4]Hunter College, Brookdale Center for Healthy Aging, New York City, United States, [5]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [6]University of California - Los Angeles Fielding School of Public Health, Epidemiology and Infectious Diseases, Los Angeles, United States, [7]Northwestern University Feinberg School of Medicine, Infectious Diseases, Chicago, United States, [8]University of Pittsburgh Graduate School of Public Health, Infectious Diseases and Microbiology, Pittsburgh, United States

Background: Midlife and older (age 40+) men who have sex with men (MSM) in the United States remain disproportionately affected by HIV. The HIV prevention toolbox has evolved over the past decade, offering biomedical methods, like pre-/post-exposure prophylaxis [PrEP/PEP]

and HIV treatment as prevention alongside traditional methods, like condom use, anal sex alternatives, and discussions about HIV status. We aimed to identify the typologies of combination HIV prevention (CHP) methods used by midlife and older MSM during recent sexual encounters.

Methods: Participants were sexually-active, midlife and older adult MSM (N=566; mean age 61.1±8.2 years; 28.4% men of color) from the Multicenter AIDS Cohort Study/ Healthy Aging Substudy (2016-2019). We asked about their/their partners' enacted CHP methods (Table 1). Latent class analyses were performed cross-sectionally to identify CHP typologies stratified by HIV serostatus.

Prompt: "Thinking of the sex you have had with other men since your last visit. Which of the following safer sex methods have you used? (check all that apply). The first column asks about YOU, the second asks about your male sexual PARTNER(S)."

	Full Sample N = 566	Seronegative Men n = 293 (51.8%)	Seropositive Men n = 273 (48.2%)		
Prevention Strategy	n (%)	n (%)	n (%)	χ^2	p
Talked about HIV status – Self	274 (48.4)	130 (44.4)	144 (52.7)	5.23	.073

Took PEP – Partner	6.9	0.0	0.0	19.6	6.4	0.0	0.4
Pulled out before cumming – Self	16.3	16.2	2.5	53.3	6.3	15.8	0.0
Pulled out before cumming – Partner	13.1	0.0	1.6	38.8	0.0	13.9	0.4
Chose not to have anal sex – Self	43.3	100.0	0.0	28.0	28.3	11.4	16.6
Chose not to have anal sex – Partner	21.0	49.6	0.0	30.6	24.1	0.0	12.5

Note: [a] Class 1 = High prevention orientation overall, Class 2 = Low prevention orientation/anal sex abstention, Class 3 = Low prevention orientation overall; [b] Class 1 = High prevention orientation overall, Class 2 = High prevention orientation/low condom use, Class 3 = Low prevention orientation/moderate condom use, Class 4 = Low prevention orientation overall

Table 2. Latent class analyses: Conditional response probabilities of final class solutions stratified by serostatus

Conclusions: Participants' CHP typologies differed by serostatus suggesting that midlife and older adult MSM's prevention behaviors are not one-size-fits-all. These findings support scaling up health providers' service capacity to ascertain MSM's prevention behaviors to promote and build self-efficacy for enacting the combination of effective strategies that align with patients' preferences.

Other new HIV prevention tools

PEMOC37

Men's voices on LA_PrEP: The acceptability and preferences of Long acting Pre-Exposure Prophylaxis (LA-PrEP) among Cis-gender men and Men who have sex with men in South Africa

M. Atujuna[1], Z. Duby[2], A. Minnis[3], T. Palanee-Phillips[4], S. Tenza[4], K. Reddy[4], N. Nkomana[1], L.-G. Bekker[1], E. Montgomery[3]

[1]University of Cape Town, Faculty of Health Sciences, School of Medicine, Desmond Tutu HIV Centre, Cape Town, South Africa, [2]University of Cape Town, Division of Social and Behavioural Sciences, School of Public Health and Family Medicine, Cape Town, South Africa, [3]Research Triangle Institute, International, Berkeley, United States, [4]Wits Reproductive Health and HIV Institute, University of Witwatersrand, Johannesburg, South Africa

Background: Cisgender men who have sex with women (MSW) and men who have sex with men (MSM) are often under-represented in HIV prevention research despite their roles as key drivers of the HIV epidemic. As HIV prevention research around long-acting pre-exposure prophylaxis (LA-PrEP) options expand in sub-Saharan Africa (SSA), it is essential to engage these key populations to ensure their buy-in.

We investigated perceptions of implants and injectables as LA-PrEP delivery platforms among MSW and MSM in SAMURAI, an end-user acceptability and preference study.

Methods: In-depth interviews were conducted with 40 MSW (n=20) and MSM (n=20) from resource-restricted communities in Cape Town and Johannesburg, aged 18-35 years who self-reported as being HIV-negative and currently sexually-active.

We explored themes around sexual behaviour and relationships, masculinities and gender, and other factors influencing attitudes towards LA-PrEP. Data analysis followed a thematic framework approach.

Results: Both MSW and MSM felt that the proposed modes of administering LA-PrEP were acceptable and more appealing than daily oral PrEP because they offered longer lasting protection, while reducing the burden related to frequent clinic visits for refills.

They described these new products as having potential to overcome the various challenges relating to consistent condom use, while offering a more acceptable tool to reduce the risk of acquiring HIV. MSW voiced hesitancy around the use of '*foreign products*', expressing concerns about infertility and fears that these products may cause birth defects in their future children.

The convenience of implants with long dosing duration was acknowledged by both populations, but injections were deemed to be more discreet and familiar. Implant use was described to be potentially stigmatizing with a greater chance of causing tissue scarring, or lead to implant robbery, a narrative that implants are forcefully removed and used as recreation drugs.

Conclusions: Evidence about men's engagement in HIV prevention and what modalities of HIV prevention may be acceptable and preferred is limited. We found that both groups were enthusiastic about LA-PrEP.
This research will inform development of a clinical study to provide further insight into safety, acceptability and use of placebo versions of LA-PrEP among MSW and MSM.

Measuring and enhancing retention and adherence in HIV prevention programmes

PEMOC38
Adherence with antiretroviral therapy among recently pregnant HIV-positive women in 8 African countries

S. Chung[1], M. Farahani[2,1], C. Wang[2], W. El-Sadr[2,1], J. Justman[2,1]
[1]*Columbia University Mailman School of Public Health, Epidemiology, New York, United States,* [2]*ICAP at Columbia University, New York, United States*

Background: Adherence to antiretroviral therapy (ART) is essential for reducing morbidity and mortality among people living with HIV and HIV transmission, particularly mother-to-child transmission for pregnant and postpartum women.
This study compared self-reported ART use with antiretroviral drug (ARV) detection in blood among HIV+ women aged 15-49 who had delivered within three years before the survey, using population-based HIV surveys (PHIAs) in Eswatini, Lesotho, Malawi, Namibia, Tanzania, Uganda, Zambia, and Zimbabwe (2015-2019), conducted by the ministries of health in collaboration with ICAP and CDC.
Methods: Consenting participants from randomly selected households provided demographic and clinical information and blood for household HIV testing. Household HIV+ results were laboratory-confirmed. Viral load suppression (VLS) was defined as VL < 1000 cp/mL.
Commonly prescribed ARVs, namely, efavirenz, nevirapine, atazanavir, and lopinavir, were assayed in dried blood spots. All analyses accounted for complex survey design, and Taylor Series Linearization methods were used for variance estimation.
Results: Of all 91,728 female participants, 2,108 were included in this analysis. Most women took ARVs before their first antenatal visit, ranging from 46% (95% CI: 44%-49%) in Tanzania to 82% (95% CI: 79%-85%) in Namibia.
VLS ranged from 77% (95% CI: 73%-80%) in Lesotho to 88% (95% CI: 85%-91%) in Malawi. ARVs were detected in the blood of most women who initiated ART before their first antenatal visit, ranging from 88% (95% CI: 84%-92%) in Lesotho to 94% (95% CI: 90%-98%) in Malawi.
Adjusted for other demographic characteristics, women who initiated ART before the first antenatal visit were more likely to have detectable ARVs than those who initiated ART during pregnancy (adjusted odds ratio (aOR): 2.2; 95% CI: 1.7-2.9). Women aged 35-49 were more likely to have detectable ARVs than those aged 15-24 (aOR: 2.2; 95% CI: 1.5-3.1).
Conclusions: ART adherence, proxied by ARV detection in blood, was lower among women who initiated ART during pregnancy than those who started ART before pregnancy, particularly among women aged 15-24 years.
Women, particularly young women, who initiate ART during pregnancy require specific attention to enhance their own outcomes and prevent mother-to-child HIV transmission.

PEMOC39
Effect of client profiling for tailored adherence support on ART retention among children and adolescents living with HIV/AIDS in an OVC program in Nigeria

U. Ezenwa[1], O. Onyezue[1], D. Atagher[1], S. Adamu-Oyegun[1], O. Olabanjo[1], I. Onwuatuelo[1], J. Osi-Samuels[1]
[1]*APIN Public Health Initiatives, Prevention and Community Services, FCT, Nigeria*

Background: ART retention rate among Children and Adolescents Living with HIV/AIDS (C/ALHIV) enrolled in a CDC funded OVC program in Nigeria has been steadily low over the last four years. Despite significant efforts, which ensure drug pickup at supported health facilities and also in non-conventional locations like Patent Medicine Stores, C/ALHIVs continue to be poorly retained, because most interventions do not take into cognizance the underlying uniqueness of members of this population.
The objective of this study was to analyze the effectiveness of client profiling as a strategy for identifying characteristic barriers inhibiting ART retention and by the provision of corresponding tailored adherence support, improve ART retention rates among C/ALHIV.
Description: Of 12,440 C/ALHIV on ART in 10 HIV high burden Local Government Areas in Benue State, in-depth interviews were conducted on 10,433 who are enrolled in OVC program using pre-designed client profile forms administered by 126 Community caseworkers, to determine unique characteristics driving vulnerability to missed appointments and the type of support or incentives required to address it.
Data was analyzed using descriptive and summary statistics after a six months period following provision of required support or incentives.
Lessons learned: Absence of mobile phone 1,262 (12%), attending school or vocational center 1,640 (16%), not pleased with venue for ARV refill 3,025 (29%) and absence of transport fare 4,506 (43%) were identified as key barriers.
Following profiling, 1,094 (10%) required home visits 1,659 (16%) required reminder phone calls/text messages, 3,696 (35%) escort to facility for ARV refill, and 3,984 (38%) re-

Author Index

quired minimum fare support. Retention rate among 10,433 profiled CALHIV who received tailored adherence support or incentive improved from 71% at baseline to 92% after six months representing 21% increase while for the 2,007 C/ALHIV who are not enrolled in OVC program and weren't profiled or received intervention, retention rate was 75% after the same period, representing 4% increase.

Conclusions/Next steps: The study revealed that client profiling and provision of corresponding tailored adherence support or incentive is effective in improving retention rate among C/ALHIV. Program interventions, which will strengthen provision of escort services and minimum fare support to C/ALHIV is highly recommended.

Background: Effective use of pre-exposure prophylaxis (PrEP) has been low among adolescent girls and young women (AGYW) in sub-Saharan Africa. The MTN-034/REACH trial offered AGYW a menu of adherence support strategies and achieved high adherence to both daily oral PrEP and the monthly dapivirine vaginal ring.

Understanding how these strategies promoted product use could inform design of adherence support systems in programmatic settings.

Methods: REACH was a randomized crossover trial evaluating safety of and adherence to the ring and oral PrEP among 247 AGYW (ages 16-21) living without HIV in South Africa, Uganda, and Zimbabwe. Adherence support included monthly counseling sessions with drug level feedback for all participants plus optional daily SMS reminders, weekly phone or SMS check-ins, peer support groups, "peer buddies", and additional counseling sessions. Through 16 focus groups, 24 sets of 3 serial in-depth interviews (IDIs), and 37 single IDIs (n=119 total), we used semi-structured guides to explore experiences with adherence support options and how they encouraged product use. Coded transcripts were analyzed thematically using the Psychological Empowerment Framework.

Results: All strategies except for peer buddies were frequently used and highly valued. Counselors were perceived as friendly, trusted, and non-judgmental; feeling 'cared for' by counselors during monthly sessions, additional sessions, and weekly check-ins increased AGYW's perceived self-worth and motivated adherence.

Drug level feedback showing high adherence increased perceived competence, while results indicating medium-to-low adherence motivated improvement and facilitated open counseling conversations to identify and address challenges.

Counseling and education increased perceived control over HIV acquisition by teaching AGYW how the products worked. In support groups, participants motivated each other, shared adherence challenges—especially on side effects, disclosure, and opposition to product use—and helped each other find solutions.

These groups built self-efficacy by normalizing experiences of experiencing and overcoming difficulties. SMS reminders and counseling exercises helped AGYW integrate oral PrEP into daily routines.

Conclusions: REACH empowered participants to adhere by creating positive, supportive environments and offering a choice of additional strategies to help identify and address use-related challenges. PrEP implementation programs could support effective use through counseling and peer support groups focused on building motivation, self-efficacy, and problem-solving skills.

HIV self-testing

PEMOC42
Adding to the HIV testing services toolkit! Caregiver-assisted oral HIV screening of children 18 months – 14 years in Uganda and Zambia

[1]Catholic Relief Services, Baltimore, United States, [2]Centers for Disease Control and Prevention, Maternal Child Health Branch, Division of Global Health & TB, Atlanta, United States, [3]Catholic Relief Services, Kampala, Uganda, [4]Catholic Relief Services, Lusaka, Zambia, [5]Makerere University, School of Public Health, Kampala, Uganda, [6]Johns Hopkins, Baltimore, United States, [7]Macha Research Trust, Choma, Zambia, [8]Centers for Disease Control and Prevention, Kampala, Uganda, [9]Centers for Disease Control and Prevention, Lusaka, Zambia, [10]Ministry of Health, Government of Uganda, HIV Testing Services, Kampala, Uganda, [11]Ministry of Health, Government of Zambia, Lusaka, Zambia

Background: An estimated 26,727 children living with HIV (CLHIV) in Uganda and 31,461 in Zambia need antiretroviral therapy (ART). Pediatric ART coverage is 68.7% in Uganda and 59.5% in Zambia for CLHIV 0-14 years. Innovative methods are needed to improve the identification of undiagnosed CLHIV.
Studies in Uganda and Zambia evaluated the acceptability, feasibility, and effectiveness of caregiver-assisted oral HIV screening of children 18 months – 14 years.
Methods: Forty-seven facilities in Uganda (32) and Zambia (15) recruited parents/caregivers living with HIV who had children with an unknown HIV status from February-October2021 to screen their children with OraQuick *Advance*©Rapid HIV-1/2 Antibody test kits at home.
Children with reactive oral HIV self-test (HIVST) results received confirmatory testing per respective national guidelines. Children confirmed HIV-positive were linked to ART.
Acceptability, feasibility and effectiveness were evaluated through study registers documenting testing uptake/results returned, and a post-use survey administered to parents/caregivers.
Results: Of the 4,059 eligible index parents/caregivers, 3,931 (96.8%) accepted to screen their 7,593 children with oral HIVST kit; 7,416 (97.7%) children completed oral HIVST with returned results.
Among 2,722 caregivers surveyed, 2,639 (97.0%) reported HIVST was easy to use and 2,615 (96.1%) would recommend HIVST to other caregivers. One hundred-nineteen (1.6%) children had a reactive HIVST, decreasing the need for facility testing by 98.4%. Of these, 116 (97.5%) completed blood-based confirmatory testing. Forty-three (37.1%) children were confirmed HIV-positive and initiated on treatment with 97.7% (42) same-day ART initiations. Eleven (0.4%) caregivers surveyed reported a child had minor reactions to oral HIVST.

Demographic Characteristics	Offered oral HIVST n	Accepted oral HIVST n (%)	Returned HIVST results n (%)	Reactive HIVST screening results n (%)	Completed confirmatory blood-based HIV test n (%)	Reactive confirmatory blood-based test result n (%)	Newly diagnosed CLHIV initiated ART within 1 day n (%)	Caregivers Surveyed n	OTK easy to use n(%)	Would recommend OTK to other parents n(%)

Table. Caregiver-assisted pediatric oral HIV screening uptake, results return, linkage to treatment, and acceptability in Uganda and Zambia.

Conclusions: Caregiver-assisted oral HIVST is an acceptable, feasible and effective option to screen high-risk children who might not otherwise receive HIV testing and decongest health facilities.
Policy makers may consider revised guidance to promote caregiver-assisted oral HIV screening for children 18 months-14 years, expanding community-based pediatric testing options during the COVID-19 pandemic.

PEMOC43
Understanding the potential for harm among men who have sex with men using HIV self-testing in the SELPHI online randomised controlled trial in England and Wales: a multi-method study

T.C. Witzel[1,2], E.J. Nicholls[2,1], L. McCabe[3], P. Weatherburn[2], S. McCormack[3], C. Bonell[2], M. Gafos[2], F.C. Lampe[1], A. Speakman[1], D.T. Dunn[3], D. Ward[3], A.N. Phillips[1], R. Peabody[4], M.M. Gabriel[3], Y. Collaco-Moraes[3], A.J. Rodger[1], F.M. Burns[1]
[1]University College London, Institute for Global Health, London, United Kingdom, [2]London School of Hygiene and Tropical Medicine, London, United Kingdom, [3]University College London, Medical Research Council Clinical Trials Unit, London, United Kingdom, [4]NAM, AidsMap, London, United Kingdom

Background: The potential of social-harms (e.g. coercion to test, relationship breakdown) resulting from HIV self-testing (HIVST) is a longstanding concern hindering widespread implementation. SELPHI (An HIV Self-Testing Public Health Intervention) is the largest randomised trial of HIVST in a high-income country. We aim to explore the relationship between HIVST and harm.
Methods: Cis/trans men who have sex with men (MSM) aged 16+, reporting life-time anal intercourse, resident in England and Wales were recruited through apps/social media, and randomised 60/40 to baseline HIVST (BT) or standard of care (no baseline HIVST (nBT)) between Feb2017-Mar2018. A subset (received HIVST in BT, remained

HIV-negative, reported risk at 3-months) were randomised to 3-monthly HIVST (RT) or not (nRT). All received an exit survey including harms to relationships, well-being, false positive results or being pressured/persuaded to test when they did not want to. Nine reporting harm in surveys were interviewed in-depth; interviews were audio-recorded, transcribed and analysed narratively.

Results: The sample of 10,111 were predominantly cis-MSM (99%), 90% white, 88% gay, 47% university educated and 7% current/former PrEP users. Final survey response rate was: nBT=26% (1056/4062), BT=47% (2802/3567), nRT=42% (510/1228), RT=48% (581/1210).

Reports of harm were rare. In BT, nRT and RT combined, harms to relationships and to well-being were reported by 1% (n=25/2675) and 1% (n=37/2658) respectively. In all arms combined, being pressured/persuaded to test was reported by 1% (n=54/3678), and false positive results in 2% (n=32/1603). Table 1 provides details by trial arm.

Type of harm	nBT %(n)	BT %(n)	nRT %(n)	RT %(n)	Overall
Relationships	N/A	1% (15/1626)	0.2% (1/468)	2% (9/581)	1% (25/2675)*
Wellbeing	N/A	1% (18/1611)	2% (8/467)	2% (11/580)	1% (37/2658)*
Pressured / persuaded to test	1% (14/1013)	1% (21/1615)	2% (8/471)	2% (11/579)	1% (54/3678)
False positive	1% (3/280)	3% (8/273)	2% (11/470)	2% (10/580)	2% (32/1603)
*Data not collected for nBT					

Table 1.

Qualitative analysis revealed harms emerged primarily from the kit itself (technological harm), the wider psychosocial intervention (intervention harms) or from the social context of the participant (socially emergent harms). Generally, intervention and socially emergent harms did not reduce HIVST acceptability, whereas technological harms did.

Conclusions: Reported harms were extremely rare in this large RCT of HIVST. Potential for harm should be considered in each context, and individuals experiencing negative impacts from HIVST linked to appropriate support services, but these concerns should not undermine rollout.

HIV testing to support identification of new cases of people living with HIV

PEMOC44

Offering HIV index contact testing to improve case identification and linkage to appropriate care among sexual partnersand biological children of PLHIV: Kavango East and West Namibia

U. Banda[1,2], H. Chirairo[2,1], R. Mulang[2,1], F. Munyayi[2,1], E. Dzinotyiweyi[3], G. Barnabee[1], M. Golden[1], T. Danda[2,1], E. Likoro[3], J. Kambanzera[2,1], M. Sindimba[2,1], N. Forster[2,1], A. Ensminger[1], G. O'Bryan[1], D. Muronga[2,1], R. Njengwa[3], R. Muruti[2,1]

[1]International Training and Education Centre for Health, Department of Global Health, University of Washington, Seattle, United States, [2]International Training and Education Centre for Health (I-TECH), University of Washington, Windhoek, Namibia, [3]Ministry of Health and Social Services, Windhoek, Namibia

Background: Despite progress in identification of people living with HIV (PLHIV), sexual contacts and biological children of PLHIV remain at significant risk of acquiring HIV. Introduction of Index Contact Testing (ICT) in routine HIV Testing Services (HTS) has improved case identification including in settings nearing epidemic control. In the Kavango regions, ICT was conducted at the facilities and in the community.

Methods: A retrospective data review of program outcomes from October 2020 to September 2021 was conducted at five selected high-volume facilities in Kavango East and West. Newly diagnosed HIV-positive individuals and PLHIV with viral loads >1000 copies/ml were offered ICT services using a structured interview guide. Recent sexual contacts and exposed biological children <18 years were listed. Index clients selected referral options for contacts following verbal informed consent and intimate partner violence (IPV) screening. Contact notification approaches included passive/self, provider, contract, and dual referral options. Contacts with unknown HIV status were notified, tested, and linked to ART or HIV preventions services depending on result. Data was captured using REDCap.

Results: ICT services were offered to 449 HIV-positive individuals, 413 (92%) consented and listed 538 contacts (1.3 contacts elicited per index client) with 443 contacts eligible for testing and 254 (57%) tested. Of contacts eligible for testing, 78 (31%) newly tested HIV-positive and 77 (99%) were linked to ART; 176 tested HIV-negative of which 110 were sexual contacts. Of the 110 sexual contacts testing HIV-negative, 78 (71%) were linked to PrEP. Overall, 32% of the listed contacts were HIV-positive.

Conclusions: Offering ICT services to sexual contacts and biological children of PLHIV identified many newly diagnosed HIV positive cases at selected high-volume sites. ICT services had a high rate of acceptance (consent), and more than one contact was elicited from each index client. A high proportion of contacts were linked to either ART or PrEP services.

Strategies to improve early retention in care (first year on ART)

PEMOC46

Attrition from antiretroviral treatment among adults in Mozambique, 2015-2019

L. Chaguala[1], A. Juga[2], F. Ponda[1], M.V. Jossefa[1], N. Kamat[2], D. Mugabe[1]
[1]National Institute of Health- Mozambique, National Health Observatory, Maputo, Mozambique, [2]Centers for Disease Control and Prevention (CDC)- Mozambique, Epidemiology Branch, Maputo, Mozambique

Background: Mozambique has one of the largest HIV epidemics in Africa. Although access to antiretroviral therapy (ART) has increased, Ministry of Health reports 32% are not retained in care. We used national data to estimate 12-month attrition and identify associated factors.

Methods: Data from adult (≥15 years) patients diagnosed with HIV who started ART between January 2015 and December 2019 were extracted from MozART, a national database covering 70% of all patients on ART in Mozambique. Attrition was defined as individuals who were either reported dead or who did not return to care for 90 days since their last clinical visit. Descriptive and multivariate regression analyses were conducted to identify attrition rates and associated factors.

Results: Of 15,634 patients who started ART between 2015-2019, 5% died and 17% did not return to care, for a 12-month attrition rate of 22% (95% CI: 21.16-22.46%). Of all patients 53% were men, 38% were married, 40% completed primary education, 84% reported no history of alcohol consumption, and 43% were in WHO clinical stage III. The median age was 35 years (IQR: 29-43) and median CD4 cell count at ART initiation was 155 cells/mm^3. WHO clinical stages IV (AOR = 2.09, 95% CI: 1.49 - 2.91) and III (AOR = 1.56, 95% CI 1.28 - 1.90), male sex (AOR = 1.53, 95% CI: 1.28 - 1.81), and increased number of partners (AOR = 1.21, 95% CI: 1.02 - 1.44) were associated with increased odds of attrition. Completing secondary education (AOR = 0.72, 95% CI: 0.56 - 0.92) and residing in the northern region of Mozambique (provinces of Cabo Delgado, Nampula and Niassa) (AOR = 0.68, 95% CI: 0.56 - 0.82) were associated with decreased odds of attrition.

Conclusions: This study shows that WHO clinical stages III or IV, and being male, were strongly associated with attrition. Reinforcement of interventions which target patients when they are still in early WHO clinical stages of disease and added support for patient groups at higher risk of attrition, could improve ART retention and thereby reduce HIV mortality in Mozambique.

Epidemiology of COVID-19

PEMOC47

Contrasting COVID-19 and AIDS orphanhood – How can AIDS inform this urgent need?

L. Sherr[1], S. Hillis[2], L. Cluver[3], S. Flaxman[4], J. Unwin[4], A. Butchart[5], A. Vilaveces[2], P. Goldman[6], L. Rawlings[7], P. Green[8], C. Desmond[9], C. Nelson[10], Global Reference Group for Children Affected by COVID-19
[1]University College London, Institute of Global Health, London, United Kingdom, [2]CDC, Washington, United States, [3]Oxford Unversity/UCT, Oxford, United Kingdom, [4]Imperial College, London, United Kingdom, [5]WHO, Geneva, Switzerland, [6]Maestral, Washington, United States, [7]World Bank, Washington, United States, [8]World without Orphans, Washington, United States, [9]University KwaZulu Natal, Durban, South Africa, [10]Harvard, Boston, United States

Background: The AIDS Epidemic highlighted the plight of orphans and vulnerable children infected and affected by HIV globally. Specific funding and evidence based responses are needed. This study firstly contrasts global COVID-19 orphanhood and parental loss with AIDS orphanhood figures to examine the global burden and inform the global response. Then secondly examines how the global HIV and AIDS evidence base can inform the COVID-19 response.

Description: Parental or caregiver loss in childhood has long term consequences for development. An analysis of global data over time has enabled the creation of a model showing the global level of COVID-19 losses of parent or primary caregivers.

This analysis shows that over 6.7 million children have lost a parent or caregiver to COVID-19. This number is greater than the current COVID-19 global death rate. The rate of orphanhood has doubled every six months.

A detailed examination of the data shows that two out of three children are adolescents with the remaining third under the age of 10. Furthermore three quarters of losses worldwide are paternal deaths leaving children vulnerable to exploitation, abuse, poverty and HIV-infection, through elevated risk behaviours. The COVID-19 data was contrasted with the HIV orphanhood and vulnerability data.It took 10 years for 5 million children to become orphaned and vulnerable due to AIDS.

In contrast it has taken 2 years for 5 million children to experience orphanhood and vulnerability due to COVID. The impact of the overlap is unknown and uncharted. The HIV response to orphaned and vulnerable children provides a blueprint for action and a potential vehicle for an integrated and informed response.

Lessons learned: A strategy of '*prevent deaths, prepare families, and protect children*' should be followed based on the learnings from the HIV AIDS epidemic.Evidence based cost effective programmes should inform the urgent response with accelerator evidence guiding programmes.

Conclusions/Next steps: COVID-19 orphanhood and caregiver loss bears similarity with AIDS related orphanhood and vulnerability – although the rate of loss is accelerated. An integrated approach for all children is urgently needed with ongoing HIV and AIDS resources supplemented.

Effects of the COVID-19 on HIV epidemiology and prevention

PEMOC48

Trends in HIV viral load testing and viral suppression in US HIV cohort, 2017-2020

E. Tedaldi[1], Q. Hou[2], C. Armon[2], F. Palella[3], J. Mahnken[2], G. Simoncini[1], J. Fuhrer[4], C. Mayer[5], K. Carlson[2], K. Chagaris[2], J. Li[6], K. Buchacz[6]

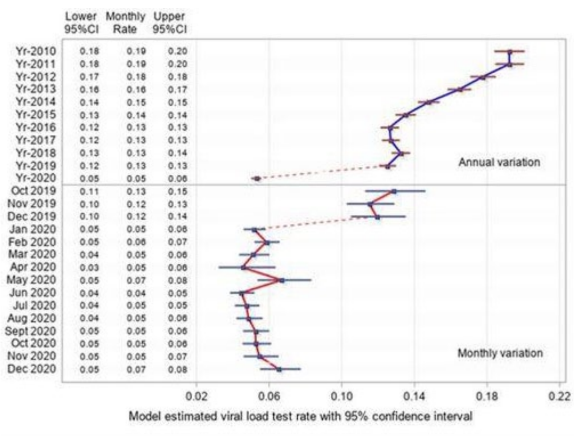
[1]Lewis Katz School of Medicine at Temple University, Medicine/General Internal Medicine, Philadelphia, United States, [2]Cerner Corporation, Kansas City, United States, [3]Northwestern University Feinberg School of Medicine, Medicine, Chicago, United States, [4]Renaissance School of Medicine Stony Brook University, Medicine, Stony Brook, United States, [5]St. Joseph's Comprehensive Research Institute, Tampa, United States, [6]Centers for Disease Control and Prevention, Division of HIV/AIDS Prevention, Atlanta, United States

Background: COVID-19 pandemic effects on ambulatory care services for persons living with HIV in the United States, including HIV viral load (VL) testing frequency, and viremia (≥ 200 copies/mL) have not been well described.

Methods: We analyzed longitudinal data of study participants seen since January 1, 2019 at 8 HIV Outpatient Study (HOPS) sites. HIV VL test monthly rates were derived from generalized linear mixed models (GLMM), using data collected January 2010 to December 2020.

We examined demographic and clinical correlates of viremia before and during the pandemic using GLMM logistic regression with the 2017-2020 data.

Results: Of 2,249 active patients, 75.8% were male, 58.1% aged ≥ 50 years, 40.6% non-Hispanic White (NHW), 38.7% non-Hispanic Black (NHB), 16.9% Hispanic/Latino (H/L), and 51.4% publicly insured. Median CD4 count was 669 cells/mm^3 and 93% had a suppressed (< 200 copies/mL) VL on their last test before January 1, 2020. Monthly VL test rates as times/month (95% Confidence Interval) declined from 0.12 (0.10-0.14) in December 2019 to 0.05 (0.05-0.06) in January 2020, and subsequently stabilized with a rate of 0.07(0.05-0.08) in December 2020 (Figure). The model-estimated percentage of VL tests ≥ 200 copies/mL out of all VL tests was 5.6% before the pandemic (2017-2019), and 4.9% in 2020 (P=0.14). We detected no associations between key sociodemographic factors. Comparing the period before (2017-2019) and during (2020) the pandemic, the frequency of viremia over time was not significantly different by ethnicity, age, gender, type of insurance.



Note: Yr-2010 to Yr-2020 represent the yearly averaged viral load test rate; Oct 2019 to Dec 2020 represent monthly viral load test rates. The horizontal solid line divides longitudinal yearly and monthly viral load test rates. The dashed line highlights the drop of viral load test rates from 2019 to 2020, and from December 2019 to January 2020. Dots and high-low bars represent point estimates with 95% confidence intervals.

Figure. Estimated yearly average (2010-2020) and monthly average (October 2019-December 2020) rate (times/month) of HIV viral load tests using generalized linear mixed model, the HIV Outpatient Study, 2010-2020.

Conclusions: In the HOPS, HIV VL testing rates dropped by about half in early 2020 without year-end recovery. The decrease in VL testing was not associated with changes in the relative frequency of viremia, both overall and by demographics including age, sex, race/ethnicity, and healthcare insurance. Longer term effects of the COVID-19 pandemic upon HIV clinical care and outcomes, including viral suppression, require ongoing investigation.

Growing up with HIV: Specific needs and interventions for children and adolescents

PEMOD51

HIV care continuum outcomes after transition from pediatric to adult care

K. Doraivelu[1], M. Goldstein[2,3], N. Shenvi[4], K. Easley[4], B. Zanoni[3], A. Camacho-González[2,3], C. Del Rio[1,3], S. Hussen[1,3]

[1]Rollins School of Public Health, Emory University, Hubert Department of Global Health, Atlanta, United States, [2]Children's Healthcare of Atlanta, Atlanta, United States, [3]Emory University School of Medicine, Atlanta, United States, [4]Rollins School of Public Health, Emory University, Biostatistics, Atlanta, United States

Background: Youth living with HIV (YLH) receiving care in pediatric/adolescent settings will ultimately undergo healthcare transition (HCT) to adult-centered care. HCT is viewed as a high-risk time for care disengagement; however, there is a paucity of research documenting HIV care outcomes after HCT.

Methods: This is a prospective, observational cohort study of HCT among 70 YLH at an HIV care center in Atlanta, Georgia. Patients within three months of HCT were

followed to determine clinical care outcomes through medical record abstractions at five timepoints: baseline, 6-,12-,18- and 24-months. Outcomes were defined as

1. *Linkage to adult care*: at least one visit with an adult provider;

2. *Retention in adult care:* one visit in each post-HCT abstraction period;

3. *Viral suppression:* maintaining HIV RNA <200 copies/mL.

Kaplan-Meier curves were used to estimate time to linkage. Retention in care and viral suppression were estimated using generalized estimating equation analyses.

Results: The majority of our cohort identified as male (88.6%), Black (92.9%), horizontally-infected (80%), and were virally suppressed (73%). Most of our cohort was linked to adult care by 6-month (74%) and 12-month (84%) follow-up periods. Mean time to linkage was 105.8 days. Of those who linked to adult care by 12-months, the retention rate was 86% (CI:78-94%) at 6-months, 76% (CI:66-86%) at 12-months, and 66% (CI:55-78%) at 18- and 24-months (Figure 1).

Among those retained in care, the proportion with viral suppression was stable (74% at 6-months, 77% at 12-months, 67% at 18-months, and 78% at 24-months).

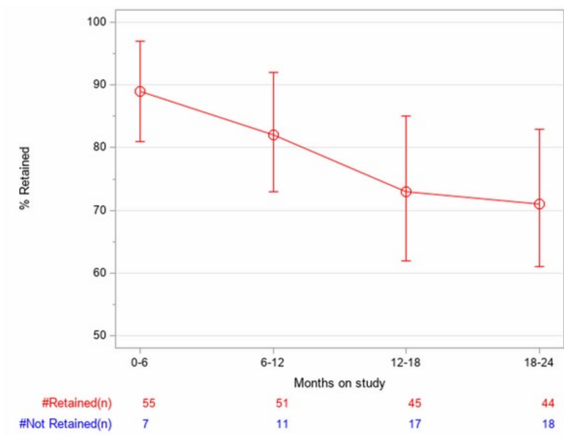


Figure 1. Retention in adult care (for participants who linked to adult care [N=62])

Conclusions: Although a majority of YLH in our cohort linked to adult care, rates of retention decreased over the 24-month follow up period. Rates of viral suppression were suboptimal, though stable.

Current interventions focus mostly on preparation for linkage to adult care; however, our data suggest that strategies to enhance retention in care after HCT will be critically important for YLH.

Experiences and impacts of antiretroviral therapy

[1]Elizabeth Glaser Pediatric AIDS Foundation, Harare, Zimbabwe, [2]Elizabeth Glaser Pediatric AIDS Foundation, Washington D.C., United States, [3]Catholic Relief Services, Baltimore, Maryland, United States, [4]Ministry of Health and Child Care, Harare, Zimbabwe, [5]Centers for Disease Control and Prevention, Harare, Zimbabwe, [6]Centers for Disease Control and Prevention, Atlanta, Georgia, [7]Elizabeth Glaser Pediatric AIDS Foundation, Washington D.C, United States

Background: In 2020, Zimbabwe adopted the World Health Organization recommendation to use raltegravir (RAL) granule-based regimens for the treatment of neonates identified with HIV through birth testing. This study explores the acceptability of RAL granule use by caregivers and health care workers (HCWs).

Methods: Interviews were conducted with 15 caregivers and 12 HCWs from a subset of 14 health facilities in Zimbabwe participating in the initial roll-out of RAL granules.HCWs identified eligible caregivers that had administered RAL to their infant and attended the 8th and/or 28th day of life appointments. Caregivers were selected in the order of whose neonates were most recently initiated on RAL, and HCWs were identified from these same facilities.

Through convenience sampling, eligible HCWs who provided RAL preparation, administration instructions, and support to caregivers with neonates on RAL for at least three months were recruited. Caregivers and HCWs were interviewed on the same day. Transcripts were coded using the MAXQDA software and thematically analyzed.

Results: Caregivers reported their babies looking healthier after initiating RAL, noting improvements in skin appearance and weight. Some caregivers wanted their child to remain on RAL at the day 28 appointment instead of switching as recommended by national guidelines, and others recommended the national roll-out of RAL. HCWs felt that RAL granules were an improvement from previous neonatal antiretroviral medications stating beliefs that RAL improved health outcomes compared to previous regimens.

HCWs reported challenges with caregivers understanding dosing instructions, measuring with a syringe, the need to swirl and not shake the medicine, discarding unused medication, and changes in dosing schedule and amount if RAL was initiated a few days after birth.

HCWs stated that adequate counseling, demonstrations, and repeat demonstrations were crucial to ensure that caregivers clearly understood RAL dosing instructions.HCWs requested more standardized training targeting nurses, guidance on handling missed doses, and clarity on instructions to not mix RAL granules with breastmilk.

Conclusions: While positive feedback was provided by caregivers who used RAL granules and HCWs, additional steps are needed for adequate training of HCWs and sufficient caregiver instruction and support to ensure that RAL granules are prepared and administered correctly.

COVID-19 social distancing and curfews: Implications for access to HIV care

PEMOD58

Impact of Covid-19 prevention measures including restrictions on socio-economic lives of people living with, at high risk of and those affected byhivonaccess, utilization of essential health services

N. Jackie[1], L. Mworeko[1], B. Ajonye[1]

[1]*International Community Of Women Living with HIV Eastern Africa, Advocacy, Kampala, Uganda*

Background: Through its COP20, PEPFAR is supporting ICWEA, HEPS Uganda and SMUG to implement a scale up phase of the Community Led Monitoring model of health services delivery in Uganda. The model trains, supports, equips affected PLHIV communities carry out routine monitoring of HIVTB services aimed at improving quality, availability, accessibility and utilization of these services. the quality and accessibility of HIV services.

Description: In June 2021, An assessment on the impact of COVID-19 prevention measures including restrictions on the socio-economic lives of people living with, at high risk of and those affected by HIV on access and utilization of essential health services. The process involved consultations with key stakeholders and communities of people living with HIV and at high risk of HIV infection.

Data was collected through face-to-face interviews and online and telephone. The assessment involved 300 respondents across 46 districts in Uganda. Most of people living had difficulties accessing social or essential health services and these were more likely to experience drop out of treatment, relapses, stigma and discrimination in the communities, shortage of some essential health commodities such as ARVs, condoms and lubricants.

Lessons learned: A total of 310 people living with HIV consented and participated in the survey. Overall, 60% were female, 38.5% were males while 1.5% preferred not to identify their gender. The survey considered participants above 18 years of age and the results show that majority of the respondents were aged above 38 years. 72% of them suffered a reduction in the number of health workers. Only 41% of the clients were able to go for their clinic appointments of the 67% who had appointments during the COVID-19 era. 75% of the respondents acknowledge that they were stigmatized, discriminated against especially by law enforcement officers while travelling for ART refills on clinic days.

Conclusions/Next steps: Interventions to reduce the spread of COVID-19 in some situations as the attention is focused on controlling the epidemic, implications on access to health services such as drug stock outs were noted at facilities. Mitigating collateral impact of lockdowns where possible interventions, ensure continuity of access to essential services and strengthen support systems of PLHIV.

PEMOD59

Assessing the impact of COVID-19 on HIV prevention among rural populations in South-West Uganda

R. Gumbie[1], L. Akullu[2], J. Van Leeuwen[1], H. Nabimanya[2], C. Buchholz[1], J. Amanya[1], I. Nkonge[2], B. Muhindo[2], H Amutuhaire[2], R. Grundy[1]

[1]*Global Livingston Institute, Denver, United States,* [2]*Reach a Hand Uganda, Kampala, Uganda*

Background: The global focus and prioritization of health systems was altered as a result of the COVID-19 pandemic. Social distancing and stay-at-home measures, termed „lockdowns" by the WHO, dominated public health approaches. Uganda was one of the countries with the strictest lockdown measures in the world, only re-opening schools in January 2022, 20 months after the pandemic began.

The full impact of the pandemic on HIV incidence and prevention is still under investigation, as the Gates' Foundation Goalkeepers report 2021 found that the global goal to fight HIV had been set back 25 years in 25 weeks.

Methods: Since 2014, the 'iKnow Kati' HIV awareness and prevention program implemented by RAHU and the GLI, has provided channels for youth to obtain HIV prevention information, testing, counselling, and treatment services. As a result, the campaign held on World AIDS Day 2020 targeted vulnerable groups that were disproportionately affected by the COVID-19 pandemic.We trained peer educators within 5 districts to collect data through a cross-sectional survey. Participants who accessed health outreach services responded to questions about the campaign and COVID-19.

Results: Out of 655 respondents, 65% were female and 35% male with the highest percentage age groups falling between 20-29 years old.When asked about how COVID-19 had impacted their health seeking behaviour, nearly 25% of respondents mentioned that lack of transportation was a barrier to seeking health services. About 12% indicated that finances played a role, while 3.7% mentioned the lockdowns, and 3% mentioned stigma and fear.

Conclusions: While the full impact of the COVID-19 pandemic on HIV services is still being researched,the Gates Foundation Goalkeeper's report identified that some of the most effective interventions have happened at the hyperlocal level, headed by leaders who have worked long and hard to earn the trust of their communities.
Our results show that access to health services through provision of accessible programs designed with specific communities in mind is effective. There is evidence that lack of transportation, finances and stigma and fear play related to COVID-19 played a role in health seeking behaviour.

PEMOD66

Impact of coronavirus disease 2019 social distancing and curfews on the people of western Uganda: implications for access to HIV care

Z. Naiga[1], R. Najjeke[2]
[1]*Kyambogo University, Social Sciences, Kampala, Uganda,* [2]*Kyambogo University, Information Technology, Kampala, Uganda*

Background: The world has been hit by the covid-19 pandemic which led to the loss of several lives across the globe. Uganda following the WHO recommendations imposed social distancing and curfew restrictions on its population as measures to combat the rapid spread of covid-19. Little or no studies have been carried out on the impact of these restrictions on HIV care by people of western Uganda.
Methods: The study was conducted between March to December 2021 at the health care centers in western Uganda. A cross-sectional study design was used by interviewing the people with HIV (n=672) attending health care centers in the region using. XLSTAT, statistical software was used to obtain the descriptive data. Significant differences between means were determined using the T-test and Analysis of variance.
Results: The study revealed that 43% of people with HIV aged (18-30) years reported being beaten by security persons denying them access to health care centres for medication. The majority (65%) of the female people with HIV reported having run out of their ARV drugs as they could not walk long distances to access the health care centres due to halting of transport means.
A good number (95%) of the male persons with HIV that got to the health care centres were not attended to. The health care practitioners were reported to have attended much more on covid-19 cases than the HIV related cases.
The people ageing with HIV (above 50years) reported having contracted co-morbidities resulting from reduced HIV care access. Significant differences were observed in access to HIV care before and during the imposing of the restrictions.
Conclusions: The covid-19 social distancing and curfew restrictions denied the people with HIV access to health care centers which put their lives at stake. The government under the ministry of health should use this study data to establish HIV care centers at the village level. This will allow the People with HIV in western Uganda to easily access these facilities even in times of crisis.

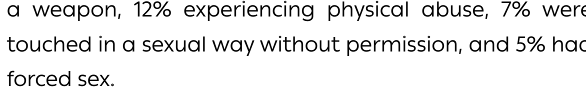
Social and behavioural aspects and approaches to COVID-19

PEMOD60

Impact of the COVID-19 pandemic and related restrictions on the lives of young people living with HIV in Kisumu, Kenya

J.M. Zech[1], A. Zerbe Buba[1], M. Mangold[2], S. Akoth[3], R. David[3], J. Odondi[3], D. Naitore[3], K. Ndede[3], M. Hawken[3], T.G. Harris[1], E.J. Abrams[1]
[1]*ICAP at Columbia University, New York City, United States,* [2]*Columbia University Irving Medical Center, New York City, United States,* [3]*ICAP Kenya, Nairobi, Kenya*

Background: Adolescents and young adults with HIV (AYAHIV) may be particularly vulnerable to the impact of the COVID-19 pandemic and associated mitigation measures which can adversely impact fragile social and economic systems. We examined the impact of the pandemic and related government mandated restrictions among AYAHIV in Kisumu, Kenya.
Methods: Between April-May 2021, a cross-sectional survey was conducted among a convenience sample of AYAHIV 18-25 years aware of their HIV status and receiving HIV care at Jaramogi Oginga Odinga Teaching and Referral Hospital. Information on demographics, COVID-19 knowledge, protective measures, and the impact of the pandemic and related restrictions (i.e., curfews, lockdowns, school/workplace closures) on their daily lives and wellbeing since the start of the pandemic was collected. Responses were analyzed using descriptive statistics.
Results: Of 275 AYAHIV enrolled: median age 22 years (IQR: 19-24 years); 178 (65%) female; 222 (81%) completed some secondary education or higher; 108 (39%) lived in an informal housing area.
Awareness of COVID-19 was high (99%), mean COVID-19 knowledge score was 4.32 (SD: 0.93; range 1-5) and most reported taking protective measures, including frequent handwashing (91%) and face mask use (85%). Over half (55%) reported recently going to a crowded place, including church (78%) and bars/clubs (13%).
Overall, 193 (70%) felt COVID-19 and associated restrictions impacted them including affecting their daily routine (38%), views on travel/immigration (22%), and relationships (14%). Almost half (49%) reported changes in living situation; 24% living with different people, 11% moved/relocated, and 5% newly living on the street.
Additionally, AYAHIV reported increased verbal arguments (30%) and physical conflict (16%) at home with 8% reporting someone having used/threatened them with



a weapon, 12% experiencing physical abuse, 7% were touched in a sexual way without permission, and 5% had forced sex.

Conclusions: AYAHIV in Kenya were knowledgeable about COVID-19 and prevention practices despite inconsistent adherence. Impacts of the pandemic and related restrictions were felt across various aspects of AYAHIV's lives, including disrupted living situations and increased exposure to verbal and physical conflict, including sexual violence. Interventions are needed to address the impact and potential negative long-term effects of the pandemic on AYAHIV health and well-being.

PEMOD61

Improving access to HIV services while minimizing potential exposure to COVID-19 among men who have sex with men (MSM) in Ghana

S.E. Owusu[1], C. Asamoah Adu[2], S.K. Wosornu[3], K. Diaba[4], C. Yalley[1], G. Ekem-Ferguson[5]

[1]Maritime Life Precious Foundation, Programs, Takoradi, Ghana, [2]Ghana-West Africa Program to Combat AIDS and STIs (WAPCAS), Executive Directorate, Accra, Ghana, [3]Maritime Life Precious Foundation, Executive Directorate, Takoradi, Ghana, [4]Ghana-West Africa Program to Combat AIDS and STIs (WAPCAS), Programs, Accra, Ghana, [5]Ghana Health Service, Clinical Psychology, Accra, Ghana

Background: Ghana experienced disruptions in providing HIV services to MSM due to COVID-19. Factors such as social distancing which restricts large group outreaches; reduced demand for services because of fear of COVID-19 transmission in facilities; and reduced availability of services as providers are assisting with pandemic response affect delivery of HIV services for MSM.

Maintaining uninterrupted access to essential HIV services for MSM during the pandemic require using integrated and community-based strategies that minimizes potential risk for COVID-19 exposure.

Description: Maritime-Foundation introduced various community-based approaches to HIV service delivery for MSM during the pandemic in three districts. Peer educators were trained to provide education on COVID-19 during their community outreach activities. Authorization was sought for outreach workers in lockdown areas and provided with PPEs during delivery of physical outreach services.

Flexible strategies were implemented to preserve access to HIV services and promote safety of staff and clients during the pandemic:

1. Social media platforms were used to engage peers for HTS and support PLHIVs through virtual case management;
2. HTS and treatment took place at homes and safe locations identified and agreed by peers at their own convenience;
3. Condoms and lubricants were made available at community-led Drop-In-Centers and outlets for easy access;
4. The program promoted multi-month dispensing of ART and PrEP to eliminate clinic visits.

Lessons learned: Introduction of community-based strategies during the pandemic reached out to more MSM and increased HIV+ yield across the three districts. During the pandemic between February to April 2020, 445 new MSM were reached and tested for HIV; 32 were diagnosed positive.

After the introduction of community-based strategies, between May and July 2020, 634 new MSM were reached and tested; 89 were diagnosed positive.

Conclusions/Next steps: CSOs can adopt tailored community-based approaches that can be integrated into HIV programs to improve results in reaching, testing and linking MSM in times of a pandemic.

Scaling up community-based approaches to HIV service delivery can help safeguard the hard-fought gains of the global HIV response. If these solutions are sustained beyond the pandemic, they may serve to modernize KP programming and position it to be more effective in our new reality

PEMOD62

Factors influencing COVID-19 vaccine acceptability in women living with, or at high risk of HIV in South Africa

H. Humphries[1], L. Lewis[1], S. Choonara[1], E. Lamontagne[2], A. Yakusik[2], K. Dikgale[1], N. Mkhize[3], B. Kuwane[4], D. Massawe[5], A. Matendawafa[5], O. Arije[6], M. Folayan[6], Q. Abdool Karim[1]

[1]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa, [2]UNAIDS, Geneva, Switzerland, [3]AIDS Foundation South Africa, Durban, South Africa, [4]Youth Health Africa, Johannesburg, South Africa, [5]African Alliance, Johannesburg, South Africa, [6]Obafemi Awolowo University, College of Health Sciences, Ile-Ife, Nigeria

Background: COVID-19 vaccines offer hope for a return to 'normality' but uptake varies. Previous research reported a 67% acceptability rate amongst the general South African population.

This study investigated factors influencing vaccine hesitancy amongst adolescent young girls and young women (AGYW), and key populations (KPs) living with, or at high risk of HIV living in South Africa.

Methods: We analyzed data from a cross-sectional survey of women (AGYW, HIV-positive women, sex workers, LGBTQ+ women, migrants and women using drugs) from four provinces in South Africa, conducted between September-November 2021. Surveys collected information on demographics, self-reported HIV status, vaccine hesitancy, and the impacts of COVID-19. We defined vaccine hesitancy as disagreeing with the statement: 'When a vaccine for COVID-19 is available to me, I will get it'.

Prevalence of vaccine hesitancy was quantified and factors associated with hesitancy were measured using multivariable logistic regression.

Results: Of the 2,812 women interviewed, 2,763 (98%) responded to the question on vaccine hesitancy and 2,332 (82.4%) reported their HIV status. From the 2,320 women with complete vaccine and HIV status data, 14.4% reported being vaccine-hesitant.

Prevalence of vaccine hesitancy was 13.4% among HIV-positive women, 18.3% among women 15-24 years-old, 16.9% among LGBTQ+ individuals, 29.3% among migrants (n=99), 17.6% among sex workers, 18.1% among women with disabilities (n=166) and 25.6% among drug-users.

The three most common reasons for vaccine hesitancy regardless of HIV-status or sub-population were being scared of side-effects (57.9%), a lack of trust in authorities (32.5%) and being anti-vaccines (23.9%).

Vaccine hesitancy was positively associated with age <25 years (adjusted odds ratio (aOR): 1.73(95% confidence interval (CI): 1.35-2.22), incomplete secondary schooling (aOR: 1.52(95% CI: 1.06-2.16), economic vulnerability (aOR: 1.43(95% CI:1.00-2.05) and reporting anxiety/depression (aOR: 1.81(95% CI: 1.35-2.42). Previous COVID-19 infection in the household was associated with reduced vaccine hesitancy (aOR: 0.41 (95% CI: 0.28-0.61).

Conclusions: This study demonstrated low vaccine hesitancy amongst AGYW and KP's. Our more granular analysis highlighted that broader contextual socioeconomic concerns, anxiety and youth affect vaccine uptake - mediated by concerns about side-effects, vaccine safety and social status. Customized interventions, adjusted with time, that build trust in vaccines and enhance uptake are needed.

PEMOD64

Project Samajh – Leveraging Social-Media for promoting COVID safety behaviors, safer sex practices, and ART adherence among the LGBTQ+ community during COVID -19 pandemic in India: lessons learned

A. Dange[1], S. Abbasi[1], Y. Singh[2], S. Kumar[1], R. Pujari[1], S. Rawat[1], M. Sivasubramanian[1], V. Anand[1]

[1]*The Humsafar Trust, Mumbai, India,* [2]*The Humsafar Trust, Delhi, India*

Background: In India, Covid-19 pandemic messaging/communication was linear thereby creating a severe knowledge gap among LGBTQ+ on transmission, prevention and HIV-related safety behaviors/measures. The Humsafar Trust (HST) envisaged, designed and implemented an LGBTQ+ community-led social media campaign to bridge this gap. Project *Samajh* (Understanding) was funded by UNAIDS India country office.

Description: Three-pronged communication strategy was implemented for LGBTQ+ communities awareness, improved services access and linkage to care. Communication content was designed by community members and focused on COVID-appropriate behaviors while addressing misconceptions, safer sex, STI protection, HIV/ART treatment, mental health, and information on NACO-govt and other helplines. Overall, 46 posters, 7 videos, 18 infographics and 24 quizzes were promoted on HST's social media pages; organisational Facebook groups, and HST's Youtube, Instagram, Twitter, and Linkedin channels. Whatsapp groups helped promote content amongst `hard -to-reach LGBTQ+'.

Influencers/micro-influencers were engaged to outreach specific local LGBTQ+ population. Better-performing posts were boosted for wider reach. In four months, *Samajh* reached 4 million persons across India. Largest audience reach 78% was achieved from paid promotions; 18% reach was achieved by eleven community influencers who also attracted 9% engagement. HST's social media handles achieved 6% engagement rate.

Lessons learned: Community inputs in designing content is critical for presenting COVID-19 information for LGBTQ+ communities. Content must be holistic, engaging and address issues such as mental health, partner safety, sexual health along with COVID-19 information. Content needs to be mobile-screen oriented as maximum consumption is on mobile phone. Age 18-24 years emerge as focus audience on social media.

Existing support services such as mental health and NACO helplines can be leveraged for further support. Social media paid promotion is able to reach a diverse set of audience based on campaign objective at a low cost however, LGBTQ+ community influencers attract higher engagement rate.

Conclusions/Next steps: Social media-based health communication is the new frontier for community based organizations to reach young/hard-to-reach populations. Effective virtual promotion strategies can be low cost and effective in behaviour change messaging.

Project Samajh experiences will be leveraged in Global Fund-supported NETREACH and other virtual outreach projects targeting virtual populations vulnerable to HIV/AIDS.

PEMOD65

South African adolescents living with HIV talk priorities! Longitudinal analysis of priorities of adolescent advisors living with HIV prior-to and during the COVID-19 pandemic

L. Gittings[1,2], Y. Price[1], A. Thomas[1], N. Kannemeyer[1], J. Kelly[1], N. Ralayo[1], L. Cluver[3], C. Logie[2], E. Toska[1]

[1]*University of Cape Town, Centre for Social Science Research, Cape Town, South Africa,* [2]*University of Toronto, Factor-Inwentash Faculty of Social Work, Toronto, Canada,* [3]*University of Oxford, Social Policy and Intervention, Oxford, United Kingdom*

Background: Growing evidence documents the indirect effects of the COVID-19 pandemic on youth. We explore and compare the priorities of youth living with HIV in the Eastern Cape province of South Africa prior to, and during the COVID-19 pandemic using longitudinal qualitative and participatory data.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

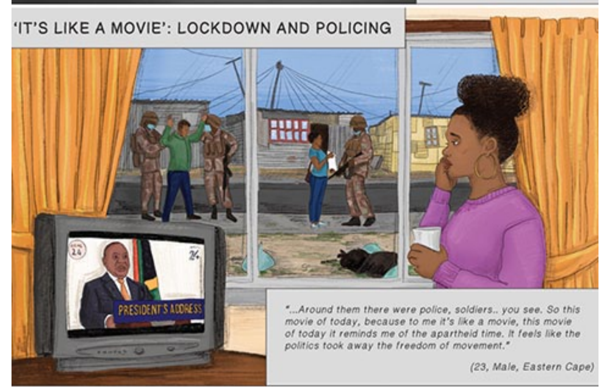
Author Index

Methods: Findings were co-generated with adolescent advisors in the Eastern Cape Province of South Africa (n=19, ages 16-21), recruited from studies of adolescents living with HIV, and young parents.

Advisors engaged in an exercise to generate youth health and development-related priorities prior to COVID-19 in 2019 and 2020. During the COVID-19 pandemic in 2020/2021, they shared their experiences, challenges and coping strategies in semi-structured telephone interviews (n=14) and group-based social media activities (n=27). We thematically analysed COVID-19 data, then compared themes with pre-pandemic priority lists.

Results: The most common priorities pre-COVID-19 were substance abuse, unemployment and career, health and medication, pregnancy, peer pressure and bullying and blessers (age disparate transactional sexual partners). These pre-COVID-19 priorities, apart from blessers, presented as strong themes in the COVID-19 data.

Additional COVID-19-related priorities that were not in the pre-pandemic exercise included: mental health and emotional well-being, describing feeling depressed and anxious over uncertain futures and new concerns over crime and policing.



Conclusions: While many topics of concern to adolescents living with HIV remain unchanged before and during COVID-19, there were also notable differences.

New COVID-19 reported challenges included crime and policing as well as mental health and emotional challenges.

This data dovetails with a growing literature on mental health concerns exacerbated COVID-19 and warrants further consideration ofyouth mental health needs brought about by COVID-19. While this data demonstrates how COVID-19 may have exacerbated pre-existing issues, analysis also suggest that COVID-19 may have brought about a new paradigm for adolescents to make sense of, and articulate their challenges.

Sexual and reproductive health, fertility, family planning, pregnancy and abortion

PEMOD63

Pregnancy history and unmet need for contraception among female sex workers living with HIV in Durban, South Africa

C. Comins[1], K. Rucinski[2], M. Mcingana[3], N. Mulumba[4], L. Shipp[1], H. Hausler[5], S. Baral[1], S. Schwartz[1]

[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States, [3]TB HIV Care, Key Populations Program, Cape Town, South Africa, [4]TB HIV Care, Key Populations Program, Durban, South Africa, [5]TB HIV Care, Cape Town, South Africa

Background: In South Africa, an estimated 60% of female sex workers (FSW) are living with HIV, with studies indicating that the majority of FSW are mothers and primary caregivers.

This analysis aims to characterize pregnancy history, fertility intentions, and unmet need for contraception among FSW living with HIV.

Methods: Non-pregnant cisgender FSW living with HIV ≥18 years of age were enrolled into the Siyaphambili trial in Durban, South Africa (June 2018-March 2020).

Fertility intentions and contraceptive and antiretroviral therapy (ART) use were captured at baseline through an interviewer-administered questionnaire; viral load was measured.

Multivariable robust Poisson regression was used to estimate the association between correlates of unmet need for contraception at enrollment, controlling for age and education.

Results: Of the 1,379 FSW living with HIV enrolled in Siyaphambili, 85.2% had previously been pregnant. History of unplanned and unwanted pregnancy was high (90.7% and 90.2%, respectively).

Nearly all (95.2%) reported it was important to "avoid pregnancy now", but 18.8% desired future children. Use of hormonal/long-acting contraception was low (35.2%), and consistent condom use in the prior 30 days was limited with both clients and non-paying partners (59.7% and 49.5%, respectively).

Of the 485 using hormonal/long-acting contraception, 80.0% used injectable birth control. Unmet need for contraception was 60.1%. Participants with ≥1 child and those on ART and virally suppressed in comparison to those not on ART were less likely to have unmet contraceptive

needs (aPR:0.77, 95% CI:0.66–0.91; aPR:0.80, 95% CI:0.67-0.95, respectively), and participants reporting current drug use were more likely to have unmet contraceptive needs (aPR:1.26, 95% CI:1.08-1.47) [Table 1].

	Univariate analysis PR (95% CI)	Multivariate analysis PR (95% CI)[b]

Monthly or less	REF	
Two times per month - four or more times a week	0.94 (0.88 - 1.01)	
ART and viral load status[d]		
Not on ART	REF	REF
On ART and not virally suppressed	0.89 (0.73 - 1.01)	0.88 (0.75 - 1.04)
On ART and virally suppressed	0.80 (0.68 - 0.95)	0.80 (0.67 - 0.95)

[a] Defined as the proportion who are not using a hormonal/long-acting contraception method out of all the women reporting it was important to not get pregnant now. A hormonal/long acting contraceptove method included birth control pill, intrauterine device, injectable birth control, implant.
[b] Factors significantly associated with unmet contraceptive need at the p<0.1 level in the univariate models were included in the multivariate, age-adjusted model.
[c] Includes marijuana, cocaine, sugar, ecstasy, methamphetamine, heroin, crack, flakka
[d] Viral suppression was defined at <50 copies/mL

Table 1. Determinants of umet needs for contraception[a] among female sex workers living with HIV in Durban, South Africa (n=1,379)

Conclusions: Moving forward, strategies to couple fertility intention screening and contraceptive care with ART are needed to optimize reproductive health and decrease vertical HIV transmission.

Further, understanding unmet contraceptive needs is critical to preventing unintended pregnancies and promoting safer conception among FSW living with HIV.

Effects of the COVID-19 on key populations

PEMOD67

Female sex workers (FSW) and police violence during the Covid-19 health crisis in 2020-21: results from the EPIC multi-country community-based research program in Argentina

I. Aristegui[1,2], J. Castro Avila[3], V. Villes[3], G. Orellano[4], M. Aguilera[5], M. Romero[5,6], L. Riegel[3], L. Kretzer[3], N. Cardozo[1,5,6], P. Radusky[1,7], D. Rojas Castro[3,8], EPIC Study Group

[1]Fundacion Huesped, Research Department, Buenos Aires, Argentina, [2]Universidad de Palermo, Buenos Aires, Argentina, [3]Coalition PLUS, Community-based Research Laboratory, Pantin, France, [4]Asociación de Mujeres Meretrices de Argentina (AMMAR), Buenos Aires, Argentina, [5]Asociación de Travestis, Transexuales y Transgenero de Argentina (ATTTA), Buenos Aires, Argentina, [6]RedLacTrans, Buenos Aires, Argentina, [7]Univesidad de Buenos Aires, Buenos Aires, Argentina, [8]Aix Marseille Université, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, Marseille, France

Background: Female sex workers (FSW) have been disproportionately impacted by the Covid-19 crisis. Data shows increases of police violence towards key populations (KP), a consequence of their greater attributions to enforce health government measures. This study aimed to identify factors associated with police violence experienced among FSW during the Covid-19 crisis in Argentina.

Methods: EPIC is a multi-country, cross-sectional, community-based research program evaluating the impact of Covid-19 among KP. In Argentina, the study was conducted by community-based organizations (CBO) working with and for FSW. 173 FSW completed an online survey (October 2020-April 2021). Police violence was measured as having experienced episodes of at least one type of violence (physical, verbal, psychological or sexual) by security forces since the start of the health crisis. Factors associated with police violence were assessed in logistic regression models.

Results: Among respondents (N=173, median age 34[IQR 27–42]), 39.3% were transgender women (TW), 78.1% declared that sex work was their only income source and 71.7% declared that their financial situation has deteriorated considerably with the health crisis. 44.5% of FSW reported experiencing police violence. Furthermore, 59 (76.6%) of them experienced more frequent violent episodes. After adjustment for age, being a TW (aOR[95%CI]= 4.00[1.69;9.45], deterioration of quality of life (4.59[1.28;16.51]), fear of being harassed/arrested by the police (6.39[2.12;19.68]) and having received medical assistance from a CBO (5.01[1.98;12.68]) were independently associated with police violence.

Conclusions: FSW in Argentina have experienced an increase in police violence since the beginning of the health crisis. Belonging to multiple KP (FSW and TW) increases the

Oral abstracts

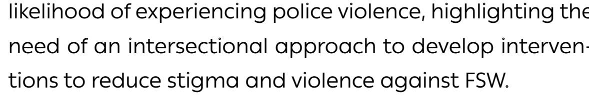
Author Index



likelihood of experiencing police violence, highlighting the need of an intersectional approach to develop interventions to reduce stigma and violence against FSW.

Police violence is related to fear of the police, possibly impeding street-based sex work, and may contribute to a decline in the financial situation and the quality of life of FSW. CBOs have responded to the needs of FSW by offering medical assistance, among other services, to support KP.

PEMOD68

Who cares if you're poz right now? Learning and adapting risk and responsibility from HIV to COVID-19 among barebackers

J. Garcia-Iglesias[1], C. Ledin[1]

[1]*University of Edinburgh, Usher Institute, Centre for Biomedicine, Self and Society, Edinburgh, United Kingdom*

Background: COVID-19 has had major impacts on sexuality and sexual practices. Barebackers, gay men who engage in condomless anal intercourse, have adapted their experiences and risk management practices from HIV to navigate the new risks of COVID-19 and balance risk and desire.

Methods: We conducted an online ethnography of the most popular barebacking online forum in English during July 2021, retrieving 112 conversations comparing HIV and COVID-19, exploring how to navigate risk and retain pleasure. These were thematically analyzed.

Results: In our findings, we found significant differences between those users who had first-hand experience of living through the AIDS crisis, who were seen as 'experts' or as having a 'badge of honor', and younger forum members. Overall, barebackers compared the AIDS crisis (not the current HIV-as-treatable-moment) with COVID-19 in several ways.

First, they repurposed individual risk reduction practices (e.g. reducing the number of partners, limiting casual sex) as a way of preventing the spread of the virus both among barebackers and to society at large.

Second, they emphasised the role of 'individual responsibility' for preventing the spread of COVID-19 and chastised those they saw as 'reckless' (e.g. those engaging in casual sex while infected with COVID-19), repurposing serophobic language (e.g. 'slut-shaming').

However, third, they also strongly emphasised their desire to retain pleasurable barebacking practices, such as group sex in clubs, and suggested that temporary risk reduction would make these possible in a post-COVID-19 future.

Conclusions: This is, to our knowledge, the first study of how barebackers have adapted HIV learnings to COVID-19. Barebackers are a community historically disproportionally affected by HIV and culturally seen as 'risk prone' or 'hedonistic'. This paper evidences not only that barebackers have adopted narratives of individual responsibility deeply influenced by the history of the AIDS crisis, but that they have done so to preserve their future 'pleasurable practices', such as group sex, after COVID-19.

Thus, this paper reveals how one key community disproportionaely affected by HIV have adapted to COVID-19 and imagined their future after it.

PEMOD69

Understanding the lived experiences of people at the intersection of HIV and COVID-19

A. Hundal[1], D.L. Bose[1], S. Rawat[2], D. Baruah[2], S. ul Hadi[1], K. Seth[1], P. Saha[1], J. Mukherjee[1]

[1]*IAVI, New Delhi, India,* [2]*Humsafar Trust, Mumbai, India*

Background: COVID-19 has been particularly challenging for marginalized communities affected by HIV. For many, this meant reliving experiences of fear, confusion, stigma and economic disenfranchisement.

To understand lived realities of those at the intersection of COVID-19 and HIV, IAVI, with Humsafar Trust, conducted a series of Community-Researcher Dialogues in India.

Description: Between November 2020 and June 2021, three virtual dialogues were conducted with 60 participants comprised of community members from FSW, PWID, MSM, AGYW and TG populations, CBOs, activists, scientists and researchers to initiate conversations and identify pressing programmatic and research needs.

Conversations were audio recorded with due participant consent and accompanied by detailed notes. This data was then coded using an inductive framework of analytic domains based on key areas of enquiry.

Lessons learned: These dialogues highlighted the following:

Poor testing and increased HIV risk-taking behaviours - Disruptions in services, fear of contracting COVID-19 at health centers, lockdown-related interruptions in transportation and mass migration led to poor testing and adherence. Food insecurity, fear of stigma and discrimination, lack of family/peer support and isolation, loss of employment, lack of access to care added to pandemic stress, pushing some to opt for unsafe sex for economic sustenance or due to limited access to safer sex options.

Mental health crises emerged as major concerns along with increased incidences of violence, especially among sexual minorities.

Existing networks/collectives of HIV-affected communities were instrumental in facilitating/creating innovative prevention/treatment service/delivery models, working with local/government health agencies to initiate strategies like multi-month dispensing and ART home delivery. In HIV knowledgeable communities, where targeted interventions have been sustained for years, adoption of COVID-19 appropriate behaviours and sharing of information among peers was easier.

Digital media also played a critical role in facilitating referral-, emergency care-, and peer support in real-time.

Conclusions/Next steps: The COVID-19 crisis has highlighted the need to rethink approaches to shared global health practices by putting communities at the centre. The role of HIV knowledgeable communities, along with the vitality of newly created networks during the pandemic, necessitate sharpened insights into how these networks were leveraged to support service uptake, and how they can be further bolstered for future pandemic preparedness.

PEMOD70

'Of the youth, by the youth, for the youth': a peer-led model for building resilience among youth living with HIV during the COVID-19 pandemic

M. Babu Raj[1], L. Reddy[1], F.T. Thomas[1], A. S[1], K. Tippanna Chitti[1], K. Lakshmikanth[1], B. Seenappa[1], G. Nethra Raju[1], K. Mehta[2], A. Shet[2]
[1]Sneha Charitable Trust, Snehagram, Bangalore, India, [2]Johns Hopkins University, Johns Hopkins Maternal and Child Health India Center, Baltimore, United States

Background: HIV care access and delivery was adversely impacted due to the COVID-19 pandemic. Youth living with HIV were particularly affected and were vulnerable to reversal of health gains. In response to this need, Sneha Charitable Trust (SCT) mobilized youth peer leaders to build a model of continued healthcare access and support for those affected during the COVID-19 pandemic in southern India.

Description: The peer-led model consisted of ten HIV-postive youth leaders, who have have demonstrated leadership skills during crises. Between January 2020-September 2021, 500 adolescents and youth aged 12-25yrs with poor healthcare acess and social support were selected as beneficiaries. During this period, the peer leaders in a 1:50 ratio, reached out to beneficiaries and built an effective program focused on addressing misinformation related to COVID-19, strengthening COVID-19-appropriate behaviours, promoted continued support ofone another, ensuring access to ART and nutrition, and support for building healthy lives during pandemic-related adversity. Contact was maintained weekly, and additional nutrition and counselling support for affected families were provided by peer leaders.

Lessons learned: COVID-19 lockdowns impeded ART access among 83.0% of children and youth. Through coordination with the State AIDS Control Society, the program facilitated a 3-month supply of ART through home delivery, which helped to restore ART acesss to 93.0%. During the intervention period, 84.0% remained healthy, 5.8% developed tuberculosis, and 3.2% required hospital admission for opportunistic infections. COVID-19 infections were present in 8.0% adolescent' households. Nutritional support was provided to 60.0% of the households for over 6 months. The peer leaders were able to build strong partnerships with clinical service teams, and facilitated the beneficiaries' healthcare access. Informal surveys administered with the beneficiaries highlighted that the support extend by the peers helped in positive adaptation to adversity, recovery from illness and adaptation and resilience amidst crises.

Conclusions/Next steps: Our unique peer-led model of care provision and confidence-building activities during the COVID-19 restrictions led to HIV-positive youth handling pandemic adversity with resilience.
This model demonstrates that amidst unprecedented crises, peer-led mutual support and partnerships at the community and systems level are critical to ensure ongoing success.

How the COVID lockdown and government measures affected gay men and transwomen's health care, sexuality, and life in Peru: a qualitative study from the EPIC multinational community research program

C. Sandoval Figueroa[1], M. Reyes Díaz[1], J.C. Enciso Durand[1], O. Apffel Font[2,3], N. Lorente[2,4,5], J. Castro Avila[2], L. Riegel[2], M. Di Caccio[2,6], D. Rojas Castro[2,7], C.F. Cáceres[1], EPIC study group
[1]Universidad Peruana Cayetano Heredia, Centro de Investigación Interdisciplinaria en Sexualidad, SIDA y Sociedad, Lima, Peru, [2]Community-based Research Laboratory, Coalition PLUS, Pantin, France, [3]Coalition des Organismes Communautaires Québécois de Lutte Contre le Sida (COCQ-SIDA), Montréal, Canada, [4]Centre d'Estudis Epidemiològics sobre les Infeccions de Transmissió Sexual i Sida de Catalunya (CEEISCAT), Departament de Salut, Generalitat de Catalunya, Badalona, Spain, [5]Centro de Investigación Biomédica en Red de Epidemiología y Salud Pública (CIBERESP), Madrid, Spain, [6]Groupe de Recherche en Psychologie Sociale (GRePS), Université Lyon 2, Lyon, France, [7]Aix Marseille Univ, Inserm, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, ISSPAM, Marseille, France

Background: EPIC-international community-based program is coordinated by Coalition PLUS to collect comparable multinational data regarding the impact of the COVID-19 crisis in key populations (KP) concerning HIV.

Methods: As part of the EPIC-international community-based program by Coalition PLUS, we designed a qualitative study to gather experiences from Peruvian MSM and transwomen (TW) about the Covid lockdown and how they dealt with it regarding health/medical care, education, and work. From September/December 2021, 16 in-depth-interviews with TW and MSM, who identified as gay men, focused on how lockdown and government measures affected their health/medical/care, work, and education.

Results: Gay Men (GM) and TW associated Covid-19 with illness/death/stress. All had friends/relatives who had been severely ill or had died from Covid-19. Many experienced

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

stress after being forced to reorganize their lives and budget, as their education/work routines had changed.
Normally excluded from stable, formal jobs, TW lost their livelihoods as hairdressers, peddlers, or sex workers, facing serious economic difficulties during the lockdown. The government formally includes KPs among vulnerable populations, but did not include TW as recipients of COVID-19 relief packages (food/money) due to technicalities, despite their clear financial vulnerability.
Regarding sexuality, GM/TW dropped out of their networks, but quickly returned to them when measures relaxed. However, sexual health services were suspended from the start of the pandemic, affecting condom and comprehensive care provision. Fortunately GM/TW with HIV picked up their treatment at the health services every three months.
Inconvenient for the general public, public movement restrictions by gender were harmful for TW, who were arrested by the police or ridiculed by the media when going out on women's days. Although this measure only lasted one week, it remained etched on the memory of those interviewed as an example of structural discrimination suffered by TWs.
Conclusions: During lockdown, TW were greatly affected, due to their social and financial vulnerability. They are not receiving government COVID-19 relief packages signals their social and structural exclusion. Public policies for vulnerable populations in Peru should take GM and TW into account. A strategic plan in sexual health services is needed for sizeable emergencies, so as not to leave aside vulnerable populations.

PEMOD72

Economic, social, and behavioural impacts of the COVID-19 pandemic on women and girls living with or at high risk of HIV in Nigeria

A. Yakusik[1], E. Lamontagne[1,2], K. Sabin[1], O. Arije[3], A. Enemo[4], A. Sunday[5], A. Muhammad[6], H. Yanusa Nyako[7], R.M. Abdullahi[8], H. Okiwu[9], M. Oluwatoyin Folayan[3,10]
[1]UNAIDS, Strategic Information, Geneva, Switzerland, [2]Aix-Marseille University, School of Economics, Marseille, France, [3]Obafemi Awolowo University, College of Health Sciences, Ile-Ife, Nigeria, [4]Nigeria Sex Workers Association, Kubwa, Nigeria, [5]African Network of Adolescent and Young Persons Development, Barnawa, Nigeria, [6]Northern Nigerian Transgender Initiative, Abuja, Nigeria, [7]Jami Al Hakeem Foundation, Jimeta-Yola, Nigeria, [8]National Association of Persons with Physical Disability, Abuja, Nigeria, [9]YouthRISE, Abuja, Nigeria, [10]Nigeria Institute of Medical Research, Lagos, Nigeria

Background: Little is known about how the COVID-19 pandemic affected women and girls living with HIV (WLHIV) or at high risk of HIV, who experience disproportionate levels of comorbidity and stigma. We describe the economic, social, and behavioural impacts of the pandemic on WLHIV or at high risk of HIV in Nigeria.

Methods: A cross-sectional survey was conducted between July and December 2021, collaboratively with community-based organizations to investigate the impact of the pandemic on WLHIV or at high risk of HIV, including those who sell sex, live with disabilities, use drugs, migrants and displaced people, and transgender women. Participants 15 years and older were recruited voluntarily, both online and face-to-face, using a combination of venue-based and snowball convenience sampling in ten states covering six geopolitical zones.
Results: There were 4541 respondents; 50% were between 19 and 30 years old, 47% reported living with HIV. 61% (2676/4411) reported a negative impact on their income, and 76% (3342/4409) had to cut back on food.
About 10% (468/4541) received assistance or cash relief. Some 25% (722/2835) started selling sex to meet their financial obligations. WLHIV or at high risk of HIV said they experienced issues accessing health services for HIV, 55% (1988/3581), sexually transmitted infections, 36% (1104/3073), tuberculosis, 22% (609/2773), family planning, 19% (510/2702), and safe abortion care, 13% (335/2570).
The biggest obstacles were financial: 54% affording transport, 39% medicines or tests, and 28% user fees at a health-care facility (Figure 1). Social and structural barriers were also reported (Figure 1).

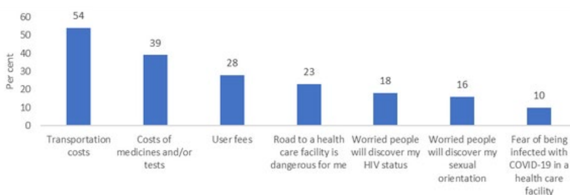

Figure 1. Barriers to health care for WLHIV or at high risk of HIV in Nigeria (N=4541)

Conclusions: Our study demonstrated the significant negative effects of the COVID-19 pandemic on WLHIV or at high risk of HIV in Nigeria. Interventions are necessary to mitigate socio-economic challenges, address structural inequality, and ensure access to health services.

PEMOD73

COVID-19 and self-perceived changes in psychosocial and behavioral outcomes of people living with HIV in community-based clinics of Mali: The EPIC programme of Coalition PLUS

L. Sagaon-Teyssier[1,2], D. Dondbzanga[3,2], M. Guindo[2], D. Traoré[2], A. Kamissoko[2], M. Cissé[2], B. Dembélé Keïta[2], L. Riegel[4], T. Cerveau[3], R. Delabre[4], D. Rojas Castro[1,4], The EPIC Working Group
[1]Aix Marseille Univ, INSERM, IRD, SESSTIM, Economic & Social Sciences of Health & Medical Information Processing, ISSPAM, SanteRCom, Marseille, France, [2]ARCAD Santé PLUS, Centre Intégré de Recherche, de Soins et d'Action Communautaire (CIRSAC), Bamako, Mali, [3]Community Research Laboratory, Coalition PLUS, Dakar, Senegal, [4]Community Research Laboratory, Coalition PLUS, Pantin, France

Background: In Mali, around 23% of the 57000 people living with HIV (PLHIV) on antiretroviral treatment (ART) are followed-up in community-based clinics. Their functioning was reorganized to guarantee the HIV-care continuum during Covid-19. We investigated changes in PLHIV's psychosocial and behavioral outcomes, associated factors to these changes, and their interrelationship.

Methods: The EPIC multi-country community-based research coordinated by Coalition PLUS was conducted in 33 countries including Mali, studying the impact of Covid-19 among PLHIV and key populations.

Analyses used data collected in March 2021 among PLHIV of 18 community-based clinics of ARCAD Santé PLUS. Face-to-face questionnaires collected participants' characteristics, and assessed perceived changes in psychosocial/behavioral and HIV-care related aspects compared before Covid-19.

Outcomes: perceived changes in day-to-day life (DDL) (negative = 1 / unchanged = 0), quality-of-life (QoL) (worse = 1 / unchanged = 0), and ART-adherence (worse = 1 / unchanged = 0). Three-equation multivariate probit model was estimated to investigate associated factors and the link between outcomes.

Results: Among 695 participants, 72.3% were female and median age was 38 years IQR[31-45]. Negative changes in DDL were declared by 74.5%; 27.2% and 40% declared poorer QoL and ART-adherence, respectively. Estimations showed deteriorated financial situation associated with worse DDL (coeff:0.805/p<0.001) and QoL (coeff:0.278/p=0.036).

Negative changes in DDL were less likely for older (coeff:-0.276/p=0.030) and those in rural areas (coeff:-0.507, p<0.013), although more likely for those with difficulties finding social support (coeff:0.640/p=0.003).

Female (coeff:0.263/p=0.040), older (coeff:0.468/p<0.001) and those in urban areas (coeff:0.568/p=0.002) were associated with poorer QoL.

Long-term ART delivery reduced QoL decline (coeff:-0.346/p=0.008). Accommodation difficulties (coeff:0.503/p=0.017), and perceiving that community-based response to Covid-19 was inadequate to PLHIV (coeff:0.331/p=0.002) were associated to negative changes in ART-adherence. Easy healthcare access (coeff:-0.653/p=0.010) and long-term ART delivery (coeff:-0.243/p=0.048) reduced ART-adherence issues.

Finally, ART-adherence and QoL changes are strongly related (correlation:0.308/p<0.001), but not ART-adherence with DDL (correlation:0.127/p=0.063). However, DDL and QoL are processes that evolve together (correlation:0.184/p=0.011).

Conclusions: QoL seems to be a key aspect in the management of negative changes in ART-adherence and DDL among Malian PLHIV, although the mechanism is different. Community-based related factors to QoL should contribute to the improvement of ART-adherence, while focusing on demographic/socioeconomic factors should contribute to the attenuation of the Covid-19 impact over DDL through the improvement of QoL.

PEMOD74

Impact of COVID-19 on access to sexually transmitted and blood-borne infections (STBBI) and harm reduction services for people who use drugs or alcohol in Canada

J. Cox[1], J. Zhang[1], M. Wong[1], D. Shublaq[1], K. Zhang[1], L. Jonah[1], J. Tarasuk[1], J. Sorge[1], E. Wong[1], M. Bryson[1], D. Paquette[1]
[1]Public Health Agency of Canada, Centre for Disease and Infection Control, Ottawa, Canada

Background: The COVID-19 pandemic has disproportionately affected people who use drugs or alcohol (PWUD). This population faces health inequities including increased risk of STBBI and severe COVID-19 illness.

Using national survey data, we describe changes in social determinants of health (SDOH) and access to STBBI-related health services among PWUD.

Methods: From January to February 2021, an anonymous, self-administered, online survey was conducted among anyone living in Canada aged 18+ years who identified as using substances, including alcohol or cannabis, in the past 6 months. Information collected included social determinants of health, substance use, and access to STBBI-related services, including harm reduction.

Results: 1034 individuals participated (61.2% cisgender female, 32.6% cisgender male; mean age 40.5, range 18-84 years). Increased use in cannabis (64.9%), alcohol (56.7%), and opioids (56.9%) was reported. Those who experienced discrimination pre-pandemic reported the highest increase in discrimination (59.7%) compared to those who never experienced it (4.4%). Worsening mental health since the beginning of the pandemic was noted, particularly among participants reporting fair-to-poor mental health prior to the pandemic (Figure 1).

Those who felt the least safe pre-pandemic reported the largest increase in feeling less safe (50.0%) since the pandemic-start, compared to those who felt somewhat

(35.6%) or very safe (19.3%) pre-pandemic. Participants reported pandemic-related difficulties accessing HIV, STI, or hepatitis C testing (58.8%) and harm reduction services (i.e. needle/syringe distribution programs, drug checking services, or drug consumption rooms) (80.6%).

Main barriers included: public health measures; reduced clinic hours; getting a referral or appointment; and concerns about stigma, discrimination, or violence.

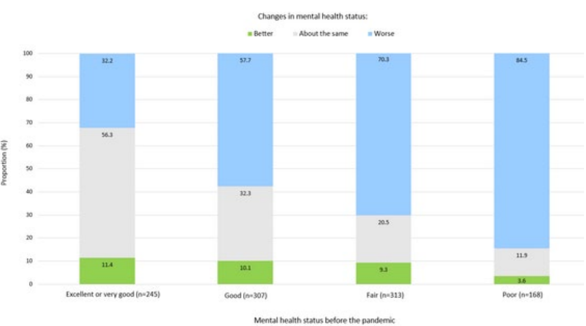

Figure 1. Changes in mental health status since the start of the COVID-19 pandemic

Conclusions: COVID-19 has exacerbated existing SDOH inequities among PWUD in Canada, and introduced challenges accessing STBBI and harm reduction services. Worsening mental health and increased substance use signal the need for improved and innovative support measures (e.g., mobile outreach) to overcome barriers from the pandemic for PWUD.

Role of social and behavioural science in biomedical responses

PEMOD75

PrEParados: a spatially explicit network visualization framework to identify Latino MSM who qualify for PrEP use

M. Kanamori[1], C.H. Shrader[2], A. Johnson[1], J. Arroyo-Flores[1], J. Skvoretz[3], E. Rodriguez[1], S. Fallon[4], J. Stoler[5], S. Doblecki-Lewis[1], A. Carrico[1], S. Safren[5]

[1]*University of Miami Miller School of Medicine, Public Health Sciences, Miami, United States,* [2]*Columbia University, New York, United States,* [3]*University of Central Florida, Tampa, United States,* [4]*Latinos Salud, Miami Beach, United States,* [5]*University of Miami, Miami, United States*

Background: Frameworks are needed to increase PrEP initiation among Latino men who have sex with men (LMSM) in Miami Florida, a US epicenter of the HIV epidemic. Our PrEParados Network Framework identifies LMSM who qualify for PrEP through friendship, sexual, and spatially-explicit networks.

Description: This framework incorporates sociocentric friendship, egocentric sexual and geospatial networks. Findings are based on cross-sectional data collected from October 2018 to August 2019 (N= 130 PrEP eligible LMSM and their 507 sexual partners). Participants were predominantly White, employed full-time, single, mean age of 28 years; and half were foreign-born.

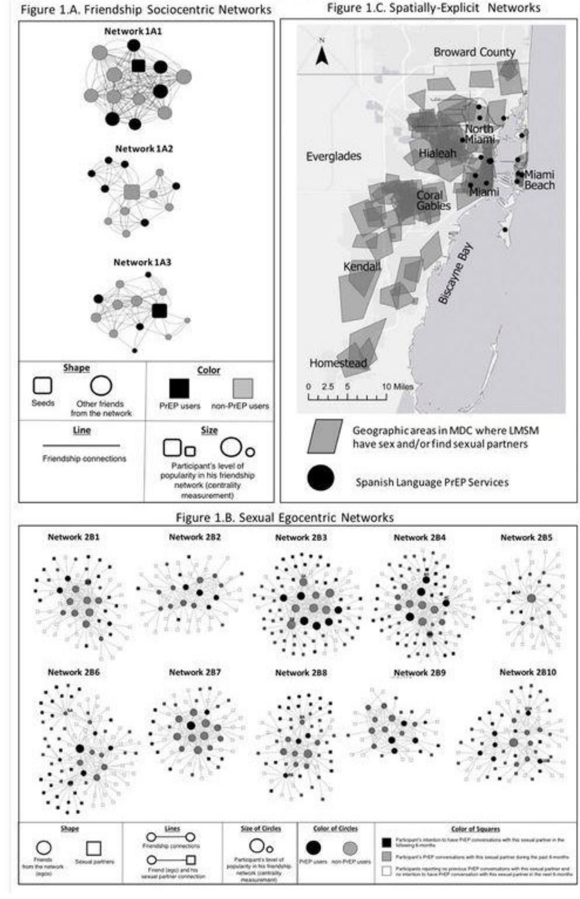

Figure 1. The PrEParados network visualization framework

Lessons learned: Friendship network structures identified correlates of PrEP communication, which included PrEP use within the network. LMSM may feel pressure to use PrEP, after hearing about or observing PrEP use through mutual acquaintances. The framework identified the characteristics of popularLMSM and their intention to disseminate PrEP messages and convince friends to use PrEP.

The PrEParados Framework also identified unconnected LMSM and opportunities to connect them through LMSM "bridges" to other members who use PrEP or encouraged their friends to use PrEP.

The majority of participants did not disclose their PrEP use status with sexual partners. We identified an increase in receptive condomless anal sex among sexual partners who reported at least one partner was on PrEP.

The spatial network found the absence ofSpanish language PrEP services in areas where LMSM find sexual partners and/or have sex, and priority locations for advertisements about HIV services.

Conclusions/Next steps: The PrEParados Network Framework incorporated sociocentric, egocentric, and geospatial networks to identify LMSM who qualify for PrEP use. This model can:

a. Identify, reach and engage key populations who qualify for PrEP but are not using PrEP,

b. Increase diffusion of accurate PrEP information and guidance to key populations, and;
c. Identify policies to increase access to PrEP services.

Social protection: New evidence and programmatic lessons

PEMOE32
Women's legal and economic empowerment project to improve HIV care and treatment outcomes: lessons from cross-border trading initiative in Northern Rwanda and Democratic Republic of Congo

H.N. Gerard Audace[1]
[1]*Universite Laic Adventiste, Economics, Kigali, Rwanda*

Background: Despite remarkable investments in health and social education, gender inequity and poverty remain the major predictors of health outcomes among HIV patients in rural and resource-constrained settings. To improve women's health and HIV outcomes among women from villages surrounding Rwanda-Congo border, LegEcoAccelerator, an innovative program combining legal and economic support were implemented. Family planning and child care services were provided.
We present results following five years of active implementation period. A mixed method evaluation was conducted to assess changes in household income, clinical outcomes before and after 60 months of active implementation. A qualitative assessment captured perceptions and acceptability of the program.
Description: Following poor outcomes among women crossing the Rwanda-RDC border for micro-businesses, we have deployed a micro-grant and saving program to empower women who had very little or no investment capital. We also launched a one-stop center for HIV care and treatment, facility planning and day care services were provided. This integrated and innovative approach was named LegEcoAccelerator program.
Lessons learned: A legal support established a joint agreement between local leadership across two borders and improved women's freedom and social economic development. Of 7623 women enrolled in the program at baseline 72% and 28% were extremely poor and very poor, respectively. A total 15,869 women participated in our LegEcoAccelerator program between January 2017-December 2021. The percent of women living in extreme poverty reduced significantly from 72% to 15%, p<0.001. The percent of women who shifted from extreme poverty and poverty to any other upper wealth categories from 20% to 81%, p<0.001.Over 70 women received childcare and nutrition support. Adherence to ARV increased from 75% to 85%,*p=0.06*. The percent of women with suppressed viral load improved by 50%. Domestic violence incidents which declined by 80%.

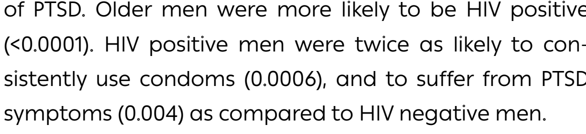
Conclusions/Next steps: Combining legal and social economic support improve the effectiveness of HIV care and treatment. This suggest that combining a legal and economic empowerment could be a strategy to improve health outcome and accelerate the pace toward ending HIV endemic. Although cross-border programs bring about better impact, there is a need for shared accountability and responsibility among neighboring countries.

Innovations in behavioural data collection and use

PEMOE33
A community-centric study of male clients of female sex workers using respondent driven sampling

J. Coetzee[1], M. Milovanovic[1], K. Hlongwe[1], K. Otwombe[1], V. Mbowane[1], G. Gray[2], R. Jewkes[3]
[1]*Perinatal HIV Research Unit, Prevention in Key Populations, Soweto, South Africa,* [2]*South African Medical Research Council, Office of the President, Capet Town, South Africa,* [3]*South African Medical Research Council, Cape Town, South Africa*

Background: In South Africa, male clients of sex workers (MCSWs) account for 40% of new HIV infections. There are currently limited understanding of the population with no interventions targeting MCSWs. Understanding their health status and risk factors for adverse health outcomes is foundational for developing evidence-based health care for this population. Describe the methodology used to successfully implement a community-centric respondent driven sampling (RDS) study of psycho-social circumstances, HIV, violence perpetration and associated factors amongst MCSWs in South Africa.
Methods: A community-centric, RDS, survey of 660 adult MCSWs in Soweto, South Africa was conducted (March–November 2021). Formative interviews and focus group discussions helped inform the RDS study design and inform the questionnaire development. Men from the sex work sector were involved in the study design and questionnaire development. Questions included: demographic, sexual behaviour, HIV testing and treatment history, and violence exposure and perpetration. HIV rapid testing, viral load, CD4 count, and HIV drug resistance genotypic testing were undertaken.
Results: 19.1% of MCSWs were HIV positive, two thirds were aged 25-34 and 35-44, the median age of purchasing sex was 21, and condoms were consistently used by 16.7%. Almost all MCSWs had experienced childhood trauma, with two thirds of men reporting some form of sexual violence in their lifetimes. Just under 30% reported perpetrating sexual violence against their intimate partner, more than half (54.1%) had raped a non-intimate parter in the past year, and almost two thirds of men had symptoms



of PTSD. Older men were more likely to be HIV positive (<0.0001). HIV positive men were twice as likely to consistently use condoms (0.0006), and to suffer from PTSD symptoms (0.004) as compared to HIV negative men.
Conclusions: This is the first study of MCSWs in South Africa, and globally, the first to use an RDS methodology for MCSWs. Data highlight the vulnerability of this population to HIV, violence and mental health. Based on the unique methodology and successful implementation, the outcome will inform tailored interventions.
Our rate of enrolment, low rate of screening failure and low proportion of missing data showed the feasibility and importance of community-centric research with marginalised, vulnerable populations.

Approaches to using data to improve programming

Case-finding, linkage to antiretroviral treatment (ART), and continuity of care: findings from "Siyenza" facilities in South Africa, 2019-2021

S. De Anda[1,2], J. Cattle[1,2], M.E. Patton[1], J. Olivier[1], G. Kindra[1], R. Taback-Esra[1], C. Biedron[1], H. Paulin[1], C. Scott[1], E. Raizes[1], S. Dawad[3], J. Otchere-Darko[4], L. Mashudu[5], S. Prusente[6], N. Kamere[7], Z. Pinini[3], J. Blandford[1], J.M. Grund[1]
[1]*Centers for Disease Control and Prevention, Pretoria, South Africa,* [2]*Public Health Institute, Oakland, United States,* [3]*South African National Department of Health, Johannesburg, South Africa,* [4]*Wits Reproductive Health and HIV Institute (Wits RHI), Atteridgeville, South Africa,* [5]*Health Systems Trust, Durban, South Africa,* [6]*TB HIV Care, Cape Town, South Africa,* [7]*The Aurum Institute, Johannesburg, South Africa*

Background: The President's Emergency Plan for AIDS Relief (PEPFAR) and the South African National Department of Health launched *Siyenza* in February 2019 to improve retention of people living with HIV (PLHIV) on antiretroviral therapy(ART). *Siyenza* used weekly program data and site visits to provide intensive technical support to 241 public facilities comprising 45% of PLHIV on ART across the Centers for Disease Control and Prevention's twelve PEPFAR-supported districts.
Description: To assess resiliency throughout COVID-19, we compared weekly numbers of persons newly diagnosed with HIV and linked to ART, PLHIV on ART at 28 days, PLHIV with missed appointments 29-89 days after appointment dates, and index contacts tested and found positive for HIV from 142 facilities with continuous *Siyenza* participation from March 30, 2019–March 27, 2020 (Y1) to March 28, 2020–March 26, 2021 (Y2). Weekly facility means were analyzed using paired t-tests. Missed appointment data for 34 facilities in eThekwini district were excluded from the analysis due to missing data.
Lessons learned: In Y1 and Y2, 108,970 and 61,286 persons were newly diagnosed with HIV, respectively, and 104,537 (95.9%) and 59,817 (97.6%) were linked to ART; 85,486 and 122,261 PLHIV missed an appointment, respectively. The number of PLHIV on ART at 28 days increased by 2.3% between the end of Y1 and Y2, from 591,230 to 604,847. In Y1, 5,272/29,854 (17.7%) of index contacts tested positive for HIV; 8,134/49,429 (16.5%) tested positive in Y2. Weekly facility means significantly decreased between Y1–Y2 for: persons newly diagnosed (Y1:767.4 [95% Confidence Interval (CI):704.3–830.4], Y2:431.6 [CI:397.3–465.9]) and PLHIV linked to ART (Y1:736.2 [CI:675.6–796.7], Y2:421.2 [CI:387.3–455.2]), and increased for index contacts tested (Y1:210.2: [CI:179.6–240.8], Y2:348.1 [CI:296.2–399.9]) and found positive (Y1:37.1 [CI:31.7–42.5], Y2:57.3 [CI:46.4–68.1]). There were no significant differences in weekly means for PLHIV on ART at 28 days (Y1:4,163.6 [CI:3,885.9–4,441.3], Y2:4,259.5 [CI:3,980.4–4,538.5]) and missed appointments (Y1:791.5 [CI:678.8–904.2], Y2:1,132.0 [CI:685.5–1,578.6]).
Conclusions/Next steps: Despite COVID-19 challenges that caused decreases in new diagnoses,*Siyenza's* hands-on approach ensured maintenance of active PLHIV on ART, prevented increases in missed appointments, and increased index contacts tested.

Innovative uses of data to strengthen systems and programmes

PEMOE35

Evaluation of Ritshidze community-led monitoring programme in South Africa

A. Yawa[1], N. Rambau[2], B. Setshogelo[2], M. Nyathi[2], S. Xaba[2,3], L. Rutter[4], B. Honermann[5], A. Sharp[6]
[1]*Treatment Action Campaign (TAC), Johannesburg, South Africa,* [2]*Ritshidze, Johannesburg, South Africa,* [3]*South African Network of Religious Leaders Living With or Personally Affected by HIV and AIDS (SANERELA+), Randburg, South Africa,* [4]*Health Global Access Project (Health GAP), Johannesburg, South Africa,* [5]*amfAR, the Foundation for AIDS Research, Washington, United States,* [6]*The O'Neill Institute for National and Global Health Law, Georgetown University, Washington, United States*

Background: Community-led monitoring (CLM), where civil society collects data on services for people living with HIV to advocate for improved services, is an emerging and powerful approach to improving quality healthcare. In 2019, the Ritshidze CLM programme was launched in South Africa to monitor HIV, TB and other health service delivery to advocate for improved primary healthcare services for all people in the country.
We compared CLM measures of service delivery after year 1 and year 2 of the programme to determine Ritshidze's impact.

Methods: Between July 2019 and September 2021, data were collected from 427 public health facilities in 30 health districts. Survey data taken from observation, patient and facility managers were gathered electronically by community monitors using the CommCare application. Priority indicators were analyzed, focusing on seven metrics: antiretroviral therapy (ART) collection and access; HIV treatment; tuberculosis; facility staff and attitudes; access to prevention, care, and support; infrastructure; and COVID-19 disruption. Longitudinal trends were calculated by the average of the quarter-by-quarter percentage change in each metric between October to December 2020 and the same period in 2021.

Results:

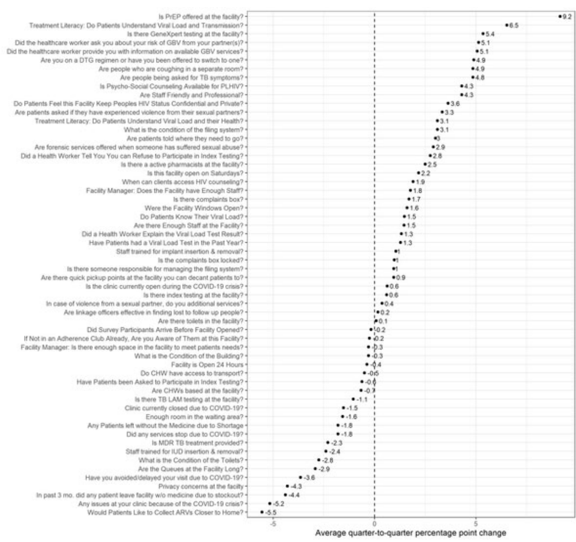

Figure 1.

Between quarter 4 (July to September) 2020 and quarter 4 2021, large changes in several indicators were observed. The largest changes were in access to PrEP (9.2% average quarter-to-quarter increase) and GeneXpert testing (5.4%), treatment literacy on viral load (6.5%), healthcare workers asking about gender-based violence (5.1%), and information on GBV services (5.1%) (Figure 1).

In this same time period, the percent of clinics reporting any COVID-19 disruption decreased an average of 5.2% each quarter.

Conclusions: Results from the Ritshidze CLM programme show early promise and suggest that CLM's can positively contribute to improving the quality, accessibility, and acceptability of HIV, TB and other health services.

Monitoring and reporting in the SDG era

Effect of district ART access on young people's wellbeing in South Africa: an econometric analysis of panel data

D. Govindasamy[1], T. Barnighausen[2], M. Neuman[3], P. Bodzo[4], C. Mathews[5], J. Seeley[3], G. Ferrari[6]

[1]*South African Medical Research Council, Health Systems Research Unit, Durban, South Africa,* [2]*University Heidelberg, Heidelberg Institute of Global Health, Faculty of Medicine, Heidelberg, Germany,* [3]*London School of Hygiene and Tropical Medicine, London, United Kingdom,* [4]*University of Cape Town, Cape Town, South Africa,* [5]*South African Medical Research Council, Cape Town, South Africa,* [6]*London School of Economics, London, South Africa*

Background: Expanded antiretroviral therapy (ART) is associated with substantial health and economic benefits. However, evidence on the population-level effects of ART scale-up on broader Sustainable Development Goals (SDGs) such as wellbeing are scarce.

We aimed to study the effects of ART access on young people's in South Africa.

Methods: We sought to assess how temporal increases in the number on ART at a district-level affected young people's life satisfaction, a measure of wellbeing. We used panel data from South Africa's National Income Dynamics Survey, which followed participants over 5 waves (2008-2017) and collected both individual- and household-level health, social and economic data. We restricted this panel data to participants aged 15-24 years in wave 1.

We then overlaid this panel dataset with district ART count and population estimates, derived from routine national HIV laboratory and census datasets, respectively. We used individual fixed effects regression models, with time and district fixed effects, to control for unobserved heterogeneity. We assessed the sensitivity of our findings using alternate regression models and a balanced sample.

Results: We analysed data on 5685 individuals (N=27 739 observations), mean age 23 years (SD=4.30), 50% female. On average, a 1-unit increase in the number of people living with HIV and on ART, was associated a 5% increase in life satisfaction scores after controlling for observed and unobserved time-invariant confounders.

Our results were robust to alternate specifications.

Conclusions: Our findings suggest that further investments into ART scale-up programmes could yield substantial wellbeing gains for young people in this region and should be leveraged as a key SDG 3 strategy.

Impact of COVID-19 on HIV prevention services

PEMOE37

Successful methods to ensure continuity of cervical cancer screening and pre-cancerous lesion treatment services for women living with HIV during COVID-19 in Mozambique

J. Barroso Pacca[1], E. Ferreira[2], A. Chauca[2], M. Prieto[3]
[1]Abt Associates, Mozambique, [2]Pathfinder International, Maputo, Mozambique, [3]ThinkWell, Maputo, Mozambique

Background: As a consequence of the COVID-19 pandemic, from March to September 2020 Mozambique experienced severe disruption to cervical cancer screening and treatment services. The Ministry of Health (MOH), along with its stakeholders, developed new guidelines to ensure the continuity of cervical cancer services despite lockdown restrictions. We describe the implementation of these new guidelines and their impact on ensuring access to cervical cancer services in four provinces in Mozambique.

Description: In September 2020, USAID's Efficiencies for Clinical HIV Outcomes (ECHO) project started implementing new guidelines for cervical cancer services in 148 health facilities supported by the project, including:

1. Online trainings for health providers;
2. Revisions of clinical files to identify patients eligible for cervical cancer screening at reception desks, pharmacies, and clinical consultations;
3. Improved organization of patients in waiting rooms to avoid crowding and provide better health education;
4. Escorting of screening-eligible patients from waiting rooms to consultation rooms;
5. Weekly data assessments to evaluate site-level performance;
6. Technical assistance and formative supervision at high-volume sites;
7. The provision of medical supplies and equipment for visual inspection with acetic acid (VIA), cryotherapy, and loop electrosurgical excision procedures (LEEP);
8. Service expansion to 54 additional sites, and
9. The provision of personal protective equipment to prevent COVID-19.

Lessons learned: As a result of the implementation of the new guidelines, the number of women living with HIV and on antiretroviral therapy (ART) who were screened for cervical cancer increased over time, with a monthly average of 6,967 women screened from October 2020 to September 2021, compared with a monthly average of 4,116 women screened from October 2019 to September 2020—a 69% increase.

Treatment coverage, defined as the percentage of women who were screened as positive and received treatment, grew on average from 43% to 72%. Key contributors to these achievements included collaboration between the MOH and its stakeholders and the provision of medical supplies and equipment, which helped ensure service continuity and even increased coverage.

Conclusions/Next steps: A well-coordinated effort between key stakeholders has been essential to the continuity and uptake of cervical cancer services in Mozambique during the COVID-19 pandemic.

Impact of COVID-19 on HIV testing services

PEMOE38

Impact of COVID-19 on HIV testing volume and positivity in 16 countries

V. Ranebennur[1], K. Stankevitz[2], C. Fischer Walker[3]
[1]FHI 360, Mumbai, India, [2]FHI 360, Durham, NC, United States, [3]FHI 360, Cincinnati, KY, United States

Background: The COVID-19 pandemic presents many challenges to HIV testing. We aimed to describe the impact of COVID-19 and country-level COVID-19 stay-at-home policies on HIV testing services provided by a large global HIV project.

Methods: We performed a retrospective analysis of monthly HIV testing data in 16 countries from January 2020 to September 2021. To account for differences in testing volume across countries, we calculated each county's percentage reduction/increase in testing by month compared to the average monthly country-level HIV testing volume in the first three months of 2020 (pre-COVID-19). Regression analysis was used to quantify the relationship between HIV testing volume, HIV case-finding rates, and national stay-at-home policies (from the Oxford COVID-19 government response tracker) by month.

Results: HIV testing volume declined dramatically early in the pandemic, with countries averaging 37.8% and 33.1% fewer HIV tests per month in April and May, respectively. Those months also saw the highest average case-finding rates, at 16.7% and 16.0%. In the ensuing months, programs adapted to the threats and restrictions of the pandemic and demonstrated a rebound in testing volume and an overall average case-finding rate consistent with the pre-COVID-19 comparator months.

*Figure. Change in HIV testing volume and case-finding rate during the COVID-19 pandemic in 16 countries**
**13 in sub-Saharan Africa, 2 in Southeast Asia, 1 in Latin America*

More stringent stay-at-home policies were associated with decreased HIV testing. Countries completed an average of 60.9% fewer tests during months when national

policies required not leaving the house (p<0.001). Positivity of testing increased an average of 1.7% during those months (p=0.09).

Conclusions: While initial decreases in HIV testing were observed, focused testing strategies led to rapid programmatic recovery and, ultimately, HIV testing volume was maintained above pre-COVID-19 levels.

Tighter stay-at-home orders were associated with decreases in testing, yet HIV case finding increased during these months.

These results demonstrate the resiliency of HIV programs to adapt during the pandemic and highlight opportunities for increased emphasis on innovative strategies for HIV testing.

PEMOE39

Measuring the impact of the COVID-19 lockdown on testing services in specialized HIV facilities in Mexico

F. Macías-González[1], H. Vermandere[1], A. Piñeirúa-Menendez[1], S. Bautista-Arredondo[1]
[1]*National Institute of Public Health, Health Economics, Cuernavaca, Mexico*

Background: Mexico's response to mitigate the spread of COVID-19 reduced the use of non-urgent health services, including those related to HIV/AIDS. This study aims to estimate the impact of the COVID-19 pandemic on HIV testing.

Methods: We used monthly data on HIV testing (2018-2021), of 78 public health facilities that provide HIV/AIDS-associated services in Mexico. We conducted a piecewise regression estimating the immediate change in HIV testing, positive test, and positivity rate. We used difference-in-difference models to measure the average impact of the lockdown in 2020 and 2021 using the average services of 2018-2019 as baseline/comparison.

We distinguished the analyses by sex, subpopulation (MSM, heterosexuals, pregnant women, transgenders, IDU, and sex workers), region, and COVID-19 mortality calculated as municipality mortality tertiles in 2020-2021.

Results: The lockdown in 2020 caused a sharp drop of 87% in testing and positive tests fell by 37%. The positivity rate, however, increased by 145%. Testing especially decreased among women, in northern Mexico and regions with low COVID19 mortality, while the positivity rate increase was highest among these same groups.

Testing practices and positivity rate among MSM changed less than in any other risk group, even though testing decreased by 55% and the positivity rate increased by 53%.

Throughout 2020, testing services remained far less used yet in 2021, the testing increased by 40% compared with 2018-2019, especially among pregnant women and people living in South Mexico.

The positivity rate decreased however in 2021, reaching a lower level compared with 2018-2019 yet the difference was not statistically significant.

Conclusions: The confinement measures negatively affected testing services during 2020, especially among those other than MSM; those who did get tested were more likely to be positive. Health facilities have increased the number of tests carried out in 2021 and even exceeded pre-pandemic values.

Despite this increase, the incidence values of HIV in 2021 seem to be lower than those recorded in 2018-2019, indicating that those most at risk might get tested less now. Research is needed to better understand these changes in positivity rate and measures must be taken to properly target at-risk populations.

Impact of COVID-19 on HIV treatment services

PEMOE40

The effects of COVID-19 on HIV care and treatment programs: a multicountry review

S. Ramachandran[1], R. Machekano[1], S. Argaw[1], A. Tiam[1]
[1]*Elizabeth Glaser Pediatric AIDS Foundation, Washington DC, United States*

Background: Since the onset of COVID-19, governments across the globe have implemented strategies to curb the spread of the pandemic. We reviewed HIV clinical cascade data to assess the effect of COVID-19 and these pandemic mitigation measures on HIV programs.

Description: We analyzed the aggregate number of individuals who received HIV testing services, number of individuals newly initiated on ART, number of individuals currently receiving ART, and the number of ART individuals who were virally suppressed (<1000 copies/ml). A relative ratio was derived by comparing EGPAF's program data from October to December 2019 (pre-pandemic period) to data from January 2020 to September 2021 (intra-pandemic period). The analysis included data from Cameroon, Cote d'Ivoire, DRC, Eswatini, Kenya, Lesotho, and Malawi.

Lessons learned: With the exception of DRC, results revealed declines across a majority of countries in the number of individuals who received HIV testing services and number of individuals who newly initiated on ART from January to September 2020 as compared to data from the pre-pandemic period (*see figure below*). While in some countries these declines showed gradual recovery starting in October 2020, in Eswatini, Lesotho, and Malawi figures for the two indicators continued falling, decreasing by an average of 55% and 37%, respectively, by September 2021 as compared to the pre-pandemic data. By contrast, the number of individuals currently on ART and the number of ART individuals virally suppressed remained steady throughout the intra-pandemic period for the majority of countries, and in some countries, these figures actually increased.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

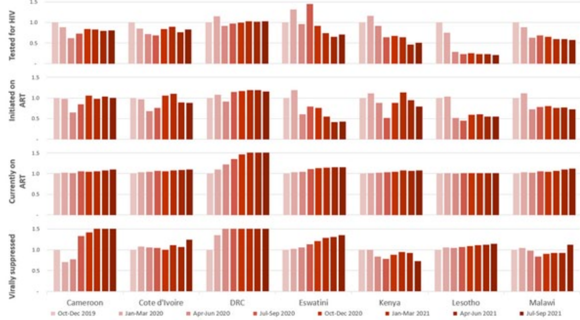

Figure.

Conclusions/Next steps: While the COVID-19 pandemic and mitigation measures have impacted HIV testing and ART initiations, there were no discernable effects on the numbers of ART patients continuing to access treatment and those who were virally suppressed. The latter finding points to utility of interventions and adaptations by HIV programs, which deserve further study and replication.

PEMOE41

Impact of COVID-19 public health measures on ART use among Ugandans living with HIV in sero-different couples

T.R. Muwonge[1], E. Feutz[2], A. Meisner[2], K. Thomas[3], N. Ware[4], M.A. Wyatt[4], F. Nambi[1], L. Nakabugo[1], J. Kibuuka[1], D. Thomas[2], J. Simoni[2], I.T. Katz[2], H. Kadama[5], J.M. Baeten[6], A. Mujugira[1], R. Heffron[2]

[1]Makerere University, Infectious Diseases Institute, Kampala, Uganda, [2]University of Washington, Seattle Washington, United States, [3]University of Washington, Seattle Washington, United States, [4]Harvard Medical School, Boston, United States, [5]Ministry of Health, AIDS Control Program, Kampala, Uganda, [6]Gilead Sciences, California, United States

Background: Approximately 30% of new HIV infections in sub-Saharan Africa occur among heterosexual HIV serodifferent couples. Effective antiretroviral therapy (ART) eliminates HIV transmission risk and is a priority intervention. We describe how the onset of COVID-19, which yielded restrictions to public transportation and strict curfews, impacted ART initiation and HIV viral load among people living with HIV in Uganda.

Methods: In a stepped-wedge cluster-randomized trial of an integrated PrEP and ART intervention for HIV-serodifferent couples at 12 ART clinics in Kampala/Wakiso, Uganda (ongoing at the outset of the Covid 19 pandemic), we compared ART initiation and viral suppression among participants enrolled during different time points defined by the initial COVID-19 lockdown.

Period-1 included participants who enrolled and had a 6-month viral load assessment before the first COVID-19 lockdown in Uganda on 18-March-2020.

Period-2 includes participants enrolled before 18 March 2020 with viral load measured thereafter (straddling pre-COVID and COVID times).

Period-3 includes participants enrolled with viral load quantified after 18 March 2020 (entirely during COVID-19). ART and viral load data, available through standard of care, were abstracted from clinic records.

Results: We enrolled 1,381 partners living with HIV, including 896 (64.9%) in Period-1, 260 (18.8%) in Period-2, and 225 (16.3%) in Period-3. Almost all participants (1371, 99.3%) initiated ART within 90 days of enrollment and more than half (59.2%) had CD4 >350 cells/mm3at enrollment.

Among those enrolled in Period-1, 88.8% were virally suppressed within 6-months of ART initiation, among those enrolled in period-2, 80.5% were suppressed, and among those in period-3, 88.2% were suppressed.

In a generalized estimating equation model with adjustment for clustering by clinic, the small number of clusters, and the intervention phase, no pairwise comparisons of viral suppression across periods were statistically significant.

The median time from ART initiation to VL assessment was greatest in period-2: Period-1 median time=128 days (IQR 95-173), Period-2 median time=175.5 (IQR 146-206.5), Period-3 median time=130.5 (IQR 97.8-168.3).

Conclusions: Despite COVID-19 lockdown measures, people living with HIV initiated ART and achieved viral suppression. Any potential challenges faced during the initial restricted conditions of lockdown waned and levels of ART initiation and viral suppression rebounded.

PEMOE42

Increased prevalence of depression and anxiety among adults initiating antiretroviral therapy during the COVID-19 pandemic in Tanzania

A. Sabasaba[1], S. Winters[2], C. A Fahey[2], P. F Njau[3], E. Katabaro[1], Y. Ndugile[4], L. Packel[2], S. I McCoy[2]

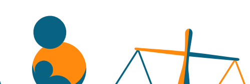
[1]Health For A Prosperous Nation (HPON), Dar es salaam, Tanzania, The United Republic of, [2]University of California, Berkeley, School of Public Health, Berkeley, United States, [3]Ministry of Health, National AIDS Control Program, Dodoma, Tanzania, The United Republic of, [4]President's Office - Regional Administration and Local Government (PO-RALG), Dodoma, Tanzania, The United Republic of

Background: Depression and anxiety are common among people living with HIV and can impair adherence to antiretroviral therapy (ART) and increase disengagement from care.

We compared the prevalence of depression and anxiety among ART initiates before and during COVID-19 in Tanzania.

Methods: We analyzed baseline data from two randomized controlled trials of adults initiating ART in Shinyanga, Tanzania between April-December 2018 (pre-COVID-19 period, n=530) and May 2021-January 2022 (COVID-19 period, n=542), respectively.

Depression and anxiety were measured using the Hopkins Symptom Checklist-25 in the pre-COVID-19 period and the Patient Health Questionnaire-2 and Generalized



Anxiety Disorder-2 scales in the COVID-19 period, respectively, and classified as binary indicators per each scale's threshold.

We also examined three mental health indicators that were similarly measured in both surveys: loss of interest, hopelessness, and uncontrolled worrying. To account for temporal differences in participant characteristics, adjusted prevalence differences (PD_a) in mental health over time were estimated using stabilized inverse probability of treatment weighting.

Propensity scores (weights) were generated from logistic regression with age, sex, primary language, education, marital status, household head, overall health, and work status as covariates.

Results: The prevalence of depression was 26.6% before and 68.6% during COVID-19 (PD_a=38.0 percentage points (pp), 95% CI: 34.1,41.9). Anxiety increased from 19.8% to 63.2% (PD_a=41.3pp, 95% CI: 37.4,45.0). Significant temporal increases were also noted in the prevalence of feeling "a lot" or "extreme" loss of interest, hopelessness, and uncontrolled worrying.

Reported Frequency	"A lot"			"Extreme" amount		
	pre-COVID-19	COVID-19	Adjusted Prevalence Difference (PD_a) (95% CI)	pre-COVID-19	COVID-19	Adjusted Prevalence Difference (PD_a) (95% CI)
Feeling little interest in things	5.3%	45.8%	38.6 (35.3,41.8)	1.3%	12.5%	9.1 (7.1,11.2)
Feeling hopeless about the future	3.8%	50.7%	46.7 (43.5,49.9)	1.7%	7.7%	4.2 (2.6,5.9)
Uncontrolled worrying	7.7%	42.9%	34.7 (31.3,38.1)	3.4%	7.7%	2.1 (0.3,4.0)

Conclusions: After applying a quasi-experimental weighting approach, the prevalence of depression and anxiety among those starting ART during COVID-19 was dramatically higher than before the pandemic.

Although depression and anxiety were measured using different, validated scales, the concurrent increases in similarly measured mental health indicators lends confidence to these findings and warrants further research to assess the impact of COVID-19 on mental health among adults living with HIV.

PEMOE43

Describing the impact of COVID-19 on AIDS Drug Assistance Program operations

K. McManus[1], A. Strumpf[1], A. Steen[1], Z. An[1], E. Schurman[1], A. Killelea[2], T. Horn[3], A. Hamp[3], J. Keim-Malpass[1]

[1]*University of Virginia, Charlottesville, United States,* [2]*Killelea Consulting, Arlington, United States,* [3]*National Alliance of State & Territorial AIDS Directors (NASTAD), Washington, United States*

Background: In the United States (U.S.), state AIDS Drug Assistance Programs' (ADAPs) are a key part of the US HIV healthcare delivery safety net. ADAPs provide free antiretroviral therapy to people with low incomes who are uninsured/underinsured. As a public service program, ADAPs' operations were impacted by the COVID-19 pandemic. To better understand how operations were affected and what changes were implemented in response, the National Alliance of State and Territorial AIDS Directors (NASTAD) surveyed ADAPs in 2021.

The objective of this mixed methods study was to characterize the programmatic challenges and subsequent innovations.

Methods: Data about COVID-19-related challenges and innovations were collected via the 2021-2022 NASTAD National Ryan White HIV/AIDS Program Part B and ADAP Monitoring Project, a cross-sectional survey of state, district, and territorial ADAPs. Descriptive statistics were used to assess proportional differences in Likert-style responses. Qualitative responses were coded and analyzed using a thematic analysis framework.

Results: Forty-seven state and D.C. ADAPs responded to the survey (92%, response rate). The majority of ADAPs reported that maintaining client eligibility (78%) and working remotely (70%) were the most challenging aspects of the pandemic, particularly in regards to implementing new telehealth and e-certification eligibility platforms. In response to COVID-19, ADAPs introduced enrollment "grace periods" (19%) while bolstering client outreach (11%), expanded medication supply for more than 30 days (79%), and provided pharmacy home delivery for clients (80%). Figure 1 provides a situational map of themes and subthemes from open-ended questions.

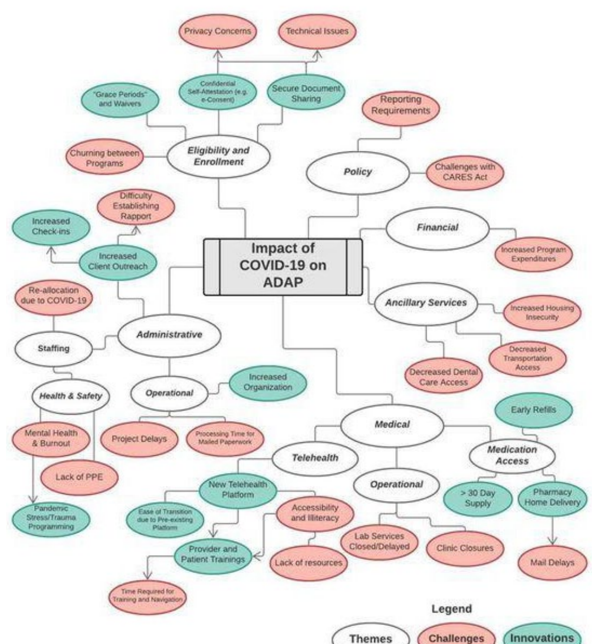


Figure 1. Situational map of themes and subthemes, describing the challenges of COVID-19 and subsequent innovations implemented by AIDS drug assistance programs in response.

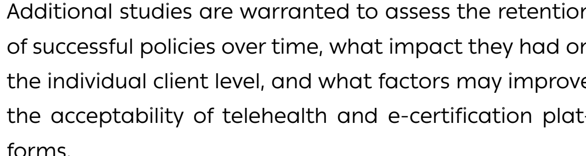
Conclusions: Despite the multifaceted challenges of the COVID-19 pandemic, state ADAPs implemented several operational innovations in order to continue providing prescription drug assistance.



Additional studies are warranted to assess the retention of successful policies over time, what impact they had on the individual client level, and what factors may improve the acceptability of telehealth and e-certification platforms.

Optimizing HIV services (prevention, testing and/or treatment) in the COVID-19 era

PEMOE44

Maintaining access to HIV services to persons living with HIV amid the COVID-19 pandemic in Nepal

R. Baskota[1], R. Baral[2]

[1]Ministry of Health and Population, Department of Health Services, Kathmandu, Nepal, [2]Ministry of Health and Population, Department of Drug Administration, Kathmandu, Nepal

Background: The surge of COVID-19 infection and subsequent lockdown resulted in closure of many public and private health facilities, including those providing HIV services. While the national prevalence of HIV was 30300 in 2020, many persons with HIV could not continue to access services from the routine health facilities.

The National Centre for AIDS and STD Control (NCASC) practiced innovative strategies with the main objective of ensuring uninterrupted access to HIV services amid the pandemic.

Description: Innovations were practised since June 2020 through May 2021 in the HIV centres of high burden districts based on key population estimates, HIV prevalence and COVID-19 hotspot mapping.

During the period of travel restrictions, risk assessment was conducted virtually to the key populations. NCASC initiated travel pass program to support organizations that provide needle syringe exchange and opioid substation therapy.

Antiretroviral drugs were delivered at home through multiple national networks of people with HIV. The targeted beneficiaries of these activities included people with HIV, pregnant women, HIV infected infants and children, and people who inject drugs.

Lessons learned: Nearly 50% of the targeted clients benefitted by the interventions. A total of 8542 virtual consultations were conducted. Through travel pass program, 2702947 syringes were distributed; benefiting 3364 people who inject drugs. Through the same program, 328 people received Methadone and 92 people received Buprenorphine. Among the 20883 people with HIV currently on ART, 9900 received home delivery of ART.

This program included 157 (73%) pregnant women with HIV, 121 (56%) mothers with HIV and 900 (71%) HIV infected infants and children. These approaches were feasible and were acceptable by the communities as they provided continuity of care while lockdown had imposed barriers to access to most HIV services.

Conclusions/Next steps: Virtual consultations, travel pass program and home delivery of medicines were effective strategies of maintaining continuity of HIV services amid the COVID-19 pandemic in Nepal. Such models can be implicated to other chronic health conditions that require long-term care in situations like the COVID-19 pandemic and related lockdowns that impose substantial barriers to access to health services. Supportive policies are needed to sustain such decentralized services in communities.

PEMOE45

Building infection prevention and control capacity across PEPFAR programs in response to the COVID-19 pandemic

D. Gomes[1], I. Lawal[2], N. Zender[3], P. Kerndt[4], T. Lucas[1], D. Forno[1], D. Goldstein[4], S. Vallabhaneni[1], B. Park[1], A. Date[1], E. Bancroft[1], C. Godfrey[3]

[1]Centers for Disease Control and Prevention, Atlanta, United States, [2]United States Department of Defense, Abuja, Nigeria, [3]United States Department of State, District of Columbia, United States, [4]United States Agency for International Development, District of Columbia, United States

Background: Effective infection prevention and control (IPC) practices are essential for safe healthcare delivery. In low- and middle-income countries, the COVID-19 pandemic exposed ineffective IPC systems which increased healthcare worker and patient risk for infection and reduced patient access to life-saving medical care.

Therefore, the President's Emergency Plan for AIDS Relief (PEPFAR), committed to ensuring the safe delivery of high-quality healthcare, identified IPC as an urgent priority.

Description: Early in the COVID-19 pandemic, a technical working group with public health and IPC experts, from United States (U.S.) Government agencies responsible for implementing PEPFAR programs, began collaborating to improve IPC in PEPFAR programs.

In July 2021, the Office of the U.S. Global AIDS Coordinator formally identified this group as the site safety short term task team (ST3).This ST3 is responsible for defining minimum IPC standards for PEPFAR-supported facilities and developing strategies for IPC implementation and monitoring.

Lessons learned: IPC priorities identified by the ST3 were added to PEPFAR's minimum program requirements and include respiratory hygiene, standard and transmission-based precautions, and healthcare worker safety such as post-exposure prophylaxis for HIV. Recommendations to support program alignment with IPC priorities were included in PEPFAR's COVID-19 guidance and in country and regional operational plan guidance. IPC was prioritized for additional COVID-19 funds received by PEPFAR; the ST3

developed recommendations to guide rational use of these funds. In addition, the ST3 developed indicators to assess adherence to IPC standards as a mandatory component of PEPFAR's facility-level quality assurance tool, a personal protective equipment forecasting calculator, and aids to prevent infections in PEPFAR-supported surgical procedures.

Conclusions/Next steps: The site safety ST3 quickly developed IPC standards for PEPFAR programs and ensured that IPC was incorporated into PEPFAR's minimum program requirements to enforce accountability across programs and facilities. Implementation of IPC standards will improve quality of care, protect healthcare workers and patients, and strengthen the resiliency of the healthcare system beyond COVID-19.

This experience highlights a cross-agency collaboration developed to rapidly respond to a critical public health need and demonstrates how PEPFAR programs can be mobilized to respond to COVID-19-like pandemics and impact health systems and health security moving forward.

PEMOE46

A pandemic over an epidemic: surveying LGBTQI+ situation during COVID-19 pandemic in Thailand

K. Honglawan[1], I.Y.-H. Chu[2], R. Olete[3], I.Q. Rendon[4], M. Poonkasetwattana[5]

[1]Adelphi University, Garden City, United States, [2]London School of Hygiene & Tropical Medicine, Department of Public Health, Environments and Society, London, United Kingdom, [3]National Cheng Kung University, Department of Nursing, Tainan, Taiwan, Province of China, [4]APCOM Foundation, Bangkok, Thailand, [5]SOAS, University of London, London, United Kingdom

Background: COVID-19-related mobility restrictions have devastated the lives of PLHIV and other key populations (KPs) worldwide. After Thailand's first national lockdown in April 2020, in collaboration with eight community-based organizations (CBOs), APCOM initiated the Khormoon ("Information" in Thai) project to identify post-COVID-19 lockdown health situations and the critical needs of KPs in Thailand.

Description: From September 2020 to November 2020, the Khormoon team administered a cross-sectional online survey co-designed by APCOM, the eight CBOs, and KP representatives. The 51-item questionnaire contained four dimensions: access to HIV services and information on COVID-19, socioeconomic status, mental health status, and life challenges.

We recruited participants and distributed the online survey through both websites and service facilities of all partnered organisations.

Lessons learned: The project reached 1,323 KPs across all regions of Thailand. Of all, 69% were identified as PLHIV, 82% of whom underwent antiretroviral treatment (ART). Most (90%) of the PLHIV suffered from psychological distress, while almost all respondents (93%) reported income losses with 44% being unemployed. Affording daily expenses and accessing medicine were considered the two most urgent needs (85% and 56%, Figure).

Although 80% of respondents reported receiving combination HIV prevention/treatment and information on COVID-19, the majority (66%) worried that sexual health services (eg., ART, PrEP, and PEP) could become inaccessible if COVID-19-related travel restrictions persist.

Regarding community support, 85% agreed that organisations had ensured their access to HIV/STI care during the COVID-19 lockdown with adaptive/innovative measures (eg., online consultations, 24-hour hotlines and door-to-door ART delivery).

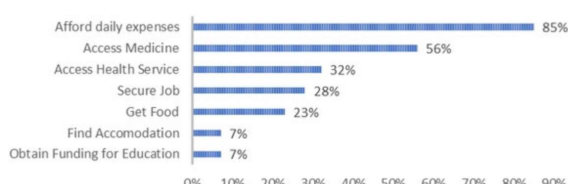


Figure.

Conclusions/Next steps:
Our Khormoon project highlights the urgent needs of KPs in Thailand, who continue requiring differentiated support to tackle socioeconomic disparities and mental distress heightened by the ongoing COVID-19 pandemic.

The findings illuminate our future projects on delivering user-centered, innovative, and comprehensive community support to people affected by HIV and COVID-19.

PEMOE47

Analyzing FY 19-21 PEPFAR PrEP uptake focusing on adolescent girls and young women and key populations

S. Straitz[1], T. English[1], L. Stubbs[1], S. Blatz[1]

[1]U.S. Department of State, Office of the Global AIDS Coordinator, Washington, United States

Background: From FY 19-21, PEPFAR significantly scaled PrEP uptake, particularly for adolescent girls and young women and key populations.

Despite the impact of SARS-CoV-2 on community mobilization for, and delivery of, PrEP to these vulnerable populations, the number of individuals newly initiated on PrEP still increased across all age and sex bands from FY 19-20 and accelerated from FY 20-21 with commensurate increases in PrEP expenditures.

Description: Annual FY19-21 (October 1, 2018-September 30, 2021) PrEP expenditures and semiannual FY19-21 PrEP_NEW, the number of individuals newly enrolled on PrEP in the past reporting period, results are included for 48 PEPFAR-supported countries.

Lessons learned: From FY19-20, global PrEP uptake increased by 91% (163,452 to 312,017) while PrEP expenditures increased 112% ($16,822,939 to $35,726,992). Adolescent girls and young women drove FY 20-21 PrEP uptake. FY20-21 global PrEP uptake accelerated by 225% (312,017 to 1,015,094) and global PrEP expenditures by 189% ($35,726,992 to $103,133,294).

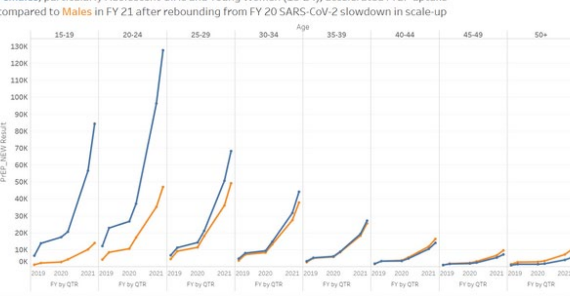

Figure.

Among key populations, female sex workers increased PrEP uptake from FY19-20 by 150% (28,018 to 69,924) and again by 185% from FY 20-21 (69,924 to 199,152). Men who have sex with men also contributed significant scale-up by 148% from FY19-20 (17,983 to 44,522) and 132% from FY20-21 (44,522 to 103,480).

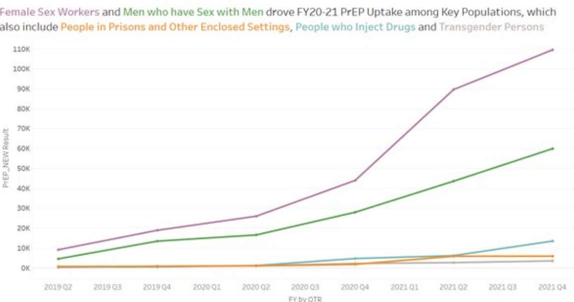

Figure.

Conclusions/Next steps: From FY19-21, PrEP uptake increased 712% from 163,452 to 1,327,111 clients on PrEP while PrEP expenditures increased 725% from $16,822,939 to $138,860,286.

Future analysis should evaluate countries with most efficient PrEP expansion by age/sex bands to determine how enabling environments to support PrEP scale-up in those countries can be replicated in other country contexts.

Legal advocacy tools and strategies

PEMOF25

Litigating against forced and coerced sterilisation in Kenya

V. Njogu[1]

[1]*KELIN, Strategic Litigation, Nairobi, Kenya*

Background: As programs for the prevention of mother to child transmission of HIV were launched around the world, discriminatory attitudes and practices toward women living with HIV continued to emerge. There were untrue beliefs that women living with HIV could not, or should not, bear children which led to a great number of them being subjected to involuntary sterilization.

Between 2005 and 2010, there was a sustained unofficial policy that led to the forced and coerced sterilization of women.

They had several things in common. They were: living with HIV, of lower social-economic status, receiving medicine and food rations for themselves and their children, as part of programs to prevent mother to child transmission , and were threatened with withdrawal of the medical and food assistance if they did not produce evidence of permanent family planning.

They were subjected to unwanted sterilization despite the fact that science had proven that with adequate medical care and essential medication, they could bear healthy children.

Description: In 2014, KELIN assisted five of these women to file suit in court against the facilities that coerced them into undergoing forced sterilization highlighting the violations they suffered.

In their claim, they are also seeking state interventions to ensure that forced sterilization never happens again.

That litigation is still pending, now in its 8th year.

Lessons learned:

1. The factors that resulted in the vulnerability of the victims to forced sterilization must be addressed alongside litigation.
2. Litigation is a lengthy, technical and sometimes emotional process, and the likelihood of retraumatising the victims is ever-present. We must anticipate delays and the needs of the victims
3. It is only one step in the journey of redress for women who are living with consequences of forced and coerced sterilization.

Conclusions/Next steps: We are expecting the conclusion to this process in 2022. Litigation is useful to secure individual redress and social change, but does not guarantee success. We will scale up other avenues for advocacy through which women living with HIV can secure justice, including social advocacy programmes to increase education about living with HIV, economic empowerment, and availability of medical and psychosocial support.

PEMOF26

Youth-led monitoring for accountability in the HIV response

C. Modi[1], G. Jones[2], E. Dupuis[3], A. Sanchez[2], T. Rufurwadzo[1], A.R. Khan[3]

[1]Global Network of Young People Living with HIV (Y+ Global), Amsterdam, Netherlands, the, [2]UNAIDS, Geneva, Switzerland, [3]The PACT, Bangkok, Thailand

Background: Youth-led data generation remains an underfunded yet potentially key aspect of the HIV response for young people in all our diversity. To address this, a youth-led monitoring tool (#UPROOT scorecard) was developed with youth-led organisations to measure progress on key issues that impact young people in the context of HIV at the country level.

From 2017-2020, The PACT, with support from UNAIDS, implemented the scorecard in 16 countries across five regions (LAC, EECA, WCA, ESA, AP). Youth-generated data was used to catalyse targeted advocacy at the country level to improve the legal, policy, and social landscape for young people.

Description: Qualitative and quantitative data are gathered to create a youth-generated snapshot of national HIV responses.

Data from the NCPI, GAM, and national databases are analysed and coupled with a participatory consensus-based exercise to determine the impact of laws, policies, and the effects of stigma and discrimination on young people in all their diversity.

Lessons learned: Young people reported that they felt empowered throughout the monitoring process.

National profiles that identify which areas of the HIV response for young people require more attention and where advocacy should be focused were created

Areas for improvement included putting more emphasis on supporting advocacy plans after the scorecard creation, and managing the consensus process to ensure a balance report of the situation in the country.

Funded by UNAIDS Technical Support Mechanism and managed globally by Y+ Global with support from The PACT, the revised methodology will be conducted in 7 countries in 2022. Results from the current implementation in 7 countries will be available by June 2022.

Conclusions/Next steps: Youth-led data generation and monitoring have the potential to more accurately represent the views of young people than mechanisms that are not designed by and for youth but that include them. Data are not often disaggregated enough for young people and do not focus on their specific needs, therefore the youth-led approach of the #UPROOT scorecard allows for young people to have a say on our experience of the HIV response. Scaling up of youth-led monitoring can help identify priority action areas for tackling the HIV epidemic in young people.

Stigma and key populations

PEMOF27

PLWH Stigma Index 2.0. in the countries of Central Asia

L. Vorontsova[1]

[1]ALE Central Asian Association of People Living with HIV, Almaty, Kazakhstan

Background: The purpose of the study is to obtain information about the problems of PLHIV related to stigmatization, discrimination and violation of their rights.

This abstract presents a comparison of study data in three countries - Kazakhstan, Tajikistan, Kyrgyzstan. These countries share the same epidemic history, HIV laws, education and public opinion. The main issues of stigma and discrimination here affect women and key populations.

Methods: The methodology of this study is based on the method developed and recommended by the GNP+, ICW, and the Joint United Nations Program on HIV/AIDS (UNAIDS).

TAJIKISTAN	KYRGYZSTAN	KAZAKHSTAN
2021	2020	2021
N=1100 PLHIV	N=664 PLHIV	N=1143 PLHIV
Dushanbe city, Khatlon region, Sughd region, GBAO, districts of republican subordination	Bishkek, Osh, Jalal-Abad region, Osh region, Chui region, Talas region	Cities of Nur-Sultan, Almaty, Pavlodar, Karaganda, Kostanay, Western, Eastern, Northern Kazakhstan, Turkestan region (Shymkent)
Venue-based sampling and chain-restricted sampling.	Non-random sample.	Venue-based sampling and chain-restricted sampling.

Table 1.

Results: Almost all PLHIV tend to hide their status from other people. About two-thirds feel devalued because of their status and many (71%) feel ashamed about it.

A large majority (87%) find it difficult to share their status with others. Women are verbally reprimanded 6 times more often than men. The majority of PLHIV are not aware of the existence of laws protecting their rights in the country, only less than a third declared their knowledge of such laws. CPs face higher levels of stigma and discrimination for reasons other than HIV.

	TAJIKISTAN	KYRGYZSTAN	KAZAKHSTAN
Woman	51,8%	44,5%	41,8%
Man	47,4%	54,6%	56,4%
Transgender	0,7% (8)	4	1% (11)
Age	30-49 years - 75%	30-50 years - 76,4%	40,2 years
Employment	68% women unemployed	Only one in six PLHIV had a full-time job.	29.05% do not work anywhere
Education	60% Secondary education	75% have no profession	49.34% Secondary education
Satisfying basic needs	Only 1/3 of those surveyed reported being able to meet their own needs most of the time	Only 13.1% of respondents indicated that they were able to basically meet their food, clothing and housing needs in the last 12 months.	46.54% can sometimes contain their basic requirements
HIV negative partners	36%	52,5%	44,25%

Table 2.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Conclusions: In all three countries, there is a high level of internalized stigma. There is low legal literacy among PLHIV. Stigma and discrimination not related to HIV is quite high. There is a problem with the confidentiality of diagnosis and informed consent in the provision of medical services. It is necessary to change a number of legal acts.

PEMOF28

Technical Support for PLHIV leadership in implementation of the PLHIV Stigma Index 2.0

P. Looze[1], K. Lalak[1], O. Syarif[1], K. Dunaway[2], S. Brion[3], L. Sprague[4], M. Chisenga Chungu[5], D. Matyushina-Ocheret[6], C. Garcia de Leon Moreno[4], G. Turpin[7], L. Lucas[7], S. Baral[7], C. Lyons[7]
[1]Global Network of People living with HIV (GNP+), PLHIV Stigma Index, Amsterdam, Netherlands, the, [2]International Community of Women Living with HIV (ICW), Stigma Index Equity Officer, Buenos Aires, Argentina, [3]International Community of Women Living with HIV (ICW), Sarasota, United States, [4]UNAIDS, Community Engagement, Geneva, Switzerland, [5]UNAIDS, Community Mobilization Community Support, Social Justice & Inclusion, Geneva, Switzerland, [6]Consultant, Geneva, Switzerland, [7]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States

Background: In 2022, stigma is understood as a fundamental barrier to ending the HIV pandemic by 2030, in just 8 years. The People Living with HIV (PLHIV) Stigma Index 2.0 (SI) represents an instrument to monitor HIV-related and intersectional stigma affecting PLHIV including key populations (KP). Standardizing the instrument and implementation of the SI facilitates measurement of progress in stigma mitigation over time and across geographies. The leadership of PLHIV in SI implementation and their ownership of the results is critically important and PLHIV networks need financial and/or technical support (TS) to implement.

Description: Since 2020, the International Partnership for SI (GNP+, ICW, John Hopkins University, and UNAIDS), funded through the UNAIDS Technical Support Mechanism, provides TS covering PLHIV leadership, partnership building and advocacy, as well as research protocol development, data collection, analysis, and report writing. Four data analysis toolkits and guidelines have been developed to strengthen implementation steps. TS has been provided to support PLHIV-led implementations in over forty countries, eight of which have finalized implementations. Non-negotiables of implementation emphasize PLHIV leadership, inclusion of all KPs living with HIV as respondents, and overall compliance with the approved methodology.

Lessons learned: The measurement and interventions focused on stigma remain controversial in many settings, resulting in challenges including leadership of PLHIV contested by national stakeholders, and the criminalization of KPs requiring coordinated efforts of communities, donors, and technical partners to safeguard the engagement of KPs as respondents. In response, we have learned that tailored technical support provision, capacity-building exercises for PLHIV-led organizations, and the clarification of the non-negotiables from the outset, can ensure quality implementation of the SI. Moreover, iteration of the SI has uncovered opportunities to enhance TS leading to the development of toolkits aimed at improving data analysis, report writing, and advocacy.

Conclusions/Next steps: Quality and long-term technical support provision, based on a partnership between communities, academia, and technical agencies create a strong foundation for community-led monitoring. Data from the stigma index 2.0 can inform advocacy approaches, policy, and community leadership—all of which are central in improving HIV outcomes and ultimately, responding to the HIV pandemic.

Discrimination and key populations

PEMOF29

Increased frequency of experiencing multiple forms of discrimination in healthcare settings during the COVID-19 pandemic among African, Caribbean, and Black (ACB) people across Canada

S. Baidoobonso[1], A. Kaida[2], J. Etowa[3], J. Osuji[4], A. Ogunleye[5], L. Azangtsop[6], E. Etowa[7], A. Odhiambo[8]
[1]Dalhousie University, Department of Community Health and Epidemiology, Halifax, Canada, [2]Simon Fraser University, Burnaby, Canada, [3]Univerity of Ottawa, Ottawa, Canada, [4]Mount Royal University, Calgary, School of Nursing & Midwifery, Calgary, Canada, [5]Black Cultural Society of PEI, Charlottetown, Canada, [6]University of Ottawa, Ottawa, Canada, [7]University of Windsor, Department of Sociology, Anthropology & Criminology, Windsor, Canada, [8]Public Health Agency of Canada, Surveillance and Epidemiology Division Centre for Communicable Diseases and Infection Control Infectious Disease Prevention and Control Branch, Ottawa, Canada

Background: In Canada, racialized communities, including African, Caribbean, and Black (ACB) people, are disproportionately affected by HIV and COVID-19. Experiencing multiple forms of discrimination (e.g., racism, sexism, genderism, ageism, classism, ableism) in healthcare settings compromises care engagement and health outcomes. Among a national sample of ACB people, we examined changes in experiencing discrimination in healthcare settings during the COVID-19 pandemic.

Methods: Cross-sectional data were collected using an online survey co-led by the Public Health Agency of Canada, University of Ottawa, and ACB community leaders and researchers to examine COVID-19 impacts on ACB people aged 18+ (May 25-July 12, 2021). Participants reported on

experiences of discrimination when accessing healthcare services in the year prior to and during the pandemic. Descriptive statistics are provided.

Results: The 1,556 participants were diverse by age, ethnic identity (Black African (63.2%), Black Caribbean (28.3%), Black Indigenous or Black Canadian (7.3%)), gender (transgender (3.0%)), and sexual orientation (11.9% identified as LGB). Among those who accessed healthcare in the year prior to COVID-19 (n=982), participants reported that they "Often" (10.2%), "Sometimes" (32.8%), or "Rarely" (19.1%) experienced discrimination. Among those who also accessed healthcare during COVID-19 (n=902), 25.2% reported increased frequency of experienced discrimination (9.2% decreased).

During the pandemic, participants reported an increase in discrimination by race (including anti-Black racism) (31.2% reported an increase), economic status (18.7%), age (18.1%), (dis)ability (17.0%), substance use (15.9%), gender (15.3%), and sexual orientation (10.8%). Between 2.9%-13.5% reported a decrease in various forms of discrimination.

Among participants living with HIV (10.3%), 26.7% cited concerns about experiencing stigma, discrimination, or violence as barriers to accessing HIV services during the pandemic, with 20.0% reporting fear of experiencing racism.

Conclusions: A sizable proportion of ACB people in Canada often/sometimes experience discrimination while accessing healthcare services, and for many, discriminatory experiences increased during the COVID-19 pandemic. One-fifth of survey participants living with HIV cited racism as a barrier to accessing HIV services. In partnership with communities, concerted efforts are needed to address multiple forms of discrimination in healthcare settings to improve care engagement and health equity among ACB communities during COVID-19 and beyond.

Punitive laws and enforcement practices directed at or impacting on key populations)

PEMOF30

Have mandatory testing laws become a serious threat to HIV responses? Lessons learned from a civil society advocacy campaign in Australia

F. Delhomme[1], M. Holt[2], A. Cogle[3]
[1]ACON, Surry Hills, Australia, [2]UNSW Sydney, Centre for Social Research in Health, Sydney, Australia, [3]National Association of People with HIV Australia, Newtown, Australia

Background: Since 2015, a coalition of civil society organisations has advocated against the introduction of new mandatory testing laws in Australia. Proposed by police unions, mandatory testing laws have been formally introduced by several state governments. They allow individuals to be tested for HIV and other blood borne viruses (BBV) without consent, including after low or no risk exposures (e.g. to saliva).

Description: The "Stop Mandatory Testing" campaign was conducted by a broad coalition of civil society organisations, including HIV and LGBTQ+ organisations, medical associations, legal aid organisations, health worker unions and public health researchers.

Aimed at convincing legislators to withdraw or amend the proposed laws, the campaign addressed lobbying efforts by police unions seeking the introduction of mandatory testing in jurisdictions across the country, including Australia's most populous state of New South Wales.

The campaign centred on the provision of scientific and empirical evidence and personal testimony to convince Australian decision-makers that compulsory testing violated rights, increased stigma and fear, could be misused punitively, and was proposed for situations that carried little to no risk of transmission (e.g., spitting).

The campaign highlighted that mandatory testing was in conflict with Australia's rights-based response to HIV/BBV, would hinder testing and stigma reduction targets, and that no occupational HIV transmission had ever been recorded in a police officer.

Strategies evolved over the course of the campaign and included the production of reports, submissions, appearances at parliamentary inquiries, a campaign website, media and targeted advertising.

Lessons learned: The failure of the campaign to stop mandatory testing laws offers a stark warning about the risk of backsliding and fracturing of HIV responses, and that evidence may be insufficient to prevent regressive laws. This failure offers important lessons for civil society, including the need for stronger influence over policymakers, tactics to generate public attention or shame lawmakers, and strategic multi-jurisdiction lobbying.

Conclusions/Next steps: Considering how evidence was overlooked and the threats posed by growing police powers, we need to consider renewed political and intersectional alliances, including with political parties and organisations and communities affected by police violence. After forty years of HIV responses, the need for community mobilisation remains.

Investing in regional HIV programmes and regional key population movements

PEMOF31

Dos and don'ts for community-led HIV programming in challenging contexts in Eastern Europe and Central Asia: lessons learned for funders and implementers

J. Rashbass[1]

[1]*Elton John AIDS Foundation, London, United Kingdom*

Background: New HIV infections and AIDS-related deaths are growing faster in Eastern Europe and Central Asia (EECA) than any other region. The epidemic is concentrated among Key Populations (KPs), who are widely marginalised. Since 2017, international HIV funding in EECA has reduced significantly.

Elton John AIDS Foundation (EJAF) implemented the EECAKPs Fund from 2018-2021 to increase KPs' access to innovative HIV services; reduce stigma and discrimination; and collate best practices. Resources were prioritised in settings with large epidemic burdens where NGOs cannot access alternative resources.

Description: Nineteen local NGO-led projects provided direct services to 149,263 people from KP communities, including 100,302 HIV tests, and initiated 8,924 PLHIV on treatment. EJAF commissioned end-of-project mixed-method evaluations of the 12 largest projects in 2021 to assess results and inform future intervention design.

Lessons learned: Marginalisation of KPs in EECA means earning trust is crucial to programmatic success. To build clients' trust:

1. Engage clients as staff and volunteers to connect with the hardest-to-reach; projects fostering collaboration between effective peer-led NGOs and government institutions also reduce stigma;
2. Adapt harm reduction services for new stimulant users to make services relevant;
3. Integrate with services that resonate with communities' needs beyond HIV.

Implementers most effectively improve HIV outcomes by:

1. Proactively reaching hard-to-reach sub-populations, such as synthetic stimulant users, women who use drugs, and MSM practicing chemsex. This correlates with higher testing yields;
2. Providing innovative entry points, including online and home-based services. This was particularly productive during COVID-19;
3. Ensuring all staff, including in remote implementation sites, can access mental health support to prevent burnout.

To ensure sustainability:

1. Secure cost-share from government;
2. Mobilise local private donations, proven feasible even for locally controversial causes;
3. Partner with diverse government agencies, including law enforcement, proven an unlikely success;
4. Strive for system changes in initial project design;
5. Bake NGO capacity development into project design so that it happens intentionally.

Conclusions/Next steps: With the HIV epidemic growing in EECA and limited domestic resources allocated to KPs, expanded international donor support is urgently needed.

The EECAKPs Fund shows effective foreign-funded community-led HIV services for KPs in challenging EECA environments are possible, if programmes intentionally earn communities' trust, optimise service modalities, and bake in sustainability approaches.

Ethical aspects and standards in research (including clinical trials)

PEMOF32

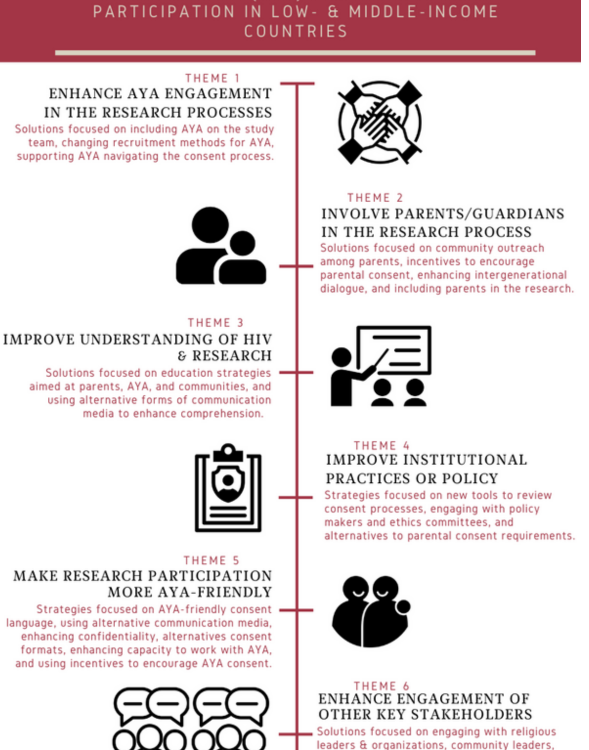
A digital crowdsourcing open call on adolescent and young adult consent for HIV research participation in low- and middle-income countries

S. Day[1], K. Tahlil[2], T. Gbaja-Biamila[3,4], E.C. Wilson[5], C. Obiezu-Umeh[3], U. Nwaozuru[6], S. Rennie[7,8], J. Iwelunmor[3], S. Shah[9,10], K. Chima[4], O. Ezechi[4], J.D. Tucker[1,11]

[1]*The University of North Carolina at Chapel Hill, Department of Medicine - Division of Infectious Diseases, Chapel Hill, United States,* [2]*The University of North Carolina at Chapel Hill, Department of Epidemiology, Chapel Hill, United States,* [3]*St. Louis University, Department of Behavioral Science and Health Education, St. Louis, United States,* [4]*Nigerian Institute of Medical Research, Clinical Sciences Department, Lagos, Nigeria,* [5]*San Francisco Department of Public Health, San Francisco, United States,* [6]*Wake Forest School of Medicine, Department of Implementation Science, Winston-Salem, United States,* [7]*The University of North Carolina at Chapel Hill, Department of Social Medicine, Chapel Hill, United States,* [8]*The University of North Carolina at Chapel Hill, UNC Center for Bioethics, Chapel Hill, United States,* [9]*Northwestern University Feinberg School of Medicine, Department of Pediatrics, Chicago, United States,* [10]*Ann and Robert H Lurie Children's Hospital of Chicago, Mary Ann and J Milburn Smith Child Health Research, Outreach, and Advocacy Center, Stanley Manne Children's Research Institute, Chicago, United States,* [11]*London School of Hygiene and Tropical Medicine, Clinical Research Department, Faculty of Infectious and Tropical Diseases, London, United Kingdom*

Background: Social, ethical and legal barriers to consent for HIV research participation among adolescents and young adults (AYA; 10-24 years old) can hinder AYA inclusion in research. Engaging AYA and other stakeholders in identifying solutions to these barriers is especially important in low- and middle-income countries (LMICs), where youth face high HIV morbidity and mortality.

Methods: A digital crowdsourcing open call for ideas to improve AYA consent in LMIC HIV research was held from August 23 – October 15, 2021. Crowdsourcing involves having a group contribute creative solutions to a problem, then sharing the results. Participation was open to anyone living or working in LMICs. Email and social media were used to reach AYA, parents, HIV researchers, community organizers, and ethicists. Submissions were scored on a 1-10 scale by three independent judges for clarity, relevance, feasibility, innovation, and potential impact, with $2000 USD for finalist prizes. Participants' demographic data were collected, and submissions were qualitatively analyzed for emergent themes in the proposed solutions.
Results: Of 110 total submissions, 65 submissions from 10 LMICs were eligible for judging per open call criteria (described a solution to improve AYA consent). Of these, 25 submissions scored 6/10 or greater. Fifty-eight participants submitted the 65 eligible submissions, including 30 (51.7%) participants age 18-24 years old, 26 (44.8%) cisgender women, and 5 (8.6%) members of key populations (e.g. men who have sex with men). Using thematic analysis, seven main themes were identified for solutions to improve AYA consent processes, including ways to enhance AYA and parental research engagement, increase awareness of HIV and research processes, and make research participation more AYA-friendly (see infographic).



Conclusions: Improving AYA consent processes in HIV research will require creative, community- and AYA-oriented solutions. Open calls engaging AYA and other stakeholders in LMICs on the topic of consent can identify promising ideas for developing practical guidance.

PEMOF35

Working apart and together, across and between: lessons learned from an Indigenous and non-Indigenous organizational partnership in Indigenous harm reduction research during the COVID-19 pandemic

C. Kendrick[1], S. Swann[2], P. McDougall[2], R. Masching[1], Research group - Environmental Scan of Community-Based Harm Reduction Services for Indigenous Peoples in response to the COVID-19 pandemic
[1]CAAN (Communities, Alliances & Networks), Fort Qu'Appelle, Canada, [2]Dr. Peter AIDS Foundation, Vancouver, Canada

Background: In Canada, Indigenous (First Nation, Inuit and Metis) harm reduction (IHR) programs, policies, and practices center holistic understandings of health and well-being. Relational care and connections to kin, culture, and community are foundational in responding to disproportionate impacts of HIV, the drug poisoning epidemic, and COVID-19 on Indigenous peoples. CAAN (Communities, Alliances & Networks) and the Dr. Peter AIDS Foundation (DPAF) have brought together decades of experience in community-based research, harm reduction and knowledge translation to identify:
1. How IHR programming for Indigenous Peoples has been impacted by COVID-19,
2. Successful adaptations that frontline organizations in providing IHR programming, and
3. Resources to address service gaps that impact Indigenous Peoples.
Description: To commemorate our partnership, First Nation Elder James Quatell joined the organizations through ceremony. An exchange of copper symbolized our commitment to working towards better health outcomes for Indigenous Peoples. Framed as a one-year environmental scan, our national project is informed by an iterative and innovative state-of-the-art literature review; sharing circles and interviews with key informants. Our outputs include a Wise Practices Asset Map of culturally responsive IHR services which will form the foundation of new programming co-led by CAAN and DPAF.
Lessons learned: IHR is a critical part of the response to the HIV and Opioid epidemics in Canada. By beginning our partnership with a Copper ceremony, we made an agreement with each other and the communities that we work with, rooted in Indigenous Ways of Knowing and Doing. For our team of Indigenous and non-Indigenous researchers, this led us to adapt our research processes to mirror the context of working in a global pandemic. This included: rethinking our sequence of data collection

events, grappling with virtual dynamics, and staying reflexively attuned to power differences. The results of our work further reflect the need for adaptations.

Conclusions/Next steps: Building meaningful research partnerships is allyship in action between Indigenous and non-Indigenous researchers, service providers, and communities. Together we are leveraging the wisdom and relationships developed over decades of HIV and harm reduction response to strategically contribute to an evolving evidence base, and improve services over time by ensuring they are accessible, people-centered, and inclusive.

COVID-19 and politics, human rights, ethics or policy

PEMOF33

The long tail of warp speed: the politics of HIV science and the role of the AIDS pandemic in generating the COVID-19 scientific response

D. Werb[1,2,3]

[1]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, [2]University of California San Diego, Department of Medicine, La Jolla, United States, [3]Centre on Drug Policy Evaluation, Toronto, Canada

Background: Humanity's control of the AIDS pandemic in the absence of a viable vaccine is one of the 20th century's greatest scientific achievements. The success of that effort is consequential in ways that go far beyond HIV itself. In fact, it is because of the decades-long effort to control AIDS that humanity is, two years into the pandemic, equipped with an assortment of vaccines, antiviral treatments, and public health protocols that have the power to stop people from dying.

Description: The profound impact of HIV science--both individual scientists and the scientific organizations created to control the AIDS pandemic--is largely unknown. Through qualitative interviews with leading HIV scientists (*n*= 29), this presentation will explore the history of HIV science and describe the key ways that this has intersected with, and driven, the scientific response to COVID-19.

Lessons learned: The scientists interviewed described three pathways by which HIV science generated the COVID-19 response. First, decades of failure on an HIV vaccine contributed to an expansion of the field of immunology, which directly led to the development and testing of mRNA vaccines. Second, the „scientific-industrial complex" created to end the AIDS pandemic—parts of which were rebranded as Operation Warp Speed, under the direction of the AIDS Clinical Trial Group—were critical to the development of antivirals and other therapies to treat COVID-19. Third, the strategy of using HIV antiviral medicines as ‚Treatment as Prevention' to end the AIDS pandemicis increasingly being considered as a way to control the impact of SARS-CoV-2 variants with escape mutations that threaten the effectiveness of vaccines.

Conclusions/Next steps: While the public discourse suggests that Operation Warp Speed brought COVID-19 science from nothing to vaccines within a matter of months, it is the continuous decades-long public funding devoted to tackling the AIDS pandemic that powered the scientific response to SARS-CoV-2. Public funding for monitoring of pandemic threats, and the continued support of scientific efforts to end the AIDS pandemic, are the most critical priority areas to protect humanity from current and future opportunistic pathogens.

PEMOF36

Assessing the impact of COVID 19 on the implementation of the HIV workplace policy in (5) organizations

J. Mensah[1]

[1]African University college of Communication, Development Communication, Accra, Ghana

Background: The National HIV and AIDS workplace policy revision in 2012 has been disseminated to most organizations to serve as a guide in the formulation of individual organizational HIV workplace policies and programs. Since the outbreak of COVID 19 epidemic, there has not been a comprehensive study to assess the implementation of these HIV workplace policies in respective organizations. The objective are to create awareness, reduce stigma and discrimination, promote healthy and safe working environment, prevent transmission of HIV and ensure issues at the not relegated to the background amidst COVID 19

Description: The study sought to assess the knowledge of employees on their HIV workplace policy and COVID 19 Protocols, the attitudes of employees towards HIV/COVID positive colleagues, and assess the level of implementation of HIV workplace policies in organizations.

A formative research was conducted as the baseline study, and the data collection used was a semi-structured questionnaire a combination of open-ended and close –ended. An online response system was created to reach employees that were not at work due to COVID 19 staff rotation policy. Five organizations were to participate in the study. A cross-section of ten (10) employees comprising managers, senior, and junior staff were sampled to partake in the study. In total fifty (50) employees were interviewed.

Lessons learned: The result showed that, 70% of respondent had received updated information about COVID 19 and not HIV in the past 6 months, organizations had visible COVID 19 preventive informative posters and none on HIV at the workplace, 78% of respondent were more comfortable engaging with colleagues who had tested positive to COVID 19 than HIV positive, COVID 19 preventive commodities like hand sanitizers, facemasks were made available to employees with no provision made for HIV preventive commodity like condoms at the workplace,

COVID 19 referral centres have been created at the workplace with no referral point for HIV.

Conclusions/Next steps:

- The results shows that little importance is given to HIV amidst COVID 19 at the workplace therefore, the Ghana AIDS Commission must strengthen corporate management capacities in implementing HIV and AIDS workplace policies.
- Monitor the implementation of the workplace policy according national guidelines.

Impact of COVID-19 on HIV risk and HIV care among refugees, migrants, asylum seekers and internally displaced persons

PEMOF34

Post COVID increase of HIV prevalence among rural migrant population and women in India – Need to re-design migrant / rural interventions

V.S. Prasad[1], E. Michael[2], M. Kumar[3], S. Dwivedi[4], K. Prasanna Viswanath[5], L. Hong[6], J. Vandenhombergh[7], A.S. Benzaken[8], F.F. Fonseca[8]

[1]AIDS Healthcare Foundation India, Management Health Care Services, New Delhi, India, [2]AIDS Healthcare Foundation India, Operations and Partnerships, New Delhi, India, [3]AIDS Healthcare Foundation India, Monitoring and Evaluation, New Delhi, India, [4]AIDS Healthcare Foundation India, Prevention Services, New Delhi, India, [5]AIDS Healthcare Foundation India, Clinical Services, New Delhi, India, [6]AIDS Healthcare Foundation, Bureau Chief India, Los Angeles, United States, [7]AIDS Healthcare Foundation, Global Quality, Amsterdam, Netherlands, the, [8]AIDS Healthcare Foundation, Clinical Services, Sao Paulo, Brazil

Background: AIDS Healthcare Foundation – India implements community based rapid HIV testing across ten states. The objective of the program is early detection and linkage to treatment and to compliment the efforts of National Program in reaching 95- 95 -95. During COVID lockdown in 2020 large numbers of male migrant labourers from Delhi and Mumbai (destination districts) returned to their native villages (source districts) due to loss of employment during lockdown.

Description: This operational study considered four source migration districts from where male migrants would travel to destination districts for employment. The Community based rapid HIV testing data (gender disaggregated) from 2019 to 2021 was analysed. The objective of the study was to compare the HIV sero positivity before and during Covid between men and women and to revisit the risk profile of the newly identified cases.

Lessons learned: The results showed that HIV sero-positivity in 2019, prior to COVID-19, in the source districts among men and women was 0.8% and 0.6% respectively. During late 2020 and 2021, when the restrictions were eased and testing resumed, the HIV sero prevalence among men was 1.3% and women 1.1%.

Based on this evidence a quick profile of the newly identified men and women was analysed, revealing that these women were wives/partners of male migrants who returned from destination districts. Most women (87%) have children and are between 19 – 30 years old. 93% of women had completed primary education only and have no knowledge about HIV.A total of 1055 (93%) of all identified HIV positives were linked to the Government ART centre for treatment and follow-up. The project initiated partner testing and as a result these women were identified.

Conclusions/Next steps: The study recommends increased access to HIV prevention, testing and treatment services to be made available at source district and FOCUS on strategies like Index Testing and Partner testing. The National program needs to re-engage and re-design rural interventions for migrants and women, especially for identifying hidden populations and linking them to care and treatment in the context of Covid 19 pandemic.

Gender equity and diversity

PEMOF37

Legal gender recognition policy briefs (Botswana and Lesotho): a guide for inclusion

A. Mmolai-Chalmers[1]

[1]Southern Africa Litigation Centre, Johannesburg, South Africa

Background: In 2019, in partnership with LEGABIBO, Matrix, and WILSA, SALC developed policy briefs to inform procedures on legal gender recognition and change of gender markers for Botswana and Lesotho Governments. The two countries laws require official identification documents that reflect one's name and gender identity to access services. The states issued official identification documents are used in daily life including accessing health. Transgender and gender non-conforming persons are unable to obtain identity documents that match their gender identity and expression.

Description: The policy briefs were developed to support Governments with guidance on the interpretation of legal gender recognition. The research was informed by community consultations with members of the transgender in the two countries where participants shared daily experiences on the impacts of not possessing official identification documents. An analysis of international laws and principles that guide legal gender recognition, case lawand domestic laws were reviewed.

Lessons learned: Transgender and gender non-conforming persons are unable to change documents to reflect their gender identity. In Botswana transgender, persons cannot change their gender marker without a court order. When they present identity documents that do not

reflect their identity, they experience violence stigma and discrimination. In Lesotho, legal gender recognition is not prohibited, but trans people still face barriers. Legal gender recognition is possible in Botswana because people can change first names and surnames. The National Registration Act allows for particulars to be changed if "material change" has occurred.

Conclusions/Next steps: States can takelegislative and administrative steps to ensure that there are procedures for legal gender recognition based on self-determination. Lesotho legal frameworks recognise gender; therefore, the terms sex/gender should continue to be used interchangeably to accommodate transgender and gender non-conforming people.

In Botswana, the Government must develop regulations and procedures to change the gender marker based on the principles of self-determination.

Single-cell sequencing of simian immunodeficiency virus DNA provides improved resolution of reservoir viral evolution and evidence of selection for long-range co-evolution

L. Droske[1,2], S. Shank[3,4], M. Cash[1,2], S. Kosakovsky Pond[3,4], M. Salemi[1,2], B. Rife Magalis[1,2]
[1]*University of Florida, Department of Pathology, Immunology and Laboratory Medicine, Gainesville, United States,* [2]*Emerging Pathogens Institute, Gainesville, United States,* [3]*Temple University, Department of Biology, Philadelphia, United States,* [4]*Institute for Genomics and Evolutionary Medicine, Philadelphia, United States*

Background: During the course of infection, human immunodeficiency virus (HIV) maintains a stably integrated and therapy-impervious reservoir of replication-competent proviruses within the host genome. Previous methods have attempted to improve HIV reservoir characterization, but lack a more complete and reliable resolution of the intra-host evolution HIV undergoes and its contribution of reservoir cells to viral rebound.
Further, currently identified co-evolving sites that may provide support during immune and/or drug selection and improve overall fitness have been strictly analyzed in sole portions of the genome rather than as a whole.
Methods: A novel single-cell sequencing platform (scDNA-seq) was optimized for sequencing of proviral and host DNA using peripheral blood mononuclear cells (PBMCs) and lymph nodes (LN) from a treatment-interrupted HIV animal model. The scDNA-seq approach comprised of targeted amplicons covering the full S[simian]IV genome, in addition to a region of the Rhesus macaque TRIM5a gene to verify platform performance. ScDNA-seq was performed on samples taken from three animals either during therapy (cART) or after (post-cART).
Phylogenetic analysis to assess signal improvement using scDNA-seq-acquired near full-length (NFL) genomes contrasted with envelope (*env*) region alone (current gold standard), was performed on collective SIV^{+} cells for individual animals with gp120 sequence data.
Additionally, a Bayesian graphical model (BGM) of covariation was utilized to evaluate interactions among sites in the SIV genome and their conditional dependence.
Results: Consensus reconstruction across all samples resulted in 1,127 SIV genomes. Phylogenetic likelihood mapping displayed significant increases in phylogenetic resolution for scDNA-seq NFL genomes when analyzed against their *env*regions, indicated by a 10-26% reduction in unresolved phylogenies.
Consequently, statistically supported branching events more than doubled for NFL genomes compared to *env*. BGM analysis revealed 12 intragenic sites shared among >1 animal, as well as several instances of intergenic co-evolution, showcasing the existence of long-range interactions. More than 50% of sites with conditional dependence (n=7) were clustered between *env*and accessory genes.
Conclusions: Taken together, adaptation of this technology to viral studies provides a mechanism for acquiring enhanced confidence in phylogenetic inferences of viral evolution, and an avenue for discovering how genes may rely on each other during the course of infection/treatment.

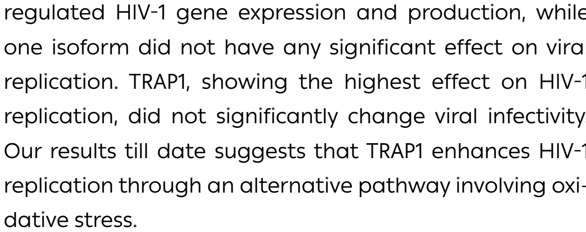
HIV biology (entry, replicative cycle, transcriptional expression and regulation)

EPA002

Non-canonical role of Hsp90 isoforms in HIV-1 infection

A. Mitra[1], D. Mitra[1]
[1]*National Centre for Cell Science, HIV Research Lab, Pune, India*

Background: Hsp90 (Heat shock protein, 90kDa) is one of the most abundant proteins in eukaryotic cells which performs a diverse range of functions due to the presence of five compartmentalized isoforms in eukaryotes. Hsp90 is well known to participate in HIV-1 replication and reactivation from latency. The pan-isoform Hsp90 inhibitors are successful in suppressing HIV-1 infection and thus Hsp90 has been suggested to be a possible host factor target for HIV-1 inhibition. While some of these isoforms exert discrete effects in other viral infections, their individual roles in HIV-1 infection remains to be studied.
Therefore, it will be interesting to also explore specific roles of Hsp90 isoforms in HIV-1 life cycle, an aspect we have tried to address in the present study.
Methods: Modulation of Hsp90 isoforms during HIV-1 infection was studied using Realtime-PCR. Over-expression and silencing of these Hsp90 isoforms were performed to test their effect on HIV-1 replication using luciferase assay and $p24^{gag}$ ELISA, and on viral infectivity by β-galactosidase assay. Since mitochondrial isoform TRAP1 showed the most significant effect on viral replication, different oxidative stress indicators were studied following HIV-1 infection to unravel further mechanism.
Results: Profiling studies revealed very low levels of one Hsp90 isoform in T cell lines, while the remaining four isoforms are differentially modulated during HIV-1 infection. Therefore, these were taken for further studies. With respect to functional relevance, three isoforms positively



regulated HIV-1 gene expression and production, while one isoform did not have any significant effect on viral replication. TRAP1, showing the highest effect on HIV-1 replication, did not significantly change viral infectivity. Our results till date suggests that TRAP1 enhances HIV-1 replication through an alternative pathway involving oxidative stress.

Conclusions: Our study indicates the functional specificity of Hsp90 isoforms during HIV-1 infection. While earlier studies have shown that Hsp90 enhances HIV-1 transcription by recruiting and stabilizing the host transcription machinery, we have shown that at least one isoform can also enhance viral replication through an alternative mechanism. These findings might help to develop novel therapeutic strategies that can target specific Hsp90 isoforms involved in HIV-1 pathogenesis.

EPA003

Characterization of novel candidate factors impacting HIV life cycle

B. Mersinoglu[1], R. Martinez[1], A. Ciuffi[1], S. Cristinelli[1]
[1]*University of Lausanne (UNIL) and Lausanne University Hospital (CHUV), Institue of Microbiology, Lausanne, Switzerland*

Background: Throughout replication, HIV interacts with host factors that can either promote (HIV dependency factors, HDF) or inhibit (HIV Inhibitory factors, HIF) viral replication. The success of HIV replication relies on the balance between HDF and HIF. Epitranscriptomics (i.e. the study of RNA modifications such as N6-methyladenosine (m^6A) and 5-methylcytosine (m^5C) methylations) provides a new layer of gene regulation and represents an additional opportunity to uncover novel cellular players involved in HIV life cycle.

Methods: We characterized the m^6A and m^5C epitranscriptomic landscape of CD4+ SupT1 cells, infected or not with an HIV-based vector. At 12h, 24h and 36h post-infection, we identified differentially methylated (DM) transcripts through bioinformatic analysis and selected candidates for further investigation using CRISPR-Cas9-mediated knock out (KO) in Jurkat cells and assessment of their impact on HIV replication.

Results: We identified 59 m^6A and 14 m^5C hypermethylated transcripts already at 12h post-infection and maintaining their modification over time (at 24h and 36h), potentially involved in the cellular response to HIV, as well as 220 m^6A and 48 m^5C present only at later stages (24h and 36h), potentially due to HIV subversion of the cell. Upon ranking according to statistical significance, we selected the top 10 DM candidates for further analysis.

Analysis of selected candidates showed an enrichment on GTPases from the GIMAP or the RGPD family. We successfully generated and validated KO Jurkat cell lines for each candidate to investigate their impact on HIV replication and evaluate their role as putative HDF/HIF.

Conclusions: Because they affect the fate of RNA molecules (such as splicing, stability or translation), epitranscriptomic modifications play an important role in cell functioning, which can be exploited by the virus to promote its own replication.

As with transcriptomics, epitranscriptomic analyses represent a new opportunity to identify novel actors modulating HIV replication, thereby improving current understanding of HIV biology and potentially providing an array of new therapeutic targets.

EPA004

Single cell imaging corroborates the link between HIV integration and transcription

J. Janssens[1], F. De Wit[1], N. Parveen[2], F. Christ[1], Z. Debyser[1]
[1]*KU Leuven, Pharmaceutical and Pharmacological Sciences, Leuven, Belgium,* [2]*Indian Institute of Technology, Department of Chemistry, Kanpur, India*

Background: Antiretrovirals fail to cure HIV infection since latent provirus resides in long-lived reservoirs, rebounding whenever therapy is discontinued. The mechanisms underlying HIV latency are complex whereby the possible link between integration site selection and the transcriptional state of the provirus is poorly understood. HIV integration is targeted towards active chromatin by the direct interaction with a host protein, LEDGF/p75. Small molecules, referred to as LEDGINs, inhibit the LEDGF/p75-integrase (IN) interaction and shift integration out of active genes resulting in residual provirus that is more latent.

Methods: We have optimized a branched DNA imaging method for simultaneous detection of viral DNA and RNA in single cells.

We investigated how LEDGIN treatment affects the location, transcription and reactivation of the provirus in cell lines and primary cells. LEDGIN CX014442 was tested and compared to equivalent concentrations of raltegravir, a clinically approved IN strand transfer inhibitor.

After infection of the cells in the presence of the compounds, the cells were kept in culture to allow silencing of the viral gene expression and were reactivated on day 7 (PBMCs) or 10 (cell lines) post infection.

Results: LEDGINs inhibited HIV infection, as shown by a decrease in the number of vDNA spots per cell.

Furthermore, the 3D nuclear location of the residual provirus after LEDGIN treatment was shifted towards the inner nucleus. LEDGIN-mediated retargeting hampered both the baseline transcriptional state and transcriptional reactivation of the provirus, as shown by a decrease in the number of vRNA spots per cell.

LEDGIN treatment reduced the vRNA expression per residual copy. Since RAL failed to reduce HIV transcription and reactivation, this effect is not merely the result of reduced infectivity.

At a higher concentration of LEDGINs, an increase in the number of vDNA spots per cell was observed in primary cells. This may reflect a positive selection of deep-latent provirus after LEDGIN treatment.
Conclusions: Retargeting integration with LEDGINs shifted the 3D location, reduced transcription and hampered reactivation of the provirus. These results corroborate the impact of integration site selection on the transcriptional state of the provirus and support block-and-lock cure strategies in which the latent reservoir is permanently silenced after retargeting.

EPA005

Barriers that limit cell-free HIV-1 entry into macrophages are overcome after cell-cell fusion with infected T cells

V. Cantaloube-Ferrieu[1], M. Han[2], M. Xie[2], M. Armani-Tourret[1], M. Woottum[2], J.-C. Pages[3], P. Colin[1], B. Lagane[1], S. Benichou[2]
[1]Inserm U1291 - Toulouse Institute for Infectious and Inflammatory Diseases (Infinity), Toulouse, France, [2]Institut Cochin, Inserm U1016, Paris, France, [3]Institut Restore - CNRS U-5070, EFS, ENVT, Inserm U1301, Toulouse, France

Background: It is increasingly recognized that macrophages (MΦ) are involved in the dissemination and persistence of HIV-1. In persons living with HIV-1, infected MΦ are found in a wide range of lymphoid and non-lymphoid tissues. Paradoxically, cellular tropism assays indicated that HIV-1 isolates are T-tropic and only rarely M-tropic, most often due to inefficient viral entry into MΦ. However, these tropism assays, because they use cell-free viral particles, might not reflect all modes of MΦ infection *in vivo*, in particular through cell-to-cell viral transfer.
Here, we investigated whether virus isolates, previously characterized as non-M-tropic viruses in cell-free infection assays, could efficiently infect MΦ through cell-cell fusion with infected CD4+ T cells, a new mode of infection of myeloid cells we recently identified.
Methods: We investigated the capacity of a panel of CCR5- and/or CXCR4-using Env-pseudotyped viruses and infectious molecular clones to infect MΦ by a cell-free mode or through viral transfer from infected CD4+ Jurkat T cells. Envs representative of the different stages of HIV-1 infection were used, including transmitted/founder Envs known to be non-M-tropic.
Results: Single-round infection and virus-cell fusion assays showed that most of these viruses in the form of cell-free particles are inefficient to enter MΦ, whereas they can effectively infect primary CD4+ T cells.
In contrast, all viruses were efficiently transferred to MΦ after Env-dependent cell-cell fusion of MΦ with infected CD4+ T cells, ultimately leading in most cases to productively infected multinucleated giant cells. These results suggested that MΦ infection through cell-cell fusion with infected T cells overcome barriers that normally restrict entry of cell-free viruses into MΦ. In line with this, formation of infected T cell/MΦ conjugates enhanced interactions between Env and CD4 and CCR5, rendering viral entry into MΦ less dependent on expression levels of those receptors.
Conclusions: These data suggest that M-tropism of HIV-1 is more widespread than initially thought based on cellular tropism assays. They also suggest that MΦ infection may be facilitated in CD4+ T cell rich tissues. These data renew our understanding of the role of MΦ in HIV-1 transmission and pathogenesis and the formation of tissue reservoirs.

Viral fitness, persistence and resistance

EPA006

Consequences of HIV-1 Gag-protease driven replication capacity for cellular inflammation and HIV-1 cell-to-cell transmission

O.O. Baiyegunhi[1], J. Mann[2], M.J. Bunders[3], M. Altfeld[4], T. Ndung'u[1,2,5,6]
[1]Africa Health Research institute, Durban, South Africa, [2]University of KwaZulu-Natal, HIV Pathogenesis Programme, Durban, South Africa, [3]University Medical Center Hamburg-Eppendorf, Department of Medicine, Hamburg, Germany, [4]Heinrich Pette Institute, Research Department Virus Immunology, Hamburg, Germany, [5]University College London, Division of Infection and Immunity, London, United Kingdom, [6]Ragon Institute of MGH, MIT, and Harvard University, Boston, United States

Background: The replication capacity (RC) of the infecting virus strains impacts the pathogenesis and disease progression of HIV/AIDS. Higher RC has been associated with greater viral loads and faster disease progression in the absence of therapy, whereas in some circumstances, lower RC viruses may be selectively favored for transmission. Understanding the underlying mechanisms of spread of viruses with variable RCs will inform novel anti-HIV interventions.
We hypothesized that viruses differ according to their RC in their ability to modulate cellular metabolism or induce inflammation. Moreover, we postulated that RC influences viral capacity for cell-to-cell spread.
Methods: Chimeric viruses containing patient-derived Gag-protease amplicons from subtypes B and C were constructed in the NL4-3 backbone (n=29). Viral RC was determined using a GFP-reporter cell line assay, the ability to induce diverse cytokines production in GXR cells was assessed using Luminex and capacity for cell-to-cell spread as well as cellular glucose and lipid uptake was measured by flow cytometry.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Results: The RC of the chimeric virus correlated with the amount of cell-to-cell spread at 24 and 48 hours (p=0.02, r=0.7). Also, high RC variants induced significantly higher amounts of IL-7, PDGF-bb, FGF-basic and IL-1b in GXR cells compared to low RC variants (all p<0.05). While subtype B infections were associated with higher production of IL-7 and PDGF-bb (both p=0.03) than subtype C infections, higher IL-4 (p=0.05) and IL-8 (p=0.0006) production was a signature of subtype C infections.

Moreover, glucose uptake was higher in HIV-infected cells compared to bystander cells (p=0.0002), but similar for infections propagated by either low or high RC viruses. Fatty acid uptake was also high in the infected cells regardless of the RC of the infecting virus.

Conclusions: These results indicate that virus RC positively correlates with capacity for cell-to-cell spread and ability to induce proinflammatory cytokines in T cells. Further, the data highlight potential subtype-specific differences in the induction of soluble mediators during HIV infection. Lastly, the results also show that HIV infection modulates the metabolic profile of infected T cells regardless of RC. These data have implications for understanding the mechanisms underlying differential clinical outcomes by viruses with variable RCs.

Background: Chronic low-level immune activation in people living with HIV on suppressive antiretroviral therapy (ART) is associated with elevated morbidity and mortality. Sources or immune activation are uncertain, but may be related to ongoing HIV RNA production from persistently infected cells. To investigate the role of HIV RNA levels in immune activation during ART, we used multi-modal statistical analyses to identify cellular immune subsets associated with HIV RNA levels.

Methods: Clinical information and peripheral blood mononuclear cells (PBMC) were collected from individuals on suppressive ART ≥3 years. Cell-associated HIV DNA and RNA levels were measured by multiplexed droplet digital PCR assays that simultaneously quantified HIV LTR and *gag* regions. Levels of unspliced HIV RNA levels were quantified per total number of proviruses (normalizing *gag* RNA to levels of LTR DNA/2) and per total number of *gag*-containing proviruses (normalizing to HIV *gag* DNA. PBMC were analyzed in extended flow cytometry panels quantifying >20 lymphocyte and activation markers.

To identify immune parameters most frequently associated with HIV *gag* production, we used 24 different statistical methods, including parametric and non-parametric correlation approaches, regression, and classification methods using varying assumptions about dataset structure.

Results: PBMC samples (N=70; 90% male; median CD4=672 cells/µl) were analyzed (N=70 for DNA, N=60 for RNA). Participants had been infected for a median ≥19.75 years (range 3.9-34.2 years). All had detectable DNA (LTR 20-17327 copies/10^6 PBMC, *gag* 7-4779 copies/10^6 PBMC). HIV RNA levels were lower (LTR 5-2219 copies/10^6 PBMC, gag 0-883 copies/10^6 PBMC); HIV RNA and DNA were quantifiable in 81% of participants. For *gag* RNA:*gag* DNA levels, proportion of natural killer (NK) cells (CD16+CD56+) positively correlated in the most models (11/24 models), followed by nadir CD4 (9/24 models) and minimum duration of infection (7/24 models). When gag was normalized to LTR DNA, NK and minimum duration of infection were strongly correlated in 14/24 and 5/24 models, respectively.

Conclusions: Levels of cell associated HIV RNA were quantifiable in the majority of individuals undergoing ART. Detailed immunophenotyping revealed correlations between cell-associated HIV *gag* RNA levels and proportion of NK cells, suggesting a key role of innate immunity in proviral RNA expression.

EPA008

HIV drug resistance among female sex workers in South Africa: a cross-sectional national study

J. Coetzee[1,2], M. Milovanovic[1,2], K. Otwombe[1], K. Hopkins[1], G. Hunt[3], K. Hlongwe[1], M. Jaffer[4], N. Martinson[1], F. Abdullah[5], R. Jewkes[5], G. Gray[6], C. Wallis[7], F. Venter[8]
[1]Perinatal HIV Research Unit, Prevention in Key Populations, Soweto, South Africa, [2]African Potential Foundation, Johannesburg, South Africa, [3]National Institute of Communicable Diseases (NICD), Johannesburg, South Africa, [4]University of the Witwatersrand, Health Sciences, Johannesburg, South Africa, [5]South African Medical Research Council, Cape Town, South Africa, [6]South African Medical Research Council, Office of the President, Capet Town, South Africa, [7]Lancel Laboratories, Johannesburg, South Africa, [8]Ezintsha, Johannesburg, South Africa

Background: HIV drug resistance (HIVDR) threatens the success of treatment programmes. Routine surveillance for HIVDR in key populations, such as FSWs, is not undertaken in South Africa. Female sex workers (FSWs) may contain high levels of HIVDR, and further profiling HIVDR is needed.

Methods: A multi-stage, community-centric, cross-sectional survey of 3,005 FSWs linked to sex worker programmes in 12 sites across all nine provinces (February to July 2019).The sub-analysis included HIV-positive FSWs with viral load (VL) ≥ 400 copies/ml. Surveys collected demographic data and self-reported ARV-exposure. CD4 and HIVDR genotyping (protease inhibitor [PI], nucleoside reverse transcriptase inhibitor [NRTI], non-NRTI [NNRTI]) was conducted.

Frequencies and percentages were assessed for categorical variables and stratified by ARV exposure (ARV exposed and unexposed)The frequency cut-off for presenting common mutations was ≥5%.

Results: Of 675 participants, 64.44% (n=435) had HIVDR, with more than half being 25-34 years of age (363/675, 53.78%). Three quarters of women who were currently or previously on ART had HIVDR mutations (284/371,76.55% or 71/97,73.2% respectively). Amongst those with no prior exposure or prior PrEP exposure, one third had HIVDR mutations (63/174,36.21% or 2/6, 33.33% respectively).

Overall, and amongst FSWs either on ART or with prior ART exposure, the most common mutations were the N103N (266/675, 39.47%; 193/371, 52.02%; 116/371, 31.27% respectively) and M184V (126/675, 20.15%; 41/97, 42.27%; 15/97, 15.46% respectively). Amongst those with no ART exposure, PMTCT exposure or PrEP exposure, the K103N was the most prevalent mutation (24/174, 13.79%; 7/27, 25.93%; 1/6, 16.67% respectively).

Conclusions: In conclusion, our study highlights the high rates of HIVDR mutations amongst FSWs in South Africa. HIVDR amongst FSWs could cause large proportions of treatment-naïve and treatment-initiated FSWs to fail first-line ARV regimens, potentially bridging HIVDR to the general population. Routine HIVDR surveillance is critical within sex worker programmes to inform stakeholders and ensure rapid response.

Systemic immune activation and inflammation

Extracellular vesicles as potential mechanism of chronic inflamation in HIV patients

M.A. Navarrete-Muñoz[1], M.J. Muñoz-Gómez[2], S. Resino[2], A. Cabello[3], M. Górgolas[3], J.M. Benito[1], N. Rallón[1]
[1]Instituto de Investigación Sanitaria-Fundación Jiménez Díaz (IIS-FJD/UAM) - Hospital Universitario Rey Juan Carlos, HIV and Viral Hepatitis Research Laboratory, Madrid, Spain, [2]Institute of Health Carlos III, Unit of Viral Infection and Immunity, National Center for Microbiology, Majadahonda, Spain, [3]Hospital Universitario Fundación Jiménez Díaz, División de Infecciosas, Madrid, Spain

Background: Increased systemic inflammation, associated with different morbidities, has emerged as a main problem in the clinical management of HIV-infected patients. Extracellular vesicles (EVs) carrying HIV elements and host pro-inflammatory molecules have been recently proposed as a potential mechanism contributing to this inflammatory state.

Herein, we have analyzed several molecules associated to systemic inflammation, endothelial activation and coagulation in plasma-derived EVs from two groups of HIV patients with controlled HIV replication (spontaneously or by cART) and in a group of non-controller patients with replicating HIV.

Methods: Thirty HIV patients were included: 10 elite controllers (EC), 10 cART-suppressed (NC-TT) and 10 cART-naive with high levels of HIV plasma viremia (NC-NT). Ten uninfected volunteers (UC) were also included as reference group. Plasma EVs were isolated by Size Exclusion Chromatography and lysed with triton X100 to release its content.

Levels of fourteen different parameters related to systemic inflammation, endothelial activation and coagulation were evaluated using a Bio-Plex 200 System-Biorad and a customized kit of ProcartaPlex. Inter-group differences and potential associations were tested by non-parametric tests.

Results: Among the different markers analyzed, the endothelial activation marker ICAM1 (intercellular cell adhesion molecule 1) and the coagulation marker PAI-1 (plasminogen activator inhibitor 1) were differentially expressed between the study groups. HIV^+patients showed increased levels of ICAM1 and PAI-1 compared to HIV^- UC volunteers (ICAM1: 8869[6780-12645] vs 6620[5877-7101] pg/mL,p=0.006; PAI-1: 45[29-75] vs 32[21-44]pg/mL,p=0.054).

Compared to UC volunteers, both NC-NT (p=0.011) and NC-TT (p=0.001) patients presented the highest levels of ICAM1 (11841[7807-15260] and 8970[6998-10624]pg/mL in NC-NT and NC-TT respectively).

In contrast, PAI-1 levels in NC-NT patients were similar to those of UC volunteers but were increased in patients with controlled viral replication, especially in NC-TT group (71[25-106] vs 32[21-44]pg/mL in NC-TT and UC respectively,p=0.029).

Conclusions: Our results show the existence of increased levels of endothelial activation and coagulation markers carried by EVs in the setting of HIV infection.

This phenomenon was observed in both uncontrolled and controlled viral replication, supporting an important role of EVs as mediators in the HIV-associated persistent inflammatory state despite the control of viral replication.

EPA010

Vesicular microRNA-155 amplifies HIV-1 infection

J. Boucher[1], A. Hubert[1], W.W. Bazié[1,2], B. Goyer[1], F. Barabé[1], C. Gilbert[3,1]

[1]Centre de Recherche du CHU de Québec-Université Laval, Axe des Maladies Infectieuses et Immunitaires, Québec, Canada, [2]Centre Muraz, Institut National de Santé Publique, Programme de Recherche sur les Maladies Infectieuses, Bobo-Dioulasso, Burkina Faso, [3]Université Laval, Département de Microbiologie, Infectiologie et d'Immunologie, Québec, Canada

Background: The hallmark of HIV-1 infection is rapid and irreversible damage to the immune system. Despite efficient suppression of viral replication by antiretroviral therapy (ART), immune dysfunction persists in people living with HIV (PLWH), leading to comorbidities and vulnerability to co-infections. A strong predictor of viral rebound and immune deficiency is the enrichment of extracellular vesicles (EVs) with microRNA-155 (miR-155). EVs are intercellular messengers that influence the state of recipient cells by transferring their contents. MiR-155 is a multifunctional microRNA that regulates genes involved in many immune functions such as immune cell development, activation, and survival. We therefore hypothesized that miR-155-rich EVs directly influence the course of HIV-1 infection.

Methods: We usedtwo viral preparations (NL4.3BE without or with miR-155-rich EVs) to infect human peripheral blood mononuclear cells (PBMCs) and humanized mice. Viral load, capsid protein p24 titration, integrated DNA quantification, and CD4/CD8 ratio were monitored. Flow cytometry was used to measure the expression of two markers of immune activation: HLA-DR (cell activation) and PD-1 (cell exhaustion). RT-qPCR was used to measure the expression of key genes (SOCS1, SHIP1, Trim32 and Lamine B1) targeted by miR-155 in infected PBMCs.

Results: MiR-155 increased NL4.3BE load in infected PBMCs. Its presence was associated with higher viral load, lower CD4/CD8 ratio and increased HLA-DR and PD-1 in mice infected by NL4.3BE with miR-155-rich EVs. SOCS1, a regulator of cytokine-mediated cell activation, was found significantly downregulated in the presence of miR-155-rich EVs.

Conclusions: More than a biomarker, vesicular miR-155 modulates viral replication directly and promotes the apparition of pro-inflammatory and exhausted phenotypes in immune cells.

These observations suggest pharmacological targeting of miR-155 to restore or prevent immune impairment early in HIV-1 infection.

EPA011

Immune preservation in HIV+ Viremic Non-Progressors is associated with downregulation of type-I IFN pathway and reduced activation of cytotoxic compartments

Á. Bayón Gil[1], I. Hernández[2,3,4], J. Dalmau[5], J.C. Nieto[2,3], V. Urrea[5], M.C. García-Guerrero[1], C. Gálvez[1], M. Salgado[1], H. Heyn[2,3,6], J. Martinez-Picado[1,7,8], M.C. Puertas[1]

[1]IrsiCaixa AIDS Research Institute, Retrovirology and Clinical Studies (GREC), Badalona, Spain, [2]CNAG-CRG, Centre for Genomic Regulation (CRG), Barcelona, Spain, [3]Barcelona Institute of Science and Technology (BIST), Barcelona, Spain, [4]Institute for Research in Biomedicine (IRB), Barcelona, Spain, [5]IrsiCaixa AIDS Research Institute, Badalona, Spain, [6]University Pompeu-Fabra (UPF), Barcelona, Spain, [7]University of Vic-Central University of Catalonia (UVic-UCC), Vic, Spain, [8]Catalan Institution for Research and Advanced Studies (ICREA), Barcelona, Spain

Background: Extreme phenotypes of infection eluding HIV-1 pathogenesis could allow the identification of novel therapeutic targets. Viremic Non-Progressors (VNPs) maintain high CD4$^+$ counts despite high-level viremia in absence of antiretroviral treatment (ART) by unknown mechanisms.

We aim to generate a comprehensive understanding of the lack of pathogenicity in VNPs.

Methods: We retrospectively selected 16 VNPs and 29 HIV progressors (control group) showing similar viral load (median logVL>4), but different CD4$^+$ decay rate (median annual CD4$^+$ count loss <10% and >10%, respectively). 43/45 total individuals are male. Patients are followed-up at Germans-Trias-Pujol University Hospital (Badalona, Spain). Experiments were conducted between 2019-2021 using cryopreserved PBMCs. Statistical differences were assessed by Wilcoxon test.

Total and intact HIV-DNA and cell-associated HIV-RNA were quantified on sorted CD4$^+$ T-cell subsets by droplet digital PCR at pre-ART and on-ART timepoints. CD4$^+$ and CD8$^+$ T-cell immunophenotype was characterized by flow cytometry. Fourteen individuals (seven matched pairs) were selected for comparative PBMCs transcriptome analysis by single-cell RNA-sequencing (scRNAseq).

Results: VNPs showed lower levels of total and intact HIV-DNA and cell-associated HIV-RNA in CD4$^+$ T-cells before ART initiation, especially among Effector Memory cells (640 vs 1928 total HIV-DNA copies/10^6cells, $p<0.05$).
However, viral reservoir size and composition were equivalent on-ART. Pre-ART CD4$^+$ T-cell subset composition and activation was similar in both groups. CD8$^+$ T-cells in untreated VNPs showed higher percentage of naive cells (24.2% vs 11.7%, $p<0.001$), lower levels of activation (HLA-DR$^+$/CD38$^+$) among memory compartments (15.5% vs 21.8%, $p<0.01$), and scRNAseq revealed lower expression of cytotoxic markers in CD8$^+$ T and NK cells.
Expression of Interferon-Stimulated Genes was significantly lower in VNPs across multiple cell types. We also found lower expression of *TGFB1* in CD4$^+$ T-cells, possibly involved in lymphoid tissue fibrosis.
Conclusions: Before ART initiation, VNPs showed lower levels of infected CD4$^+$ T-cells and lower expression of CD8$^+$ T and NK cell activation/cytotoxicity markers than HIV progressors in periphery.
However, the preservation of the CD4$^+$ compartment could be driven by downregulation of the chronic type-I IFN response and reduced damage at lymphoid tissues.
These pathways might be potential therapeutic targets for HIV$^+$ immunological non-responders that do not recover CD4$^+$ counts despite suppressive ART.

EPA012
Impact of early ART initiation on the dynamics of regulatory CD8 T-cells in acute HIV infection

A. Yero[1], S. Tao[1], M. Durand[2], C. Tremblay[2,3], J.-P. Routy[4,5], C.T. Costiniuk[5,4], M.-A. Jenabian[1]
[1]Université du Québec a Montréal (UQAM), Biological Sciences, Montreal, Canada, [2]CHUM-Research Centre, Montreal, Canada, [3]Université de Montréal (UdeM), Department of Microbiology, Infectiology and Immunology, Montreal, Canada, [4]Research Institute of McGill University Health Centre, Montreal, Canada, [5]McGill University, Chronic Viral Illness Service, Division of Infectious Disease, Department of Medicine, Glen Site, McGill University Health Centre, Montreal, Canada

Background: Increased frequencies of immunosuppressive FoxP3$^+$ CD8 Tregs during HIV infection is associated with immune dysfunction and disease progression.
However, the dynamics of CD8 Tregs in acute HIV infection and following early ART initiation remain understudied.
Methods: Peripheral blood mononuclear cells (PBMCs) were collected from untreated acute (n=26) and untreated chronic (n=10) HIV-infected individuals, early ART-treated in acute infection (n=10, median of ART initiation: 5,5 months post-infection), ART-treated in chronic infection (n=10), elite controllers (n=18), and HIV-uninfected controls (n=21). CD8 Tregs subsets were characterized by multiparameter flow cytometry.
Results: HIV infection was associated with increased total CD8 Tregs, effector memory, and terminally differentiated CD8 Tregs in acute and chronic infection, while early ART normalized only the frequencies of total and terminally differentiated CD8 Tregs. CD8 Treg expression of CD31, a marker of recent Tregs migrating from the thymus, increased in the acute phase but declined in chronic infection, indicating the extra-thymic differentiation of CD8 Tregs in the acute infection, while normalized by early ART initiation.
We also observed an overtime increase in CD8 Treg immune activation (HLADR$^+$CD38$^+$), immune senescence (CD57$^+$CD28$^-$), and PD-1 expression during both acute and chronic infection, while early ART initiation was unable to normalize these parameters. CD8 Tregs in untreated individuals expressed higher levels of immunosuppressive LAP(TGF-β1) and CD39 compared to uninfected controls, while early ART only normalized the LAP(TGF-β1).
Additionally, the expression of gut homing markers CCR9 and Integrin-β7 by total CD8 Tregs and CD39$^+$ and LAP(TGF-β1)$^+$ CD8 Tregs increased in both acute and chronic infections and remained higher than uninfected controls despite early ART. The frequencies of CD8 Treg subsets correlate positively with plasma viral load and T-cell immune activation and negatively with CD4 count and CD4/CD8 ratio. HIV elite controllers share most of the CD8 Treg characteristics in uninfected or early ART-treated individuals.
Conclusions: Although early ART initiation resulted in normalization of total CD8 Tregs frequencies, it was unable to reduce CD8 Treg gut homing potential nor LAP(TGF-β1) production, which in turn, may contribute to gut fibrosis, disease progression, and immune dysfunction despite early ART initiation.

EPA013
Recreational marijuana normalizes genes and pathways perturbed by tobacco alone or in combination with marijuana in virally suppressed youth with HIV

S. Borkar[1], L. Yin[1], K.-F. Chang[1], J. Shen[1], J. Kim-Chang[2], J. Sleasman[2], M. Goodenow[1]
[1]National Institute of Health, Molecular HIV Host Interactions Section, Bethesda, United States, [2]Duke University School of Medicine, Pediatric Allergy and Immunology, Durham, United States

Background: Chronic Inflammation and immune activation persist despite effective antiretroviral therapy (ART) in youth with HIV (YWH). Marijuana and tobacco co-use is prevalent among YWH, and may affect inflammatory pathways and long-term clinical outcomes in YWH with optimal viral suppression on ART. Genome-wide transcriptome analysis was performed to evaluate the effect of co-use along with marijuana/tobacco single use in YWH in comparison to youth without HIV (YWOH) who used no substance.

Methods: Peripheral blood cell mRNA was extracted and sequenced using Illumina HiSeq 2500 for 25 YWH (ages 18-23 years) and 25 YWOH balanced for age, gender and race. Amongst 25 YWH with undetectable viral load after a median of 2.6 years on ART(< 50 RNA copies per ml), 15 co-used recreational marijuana and tobacco; 7 used recreational marijuana only and 3 used tobacco only. Marijuana and tobacco use was assessed by self-report and validated by plasma toxicology.

Differentially expressed genes (DEGs) were analyzed using R package LIMMA(|FC| ≥ 1.3 and FDR ≤ 0.2). Pathway analysis was performed on DEGs with Ingenuity Pathway Analysis(P< 0.001;Z-scores ≥ 1/≤ -1). Perturbed pathways were classified and visualized using R package ClusterProfiler with a gene-concept network plot.

Results: Compared to YWOH, marijuana and tobacco co-users among YWH expressed 1,145 DEGs (571 upregulated and 574 downregulated), mainly enriched for interferon signaling, natural killer cell signaling, role of PKR in interferon induction, and STAT3 signaling, indicating a molecular signature of immune activation.

Pathways, such as RAC signaling or ERK/MAPK signaling, were perturbed in marijuana and tobacco co-users, as well as tobacco only users (744 DEGs), which may stem from a dominant effect of tobacco use on inflammatory pathways.

In marijuana only users, all of these pathways and most the DEGs were normalized, signifying a potential anti-inflammatory effect of marijuana. Genes, such as IFNG, STAT1, JAK2, MAP2K1, NRAS, PDPK1 were identified as hub genes connecting multiple pathways involved in the mechanisms of immune activation in response to marijuana and tobacco co-use in YWH.

Conclusions: Recreational marijuana use attenuates inflammatory genes and pathways perturbed by tobacco use in virally suppressed YWH on ART.

EPA014

Plasma extracellular vesicles and cell-free mitochondrial DNA are associated with cognitive dysfunction in treated older adults with HIV

C. Johnston[1], E. Marques de Menezes[2], S. Bowler[1], E. Siegler[3], C. Friday[1], P. Norris[2], M. Rice[4], M. Choi[4], M. Glesby[1], L. Ndhlovu[1]

[1]Weill Cornell, Infectious Diseases, New York, United States, [2]Vitalant, San Francisco, United States, [3]Weill Cornell, Geriatrics and Palliative Medicine, New York, United States, [4]Weill Cornell, Nephrology and Hypertension, New York, United States

Background: Extracellular vesicles (EVs) are small structures with a range of functions including cell-to-cell communication and inflammation. Neurons and microglia can secrete EVs that cross the blood brain barrier. Plasma cell-free mitochondrial DNA (cfmtDNA) has been associated with cognitive dysfunction, and urine cfmtDNA with unintentional weight loss in older adults with HIV (OAH). We hypothesized that plasma EVs would be associated with cognitive dysfunction in OAH.

Methods: A case-control study compared OAH age ≥54 with cognitive dysfunction (Montreal Cognitive Assessment [MoCA] score <23) to demographically similar OAH controls (MoCA >26). Frailty testing was conducted using the Fried Frailty Index. Participants with HIV viral load >40 copies/ml were excluded.

PlasmaEVs were measured by flow cytometry and plasma/urine cfmtDNA by PCR for NADH dehydrogenase 1 gene. EVs measured included CD4, CD14, CD16, CD19, CX-3CR1, WGA, CCR5, CD62p, CD41a, CD163, CCR2, CCR5, MAL-1, CD11b, CD200, Neurofilament, S100B, GFAP, MAP2, CD9, CD63, MHCII, GLUT-1, CD66b, and CD36.

A support vector machine learning-based model using recursive feature elimination was employed for analyses and area under the curve of the receiver operating characteristic (AUC-ROC) assessed the probability of discriminating cognitive function.

Results: The 49 participants had median age 60(IQR 57-65), were 37% female, 53% Black and 25% Hispanic, had a median CD4 T-cell count of 683(IQR: 474-877), and 61% met the criteria for pre-frail/frail. A model including urine cfmtDNA, 4-meter walk time, CCR5+ and GLUT-1+ EVs classified cognitive status with an AUC-ROC of 0.86 (95% CI 70-100 and an AUC-precision recall curve of 0.97 (0.93 - 0.99).

	Total Cohort (n=49)	Cognitively Impaired (n=25)	Cognitively Non-Impaired (n=24)	p-value (Low v High)
Age, years, median [IQR]	62 [57, 65]	63 [57, 67]	60 [57, 63]	0.311
Sex, Male, n (%)	31 (63.3%)	15 (60.0%)	16 (66.7%)	0.632
HIV Duration, years, median [IQR]	24 [22, 29]	24 [22, 27]	24 [22, 30]	0.711
CD4 T cell count, median [IQR]	683 [474, 877]	641 [485, 794]	727 [460, 1055]	0.569
Plasma cfmtDNA copies/mL, geometric mean [IQR]	5.57 [5.05, 5.90]	5.59 [5.29, 6.38]	5.30 [4.91, 5.77]	0.041
Urine cfmtDNA copies/g of urine creatinine, geometric mean [IQR]	19.25 [18.09, 20.16]	19.00 [17.76, 20.03]	19.51 [18.17, 20.41]	0.11
Not Frail*	17 (34.7%)	6 (24.0%)	11 (45.8%)	0.064
Pre-frail/Frail*	30 (61.2%)	19 (76.0%)	11 (45.8%)	0.064
4m Walk Time, seconds, median [IQR]	4.83 [3.78, 5.58]	5.21 [4.42, 5.90]	4.15 [3.57. 5.09]	0.007

Table.

Conclusions: Our machine learning model predicted cognitive dysfunction with 86% certainty (+/- 16%) using urine cfmtDNA, 4-meter walk, and CCR5+ and GLUT-1+ EVs.CCR5 and GLUT-1+ EVs may reflect inflammatory and metabolic activity respectively in the CNS.

Our findings suggest s role of EVs and cfmtDNA as potential biomarkers of cognitive dysfunction and warrant further investigation.

EPA015

People living with HIV have higher endothelial colony-forming cell frequencies: characterisation of patient-derived vascular endothelium

A.A. Khawaja[1], R.T. Maughan[1], K.E. Paschalaki[1], C. Pericleous[1], J.C. Mason[1], M. Nelson[2,3], G.P. Taylor[2], A.M. Randi[1], M. Boffito[2,3], M. Emerson[1]

[1]Imperial College London, National Heart and Lung Institute, London, United Kingdom, [2]Imperial College London, Department of Infectious Disease, London, United Kingdom, [3]Chelsea and Westminster Hospital NHS Foundation Trust, London, United Kingdom

Background: Cardiovascular disease, which is driven in part by endothelial dysfunction, is more prevalent among people living with HIV (PLWH). The reasons for this increased risk are unclear, but may be in part due to low grade inflammation associated with HIV seropositivity and side effects of antiretroviral therapy.

Patient-derived endothelial colony-forming cells (ECFCs) are generated from circulating progenitor cells, which after isolation, retain the donor's endothelial phenotypic characteristics. ECFCs are therefore a powerful tool to study the underlying mechanisms driving endothelial dysfunction in patient cohorts.

Although HIV acquisition and certain antiretrovirals have been shown to affect endothelial activation and are linked to increased cardiovascular risk, ECFCs have not been exploited within the context of HIV.

We therefore aimed to isolate and characterise ECFCs from PLWH.

Methods: Whole blood was obtained from PLWH on effective antiretroviral therapy (ART) (n=10) or HIV-negative people accessing Pre-Exposure Prophylaxis (PrEP, n=10). Peripheral blood mononuclear cells were isolated and monitored for ECFCs growth. Day of colony emergence, time to first split (colony establishment), and ECFC frequency were used to define isolation kinetics.

A previously isolated control group was used as a reference group. Statistical significance was determined by one-way ANOVA with Tukey's multiple comparison test.

Results: ECFCs emerged in 10/10 PLWH on ART, 8/10 PrEP users and 12/13 controls. From the first colony emerging, PLWH-ECFCs took 22.5 ±1.5 days (mean ±SEM) for colonies to establish for first split, which was significantly longer than both PrEP-ECFCs (15.4 ±2.1 days, $p<0.05$) and reference ECFCs (14.9 ±1.1 days, $p<0.01$).

PLWH also had higher ECFC frequencies (0.52 ±0.15 colonies/1x10^{6}PBCMs) compared to both the PrEP group (0.21 ±0.06 colonies/1x10^{6}PBCMs, $p<0.05$) and the reference control group (0.13 ±0.03 colonies/1x10^{6}PBCMs, $p<0.01$).

Conclusions: ECFCs from PLWH on effective therapy can be isolated and will be used to explore in detail the molecular effects of ART and HIV infection upon endothelial thrombo-inflammatory properties and cardiovascular health.

The significance of higher ECFC frequency and the longer time for colony establishment in PLWH is currently unknown, but may provide a route to defining, preventing and treating endothelial dysfunction in this population.

EPA016

IL-32γ induces the expression of a heart-homing signature on a subset of memory CD4 T-cells with increased permissiveness to HIV-1 infection: a potential role in cardiovascular disease

H. Ramani[1,2], A. Gosselin[2], M.A. Jenabian[3], M. Durand[4,2], C. Chartrand-Lefebvre[5,2], N. Chomont[1,2], J.-P. Routy[6], R. Thomas[7], B. Trottier[8], A. Landay[9], P. Ancuta[1,2], M. El-Far[2], C. Tremblay[1,2]

[1]Université de Montréal, Département de microbiologie, infectiologie et immunologie, Montreal, Canada, [2]Centre de Recherche du Centre Hospitalier de l'Université de Montréal (CRCHUM), Montréal, Canada, [3]Université du Québec, Montréal (UQAM), Department of Biological Sciences, Montréal, Canada, [4]Université de Montréal, Département de Médecine, Montréal, Canada, [5]Université de Montréal, Département de Radiologie, Radio-oncologie et Médecine Nucléaire, Montréal, Canada, [6]Research Institute of McGill University Health Centre, Montréal, Canada, [7]Clinique Médicale l'Actuel, Montréal, Canada, [8]Centre de Médecine Urbaine du Quartier Latin, Montréal, Canada, [9]Rush University Medical Center, Department of Internal Medicine, Chicago, United States

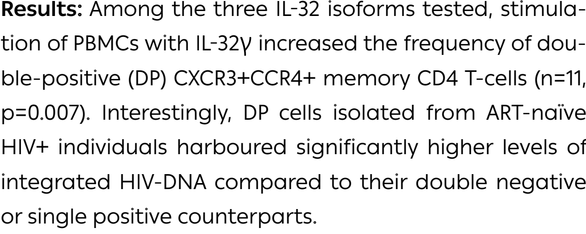
Background: Chronic inflammation in HIV infection increases the risk of cardiovascular diseases (CVD), even under antiretroviral therapy (ART). We recently demonstrated that the chronic upregulation of the multi-isoform proinflammatory cytokine interleukin-32 (IL-32) is associated with increased CVD risk in people living with HIV (PLWH) receiving ART. IL-32 isoforms exhibit diverse roles in T-cell differentiation, functions, and migration.

However, the effect of IL-32 on T-cell heart-tropism, a mechanism that contributes to plaque formation, remains unknown.

Here, we investigated the impact of IL-32 isoforms on the induction of the heart-homing signature c-Met+CCR4+CXCR3+ in memory CD4 T-cells in relationship with HIV-DNA persistence in these cells.

Methods: Peripheral blood mononuclear cells (PBMCs) and plasma samples from ART-treated PLWH and non-infected control participants (n=20/group) were obtained from the Canadian HIV and Aging Cohort Study (CHACS). PBMCs were exposed to 500ng/ml of recombinant IL-32 isoforms (α, β and γ). Expression of c-Met, CCR4, and CXCR3 was measured by flow cytometry on CD4 T-cell subsets.Hepatocyte growth factor (HGF;c-Met ligand) was quantified by ELISA in plasma.

Integrated HIV-DNA was quantified by Alu real-time PCR in sorted central memory CD4 T-cell from ART-naïve individuals (n=5, average CD4 counts: 557 cells/ml, and plasma viral load: 109,257 HIV RNA copies/ml).



Results: Among the three IL-32 isoforms tested, stimulation of PBMCs with IL-32γ increased the frequency of double-positive (DP) CXCR3+CCR4+ memory CD4 T-cells (n=11, p=0.007). Interestingly, DP cells isolated from ART-naïve HIV+ individuals harboured significantly higher levels of integrated HIV-DNA compared to their double negative or single positive counterparts.
Additionally, the DP subset was enriched in cells expressing c-met, indicative of an IL-32-mediated increase in the frequency of the heart-homing triple-positive cMet+CCR4+CXCR3+ population.
Finally, we observed that the c-met ligand HGF was significantly higher in plasma from PLWH compared to HIV-individuals (p=0.0009).
Conclusions: Our results suggest that IL-32 is contributing to heart inflammation by increasing the frequency of T-cells with heart-homing tropism that harbour proviral HIV-DNA. These cells may serve as a Trojan horse to bring HIV to the plaque-forming sites in heart arteries, which could further worsen the local inflammation. Thus IL-32 might represent a potential therapeutic target in CVD.

EPA018

Alterations in B lymphocyte subsets in virologically suppressed HIV-positive individuals did not impact 17DD yellow fever vaccine immunogenicity – ANRS 12403

D.G. Caetano[1], T.S. Toledo[1], A.C.S. Lima[1], V.N.R. Cardoso[1], C.B.W.G. Gripp[1], D.V. Almeida[1], M. Morata[2], B. Grinsztejn[2], S.W. Cardoso[2], M.D. Costa[2], L.G.P. Brandão[2], A.B. Fillipis[3], A.d.S. Azevedo[4], S.M.B. Lima[4], D. Scott-Algara[5], L.E. Coelho[2], F.H. Côrtes[1]

[1]Oswaldo Cruz Institute, Laboratory of AIDS and Molecular Immunology, Rio de Janeiro, Brazil, [2]National Institute of Infectology Evandro Chagas, Rio de Janeiro, Brazil, [3]Oswaldo Cruz Institute, Laboratory of Flavivirus, Rio de Janeiro, Brazil, [4]BioManguinhos, Laboratory of Virological Technology, Rio de Janeiro, Brazil, [5]Pasteur Institute, Lymphocyte Cell Biology Unit, Paris, France

Background: HIV infection is characterized by disequilibrium in several components of cellular and humoral immune responses. In this context, alterations in B lymphocytes and T follicular helper cells (Tfh) in HIV positive individuals impairs not only immune response against HIV, but could also diminish vaccinal responses.
Methods: To assess if HIV infection blunts immune response against 17-DD yellow fever vaccine, we evaluated the pre-vaccination frequency of peripheral(pTfh) and B lymphocytes subsets (Transitional - TR; Marginal zone B - MZ; Naïve - N; Activated Memory - AM; Intermediate Memory – IM; Resting Memory – RM; Tissue-like memory – TLM) by flow cytometry in two groups of HIV positive individuals on ART and virologically suppressed – one group with T CD4 counts higher than 500 cells/mm^3 (CD4>500; n=20) and between 250-500 cells/mm^3 (CD4<=500; n=26) and a group of HIV negative individuals (HIVneg; n=18). The vaccine immunogenicity was evaluated by neutralization levels postvaccination obtained through micro plaque reduction neutralization test (µPRNT) at days 30 and 365 post-vaccination.
Results: cTfh analyses revealed similar frequencies of these cells in all evaluated groups. For B lymphocyte subsets analyses, the group CD4<500 presented lower frequencies of MZ (p=0.006) and higher frequencies of N (p<0.034) in comparison to HIVneg, while the frequencies of BTR did not differ between groups.
Regarding B memory subsets, both HIV groups presented lower frequencies of AM (p<0.014 for CD4>500; p<0.039 for CD4<500) and RM (p<0.005 for CD4>500; p<0.0001 for CD4<500), but no differences were observed for TLM and IM subsets. µPRNT neutralization levels at 30 and 365 days postvaccination did not differ between the three evaluated groups, and those levels did not correlate to any of the subsets evaluated.
Conclusions: Our data showed that B lymphocytes immune response is altered in HIV-infected individuals despite suppressed viral load and high T CD4 counts. Those individuals present disbalance in BN, BMZ, BAM, and BRM frequencies when compared to HIV-uninfected individuals. Despite that, 17DD-YFV neutralization titers were similar between HIV-infected and uninfected individuals and did not correlate with cell subsets, indicating that immunogenicity against 17DD-YFV one year after vaccination is not impaired in HIV-infected individuals.

Correlates of HIV susceptibility, and progression versus control (biomarkers and genetics)

Penile barrier integrity and a mechanistic search for the effectiveness of medical male circumcision in preventing HIV acquisition

C.L. Rametse[1], M.M. Mndini[1], Y. Ganief[1], O. Alinde[1], K. O'Hagan[1], R.L. Redondo[2], H.B. Jaspan[1], T.J. Hope[3], C.M. Gray[1]

[1]University of Cape Town, Human Pathology, Cape Town, South Africa, [2]Northwestern University, Department of Medicine, Division of Infectious Disease & Immunology, Chicago, Illinois, United States, [3]Northwestern University, Cell & Molecular Biology, Chicago, United States

Background: The biological mechanisms underlying HIV risk reduction following medical circumcision remain ill-defined. We sought to understand two aspects, whether circumcision can improve skin barrier integrity of the penis: in the absence and presence of an asymptomatic sexually transmitted infection (aSTI); the rationale being that changes in skin barrier integrity leads to lower risk of HIV susceptibility.

Objectives: We used hand-held meter devices to measure changes to skin barrier integrity in various sites on the penis of adults assigned male sex at birth. In vivo measurements of transepithelial water loss (TEWL) and skin hydration (proxies for barrier integrity) were taken directly on penile skin before and after MMC and in the absence/presence of an aSTI, the most common being Chlamydia trachomatis (approx. 11%).
Methods: Vapometers and moisture meters SC, D and EpiD were used to measure TEWL (n=155) and dermal surface hydration (n=170) of the glans, inner foreskin and penile shaft before circumcision. Follow-up measurements were made at 2, 12 and 24 weeks after circumcision in the glans and shaft (n=16). Urines were collected for aSTI screening.
Results: Compared to the shaft (16 $g/hr/m^2$), there was higher TEWL in the inner foreskin and glans in the absence of an aSTI (Medians of 27.6 and 22.3 $g/hr/m^2$; both q<0,0001 respectively).
Furthermore, the inner foreskin (Median 86,46 au) had increased hydration compared to the shaft (Median 54,61 au) q value<0,0001. Follow-up at six months after circumcision showed a significant decrease in TEWL in the glans (q=0.011) from the baseline, matching that of the shaft. Finally, prior to circumcision, the glans of participants with aSTI showed higher hydration compared to STI negative participants (97.4 vs 52.3 au; q= 0.0380).
Conclusions: Reduced TEWL after MMC in the glans without an aSTI suggests that skin barrier integrity increases after medical circumcision and may partly contribute to lower HIV-1 susceptibility. The higher glans skin moisture content in the presence of an aSTI before circumcision could create an infection-friendly niche and potentially lead to higher HIV-1 susceptibility.

Innate immunity (including NK cells)

HIV-1 subtype C Vif transmitted/founder (T/F) variants preferentially degrade APOBEC3G over APOBEC3F

N. Reddy[1], K. Reddy[1], K. Gounder[1,2], T. Ndung'u[1,2]
[1]*Africa Health Research Institute (AHRI), Durban, South Africa,* [2]*HIV Pathogenesis Programme (HPP), Durban, South Africa*

Background: APOBEC3 proteins are a key component of innate defence against HIV but are counteracted by the viral protein Vif. The relative contribution of diverse APOBEC3 proteins to anti-HIV immunity is not fully understood.
We hypothesized that the transmitted/founder (T/F) virus Vif adapts in vivo to specific APOBEC3 proteins that mediate immune pressure.

Methods: Study participants were 24 South African women with acute HIV-1 infection. HIV-1 *vif* was cloned into an expression vector at 1-month and 1-year post-infection. HIV-1 *vif* clones were sequenced and assessed for their ability to counteract APOBEC3G (A3G), -3F (A3F) and -3H (A3H) using Western blot and single-cycle infectivity assays.*In vivo* A3G and -3F expression was measured using droplet digital PCR (ddPCR).
Results: All sequences were subtype C and *vif* clonal sequences from each patient clustered independently. Limited intra-patient diversity amongst *vif* clones were observed (0.02-0.21%). APOBEC3G, -3F and -3H binding sites on Vif were 86% conserved.
Notably, at Vif position 17, within the APOBEC3F binding site 14DRMK17, 64% of 1-month post infection (T/F) viruses were non-consensus subtype C arginine (R) which increased to 71% at 1-year post-infection. Functional assessment showed heterogeneity amongst T/F Vif variants in their ability to degrade A3G, -F and –H and to rescue infectivity. However, T/F virus Vif preferentially degraded A3G compared to A3F (p=0.0503). At one-year post-infection, Vif variants showed an increased ability to degrade and rescue infectivity against A3F, compared to T/F Vif (p=0.0160). In vivo, A3F expression was significantly higher than A3G expression during acute infection (p=0.00457).
However, both A3G (p=0.0003) and A3F (p=0.0027) expression was downregulated over one year of infection. Site directed mutagenesis at Vif position 17 showed no functional impact on anti-APOBEC3 activity in selected study participants.
Conclusions: These data, show that T/F HIV-1 Vif preferentially degrades A3G, however its capacity to degrade A3F increases over one-year of infection, suggesting that Vif preferentially targets the most potent APOBEC protein (A3G) and may adapt to target other APOBEC proteins over time.
Understanding the contribution of diverse cytidine deaminases to the immune control of HIV-1 may inform the design of therapies to target the interaction between APOBEC and Vif proteins.

EPA022
Impact of chronic HIV infection on NK cell response through the HLA-E/NKG2x axis

L. Romero Martín[1], C. Duran Castells[1], M. Ruiz Riol[1], A. Olvera van der Stoep[1], C. Brander[1]
[1]*IrsiCaixa (AIDS Research Institute), Barcelona, Spain*

Background: Previous studies reported functional unresponsive and exhausted NK cell profiles in HIV infected individuals compared to uninfected ones. We hypothesized that an increased HLA-E surface expression in untreated, chronically viremic HIV-infected individuals leads to a continuous NK stimulation through the HLA-E/NKG2X axis, causing a disruption of the NKG2A/NKG2C balance and inducing an impaired NK cell response.

Methods: HLA-E expression was assessed by RT-PCR in PBMC from HIV infected individuals not receiving cART with high (HIV-high, n=8) or low viral loads (HIV-low, n=8) and HIV seronegative (SN=12) individuals. The expression of CD57, NKG2A and NKG2C was assessed in NK sub-populations (CD16 and CD56) by flow cytometry. K562 cells lacking HLA-E expression were used as target cells in *in-vitro* functional assays to determine NK cytotoxicity, degranulation and cytokine secretion. NK effector functions were then related to the clinical parameters, NK phenotypic markers and levels of HLA-E expression.
Results: The abundance of $CD56^{bright}$ NK cells was significantly decreased in HIV-high compared to HIV-low and SN. NKG2A/NKG2C ratios in total NK cells, $CD56^{bright}$ and adaptive NK cells were reverted in chronic HIV infection, especially in HIV-high compared to SN.
The expression of NKG2A in total and adaptive NK cells, as well as the abundance of $CD56^{bright}$ cells, correlated negatively with plasma viral load and positively with CD4 count. NK cells from chronically HIV infected individuals showed a significant decrease in cytotoxic capacity and IFN-γ secretion, especially in the $CD56^{bright}$ and adaptive subsets. Of note, HLA-E expression correlated negatively with cytotoxic capacity, degranulation and IFN-γ secretion.
Conclusions: Our data suggest that chronic, viremic HIV infection drives high HLA-E expression, continuously stimulating NK cells through the NKG2X receptors. This, in turn, may cause changes in NK subpopulations and a profound disruption in the regulation of the NK activation pathway through the HLA-E/NKG2X axis.

EPA023
Immunotherapeutic blockades targeting LAG-3 and PD-1 immune checkpoint inhibitors on invariant Natural Killer T cells: implications in chronic HIV infection

A. Balasko[1], J. LaJoie[1,2], K.R. Fowke[1,2,3,4]
[1]University of Manitoba, Medical Microbiology and Infectious Diseases, Winnipeg, Canada, [2]University of Nairobi, Medical Microbiology, Nairobi, Kenya, [3]University of Manitoba, Community Health Sciences, Winnipeg, Canada, [4]Partners for Health and Development in Africa, Nairobi, Kenya

Background: Invariant Natural Killer T (iNKT) cells are innate lymphocytes critical in combatting viral infection by bridging the innate and adaptive immune systems. Our lab showed in HIV infection, expression of lymphocyte activation gene 3 (LAG-3), an inhibitory immune checkpoint marker, is increased on iNKT cells and correlated with decreased functionality.
Another checkpoint molecule, program cell-death-1 (PD-1), is shown to be increased on iNKT cells in HIV infection, correlating to decreased function. LAG-3 and PD-1 expression kinetics and relationship to iNKT cellular function is not well characterized, and we hypothesize that blocking LAG-3 alone, or in conjunction with PD-1 via immunotherapeutic blockades, will restore iNKT function and immune effectiveness.
Methods: Utilizing peripheral blood mononuclear cells from HIV-uninfected donors (n=4), iNKT expression of LAG-3 and PD-1 was assessed via a multi-day *in vitro* stimulation (24hr, 48hr, 4, 7, 10 day). Efficacy of anti-LAG-3 and anti-PD-1 antibody blockades were assessed via a 10-day assay, with enhanced proliferation as the main outcome monitored.
Results: Percent and median fluorescence intensity (MFI) of both LAG-3 and PD-1 peaked at Day 7 (LAG-3: 88.5%, 6163.8 MFI; PD-1: 80.5%, 7731.8 MFI), with a steep decrease by Day 10, when iNKT proliferation was at its peak.
In the presence of the anti-LAG-3 or anti-PD-1 antibody blockades, there was a 14-fold increase and 17-fold increase of the iNKT population, respectively. Combining anti-LAG-3 and anti-PD-1 blockade systems resulted in a 22-fold increase in proliferation.
Conclusions: This study is the first to report the kinetics of LAG-3 and PD-1 expression on iNKT cells, and it also provides proof-of-concept for LAG-3 and PD-1 as immunotherapeutic targets, by restoring iNKT cellular proliferative ability.
This blockade system will be applied *in vitro* to HIV-positive samples to assess if HIV-mediated dysregulation of iNKT function can be reversed and thereby ameliorate immune responses to various opportunistic infections, as well as boost viral control in a functional HIV cure approach.

The effects of *in utero* HIV and anti-retroviral therapy exposure on infant T-cell and monocyte activation, function and regulation of immune-modulatory pathways

A. Prinsloo[1], H. Steel[1], U. Feucht[2], T. Rossouw[1]
[1]University of Pretoria, Immunology, Pretoria, South Africa, [2]University of Pretoria, Research Centre for Maternal, Fetal, Newborn & Child Health Care Strategies, Pretoria, South Africa

Background: The growing number of HIV-exposed-but-uninfected (HEU) infants suffering from immune dysfunction, inflammation, and cognitive as well as metabolic abnormalities is a great cause for concern. The underlying mechanisms involved are still unclear. Chronic immune activation is a distinct feature of HIV, which might result in increased T-cell and monocyte/macrophage activation and exhaustion in HIV-infected mothers and potentially in their infants. Several studies have investigated immunological changes in pregnant HIV-positive mothers and their infants, but few have included the effect of these changes on clinical outcomes.
This study assessed whether maternal HIV status impacts infant T-cell activation and regulation as well as monocyte activation, regulation, and responsiveness to stimu-

lation at birth and early infancy. It further investigated whether immunological changes impact early infant growth, development, and susceptibility to infection in the first six months of life.

Methods: Pregnant women with singleton pregnancies (69 HIV-positive, 83 HIV-negative) were recruited from antenatal clinics in Southwest Tshwane, South Africa. Maternal blood samples were taken at 28 weeks of pregnancy and paired maternal-infant samples taken at birth, ten weeks, and six months postpartum. Women with co-morbidities, e.g. diabetes mellitus and obesity, were excluded. All infants tested HIV-negative. Key maternal, fetal, and post-partum clinical data were also captured on standardized and validated forms.

Multicolor flow cytometry was used to characterize markers of CD4+ and CD8+ T-cell, and monocyte activation. Whole blood stimulation (WBS) testing with lipopolysaccharide and polyinosinic:polycytidylic acid was performed to assess monocyte function. Dimension reduction analysis was used to analyze multicolor flow cytometry using Cytobank software (Beckman Coulter, CA, USA).

Results: Preliminary data analysis demonstrated decreased CCR7 and increased CD27 expression in CD8+ T-cells from HIV-positive mothers at birth. HEU infants had increased CCR2 and CD86 expression on monocytes at ten weeks; CD86 differences persisted at six months. Currently, WBS data is being analyzed andimmunological findings are assessed for relevant clinical associations.

Conclusions: Preliminary analysis shows differences in T-cell and monocyte subsets in HIV-positive mothers and HEU infants. Understanding the impact of these immunological changes on clinical endpoints may contribute to development of targeted interventions, potentially improving health outcomes in HEU.

[1]Walter Reed Army Institute of Research, US. Military HIV Research Program (MHRP), Silver Spring, United States, [2]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States, [3]Fred Hutchinson Cancer Research Center, Vaccine and Infectious Disease Division, Seattle, United States, [4]National Institutes of Health, Center for Human Immunology, Bethesda, United States, [5]National Institutes of Health, Office of AIDS Research, Bethesda, United States, [6]Institute of HIV Research and Innovation, Bangkok, Thailand, [7]University of Amsterdam, Department of Global Health, Amsterdam, Netherlands, the, [8]Walter Reed Army Institute of Research, Silver Spring, United States

Background: Human leukocyte antigen (HLA) associations with HIV-1 disease outcomes have been reported in antiretroviral therapy (ART)-naïve cohorts from populations of European and African ancestry but remain understudied in Asia.

Consequently, we investigated associations of HLA alleles with HIV-1 acquisition, disease progression, and reservoir size in 1318 individuals from three independent Thai cohorts including a high incidence natural history study, a vaccine efficacy trial, and a study of people who initiated ART during acute HIV infection (AHI).

Methods: HLA class I alleles were genotyped using next-generation sequencing and alleles with frequencies >5% were tested for the following associations: HIV acquisition was tested in a cohort of high HIV incidence of men who have sex with men (N=678); disease progression outcomes included time to decline of CD4+T cells (<350 cells/mm³), time to ART initiation and levels of VL (copies/ml) in two cohorts with long term follow-up prior to treatment (N=321); reservoir size was assessed in an AHI cohort (N=526).

Mechanistic effects of HLA alleles were examined by investigating cellular responses to overlapping HIV peptides by ELIspot assays, transcriptomics by RNA-seq in sorted cell subsets and single cell mRNA and surface protein expression using CITE-seq.

Results: We identified reproducible significant associations of HLA-B*46:01, the most frequent class I allele in Thailand, with lower absolute CD4 counts (p=0.001-0.05), accelerated CD4 decline (HR=5.01-1.5, p=0.0001-0.048, q=0.004-0.07) and increased VL (Geometric Mean Ratio =2.74-2.09, p=0.007-0.044, q=0.2-0.07) in ART-naïve samples in independent cohorts. We detected no effect of B*46 as-

sociated presentation of viral epitopes by T cells, but this allele is unusual in encoding an HLA-C epitope that binds inhibitory receptors on natural killer (NK) cells. Unbiased transcriptomic screens showed a phenotype of increased NK cell activation in people living with HIV without B*46. Simultaneous profiling of surface proteins and transcriptomes in single cells revealed a subset of NK cells with phenotype primed for increased responses in the absence of B*46.

Conclusions: These findings demonstrate contemporaneous cohorts can display host genetic effects in HIV infection, and support a role for NK cells in HIV pathogenesis revealed by unique properties of the B*46 allele which is commonly present only in Asia.

Characterizing the effect of intracellular storage pools of RANTES/CCL5 on HIV infection in macrophages

A.T. Persaud[1,2], J. Burnie[1,2], C. Guzzo[1,2]
[1]University of Toronto, Cell and Systems Biology, Toronto, Canada, [2]University of Toronto Scarborough, Department of Biological Sciences, Toronto, Canada

Background: Under inflammatory conditions, monocytes can extravasate from circulation into tissues and differentiate in monocyte-derived macrophages (MDMs), a process accompanied by transcriptomic and proteomic reorganizations that give MDMs their macrophage phenotypes. Moreover, the primary (CD4) and secondary (CCR5) entry receptors for HIV-1 are upregulated upon monocyte differentiation, making MDMs more susceptible to HIV infection than their precursors.

Our research recently reported a novel phenomenon, whereby human monocytes have the capacity to store large amounts of RANTES/CCL5 in resting state, a significant finding since CCL5 is natural ligand for CCR5 and an inherent inhibitor of R5-mediated HIV entry.

Methods: Primary human monocytes were isolated from whole blood donations of healthy donors and differentiated into macrophages via adherence protocols *in vitro*. Macrophages were infected with R5-tropic HIV-1 isolates and levels of RANTES/CCL5 and CCR5 were be monitored by confocal microscopy, ELISA, and flow cytometry.

We also characterized CCL5 and CCR5 levels at different stages of infection, including attachment and entry, after multiple rounds of virus replication.

Results: Our preliminary data indicates that the intracellular pool of CCL5 in resting monocytes is retained upon differentiation into MDMs *in vitro,* highlighting a novel mechanism for CCL5 regulation in macrophages. The mobilization of CCL5 from intracellular stores appears to have differential kinetics depending on the monocyte/macrophage stimulus used, and the biology of these storage vesicles is under ongoing investigation. We are currently characterizing the intracellular storage pools of CCL5 and its receptor (CCR5) upon HIV infection, in an effort to determine the impact of intracellular CCL5-CCR5 interactions on HIV infection.

Conclusions: We anticipate that there may be chemokine ligand-receptor interactions (i.e., CCL5-CCR5 interactions) occurring intracellularly that may sequester these proteins into specific subcellular compartments (or vesicles), which may divert from their canonical functions. Given the respective roles of CCL5 and CCR5 in HIV infection, we believe this work will characterize new mechanisms of HIV control and restriction.

HIV-1 Vpu limits Fc-mediated effector functions in vivo

J. Prévost[1,2], S.P. Anand[1,3], J. Krishnaswamy Rajashekar[4], J. Richard[1,2], G. Goyette[1], H. Medjahed[1], G. Gendron-Lepage[1], H.-C. Chen[5], J.A. Horwitz[6], S. Zolla-Pazner[7], D.R. Burton[8], F. Kirchhoff[9], B.H. Hahn[5], A.B. Smith III[5], M. Pazgier[10], M.C. Nussenzweig[6], P. Kumar[4], A. Finzi[1,2,3]
[1]Centre de Recherche du CHUM, Montreal, Canada, [2]Université de Montréal, Montreal, Canada, [3]McGill University, Montreal, Canada, [4]Yale University, New Haven, United States, [5]University of Pennsylvania, Philadelphia, United States, [6]The Rockefeller University, New York, United States, [7]Icahn School of Medicine at Mount Sinai, New York, United States, [8]The Scripps Research Institute, La Jolla, United States, [9]Ulm University Medical Center, Ulm, Germany, [10]Uniformed Services University of the Health Sciences, Bethesda, United States

Background: Non-neutralizing antibody (nnAb) functions, such as the elimination of HIV-1-infected cells by antibody-dependent cellular cytotoxicity (ADCC), were associated with the protection observed in the RV144 vaccine trial. While the antibody specificities and effector functions underlying this protection have not been clearly defined, Fc-mediated effector functions of nnAbs were shown to alter the course of HIV-1 infection in vivo (Horwitz et al., Cell 2017).

Methods: To better understand the capacity of nnAbs at eliminating HIV-1-infected cells, we infected primary CD4+ T cells with the virus used in the Horwitz study (HIV-$1_{NL4.3}$YU2) and evaluated the capacity of nnAbs to recognize and eliminate infected cells by ADCC *in vitro*. We also used a humanized mouse model to confirm our findings *in vivo*.

Results: In agreement with the Horwitz study, we found good recognition of infected cells by the panel of nnAbs tested. Antibody recognition of the infected cells and FcγR

engagement strongly correlated with their capacity to mediate ADCC. However, since the HIV-$1_{NL4.3}$YU2 does not express the accessory protein Vpu, due to a mutation in the start codon of the *vpu* gene, we asked whether the observed recognition by nnAbs and susceptibility of infected cells to ADCC was linked to the lack of Vpu expression in this virus.

We re-established the *vpu* open reading frame, verified Vpu expression and its capacity to downregulate several of its substrates including CD4 and BST-2 by flow cytometry. Primary CD4+ T cells infected with the HIV-$1_{NL4.3}$YU2 Vpu+ virus downregulated all these substrates efficiently but the HIV-$1_{NL4.3}$YU2 (Vpu-) did not. Strikingly, cells infected with the Vpu+ virus were less efficiently recognized by nnAbs and became resistant to ADCC responses.

Using small CD4 mimetics to "open" Env, we were able to sensitize infected cells to nnAbs, indicating that the observed ADCC resistance was linked to the lack of nnAb epitope exposure on cells infected with a Vpu+ virus.

Finally, therapeutic administration of a nnAb decreased plasma viral loads (PVLs) in humanized mice infected with the Vpu- but not the Vpu+ virus.

Conclusions: This study highlights the critical role of Vpu in limiting humoral responses and maintaining viral replication *in vivo*.

Metabolic gene profiling of activated, terminally differentiated effector memory and exhausted CD8+ T cells in people living with HIV

Y.T. Chan[1], A. Kamarulzaman[2,3], R. Rajasuriar[2,3,4], W.F. Wong[1]

[1]*University of Malaya, Department of Medical Microbiology, Kuala Lumpur, Malaysia,* [2]*University of Malaya, Department of Medicine, Kuala Lumpur, Malaysia,* [3]*University of Malaya, Centre of Excellence for Research in AIDS (CERiA), Kuala Lumpur, Malaysia,* [4]*Melbourne University, Peter Doherty Institute for Infection and Immunity, Melbourne, Australia*

Background: Chronic human immunodeficiency virus (HIV) infection often results in CD8+ T cell exhaustion, which is associated with cellular metabolic alterations. A comprehensive study of metabolic changes at the genetic regulatory level can provide insights to potential targets to overcome T cell exhaustion in chronic HIV infection.

In this study, we investigated the differential expression of the genes encoding metabolic pathway proteins in the exhausted CD8+ T cells, compared to the naïve, activated and terminally differentiated effector memory (T_{EMRA}) CD8+ T cells, from people living with HIV (PLWH).

Methods: A total of 62 PLWH were recruited from the University of Malaya Medical Centre, Malaysia between September and December 2019. There were two arms: aviremic ART-treated (viral load < 20 copies/ml) and viremic treatment-failure or treatment-naïve (viral load > 20 copies/ml). Peripheral blood mononuclear cells (PBMCs) were immunophenotyped and sorted by the following subsets: naïve (CCR7+ CD45RA+), T_{EMRA} (CCR7- CD45RA+), activated (PD1- CD107a+) and exhausted (PD1+ CD107a-). RNA was extracted from each subset and gene expression for metabolic pathways was characterised using NanoString technology.

Results: Our results demonstrated that several genes in the activated subsets were significantly upregulated (log_2 fold change >1), including *LAG3*, *TBX21*, *TYMP*, *PDK2*, *IDH2* and *NDUFA2*, which are involved in T cell signalling, transcriptional regulation, nucleotide biosynthesis and mitochondrial pathways.

In contrast, these pathways were suppressed in both T_{EMRA} and exhausted subsets, as shown by the downregulation of*PDPK1*, *HSF2*, *AMPD2*, *AMPD3*, *NFS1*, *PDK2*, *NDUFS7* genes (log_2 fold change < -1).

Of note, the expression of *SOD2* gene that responds to oxidative stress in mitochondria, was significantly increased in the exhausted cells (log_2 fold change = 0.719). This was complemented by an observed decrease in expression of genes involved in mitochondrial electron transport chain, indicating high levels of reactive oxygen species contributing to the mitochondrial dysfunction.

Conclusions: Higher levels of CD8+ T cell exhaustion and mitochondrial impairment were found in viremic vs aviremic PLWH. Metabolic defects in the mitochondria could be potential targets for novel therapies to restore the CD8+ T cell function.

Future evaluation could combine different strategies including, but not limited to immune-metabolic reprogramming and anti-retroviral treatment.

BNT162b2 vaccine elicits impaired B cell and CD8 T cell responses combined with skewed CD4 T responses in patients receiving hemodialysis

G. Sannier[1,2], A. Nicolas[1,2], L. Marchitto[1,2], M. Dubé[1], M. Nayrac[1,2], O. Tastet[1], S. Ding[1], A. Tauzin[1,2], R. Goupil[3,4], W. Beaubien-Souligny[4,5], A. Finzi[1,2,6], R.S. Suri[6], D.E. Kaufmann[1,2,4,7]

[1]Centre de Recherche du Centre Hospitalier de l'Université de Montréal, Montréal, Canada, [2]Université de Montréal, Département de Microbiologie, Infectiologie et Immunologie, Montréal, Canada, [3]Centre de Recherche of the Hôpital du Sacré-Coeur de Montréal, Montréal, Canada, [4]Université de Montréal, Département de Médecine, Montréal, Canada, [5]Department of Anesthesiology and Intensive Care Montreal Heart Institute, Montréal, Canada, [6]McGill University, Department of Microbiology and Immunology, Montréal, Canada, [7]Consortium for HIV/AIDS Vaccine Development (CHAVD), La Jolla, United States

Background: People receiving hemodialysis (HD) are vulnerable to COVID-19 and have low antibody responses after vaccination. The underlying immune defects are poorly understood.

Methods: We followed 27 HD patients who received two doses of BNT162b2 mRNA vaccine four weeks apart and studied their immune responses before vaccination, 4 weeks after first dose (priming), 4 weeks after second dose (boost), and at 12 weeks (memory). Health-care workers (HCW) who received two BNT162b2 doses 16 weeks apart served as controls.

All participants were confirmed as SARS-CoV-2 naïve. To examine different arms of immunity, we characterized:

i. Humoral responses by receptor-binding domain (RBD) ELISA and cell-based assays

ii. RBD-specific B cell profiles by flow cytometry;

iii. Spike (S)-specific CD4 and CD8 T cell phenotypes identified by activation-induced marker (AIM) assays;

iv. Effector functions of S-specific CD4 and CD8 T cells by intracellular staining (ICS).

Results: Compared to HCW, in HD patients antibody and B cell responses were weaker after priming, increased more sharply after boost, and showed similar decline at the memory timepoint. These responses were significantly lower at each timepoint in HD than in HCW. In contrast, longitudinal CD4 T cell responses were quantitatively equivalent in both cohorts, with both AIM and ICS data showing robust increases after priming and maintenance after boosting.

However, T-helper immunity differed qualitatively in HD. Unsupervised clustering analyses identified fine qualitative differences such as dominance of some TNFα clusters observed in HD participants as well as CD4 T responses skewing toward IFNγ upon boosting in HCW. Those results were confirmed by univariate analyzes. Qualitative differences waned as the responses declined toward the memory timepoint. Also, CD8 T cell responses remained insignificant in HD while elicited in HCW after each dose.

Conclusions: Humoral, B cell and CD8 T responses are quantitatively impaired after BNT162b2 vaccination in HD patients, while CD4 T responses are qualitatively skewed. These data suggest that HD patients have defects in all arms of immunity after vaccination, which may increase their vulnerability to COVID-19 breakthrough infections.

HIV-1-specific T-cells in an HIV-1-infected but HIV-1 antibody negative patient on long-term antiretroviral therapy

B. El Kenz[1,2], K. Korn[1], P. Steininger[1], K.G. Schmidt[2], K. Nganou[1], T. Harrer[2]

[1]Institute of Clinical and Molecular Virology, Universitätsklinikum Erlangen, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany, [2]Infectious Diseases and Immunodeficiency Section, Department of Internal Medicine 3, Universitätsklinikum Erlangen, Friedrich-Alexander-University Erlangen-Nürnberg, Erlangen, Germany

Background: HIV-1-specific antibodies usually develop about 3 weeks after infection and persist on antiretroviral therapy (ART). Here, we report on a vertically HIV-1 infected patient presenting with negative HIV-1 antibody tests after 13 years on ART.

Methods: Vertical HIV-1 infection with high HIV-1 viremia was diagnosed in the male patient at the age of 15 months during an episode of gastroenteritis. Since then, he has been treated with varying antiretroviral drug combinations. The patient presented in our clinic for the first time at the age of 14 years on therapy with raltegravir, abacavir and lamivudine. HIV-1-specific antibodies were measured by ELISA and immunochromatographic assays. Proviral PCR was performed using specific primers for gag and RT/protease. HIV-1-specific T-cells were analysed by g-IFN-ELISpot assays using synthetic peptides and both freshly isolated PBMC and peptide stimulated T-cell cultures.

Results: HIV-1 antibodies were undetectable in an HIV-1/2-screening ELISA (Abbott Architect) and an HIV-1/2-specific immunochromatographic test (Geenius HIV 1/2 Confirmatory Assay). HIV-1 viral load in plasma was negative as well as Gag-specific proviral PCR in whole blood.

Analysis for resistance in Protease/RT using proviral DNA demonstrated infection by HIV-1 subtype A6 with no resistance-associated mutations. Normal CD4 T cell count of 750 cells/µl and CD4/CD8-ratio of 1.0 were measured. There was no evidence of humoral immunodeficiency as B-cells were slightly elevated (800 cells/µl) and serum levels of total IgG, IgA and IgM were within normal range. In addition, specific IgGs for several other pathogens (EBV, CMV, hepatitis B virus, mumps virus) were detected in se-

rum. G-IFN-ELISpot analyses for HIV-1 specific T-cells were negative using freshly isolated PBMC, however, peptide stimulation assays revealed a polyclonal T-cell response with recognition of at least 6 CTL epitopes in RT, Nef and Gag.

Conclusions: HIV-1-specific antibody tests may be negative in HIV-1-infected patients on long-term antiretroviral therapy initiated in early childhood.

In addition to proviral PCRs for different HIV-1 targets, the detection of HIV-1 specific T-cells can confirm the presence of HIV-1 infection in seronegative subjects.

Background: Chronic HIV infection is characterised by CD8+ T cell and NK cell dysfunction that persists despite suppressive ART.

We investigated the capacity of pomalidomide, a well-tolerated immunomodulatory drug licensed for the treatment of multiple myeloma and Kaposi's Sarcoma, to augment anti-HIV immune responses.

Methods: We stimulated peripheral blood mononuclear cells (PBMCs) from uninfected donors and ART-suppressed people living with HIV with therapeutically relevant concentrations of pomalidomide. HIV-specific CD8+ T cell cytotoxicity assays were performed against HIV-peptide loaded autologous CD4+ T cells, and NK cell killing assays were performed against the K562 cell line, 8E5 cell line (for antibody dependent cellular cytotoxicity (ADCC)), and against *in vitro* HIV-infected CD4+ T cells. Cytotoxic and phenotypic profiles were measured by multiparameter flow cytometry.

Results: In the presence of HIV peptide stimulation, pomalidomide compared to DMSO significantly expanded absolute numbers of HIV-specific CD8+ T cells by 2.97-fold (P=0.0234). This expansion of HIV-specific CD8+ T cells resulted in an overall 29.3% (P=0.0011) increase in specific lysis of HIV peptide-presenting CD4+ T cells (targets) in CD8 T cell effector:target co-cultures, compared to DMSO.

Following the addition of pomalidomide, we observed a significant decrease of PD-1 and TIGIT compared to the DMSO control, and an increase of TIM-3 expression on expanded HIV-specific effector memory CD8+ T cells, suggesting these cells have transitioned from an exhaustive state to an activated state.

In addition, pomalidomide significantly reduced the frequency of the "dysfunctional" NK cell subset (CD56-CD16+), whilst expanding the "cytotoxic" subset (CD56dimCD16+) with reduced TIGIT expression and greater degranulation (CD107a) and TNFα production. NK cell killing of K562 cells was significantly enhanced with pomalidomide with 34.7% (P=0.0002) greater killing capacity relative to DMSO. Pomalidomide also significantly enhanced direct NK-mediated killing of *in vitro* HIV-infected autologous CD4+ T cells (p=0.0164) but showed no effect on anti-HIV ADCC *ex vivo*.

Conclusions: These data demonstrate that pomalidomide can enhance HIV-specific CD8+ T cell and NK cell cytotoxicity in samples from ART-suppressed people living with HIV. Given the favourable safety profile of pomalidomide clinically, it may be of great benefit in therapeutic strategies to eliminate or control the persisting HIV reservoir.

EPA032

Virtual memory CD8+ T-cells exhibit highly cytotoxic profiles in people with HIV, and are expanded by N-803

T.M. Mota[1], J. Weiler[1], S. Terry[1], L. Ehui[2], A. Wimpelberg[2], C. Cannon[2], S. Henn[2], E. Benko[3], C. Kovacs[3], J. Safrit[4], R.B. Jones[1]

[1]*Weill Cornell Medicine, Medicine, Infectious Diseases, New York, United States,* [2]*Whitman Walker Health, Washington, United States,* [3]*Maple Leaf Clinic, Toronto, Canada,* [4]*Immunity Bio, Los Angeles, United States*

Background: Virtual Memory CD8$^+$ T (T_{VM}) cells express markers of immunological memory yet remain antigen-inexperienced[1,2]. T_{VM} respond to cells expressing stress ligands and participate in the innate immune response to some viral infections, but their role in HIV remains poorly defined. In mice, T_{VM} develop from naïve CD8$^+$ T-cells (T_N) in the periphery from exposure to IL-15, and proliferate robustly in response to IL-15 treatment[3]. N-803, an IL-15 superagonist, is under investigation in clinical trials - including in people with HIV (PWH).

We aimed to characterize T_{VM} phenotypes in PWH, and investigate the impact of N-803 treatment on T_N, with the hypothesis that N-803 may induce T_{VM} phenotypes from human T_N.

Methods: CD8$^+$ T-cell subsets were characterized by flow cytometry in *ex vivo* PBMCs from PWH (n=12), including T_N, T_{VM}, effector memory that reverted to an RA$^+$ phenotype (T_{EMRA}), central memory (T_{CM}), and effector memory (T_{EM}). T_N were isolated by negative immunomagnetic selec-

tion and left unstimulated or treated with N-803 (4.4nM) for two weeks. T_{VM} were defined as previously described[4]: $CD3^+CD8^+CD45RA^+$ plus $PanKIR^+$ (KIR2D/KIR3DL1) and/or NK-$G2A^+$.

Results: In PBMCs, T_{VM} comprised a median 9.1% (IQR:7.6-17%) of total $CD8^+$ T-cells and expressed greater levels of cytotoxic granules than T_{CM}, T_{EM}, or T_{EMRA} (for each comparison Friedman test p<0.0001 for perforin, granzyme A [GZMA], and granzyme B [GZMB]).

In isolated T_N, N-803 drove significant increases in the frequencies of cells with the T_{VM} phenotype defined above (7.9FC, p=0.002), indicating either expansion of the very small pool of existing T_{VM} (T_N isolation removed the majority of T_{VM} and all T_{EMRA}) or N-803-mediated differentiation from T_N.

Compared to unstimulated T_N, these resulting T_{VM} had significantly higher GZMA (mean 0.7% expression vs 71%; p=0.0007) and GZMB (0.07% vs 26%; p=0.03), perforin (mean FC of MFI 2.1; p=0.05), IL-15Rb (2.5FC; p=0.006), NKG2D (2FC; p=0.0003), and CD16 (2.3FC; p=0.001) expression.

Conclusions: T_{VM} were present in PBMC of PWH, exhibiting highly cytotoxic profiles. N-803 treatment altered the phenotype of $CD8^+$ T-cells and induced and/or drove proliferation of T_{VM} *ex vivo.* These results provide both rationale and guidance for assessing the potential impact of N-803 on T_{VM} in clinical trials in PWH.

EPA033

Persistent dysregulation of Vδ1 T lymphocytes in ART-suppressed people living with HIV

B. Mann[1], A. Chitrakar-Hall[1], P. Ryan[2], L. Witkin[3], M. Siegel[3], D. Pennington[2], N. Soriano-Sarabia[1]

[1]George Washington University, Microbiology, Immunology, and Tropical Medicine, Washington, DC, United States, [2]Centre for Immunobiology - Blizard Institute, Queen Mary University of London, London, United Kingdom, [3]George Washington University Medical Center, Washington, DC, United States

Background: Major human gammadelta (γδ) T cell populations, Vδ1 and Vδ2 cells, are critical components of immunity both as potent cytotoxic effectors and modulators of adaptive responses. Our previous study suggests factors such as age, biological sex, and race may account for interpersonal differences in Vδ2 cells in people living with HIV (PLWH). During early HIV infection, Vδ1 cells expand and Vδ2 cells are depleted, preceding the inversion of the CD4/CD8 T cell ratio. The consequences of these events and whether the phenotype or functionality of Vδ1 cells remain intact after prolonged suppressive antiretroviral therapy (ART) is unknown.

Methods: TCR repertoire, phenotype, and cytotoxic function of both γδ T cell subsets was compared in PLWH on suppressive ART (HIV RNA <50 copies/mL for >1 year) and uninfected individuals. Demographic information such as race and age was available for 15 PLWH. Immune repertoire sequencing (Illumina) was used to assess TCR diversity. Cytotoxic (CD56/CD16) and exhaustion (PD-1/TIGIT) markers were analyzed by flow cytometry and direct cytotoxic function of Vδ1 and Vδ2 cells was measured in cytotoxic assays by target Daudi cell death after in vitro coculture.

Results: Vδ1-TCR, but not Vδ2-TCR in PLWH showed more diversity than controls. Higher CD56 and CD16 expression in Vδ1 cells from PLWH than in uninfected individuals did not translate into increased Daudi cell killing. PD-1 and TIGIT expression was comparable in both subsets between donor groups suggesting the reduction in cytotoxic function may not be due to immune exhaustion. Vδ1 cells from Caucasian donors expressed higher levels of CD56, but not CD16 compared to African Americans.

Conclusions: Higher Vδ1 cell TCR repertoire diversity and cytotoxic marker expression in the absence of increased killing capacity may indicate selection or expansion of a dysfunctional subset of Vδ1 cell clones in PLWH.

These results suggest that ART may reverse some, but not all γδ T cell dysregulation with greater implications towards restoring the complete immune response in PLWH.

Mucosal immunity

Characterization of tissue-resident CD8 T-cells in the pulmonary mucosa of people living with HIV on long-term ART

Y. Alexandrova[1,2,3], A. Yero Diaz[2], R. Olivenstein[4], M. Orlova[1], E. Schurr[1,5], C. Costiniuk[1,3,6], M.-A. Jenabian[2]

[1]Research Institute of McGill University Health Centre, Infectious Diseases and Immunity in Global Health Program, Montreal, Canada, [2]Université du Québec à Montréal, Department of Biological Sciences, Montreal, Canada, [3]McGill University, Department of Microbiology and Immunology, Montreal, Canada, [4]McGill University, Division of Respirology, Department of Medicine, Montreal, Canada, [5]McGill University, Department of Human Genetics, Montreal, Canada, [6]McGill University Health Center, Division of Infectious Diseases and Chronic Viral Illness Service, Montreal, Canada

Background: Despite the success of antiretroviral therapy (ART), people living with HIV (PLWH) suffer from a high burden of infectious and non-infectious pulmonary diseases, suggesting that their lung immunity is not fully restored. Cytotoxic CD8 T-cells are essential in controlling chronic viral infections. However, excessive CD8 T-cell activation during HIV infection can contribute to lung mucosal tissue damage.

Furthermore, tobacco smoking is part of the lifestyle of many PLWH and smoking changes the lung environment, thus promoting pulmonary inflammation.

Herein, we characterize the effects of HIV and smoking on cytotoxic tissue-resident memory (Trm) CD8 T-cell dynamics in the human lung.

Methods: Bronchoalveolar lavage (BAL) fluid and matched blood were obtained from asymptomatic ART-treated PLWH (median undetectable viral load: 8 years) smokers and non-smokers, and, HIV-uninfected smokers and non-smokers (n=4-7/group). Lymphocytes were isolated and CD8 subsets were characterized by multiparameter flow cytometry. Naïve CD8 T-cells (CD45RA+/CCR7+) were excluded from the analysis. The remaining memory cells were stratified based on expression of CD103 (E-cadherin receptor), CD69 (S1P1 signaling inhibitor), and CD49a (collagen IV receptor). CCR7- memory CD8 T-cells expressing at least one of these markers were defined as Trm. Memory CD8 Non-Trm were defined as CD103-CD69-CD49a-CCR7+/- cells.

Results: Both smoking and HIV infection were independently associated with a significant increase in total CD8 T-cell frequencies in BAL. Within all study groups, CD69+ CD8 T-cell subsets were the most abundant (CD103+CD69+CD49a+: median = 55.8%; CD103-CD69+CD49a+: median = 13.8%; CD103+CD69+CD49a-: median = 4.7%; CD103-CD69+CD49a-: median = 8.2%), while the CD69- subsets were the least abundant.

Furthermore, smoking, but not HIV status, was associated with a significant reduction of CD103-CD8 Trm subsets (CD103-CD69+CD49a+; CD103-CD69+CD49a-).

Moreover, CD103-CD8 T-cells from HIV+ *versus*HIV- study participants displayed higher levels of cytotoxic effector molecules granzymes A/B, with memory Non-Trm cells also showing increased perforin expression.

In all study groups, CD8 non-Trm *versus* CD8 Trm showed significantly lower frequencies of CXCR6+/CXCR3+ cells.

Conclusions: Despite long-term ART,chronic pulmonary inflammation caused by HIV infection may dysregulate mucosal CD8 T-cell cytolytic functions. Lack of CXCR6/CXCR3 co-expression by CD8 non-Trm cells suggests their origin from the circulation. Smoking could promote CD8 T-cell retention in the lung via upregulation of CD103.

EPA035

HIV clade C gp140-SIV-Gag/Nef protein vaccine adjuvanted with NE/AS01B enhanced antibody-mediated effector function and reduced viral loads in SHIV-infected macaques

M. Thurman[1], V. Chokkvaelu[2], S. Johnson[1], O. Olwenyi[1], M. Johnston[1], K. Pandey[1], S. Adeniji[3], K. Hong[3], M. Abdel-Mohsen[3], S. Byrareddy[1]

[1]University of Nebraska Medical Center, Pharmacology & Experimental Neurosciences, Omaha, United States, [2]Fort Myers, Clinical Infectious Unit, Florida, United States, [3]The Wistar Institute, Philadelphia, United States

Background: More than 90% of HIV infections are transmitted across mucosal tissues, signifying the importance of effective mucosal vaccines. We tested the hypothesis that combining AS01B and nanoemulsion (NE) adjuvants (enhanced gut homing properties) with HIV-1 env-gag-nef antigens, will elicit robust immune responses in macaques.

Methods: Four female rhesus macaques (Macaca mulatta) were immunized with clade C HIV gp140 envelope glycoprotein and SIVmac239 P55 Gag and Nef antigens delivered in 3xNE Pure Soybean oil-nano emulsion and AS01B mucosal adjuvants via intranasal primes and subsequent intramuscular and subcutaneous boosts. Vaccinated macaques and three control monkeys were challenged at week 26 with a weekly intrarectal low dose of SHIV-4MTF and followed for 28 additional weeks. Blood, Cerebrospinal fluid, and rectal biopsies were collected longitudinally to quantify viral loads and measure intracellular cytokine staining (ICS), antibody-mediated phagocytosis (ADCP) complement deposition (ADCD), and antibody neutralization ability.

Results: Immunization did not protect against SHIV infection. However, vaccinated animals had significantly reduced viral loads in the plasma (P=0.003) and CSF (P=0.001) compared to the unvaccinated controls. In vaccinated macaques, we observed:

1. Gag specific CD107a+ responses in lymph node CD4+ T cells (all P>0.05 but <0.07);
2. Gag specific IFNγ or TNFα+ responses in lymph node CD8+ T cells (P<0.05);
3. Gag specific CD107a+ responses in PBMCs CD8+ (P=0.057), compared to unvaccinated animals.

While vaccine-mediated antibodies were not neutralizing, they elicited a robust ADCP and ADCD activities against gp140 (P<0.01) compared to control animals.

Additionally, vaccination protected against acute Roseburia depletion (dysbiosis biomarker) (Controls: .85% to .16%; P=0.03).

Conclusions: AS01B and NE adjuvanted with HIV-1 env-gag-nef antigens is immunogenic and safe in macaques. This vaccine strategy generated polyfunctional CD4+ and CD8+ T-cell virus-specific responses within the periphery and lymphoid tissue.

Further, vaccine-mediated antibodies elicited robust ADCD and ADCP responses and preserved barrier-protecting butyrate-producing bacteria. These combined immune responses were accompanied with enhanced virologic control throughout the infection. The gut-homing properties of the NE adjuvants could aid in improving cellular and humoral-mediated immunity in the context of an HIV vaccine and may be pursued as a mucosal adjuvant in future HIV vaccine design studies.

Interplay between the lung microbiome, pulmonary immunity and HIV reservoirs in people living with HIV

Y. Alexandrova[1,2,3], Z. Wang[2], A. Pagliuzza[4], R. Olivenstein[5], N. Chomont[4,6], S. W. Kembel[2], M.-A. Jenabian[2], C. Costiniuk[1,3,7]

[1]*Research Institute of McGill University Health Centre, Infectious Diseases and Immunity in Global Health Program, Montreal, Canada,* [2]*Université du Québec à Montréal, Department of Biological Sciences, Montreal, Canada,* [3]*McGill University, Department of Microbiology and Immunology, Montreal, Canada,* [4]*Centre de Recherche du CHUM, Montreal, Canada,* [5]*McGill University, Division of Respirology, Department of Medicine, Montreal, Canada,* [6]*Université de Montréal, Département de Microbiologie, Infectiologie et Immunologie, Montreal, Canada,* [7]*McGill University Health Center, Division of Infectious Diseases and Chronic Viral Illness Service, Montreal, Canada*

Background: Pulmonary dysbiosis renders individuals susceptible to infectious and non-infectious lung diseases. While the composition of the lung microbiome differs in people living with HIV (PLWH) versus uninfected individuals, the interplay between the lung microbiome, HIV reservoir size and pulmonary immunity has not been previously explored.

Here, we assessed whether intrapulmonary HIV reservoir size and immune disruption are associated with a reduction in bacterial lung diversity in PLWH, which may predispose PLWH to chronic lung disease.

Methods: Bronchoalveolar lavage (BAL) fluid was obtained from 19 individuals (8 smokers, 11 non-smokers) with well-controlled HIV on suppressive antiretroviral therapy (ART) (undetectable viral load for ≥3 years) and 9 HIV-negative controls (4 smokers, 5 non-smokers). Bacterial DNA was extracted and PCR-amplified from cell-free BAL fluid, targeting the bacterial 16S rRNA gene. Multiplexed amplicon libraries were sequenced. Data sets consisting of amplicon sequence variant (ASV) relative abundances and taxonomic identities were analyzed using joint species distribution modeling. HIV-DNA was quantified from FACS-sorted pulmonary CD4 T-cells using ultra-sensitive PCR. Multiparameter flow cytometry was used to characterise subsets of activated (HLA-DR$^+$), exhausted (PD1$^+$) senescent (CD28$^-$CD57$^+$) T-cells.

Results: The bacterial phyla *Actinobacteria* and *Proteobacteria* are more abundant in smokers, while several other taxa including *Bacteroidetes, Fusobacteria,* and *Patescibacteria* were less abundant in smokers. For PLWH, microbiome diversity (Shannon index of relative abundance of amplicon sequence variants [ASVs] per sample) was lower in smokers than non-smokers (p<0.001).

Frequencies of effector memory BAL CD4 T-cells were positively correlated with abundance of bacterial families. Meanwhile, frequencies of BAL CD4 T-cells expressing HLA-DR+ and CD38+HLA-DR+ were negatively correlated with the abundance of most bacterial families in the lungs. Higher HIV-DNA levels in pulmonary CD4 T-cells and greater proportions of senescent CD8 T-cells were correlated with reduced bacterial diversity (p=0.02 and p=0.02, respectively) in PLWH.

Conclusions: While bacteria community composition deviated between smokers and non-smokers for HIV- individuals, this was not observed in PLWH. This finding suggest that HIV infection may weaken the response of the lung microbiome to smoking.

For the first time, we show that lung reservoir size and immune activation status may impact the lung microbiome, predisposing PLWH to pulmonary comorbidities.

Novel vectors, adjuvants and strategies

MVA/Protein HIV-1 vaccine protects against heterologous SHIV infection by modulating IgG glycosylation and T helper response in macaques

A. Sahoo[1], A.T. Jones[1], N. Cheedarla[1], S. Gangadhara[1], V. Roy[2], T.T. Styles[1], A. Shiferaw[1], K.L. Walter[3], L.D. Williams[4], X. Shen[4], G. Ozorowski[5], W.-H. Lee[5], S. Burton[1], L. Yi[1], X. Song[1], Z. Qin[1], C.A. Derdeyn[1], A.B. Ward[5], J.D. Clements[6], R. Varadarajan[7], G.D. Tomaras[4], P.A. Kozlowski[3], G. Alter[2], R.R. Amara[1]

[1]*Emory University, Atlanta, United States,* [2]*Ragon Institute of MGH, MIT, and Harvard, Cambridge, United States,* [3]*Louisiana State University Health Sciences Center, New Orleans, United States,* [4]*Duke University Medical School, Duke University, Durham, United States,* [5]*The Scripps Research Institute, San Diego, United States,* [6]*Tulane University School of Medicine, New Orleans, United States,* [7]*Indian Institute of Science, Bangalore, India*

Background: Current global HIV-1 burden, in particular the prevalence of clade C infections across the world has defined an urgent need for the development of a clade C focused preventive HIV-1 vaccine providing heterologous protection.

Methods: Here, we developed and compared the protective efficacy of a clade C HIV-1 vaccine consisting of priming with modified vaccinia Ankara (MVA) and boosting with cyclically permuted trimeric gp120 (CycP-gp120) protein delivered either orally using a needle-free injector or through parenteral injection against intrarectal challenges with a pathogenic heterologous clade C SHIV infection in male rhesus macaques.

All experiments involving rhesus macaques were conducted at Yerkes National Primate Research Center in compliance with Emory University Institutional Animal Care and

Use Committee (IACUC) protocol YER2003491, under USDA regulations and *Guide for the Care and Use of Laboratory Animals* guidelines.

Results: Both routes of vaccination induced a strong envelope-specific IgG in serum and rectal secretions directed against V1V2 scaffolds from a global panel of viruses with polyfunctional activities. Envelope-specific IgG showed lower fucosylation compared to total IgG, and the majority of vaccine-induced proliferating blood $CD4^+$ T cells did not express CCR5 and a4b7, markers associated with HIV target cells. Following SHIV challenge, both routes of vaccination conferred significant and equivalent protection at the end of six weekly repeated challenges with an estimated efficacy of 68% per exposure.

Induction of envelope-specific IgG with G1FB profile correlated positively and G2S2F linked to decreased ADCVI activity correlated negatively with protection. Vaccine-specific mucosal poly-functional $IFNg^+TNFa^+$ $CD8^+$ T cells and TNFa producing $CD4^+$ T cells expressing low levels of CCR5 at pre-challenge were associated with decreased risk of SHIV acquisition.

Additionally, animals that generated high frequencies of proliferating circulating $CD4^+$ T cells during vaccination showed early acquisition of infection.

Conclusions: Thus, the results demonstrate that the clade C MVA/CycP-gp120 vaccine provides heterologous protection by inducing distinct humoral and cell-mediated immune responses that are resistant to HIV infection.

The effectiveness of an HIV-1 vaccine depends on its ability to elicit multidimensional balanced immune responses.

Immune mechanisms of natural or post-treatment control

EPA038

Genetic polymorphism of toll-like receptors (TLRs) in HIV-I infected patients with and without tuberculosis (TB) co-infection

G. Kaushik[1], R. Vashishtha[2], R. Yadav[3]

[1]Sharda University, Greater Noida, School of Allied Health Sciences, Mohali, India, [2]Biotechnology Industrial Research Assistance Council (BIRAC), Program Management Unit, Delhi, India, [3]National Institute of Tuberculosis and Respiratory Diseases, Microbiology, New Delhi, India

Background: TLRs are identified as one of the key components of innate immune system due to their ability to sense conserved molecular motifs associated with several pathogens. It has been implicated from several evidences that mutations in genes encoding TLRs are associated with increased or decreased susceptibility to various infectious diseases.

Methods: The study was prospective, cross sectional as well as longitudinal in nature which includes 223 HIV-positive patients, 150 HIV-positive patients with latent tuberculosis infection, 150 HIV-positive patients with active tuberculosis, 200 HIV negative newly diagnosed sputum smear positive pulmonary tuberculosis patients and 205 healthy subjects.

Results: Statistically significant difference was observed in allelic frequencies of TLR4 between healthy subjects and HIV+TB patients ($p<0.001$), healthy subjects and PTB Cat I patients ($p<0.01$), and between healthy subjects and HIV+TB patients ($p<0.001$). TLR4 genotype frequencies were also significantly different between healthy subjects and PTB Cat I patients ($p<0.001$), HIV+ and HIV+TB patients ($p<0.01$).

Statistically significant difference was also observed between HIV+ and PTB Cat I patients ($p=0.04$), HIV+LTBI and HIV+TB patients ($p=0.01$) and between HIV+TB and PTB Cat I patients ($p<0.01$).

Conclusions: This study implicates that Asp299Gly polymorphism in TLR4 gene is associated with increased susceptibility to active TB in HIVseropositive patients. Increased frequency of A allele in TLR9 gene was also discovered at the time of active TB development in ART naïve HIV+ patients, who developed active TB on follow-up.

EPA039

Spontaneous HIV control is associated with concentrations, and not the biophysical characteristics, of polyfunctional anti-Env specific antibody responses

[1]McGill University, Division of Experimental Medicine, Department of Medicine, Montreal, Canada, [2]The Research Institute of the McGill University Health Centre, Montreal, Canada, [3]Infectious Diseases, Immunology and Global Health Program, Montreal, Canada, [4]Faculté de Médecine de l'Université de Lille Henri Warembourg, Lille, France, [5]Lille University Hospital, Lille, France, [6]McGill University Health Centre, Division of Hematology, Montreal, Canada, [7]McGill University Health Centre, Chronic Viral Illness Service, Montreal, Canada, [8]Centre de Recherche du Centre Hospitalier de l'Université de Montréal, Montreal, Canada, [9]Université de Montréal, Départment de Microbiologie Infectiologie et Immunologie, Montreal, Canada, [10]Clinique Médicale l'Actuel, Montreal, Canada, [11]Clinique de Medecine Urbaine du Quartier Latin, Montreal, Canada, [12]Clinique Médicale Opus, Montreal, Canada, [13]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [14]The Research Institute of the McGill University Health Centre, Division of Clinical Immunology, Montreal, Canada

Background: A small subset of people living with HIV (PLWH), called elite controllers (EC), sustain undetectable viral loads (VL) while viremic controllers (VC) maintain VLs at <3000 copies of HIV RNA/ml of plasma without

treatment. Understanding immunological mechanisms behind this spontaneous control may inform how to extend this functional cure phenotype to non-controllers. The RV144 vaccine trial, which showed modest protection against HIV found that anti-HIV gp120-specific antibody dependent (AD) cellular cytotoxicity (ADCC) was as an immune correlate of protection from infection.

Here we investigated whether AD functions play a role in HIV control. If so, then ECs and VCs would be expected to have more potent AD functions compared to PLWH who are untreated (UTP) or treated progressors (TP).

Methods: Plasma from 18 UTPs, 24 TPs, 37 ECs, and 16 VCs was tested for anti-Env specific antibody (Ab) concentrations and AD functions. Target cells were an in-house generated, novel HIV-infected target cell line expressing closed conformation Env (siCEM). Four AD functions were tested: monocyte-mediated phagocytosis (ADCP) and trogocytosis (ADCT), NK cell-mediated ADCC and activation of the complement cascade (ADCD).

The size of HIV reservoir was measured in HIV controllers (ECs and VCs) by integrated HIV DNA PCR. Anti-Env Ab biophysical characteristics were measured by capillary electrophoresis.

Results: Anti-Env-specific Abs from EC, VC and UTP had similar AD function levels that were higher than those in TP. ECs differed from all the other groups by having a more strongly correlated, polyfunctional anti-Env-specific AD response. Multivariate dimensionality-reduction tools could not distinguish the four subject groups based on IgG subclass and glycosylation.

Between-group differences in AD functions were lost when normalised by anti-Env Ab concentrations, suggesting that quantity, rather than Ab potency drove AD function levels. ADCC function was significantly higher in controllers who maintained an undetectable versus a detectable HIV reservoir size.

Conclusions: Env-specific AD functions were dictated by the quantity, and not the quality of anti-Env Abs. As compared to any other study group, ECs demonstrated highly correlated polyfunctional AD responses. ADCC response levels were associated with HIV reservoir size.

EPA040

Investigating mechanisms of antigen-independent CD8+ T cell enforcement of HIV latency

T. Mota[1], J. Weiler[1], L. Leyre[1], S. Terry[1], L. Ehui[2], A. Wimpelberg[2], C. Cannon[2], E. Benko[3], C. Kovacs[3], S. Henn[2], R.B. Jones[1]

[1]Weill Cornell Medicine, Medicine, Infectious Diseases, New York, United States, [2]Whitman Walker Health, Washington, United States, [3]Maple Leaf Clinic, Toronto, Canada

Background: Recent research supports the possibility that non-canonical behaviors of CD8⁺ T-cells can reduce HIV expression in infected cells in an antigen-independent noncytolytic manner, paralleling observations from other pathogenic infections. We aimed to confirm this behavior using a precise antigen-independent experimental system by:

1. Abrogating surface expression of MHC Class I so that HIV-infected $CD4^+$ T-cells cannot present antigen to HIV-specific CD8+ T-cells, and by;
2. Ruling out common death-receptor pathways of $CD8^+$ T-cell mediated killing that may otherwise function without MHC I recognition.

Methods: To investigate the antigen-independent impact of $CD8^+$T-cells on HIV expression in $CD4^+$ T-cells, we established a system to abrogate surface expression of MHC I (HLA-A/B/C/E) using CRISPR/Cas9 and two guide RNAs against beta-2-microglobulin (b2M). MHC I KO was performed in HIV-JRCSF-infected $CD4^+$ T-cells from people with HIV and exposed overnight to autologous primary unstimulated or TCR-stimulated $CD8^+$ T-cells (n=6), including $CD8^+$ T-cells with CRISPR KO of cytotoxic granules including Perforin, Granzyme A and B, the TCR, and death receptor ligands including FasL, TRAIL, and NKG2D (n=2).

Results: CRISPR/Cas9 targeting b2M abrogated MHC I surface expression in up to 98% of cells within 48hrs. In HIV-JRCSF-infected $CD4^+$ T-cells, co-culture with unstimulated primary CD8+ T-cells resulted in a median of 5% reductions in Gag+ cells within the MHC-I^{pos} cells (not significant), while co-culture with anti-CD3/28-stimulated $CD8^+$ T-cells drove a 29% reduction (Friedman test; p<0.01).

In MHC-I^{neg} cells (which cannot present antigens to CTLs), medians of 4% (ns) and 17% (Friedman test; p<0.01) reductions in the proportions of $CD4^+$T-cells expressing Gag were observed when exposed to unstimulated and TCR-stimulated $CD8^+$ T-cells, respectively (Friedman test; p<0.001 for both). The reduction in Gag occurred in the absence of cell death.

Although these studies are ongoing, thus far, knocking out cytotoxic effector molecules or death receptors/ligands has not impaired this effect.

Conclusions: These results add to the evidence suggesting that an antigen-independent noncytolytic activity contributes to $CD8^+$ T-cell-mediated suppression of HIV. This provides further impetus to study underlying mechanisms, which may reveal potential therapeutic targets to either augment viral suppression or enhance latency reversal.

Host cellular factors and viral mechanisms of HIV/SIV persistence and latency

EPA041

Higher levels of RNA and protein in plasma-derived exosomes of elite controllers

M.A. Navarrete-Muñoz[1], H. Peinado[2], A. Cabello[3], M. Górgolas[3], J.M. Benito[1], N. Rallon[1]
[1]Instituto de Investigación Sanitaria-Fundación Jiménez Díaz (IIS-FJD/UAM) - Hospital Universitario Rey Juan Carlos, HIV and Viral Hepatitis Research Laboratory, Madrid, Spain, [2]Spanish National Cancer Research Center (CNIO), Microenvironment and Metastasis Group, Madrid, Spain, [3]Hospital Universitario Fundación Jiménez Díaz, División de Infecciosas, Madrid, Spain

Background: Extracellular vesicles (EVs) have recently been proposed as agents involved in the HIV pathogenesis and latency. EVs may contribute to an anti-viral response by carring HIV restriction factors (mRNAs, miRNAs and proteins) to nearby cells or by presenting viral antigens. Moreover, EVs could play a relevant role in the reactivation of HIV reservoir.
Herein, we have analyzed abundance and cargo of EVs derived from plasma of patients with different degrees of virologic control.
Methods: Thirty HIV patients were included: 10 elite controllers (EC), 10 non-controllers under successful cART (NC-TT) and 10 non-controllers cART-naïve with replicating HIV (NC-NT). Ten uninfected controls (UC) were included. Plasma EVs were purified by Size Exclusion Chromatography-SEC. EVs size and abundance were measured by Nanoparticle Tracking Analysis. Size was confirmed by microscopy-TEM. Quality and concentration of isolated total EVs-RNA were evaluated by Bionalyzer 2100 system. EVs-protein was quantified by BCA. HIV-DNA content was assessed in purified CD4 resting memory cells by ddPCR. Inter-group differences and potential associations were tested by non-parametric tests.
Results: SEC allowed to purify exosomes since EVs size (nm) was 117[108-130] for HIV^+ and 120[113-124] for HIV^- (p=0.68) volunteers, verified by TEM. There were no differences (p=0.18) in abundance (EVs/mL) of EVs between HIV^- ($6.30x10^{11}$[$3.89x10^{11}$-$7.11x10^{11}$]) vs HIV^+ ($7.15x10^{11}$[$4.27x10^{11}$-$1.11x10^{12}$]) volunteers. Interestingly, level of EVs-RNA (fg/10^6EVs) was significantly higher in EC (92.65[45.42-271.64]) vs NC-TT (49.7[38.47-65.96])(p=0.05).
Similarly, level of EVs-protein (pg/10^6EVs) was higher in EC (346.44[224.81-637.08]) vs NC-TT (256.46[179.67-308.91]) (p=0.06). Of note, a significant and positive correlation was found between HIV-DNA levels and EVs-protein levels (rho=0.661,p=0.038) only in NC-NT group.
Conclusions: Our results show that the relevance of EVs, specifically exosomes, in HIV infection does not lie in their abundance but in their content. Higher levels of RNA and protein in plasma EVs of elite controllers compared to cART-patients suggest an anti-viral role of EVs in HIV infection. Moreover association between HIV-DNA levels and EVs-protein cargo in NC-NT patients suggests that non-controlled HIV may induce protein factors packaging in EVs to enhance HIV reservoir.
Further analysis of the EVs cargo regarding the type of RNA molecules and proteins are necessary to confirm the anti-viral role of EVs in EC subjects.

EPA042

Nef expression promotes persistent HIV-1 in effector memory CD4+ T-cells

G. Duette[1], B. Hiener[1,2], V. Mathivanan[3], A. Shaik[3], S. Turville[3], S.G. Deeks[4], A.D. Kelleher[3], S. Palmer[1,2]
[1]The Westmead Institute for Medical Research, Centre for Virus Research, Westmead, Australia, [2]The University of Sydney, Sydney Medical School, Faculty of Medicine and Health, Sydney, Australia, [3]The Kirby Institute, University of New South Wales, Sydney, Australia, [4]University of California San Francisco, Department of Medicine, San Francisco, United States

Background: The expression of the Nef protein contributes to the persistence of HIV-1 by downregulating cell-surface MHC-I and antigen presentation which allows the virus to evade clearance by CD8 T-cells. However, the expression of Nef across memory T-cell subsets and its contribution to the maintenance of defective HIV-1 proviruses which make up the majority of the persistent reservoir is unclear.
To address this issue, we determined the expression of Nef within memory T-cell subsets and whether proviral sequences containing large internal deletions can express Nef.
Methods: Central (T_{CM}), transitional (T_{TM}), and effector (T_{EM}) memory CD4+ T-cells were sorted from four HIV-1 negative HLA-A*02 donors and infected with HIV-NL4-3 containing green fluorescent protein introduced into the *nef*open reading frame (HIV GFP-Nef). This allows for the quantification of Nef expression within these T-cell subsets. Cell surface MHC-I (HLA-A*02) molecules were quantified using flow cytometry.
In addition, seven viral constructs based on participant sequences that contained large internal deletions, but genetically-intact *gag* and *nef*, were introduced into the HIV GFP-Nef molecular clone. HEK-293T cells were transfected with these viral constructs containing the defective proviruses. Gag and Nef expression was assessed by western blot and flow cytometry. MHC-I (HLA-A*02) molecules on the surface of the HEK-293T cells were quantified using flow cytometry.
Results: We observed significantly higher levels of Nef expression in T_{EM} cells compared with T_{CM} cells (p<0.05). The MHC-I downmodulation on the surface of T_{EM} cells was also more pronounced compared to T_{CM} (p<0.05). Moreover, MHC-I expression in T_{EM} cells was negatively correlat-

ed with Nef expression (Spearman r=-0.8040, p=0.0026). The transfection of HEK-293T cells with defective proviruses containing genetically-intact *gag* and *nef* led to the expression of Gag and Nef proteins. The expression of Nef from these defective proviruses caused the downmodulation of MHC-I.

Conclusions: Nef-mediated MHC-I downmodulation observed in T_{EM} cells supports the role of Nef in protecting these HIV-1-infected cells from clearance by CD8 T-cells. Furthermore, cells infected with defective proviruses containing immunogenic genes such as *gag*, may be protected by Nef expression. This suggests targeting Nef would enhance immune clearance of HIV-1 infected cells during effective therapy.

Retinoic acid boosts HIV-1 replication in Monocyte-Derived Macrophages

J. Dias[1,2], A. Cattin[1,2], J.-P. Goulet[3], L. Raymond Marchand[2], A. Fert[1,2], T. Raul Wiche Salinas[1,2], C.-D. Ngassaki Yoka[1,2], E. Moreira Gabriel[1,2], J.-P. Routy[4,5,6], P. Ancuta[1,2]

[1]Université de Montréal, Microbiologie, Infectiologie et Immunologie, Montréal, Canada, [2]Centre de Recherche du Centre Hospitalier de l'Université de Montréal, Montréal, Canada, [3]Caprion, Montréal, Canada, [4]McGill University Health Centre, Infectious Diseases and Immunity in Global Health Program, Montréal, Canada, [5]McGill University Health Centre, Chronic Viral Illness Service, Montréal, Canada, [6]McGill University Health Centre, Division of Hematology, Montréal, Canada

Background: While the persistence of viral reservoirs (VR) in long-lived CD4⁺T-cells of people living with HIV (PLWH) receiving viral-suppressive antiretroviral therapy (ART) is well-established, the contribution of myeloid cells, such as tissue resident macrophages (MFs), remains a subject of debate.

Our previous studies demonstrated that, in the colon of ART-treated PLWH, CD4⁺T-cells carry high levels of integrated HIV-DNA, while integrative infection in MFs is rarely observed.

Noteworthy, the intestinal environment is rich in retinoic acid (RA), a booster of HIV replication in CD4⁺T-cells. Thus, we investigated the impact of RA on HIV replication in monocyte-derived MFs (MDMs).

Methods: Monocytes isolated by negative selection from the blood of HIV-uninfected individuals were differentiated into MDMs by culturing in the presence of M-CSF for 6 days and in the presence or the absence of*all-trans*RA (ATRA). MDMs were infected with replication competent CCR5-tropic (NL4.3BaL, transmitted/founder (T/F) THRO), or single-round VSV-G-pseudotyped HIV (HIV_{V-SVG}). Phenotyping was performed by flow cytometry.

Levels of early (RU5) and late (Gag) reverse transcripts and integrated (Alu/LTR) HIV-DNA levels were quantified by nested real-time PCR. HIV replication was measured by HIV-p24 ELISA. Protein expression was measured by western blot. Differentially expressed genes were identified by RNA-sequencing.

Results: ATRA significantly increased CCR5 but not CXCR4 expression in MDMs. ATRA also increased CCR5 tropic $HIV_{NL4.3BaL}$ and HIV_{THRO} replication. Single-round infection with VSV-G-pseudotyped HIV demonstrated that ATRA increases HIV permissiveness in MDMs by acting at post-entry levels, between reverse transcription and integration. The INK128, an inhibitor of the mTOR pathway can counteract the effect of ATRA by reducing CCR5 expression, HIV integration and HIV replication.

Finally, RNA-sequencing revealed that ATRA transcriptionally reprograms MDMs for increased HIV replication through the TCF4/Wnt/β-catenin pathway, a mediator of HIV transcription.

Conclusions: These results support a model in which MDMs in a RA rich environment, such as the intestine, are important HIV infection targets, especially when exposed to highly virulent T/F HIV strains.

Therefore, the rarity of VR in colon-infiltrating MDMs of ART-treated PLWH is likely not due to their resistance to infection but may be rather explained by their rapid turnover*in vivo*.

Cross-sectional analysis reveals limited genetic diversity in genes that affect integration site targeting (Integrase and Capsid) in acute HIV-1 subtype C infection in South Africa

T.J.B. Chikowore[1,2], K. Reddy[1,3], K. Gounder[1,4], N. Reddy[1,3], K. Dong[5,4], G. Lee[6], T. Ndung'u[1,2,3,4,5]

[1]Africa Health Research Institute, Durban, South Africa, [2]University College London, London, United Kingdom, [3]University of KwaZulu-Natal, Durban, South Africa, [4]HIV Pathogenesis Programme, Doris Duke Medical Research Institute, University of KwaZulu-Natal, Durban, South Africa, [5]Ragon Institute of MGH, MIT and Harvard University, Cambridge, United States, [6]Weill Cornell Medicine, New York, United States

Background: Despite its many benefits, antiretroviral therapy (ART), is lifelong and is not curative because it does not eliminate the latent reservoir of integrated provirus. Understanding the factors that may determine landscape of the reservoir such as the size, cellular distribution and reactivation potential may lead to novel curative strategies.

We performed a cross-sectional analysis of HIV-1 subtype C genetic diversity in the integrase (IN) and capsid (CA) gene loci that are known to affect integration site targeting to elucidate some of the factors affecting HIV integration.

Methods: Study participants were 33 women with acute HIV-1 infection in South Africa. Bulk PCR and Full-Length Individual Proviral Sequencing (FLIP-Seq) using PACBIO and Illumina platforms were used to describe both the

integrated DNA and circulating RNA isolated from transmitted/founder HIV-1 subtype C infection. The resultant sequences (n=215 (IN) and 238 (CA)) were subjected to phylogenetic and population genetic diversity analysis.

Results: In both IN and CA, there was limited phylogenetic diversity in the transmitted/founder virus with sequences clustering independently for each participant. The data also showed relative sequence conservation in both IN and CA (C=0.31 and 0.56 respectively). Low nucleotide diversities were observed at both the inter participant (ϖ=0.0568 (IN) and 0.0602 (CA)) and intra participant (ϖ=0.00-0.0428 (IN) and 0.000-0.0365 (CA)) level. Both IN and CA showed negative selection (Tajima's D=-2.21831, p<0.01 and -0.97528, p>0.10 respectively).

There was amino acid variation in 25% of the genotypes at positions S119 and R231 in IN, previously shown to affect integration site targeting.No notable amino acid variation was observed in CA at position N74, which affects virus-host interactions and integration localization.

Conclusions: Both IN and CA regions of the HIV-1 were relatively conserved with low nucleotide diversity between and within participants. Negative selection was also observed in both genes, consistent with the population bottleneck of transmitted/founder HIV-1 virus seen in early infection.

We identified variants within IN which have been previously associated with viral retargeting of integration sites as well as disease progression in chronic infection.

Understanding the factors governing the integration of the persistent, replication-competent provirus could provide key insights into targeting and eliminating the reservoir.

Multi-modal statistical analysis strategies identify biomarkers of cell-associated Gag RNA expression levels during ART

M. Adan[1], C.-Y. Lau[1], T. Nguyen[2], B. Yang[1], A. Savramis[1], R. Dewar[3], J. Higgins[4], C. Rehm[5], A. Ganesan[6], D. McMahon[7], E. Anderson[8], R. Gorelick[9], F. Maldarelli[2], B. Luke[9]

[1]National Cancer Institute, HIV Dynamics and Replication Program, Bethesda, United States, [2]National Cancer Institute, HIV Dynamics and Replication Program, Frederick, United States, [3]Frederick National Laboratory for Cancer Research, Virus Isolation and Serology Laboratory, Frederick, United States, [4]National Cancer Institute, AIDS Monitoring Laboratory, Frederick, United States, [5]National Institute of Allergy and Infectious Diseases, Laboratory of Immunoregulation, Bethesda, United States, [6]Walter Reed National Military Medical Center, Infectious Diseases Clinical Research Program, Bethesda, United States, [7]University of Pittsburgh, Division of Infectious Diseases, Pittsburgh, United States, [8]US Department of Health and Human Services, Office of the Assistant Secretary for Health, Philadelphia, United States, [9]Frederick National Laboratory for Cancer Research, Frederick, United States

Background: The forces responsible for persistence and clonal expansion of HIV-infected cells during ART are not well characterized. Levels of several immune activation markers are reported to correlate with levels of cell associated HIV-DNA or RNA (caDNA and caRNA, respectively) and are potential drivers of persistence.

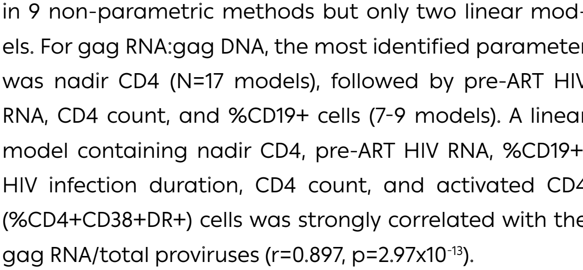
In general, these correlations have been identified via statistical methods using assumptions, including normal distribution of biomarker levels, which may not be appropriate for all factors. New approaches using more comprehensive analyses are necessary.

Here, we evaluated 24 different statistical methods to investigate relationships between HIV caRNA levels and cellular immune markers.

Methods: Clinical data and peripheral blood mononuclear cells were collected from 35 adults (86% male) on ART for >3 years (mean=16yrs). Proportions of cells in T-cell subsets or expressing activation markers were measured with flow cytometry. caRNA and caDNA levels were determined using multiplexed droplet digital PCR, simultaneously targeting HIV LTR and gag DNA or RNA. Levels of caRNA were expressed as levels of gag RNA normalized to total number of proviruses, (LTR DNA copies/2), or to total number of gag-containing proviruses (gag DNA copies).

We investigated correlations between caRNA and clinical/immune characteristics using 24 different methods, including parametric and non-parametric correlation approaches, regression, and classification methods using varying assumptions about dataset structure.

Results: Few characteristics were consistently associated with HIV caRNA. gag RNA:total proviruses was strongly associated with nadir CD4 and pre-ART HIV RNA by 11 different methods; pre-ART HIV RNA was strongly associated



in 9 non-parametric methods but only two linear models. For gag RNA:gag DNA, the most identified parameter was nadir CD4 (N=17 models), followed by pre-ART HIV RNA, CD4 count, and %CD19+ cells (7-9 models). A linear model containing nadir CD4, pre-ART HIV RNA, %CD19+, HIV infection duration, CD4 count, and activated CD4 (%CD4+CD38+DR+) cells was strongly correlated with the gag RNA/total proviruses (r=0.897, p=2.97x10^{-13}).

Conclusions: Nadir CD4 and pre-ART RNA levels have long-lasting effects on levels of HIV caRNA, even after prolonged ART. Linear models incorporating these pre-therapy characteristics with proportions of activated CD4 cells and B cells are strong predictors of HIV caRNA levels during ART.

Results: Our data show HIV-1C P21A mutant had significantly lower transactivation (p = 0.0004) compared to wildtype Tat. Co-immunoprecipitation revealed that this mutant formed a complex with CycT1 and CDK9. Moreover, results from EMSAs showed that the TatP21A mutant is able to bind to the TAR element.

Taken together, our data suggest that HIV-1C Tat P21A mutant significantly reduced its transactivation activity but does not affect its ability to bind to the TAR element and recruit P-TEFb during HIV replication.

Conclusions: Further investigation is required to elucidate other possible mechanisms by which HIV-1C P21A mutant results in lower transactivation activity and whether it plays a role in the development or reversal of HIV latency.

EPA046

Effect of human immunodeficiency virus type 1 (HIV-1) subtype C transactivator of transcription (Tat) P21A variant on nuclear levels of active positive transcription elongation factor b (P-TEFb)

Z. Mkhize[1], P. Madlala[1], D. Boehm[2], M. Ott[2], T. Ndung'u[3,1]

[1]University of KwaZulu-Natal, HIV Pathogenesis Program, Durban, South Africa, [2]University of California San Francisco, Gladstone Institute, San Francisco, United States, [3]Africa Health Research Institute, Durban, South Africa

Background: Although combination antiretroviral therapy (cART) effectively suppresses human immunodeficiency virus type 1 (HIV-1) replication, it is not curative due to the existence of latent viral reservoir. However, mechanisms that govern viral latency are unknown. The HIV-1 transactivator of transcription (Tat) enhances viral gene transcription and is important for HIV-1 pathogenesis. Inter- and intra-subtype Tat genetic variation that translate to functional differences has been reported. Specifically, HIV-1 subtype C (HIV-1C) Tat P21A mutant was reported to be associated with reduced Tat transactivation activity. Although it is well established that Tat binds to the transactivator RNA (TAR) element of the 5' long terminal repeat (LTR) and subsequently recruits the host positive transcription elongation factor b (P-TEFb) for efficient viral gene transcription, the effect of Tat variation on its ability to recruit P-TEFb is unknown.

Therefore, this study aimed to determine the effect of HIV-1 subtype C Tat P21A mutant alone and/or in combination with other Tat mutations on the ability of Tat to recruit P-TEFb to 5' LTR to enhance viral gene transcription.

Methods: To this effect, site-directed mutagenesis was performed to introduce Tat P21A mutation alone or together with other mutations to a pcTat plasmid. Following this, transactivational activity of Tat mutants was measured using Tat transactivation assay. Co-immunoprecipitation was performed using mutant P21A Tat protein and CycT1 and CDK9 proteins, components of P-TEFb. Lastly, electron mobility shift assays (EMSAs) were performed using radioactively labelled P21A mutant.

EPA047

Identification and characterization of novel chromatin regulators involved in HIV transcription and latency

L. Mori[1], C. Li[1], T. Venables[1], M. Pipkin[1], S. Valente[1]

[1]The Scripps Research Institute, Immunology and Microbiology, Jupiter, United States

Background: HIV transcription depends on the assembly of multiple cellular transcription factors and RNA polymerase II (RNAPII) at the HIV-1 5' long terminal repeat (LTR). Furthermore, HIV transcription is heavily influenced by the site of integration and the chromatin environment surrounding the HIV promoter. Current HIV cure approaches, such as the block-and-lock and shock-and-kill strategies, depend on a complete understanding of the regulation of HIV transcription and the surrounding chromatin environment.

There are approximately 320 chromatin remodeling enzymes and readers, writers and erasers of the histone code, which alter chromatin structure in a complex process involving multiple factors.

Characterization of host factors involved in HIV-1 transcription and latency, and how these interact with viral factors, will potentiate development of multiangled approaches towards HIV-1 transcriptional regulation.

Methods: We performed a pooled RNAi screen utilizing short hairpin RNAs embedded in a microRNA backbone (shRNAmirs) to probe all human chromatin regulatory factors (CRFs) simultaneously in the J-Lat 10.6 T cell model of latency. The goal was to identify factors which RNAi loss resulted in either spontaneous reactivation or inhibition of HIV-1 transcription.

Results: We identified 20 top candidate CRFs whose RNAi-effects promote HIV latency and 20 CRFs that promote HIV reactivation, many currently unrecognized factors that could be important. Based on multiple criteria, we are prioritizing identified CRFs and are validating their functions using CD4+T cells from PLWH and *ex vivo* HIV-infected primary CD4+ T cells. Data from RNA-seq, ChIP-seq and ATAC-Seq analyses will inform mechanism of action of these novel host regulators of HIV transcription.

Conclusions: Through a pooled RNAi screen of all human chromatin regulators, we have identified ~40 candidate CRFs with potentially important roles in HIV latency.
Using combinatorial approaches, we will be able to correlate with high-resolution nucleosome architecture data with their binding to chromatin and develop a comprehensive picture of the signals and factors that drive chromatin activity at the latent provirus.

EPA048

Proviral populations persisting in galt during long-term art are highly decayed

E. Madeen[1], T. Nguyen[2], R. Gorelick[2], M.-E. Zipparo[2], L. Adams[2], S. Hill[2], M. Adan[2], N. Wulan[2], C.-Y. Lau[2], F. Maldarelli[2]
[1]*National Institutes of Health, National Cancer Institute, Bethesda, United States,* [2]*National Cancer Institute, Frederick, United States*

Background: Antiretroviral therapy (ART) controls but does not cure HIV infection. Understanding persistence and clonal expansion of HIV infected cells in tissue compartments is essential to developing ART-free HIV eradication and control strategies. The total level of proviruses remains stable over time while the proportion of proviruses presenting a loss of HIV genes (deletion/decay) increases relative to complete proviruses in peripheral blood. The dynamics of HIV decay in tissues, and the relationship to peripheral blood HIV decay, is not well understood.
To investigate HIV proviral decay in lymphoid tissue we characterized levels of total and decayed proviruses in blood, ileum, and colon from HIV-infected individuals undergoing long-term ART.
Methods: Volunteers (N=6) undergoing suppressive ART for >3 years underwent concurrent phlebotomy and research colonoscopy for sampling of ileum and colon. Peripheral blood mononuclear cells (PBMC) were obtained by ficoll separation; single cell suspensions of colon and ileum were obtained using collagenase digestion procedures.Integrated HIV genes were quantitatively measured using a multiplexed droplet digital PCR assay for HIV LTR and *gag*.LTR represents cells containing HIV provirus and the presence or lack of *gag*represents intact or decayed provirus, respectively.
The proportion of decayed proviruses was quantified by determining LTR/gag ratio; CCR5 copy number was used to normalize HIV copy numbers per million host cells,(Anderson et al., 2020).Levels of HIV DNA species and LTR/*gag* ratios were analyzed using Pearson correlation and wilcoxon non-parametric analyses.
Results: Approximately 30 biopsies from each volunteer were obtained from ileum and colon. As expected, median levels of HIV LTR and *gag* DNA in PBMC (320 copies/million PBMC and 39 copies/million PBMC, respectively) were 3.5-34-fold higher than that detected in colon or ileum samples, which contain a majority of non-lymphoid tissue cells. Proportion of decayed proviruses, measured by ratio of LTR/gag, was significantly higher in ileum or in colon than in PBMC: median LTR/gag 7.0 (ileum), 6.3 (colon), 3.4 (PBMC, Wilcoxon $p<0.025$ for each PBMC comparison).
Conclusions: HIV proviruses persisting in GALT during long-term ART are more highly decayed than those detected in peripheral blood, suggesting a role for tissue-specific factors in enrichment in the proportion of decayed proviruses.

EPA049

Endogenous retrovirus expression distinguishes latent from actively infected cells in novel dual-reporter HIV latency model

J. Marston[1], K. Randall[2], Y. Elgabori[3], B. Singh[1], M. Bendall[1], D. Nixon[1]
[1]*Weill Cornell Medicine, Department of Medicine, New York, United States,* [2]*San Jose State University, San Jose, United States,* [3]*Connecticut College, New London, United States*

Background: While current antiretroviral drug therapies effectively inhibit the progression of HIV to AIDS, elimination of the virus is complicated by reservoirs of HIV in latently infected cells. Many studies have attempted to discern low levels of transcripts in cells which could both help identify a latent cell and inform on mechanisms which could be therapeutically targeted. Yet humans already have retroviruses in all their cells, which are normally silenced.
The full effect of human endogenous retroviruses (HERV) that are transcribed during HIV infection of CD4+ T-cells is unknown but analysis of the retrotranscriptome under these infection modalities could help uncover answers about HIV latency or infection.
Methods: Here, we utilize published bulk RNA-seq data from a novel dual-reporter HIV latency model and a bioinformatic tool, Telescope, to compare the differential expression of HERVs of peripheral blood mononuclear cells (PBMC) from donor-derived CD4 T-cells infected with HIV*in vitro*and fluorescently labeled and sorted as latently infected or actively infected cells.
Results: We show that HIV latent cells in this model have a unique retrotranscriptomic expression profile compared to actively infected cells, with a higher expression of diverse HERV families in latency. The HERVL, HERVE, HERVH and ERV316A3 families were enriched among upregulated HERV transcripts in latent cells and, specifically, HERVL74_17q12 was significantly upregulated in latently infected cells compared to actively infected.
Only three HERV transcripts were significantly upregulated in the actively infected cells in comparison to latent cells.
Conclusions: This endogenous retrovirus expression signature in latent cells may aid in efforts to identify a unique marker of an HIV infected latent cell, and better understand the mechanisms by which integrated retro-

Tissues as tools in HIV-1 cure research

J. Crater[1], K.L. Newcombe[1], L.P. Iñiguez[1], S. Avila[2], P.M. Del Río Estrada[2], D. Copertino[1], M. De Mulder Rougvie[1], R. Singhania[1], X. Tang[1], T. Premeaux[1], S. Valente[1], H.A. Fine[1], R.E. Schwartz[1], S. Chen[1], L. Ndhlovu[1], D.F. Nixon[1], R.L. Furler[1]
[1]*Weill Cornell Medicine, Department of Medicine, New York, United States,* [2]*Centro de Investigaciones en Enfermedades Infecciosas, Mexico City, Mexico*

Background: Persistent HIV reservoirs that reside within human tissues are a major hurdle in the fight against HIV. Although peripheral blood analysis and animal models are highly utilized and necessary, human tissues and organoids may provide a more physiological model to study HIV and bridge classic *in vitro* experiments to human HIV-1 clinical trials.

Methods: We have developed several tissue explant and iPSC-derived organoid models that can be productively infected with HIV-1 and suppressed with ART to model latency. Human tonsil explants, iPSC derived CNS, hepatocyte, and colon organoids were each infected with HIV-1 and Gag p24 protein production was measured over time.

In addition to our tissue modeling of HIV latency, we used the 10X Visium platform to spatially characterize the transcriptomic profile of persistent HIV reservoirs in two primary human lymph nodes from ART-suppressed PLWH.

Results: We have been able to establish productive HIV-1 infection and latency in four human tissue explant or iPSC-derived organoid models representing lymphatic, central nervous system, colon, and hepatocyte tissues. Colon organoids were found to be infectable without monocyte coculture, while the CNS organoids required either microglia or monocyte incorporation to establish productive infection. HIV-1 infected hepatocyte + monocyte cocultures showed an altered response to ARVs when compared to the mock infected condition.

In the spatial transcriptomic analysis of primary human lymph nodes, checkpoint inhibitors were upregulated in younger participants regardless of HIV status, while pro-inflammatory markers were upregulated in lymph nodes from the older participant.

Conclusions: Our novel human organoid and tissue explant models show productive HIV-1 infection and ARV-induced latency. Our future direction for these models are to test HIV-1 Cure strategies and characterize the latent reservoir in greater detail using these models. Molecular characterization and biomarker identification of persistent HIV reservoirs that reside within human tissues has been a major hurdle in the fight against HIV.

To address this, we analyzed human lymph nodes using the novel 10X Visium platform to spatially characterize the transcriptomic profile of persistent HIV reservoirs in human lymph nodes. Future directions for this project include adding HIV-1 DNAscope to pinpoint cells with integrated provirus.

EPA051
A new in-vitro model to monitor HIV-1 proviral transcription by Timer-fluorescence protein

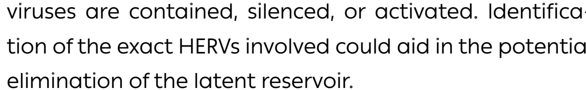
O. Reda[1,2], K. Monde[3], K. Sugata[1], A. Rahman[1], W. Sakhor[1], B. Jy Tan[1], M. Matsuo[1], H. Takeuchi[4], M. Ono[5], Y. Satou[1]
[1]*Kumamoto University, Joint Research Center for Human Retrovirus Infection, Division of Genomics and Transcriptomics, Kumamoto, Japan,* [2]*Alexandria University, High Institute of Public Health, Microbiology, Alexandria, Egypt,* [3]*Kumamoto University, Microbiology Department, Kumamoto, Japan,* [4]*Tokyo Medical and Dental University, Department of Molecular Virology, Tokyo, Japan,* [5]*Imperial College London, Department of Life Sciences, London, United Kingdom*

Background: HIV-1 persistence under umbrella of ARTs is linked to its ability to integrate and maintain transcriptional silence which is not permanent; reactivation can occur spontaneously or by drug induction. Fluorescent reporters so far weren't able to explain the heterogenic nature of latent reservoir which hinders its elimination.

In this study, we utilized the unique fluorescent features of Timer protein; which spontaneously shifts its emission spectrum from blue to red; to capture the real-time dynamics of provirus silencing and reactivation.

Methods: We infected Jurkat and THP-1 cell lines with HIV-NL4-3 single-round construct equipped with Timer under 5'LTR control and quantified expression by flow cytometry. We performed limiting dilution to obtain single clones. Provirus integration and genetic environment were identified in clones and bulk infected cells by DNA-cap-seq and LM-PCR library high throughput sequencing respectively. We further utilized single clones to demonstrate provirus response to LRAs/LPAs.

Results: In Bulk infection, we were able to separate infected populations with de novo virus expression (Blue+), sustained expression (Blue+ Red+); from populations with arrested provirus transcription (Red+). By obtaining single clones, we observed strong heterogeneity in provirus expression by timer pattern both within and between clones. By provirus sequence and integration characterization, we identified one clone with provirus integrated in an active transcribed gene but with low basal timer expression and other clone with high basal expression



and a provirus integrated in silenced gene. This encouraged us to further employ them for visualizing provirus response to LRAs/LPAs. With LRAs, besides expected provirus reactivation in both clones, we observed accumulation of (Red+) population across time, which may denote the generation of transiently inducible population.
With LPAs treatment, we observed clear suppression of provirus expression by loss of (Blue+) and appearance of (Red+) populations before reaching final provirus silence. To better characterize (Red+) population, we analyzed integration characteristics for this peculiar population from bulk infection. A tendency of provirus integration in low expressing genes was noticed and under further confirmation.
Conclusions: In summary, we describe a distinctive HIV-1 latency model which can precisely address the heterogenous nature of latent reservoir and offers a new scope for evaluating eradication strategies.

Background: Comprehensive understanding of archived HIV proviral DNA in different cellular reservoirs is essential to durable HIV eradication. The lung remains an understudied site of HIV persistence. We characterized proviral diversity and compartmentalization in blood and broncheoalveolar lavage (BAL) during long-term ART.
Methods: Subgenomic single-genome HIV sequences (*nef*) were collected from matched blood, BAL, and plasma (where available) from 9 individuals with suppressed viremia on ART. Markov chain Monte Carlo methods were used to infer 7500 within-host phylogenies/participant. Diversity metrics were calculated from the highest-likelihood phylogeny.
Genetic compartmentalization was assessed using Hudson, Boos and Kaplan's nonparametric test(K_{ST}), Analysis of Molecular Variance (AMOVA), and the Slatkin-Maddison (SM) test, with the latter conditioned over all trees.
Results: We isolated1025 proviral (*nef)*sequences from blood (N=788) and BAL (N=237). Of these, 882 (86%) were genetically intact and non-hypermutated, yielding medians of 78 (Q1-Q3=58-90) and 14 (Q1-Q3=6-37) intact sequences/individual for blood and BAL, respectively. Consistent with clonal expansion, 331/882 (38%) intact sequences were identical to another collected, where 7/9 individuals harbored at least one shared sequence across blood and BAL. Identical sequences represented ≥50% of 3 participants' proviral pools; for others, most sequences were unique.
Overall, diversity of unique proviral sequences in blood reflected that in BAL (Spearman's r=0.85, p=0.006). Considering unique sequences/compartment, strong evidence for compartmentalization, defined as statistically significant support in 2/3 tests, was observed for one participant.
Considering all sequences, the number of participants with compartmentalization rose to four. For two participants we also isolated 164 unique HIV RNA (*nef)*sequences from longitudinal historic off-ART plasma samples. Unique plasma and on-ART proviral (blood/BAL) sequences were strongly compartmentalized in both participants, with opposing trends.
For one participant, plasma viruses constituted a subset of proviral diversity, whereas for the other, for whom plasma was sampled over a >12-year period, proviruses predominantly interspersed with more recent plasma sequences.
Conclusions: Results reveal limited genetic compartmentalization between proviruses persisting in blood and lung during long-term ART. Presence of shared HIV sequences in blood and lung is consistent with migration of clonally-expanded reservoir cells between sites. Eradication strategies will need to contend with genetically diverse HIV in blood and tissues.

EPA053
The impact of CoVID-19 on the proviral landscape of ART-treated individuals

R. Hua[1], A. Niesar[1], C. Gao[1], E. Parsons[1], N. Miranda[1], X. Yu[1], S. Deeks[2], M. Peluso[2], T. Henrich[2], M. Lichterfeld[1]
[1]Ragon Institute, Cambridge, United States, [2]UCSF, San Francisco, United States

Background: Anti-retroviral therapy (ART) suppresses HIV replication but is unable to eliminate HIV-infected cells harboring chromosomally-integrated proviruses. Immune activation may induce HIV-1 transcription and increase the vulnerability of infected cells to host immune effects.
CoVID-19 can be associated with profound immune activation and may possibly affect the frequency or composition of the HIV-1 reservoir cell pool.
Methods: Five HIV-1 patients from whom PBMC samples were available before and after documented, mild-to-moderate CoVID-19 infection were included in the study.
The average interval between both sampling timepoints was 1.6 years. Proviral sequences were identified by single-genome, near full-length next-generation sequencing (FLIP-seq). Chromosomal integration sites of proviruses were determined using matched integration site and proviral sequencing (MIP-Seq), according to a previously described protocol.

Results: In total, 306 sequences were analyzed from pre-CoVID-19 timepoints and 358 sequences from the post-CoVID-19 timepoints. An average of 867.49 and 1382.54 total copies of HIV-1 DNA/million PBMCs were detected before and after CoV2-infection, respectively.
Moreover, 32.62 intact HIV DNA copies/million PBMCs were detected at the pre-CoVID-19 timepoint and 38.82 intact HIV DNA copies/million PBMCs were detected at the post-CoVID-19 timepoint. 9.35% of proviruses were genome-intact before infection and 6.32% were intact after infection.
Similarly, the proportion of proviruses with defined structural defects did not significantly change during the two study timepoints. Proviral integration sites were detected for n=37 proviruses before infection and n=21 proviruses detected after infection. 13.5% of proviruses were integrated into non-genic genomic areas before CoV2-infection and 14.29% were integrated into non-genic areas after infection.
Among intact sequences, 20% integrated into non-genic areas before infection and 37.50% integrated into non-genic areas after infection (p = n.s.).
Conclusions: We do not find evidence that moderate COVID-19 infection influences the viral reservoir in a significant way. The results emphasize the longitudinal stability of the HIV-1 reservoir and suggest that immune activation associated with CoVID-19 does not notably influence the HIV-1 reservoir profile.

EPA054

Memory CD4 T cells from the liver are infected during SIV infection in Rhesus Macaques

J. Clain[1], J. Dewatines[1], H. Rabezanahary[1], G. Racine[1], O. Zghidi-Abouzid[1], J. Estaquier[1]
[1]*Centre de Recherche du CHU de Québec-Université Laval, Quebec, Canada*

Background: Despite the introduction of highly active antiretroviral therapy, HIV infection continues to be a major global public health issue as a chronic disease. The liver has been shown to be an HIV-infected organ causing liver disease and co-morbidity in HIV-infected individuals.
We have established a model of Rhesus Macaque infected with SIV, taking the opportunity to analyze more in deep the nature of infected cells in the liver. Herein, we specifically assessed the role of CD4+ T cells.
Methods: Rhesus Macaques (RMs) were infected with the SIVmac251 (20 AID50). RMs were sacrified at different times post-infection and cells from the liver were recovered. CD4+ T cells were stained with specific antibodies and analyzed by flow cytometry. Cell sorting was used to isolate CD4 T cells and to quantify the frequency of viral DNA and RNA.
Results: First, we observed that the frequency of CD4T cells was lower in SIV-infected RMs (12%) in comparison to healthy RMs (31%). After cell staining, we found that more than 40% of CD4 T cells expressed CCR5, a chemokine receptor used by SIV to infect the cells, in comparison to 8% in the blood. The majority of these cells are memory CD4 T cells (CD45RAneg and CD62Lneg). The phenotype of these cells indicated a specific phenotype of CD4 liver cells and not only a contamination from blood CD4 T cells.
After cell sorting, we found that liver CD4+ T cells are infected cells. In comparison to CD4 T cells from the blood, the levels of viral DNA in the liver are similar.
Conclusions: Altogether, our results indicated that CD4 T cells from the liver of SIV-infected RMs could be a possible viral reservoir. Further analyses are in progress to assess the extent of viral infection of CD4 T cells under ART.

EPA055

Characterization of Hiv-1 intact and near-full length defective proviral populations during long-term suppression on antiretroviral therapy

T. Nguyen[1], L. Adams[1], M.-E. Zipparo[1], E. Madeen[1], U. Santamaria[2], C. A Rehm[3], J. Earhart[1], S. Hill[1], C.-Y. Lau[1], F. Maldarelli[1]
[1]*National Cancer Institute, National Institutes of Health, HIV Dynamics and Replication Program, Frederick, United States,* [2]*Leidos Biomedical Research, Inc., Frederick National Laboratory for Cancer Research, Frederick, United States,* [3]*Clinical Research Section, National Institute of Allergy and Infectious Diseases, Bethesda, United States*

Background: The persistence of the HIV-1 reservoir is a barrier to cure. The differential decay rate of replication-competent (intact) and -incompetent (defective) proviruses during antiretroviral therapy (ART) suggests selective pressures of therapy and the immune system on the reservoir.
To investigate the role of ART in shaping the proviral landscape, we performed a comparative analysis of intact and near-full length (NFL) defective proviruses using samples obtained prior to and following long-term ART.
Methods: Peripheral mononuclear blood cells were collected longitudinally from 9 participants at pretherapy (n=8) and multiple timepoints during ART (n=17, 0.5-20 years on ART). We amplified single genomes of near full-length (NFL) proviruses and sequenced fragments > 7kb by Illumina MiSeq.
Viral population structure of intact vs NFL defective proviruses from pretherapy and long-term ART samples was assessed by phylogenetic analysis, average pairwise distance (APD), tests for population subdivision (panmixia, p <10^-6 and Slatkin Maddison, p<0.05). Hypermutated sequences were removed, and identical sequences were collapsed prior to the above analyses.
Results: We obtained 950 NFL proviruses (348 intact, 602 defective) from all participants. The median proportion of intact/total PCR-amplified proviruses was 17.56% at pretherapy and 1.63% during ART. Identical intact proviruses were detected in 0-12.50% of the proviral populations at

pretherapy and 0-73.68% on ART while identical NFL defective proviruses were present in 0-11.11% of the populations at pretherapy and 0-50.00% on ART.
No significant differences in diversity were found between intact and NFL defective populations at pretherapy vs long-term ART in any participant; median APD was 1.66% at pretherapy vs 0.63% on ART for intact proviruses while it was 1.87% vs 0.71% for defective proviruses.
Comparing the structure of proviral populations between pretherapy and during ART, two participants harbored distinct intact populations while two others harbored distinct NFL defective populations.
Conclusions: We observed similar frequencies of identical sequences in intact and NFL defective HIV-1 proviruses at pretherapy and during ART; distinct intact and NFL defective proviral populations from pretherapy to long-term ART were present in several participants.
The differential decay rate of intact and defective proviruses is not explained by either the composition of the viral genome or by ART alone.

EPA056
An ultrasensitive planar array p24 Gag ELISA to detect HIV-1 in diverse biological matrixes

C. Levinger[1], J.N. Howard[1], J. Cheng[2], A. Joshi[3], M. Catalfamo[2], A. Bosque[1]
[1]The George Washington University, Washington, United States, [2]Georgetown University, Washington, United States, [3]Quanterix Corporation, Massachusetts, United States

Background: Human Immunodeficiency virus-1 (HIV-1) persistence in the presence of antiretroviral therapy (ART) has halted the development of curative strategies. Most available assays to measure HIV persistence are nucleic acid-based, however they are limited in measuring translational competent viral reservoirs.
We have developed an ultrasensitive p24 ELISA assay that can aid in the detection of translational competent viruses in HIV cure approaches.
Methods: We used a homebrew planar array ELISA to optimize an ultrasensitive p24 ELISA. We used two HIV p24 antibodies and a p24 antigen standard to optimize the assay in different biological matrixes, including Quanterix assay diluent; commercially available human breast milk, cerebrospinal fluid (CSF), tissue culture media, and plasma with six different anticoagulants; and cell lysates from HIV-infected primary CD4T cells. We validated the assay using cells isolated from people living with HIV (PLWH)
Results: Our results demonstrate that the homebrew p24 ELISA has a limit of detection (LOD) for HIV p24 of 2.3+/-1.9 fg/ml in assay diluent. The assay can be performed directly in breast milk (LOD=2.5+/-1.9 fg/ml), CSF (LOD=5.9+/-4.9 fg/ml), RPMI plus 10%FBS (LOD=8.1+/-6 fg/ml) or RPMI plus 10%hiFBS (LOD=6+/-4.5 fg/ml) without major loss of sensitivity or reproducibility. Human serum can influence the sensitivity of the assay both alone (LOD=144+/-125 fg/ml) or when in tissue culture media (LOD=251+/-259 fg/ml). Among the plasmas tested, K2EDTA plasma has the lowest LOD of 12+/-14.4 fg/ml.
Using cell lysates, the assay could detect an individual infected cell expressing p24 in 500,000 uninfected CD4T cells. Finally, this assay also detects p24 in supernatants and cell lysates from cells isolated from PLWH.
Conclusions: The homebrew p24 ELISA allows the detection of HIV p24 in different biological matrixes, including breast milk, CSF, tissue culture media, plasma and cell lysates with limited amount of sample (50 ml/sample).
The results also show that this assay can detect as low as a single HIV viral particle in these biological matrixes. As such, this assay could be used to evaluate cure strategies such as "shock-and-kill" to measure HIV-1 Gag expression in diverse biological fluids and cell lysates after LRA administration when limited sample is available.

EPA057
Viral genome-intactness bioinformatics for subtype A1 and D HIV-1

P. Khadka[1], R.B. Jones[1], Z. Brumme[2,3], J. Kasule[4], T. Kityamuweesi[4], P. Buule[4], S. Reynolds[5,6], T. Quinn[5,6], J. Prodger[7], A.D. Redd[5,6], G.Q. Lee[1]
[1]Weill Cornell Medical College, Department of Medicine, Division of Infectious Diseases, New York, United States, [2]Simon Fraser University, Burnaby, Canada, [3]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [4]Rakai Health Sciences Program, Kalisizo, Uganda, [5]National Institute of Allergy and Infectious Diseases, Division of Intramural Research, Bethesda, United States, [6]Johns Hopkins University School of Medicine, Department of Medicine, Baltimore, United States, [7]Western University, Department of Microbiology and Immunology, London, Canada

Background: To determine whether a HIV-1 DNA genome is intact, automated bioinformatics pipelines such as HIVSeqinR were previously developed using subtypes B and C data (Lee GQ Nat Comm 2019). Here, we evaluate this pipeline for subtype A1 and D HIV-1 DNA genome-intactness determination.
Methods: Blood samples were collected from 23 Ugandans with chronic HIV-1 infection, representing subtypes A1, D, and recombinant forms. DNA extracted from CD4$^+$ cells was limiting diluted, subjected to HIV-1-specific nested PCR (HXB2 638-9632) and Illumina sequenced.
Four components in HIVSeqinR that had subtype-sensitive parameters were evaluated: NCBI BLAST+, an in-house adaptation of web tool Hypermut 2.0, definition of premature stop codons, and definition of psi defects.
Results: We evaluated 1022 *de novo* assembled PCR-derived sequences. BLAST+ was used to screen out non-HIV-amplicons: The use of reference HXB2 (subtype B, default) identified 721/1022, whereas subtype A1 and D references identified 731 and 709 as HIV-1 respectively. Discordant cases were 144-5055 nucleotides in length, contained

Oral abstracts

Poster exhibition

E-posters

Author Index

large truncations, and were not candidates for genome-intactness. An in-house adaptation of Hypermut 2.0 was used to identify APOBEC-3G/3F-associated hypermutations. Regardless of the reference used (A1, B default or D), genomes identified as hypermutated were 100% concordant.

At default settings, a genome was defined as defective with premature stop codons if the translated amino acid sequences of *gag*, *pol* and/or *env* were <95% of the expected length of the subtype B reference. In subtype A1 and D, the consensus translated lengths of *gag*, *pol* and *env* were >=95% of the subtype B reference, suggesting this cut-off was appropriate.

Also at default settings, a psi region is considered defective if it contains >=15 nucleotides insertion/deletion relative to HXB2. The use of both A1 and D psi reference sequences produced results 100% concordant with B after subtype-matched manual evaluations.

Conclusions: HIVSeqinR achieves bioinformatics automation for genome-intactness determination. This study provides evidence that this pipeline previously optimized for subtype B and C is compatible with subtype A1 and D. Future studies should apply this pipeline, which is freely available in GitHub, to evaluate reservoir characteristics of subtype A1 and D infections to inform HIV cure research.

Strategies to reduce/eliminate viral reservoirs

EPA058

Rufinamide-induced autophagy cell death in HIV-1-infected macrophages

M. Reece[1], N. Bowen[2], L. Ramirez[2], C. Gavegnano[1], B. Kim[2]
[1]*Emory University, Department of Pathology and Laboratory Medicine, Atlanta, United States,* [2]*Emory University, Department of Pediatrics, Atlanta, United States*

Background: The major barrier to HIV cure is the HIV-1 reservoir. Macrophage reservoirs contribute to HIV-1 persistence including reservoir reactivation and reseeding, disease progression, and comorbidities in people living with HIV, including HIV-associated neurocognitive disorders, and cardiovascular disease. Unlike dividing CD4+ T cells, which experience rapid cell-death due to accelerated viral replication, macrophages experience slow viral replication kinetics, and do not die upon HIV-1 infection.

We hypothesized that accelerating HIV-1 replication in macrophages would result in cell-death of only infected macrophages, decaying the reservoir.

Methods: We launched a screening campaign of > 2700 agents (FDA approved/Phase 3) to identify agents that increase viral replication kinetics and confer cell-death only to infected macrophages (flow-cytometry). Data were confirmed using a replication competent HIV-1 (89.6).Toxicity across relevant human uninfected cells were measured (flow-cytometry). Measure of effect of identified agents on SAMHD1 and dNTP were measured (western blots). Death markers were measured (flow-cytometry). Autophagosomes were visualized (electron microscopy; EM).

Results: We identified rufinamide, a blood-brain-barrier penetrant, FDA approved agent that specifically kills only infected macrophages, including newly established infection and already-existing infection, without toxicity to uninfected macrophages or other relevant human cells. Rufinamide does not increase dNTP levels or SAMHD1/pSAMHD1, implying the phenotype is not related to increase in dNTP pools. Impact of HIV-1 accessory protein *Vpr* was evaluated due to known role in toxicity/cell-death. A *Vpr* deletant HIV-1 replication kinetics were not affected by rufinamide, indicating *Vpr* plays a role in the cell-death phenotype induced by rufinamide. Autophagosomes were observed via EM in rufinamide-treated HIV-vector treated macrophages, as were autophagy markers including Beclin-1, demonstrating autophagy as a contributing cell-death mechanism.

Conclusions: Rufinamide induces cell-death specific to HIV-1 infected macrophages, independent of SAMHD1 or dNTP levels. Autophagy is a mechanistic contributor.

These data are promising towards eventual human trials to purge the myeloid reservoir, given its repurposed status and existing body of safety in humans.

EPA059

Effect of novel latency reversal agents on transposable element expression profile in T-cell memory subsets of HIV clinical samples

G. Curty[1], L.P. Iñiguez[2], M.A. Soares[1], D.F. Nixon[2], M. de Mulder Rougvie[2,3]
[1]*Instituto Nacional de Cancer, Oncovirology Program, Rio de Janeiro, Brazil,* [2]*Weill Cornell Medicine, Division of Infectious Diseases, New York, United States,* [3]*Weill Cornell Medicine, Department of Genetic Medicine, New York, United States*

Background: A wide spectrum of drugs has been assessed as latency reversal agents (LRA) to reactivate HIV-1 from cellular reservoirs. However, LRAs can also affect expression of other genes. Therefore, we analyzed differential expression of transposable element (TEs) in CD4+ T-cells treated with LRAs.

Methods: We evaluated the effect of canonical and non-canonical NF-kB activation on TE expression through LRA treatment (PKC agonist (Bryostatin and Ingenol B) and SMAC mimetic (AZD5582)).

Briefly, we analyzed public datasets from studies using ex-vivo memory CD4 T-cell subsets, such as central memory (CM), transition memory (TM) and effector memory (EM) memory, from ART suppressed HIV infected individuals treated in vitro with LRAs. After 24h of LRA-treatment, RNA

was isolated and sequenced through Illumina platform. Datasets were downloaded from Gene Expression Omnibus and filtered for length and quality. Filtered reads were aligned to the human genome using Bowtie2 and analyzed for TE expression using Telescope.
Differential expression analysis was performed with DESeq2 and TE with adjusted p-values <0.05 and absolute log2FoldChange > 1.5 were considered differentially expressed.
Results: EM cells were more affected by Bryostatin compared to other T-cell subsets, with 121 (107 upregulated and 14 downregulated) differentially expressed (DE) TEs. Of these, 31% (n=37) were HERVs, and 69 % (n=84) were LINE-1 (L1) sequences. In contrast, we found three full-length HERV (HML2_14q11.2, HML3_5p15.33b and HML3_Xq13.3 loci) exclusively upregulated in CMcells treated with Bryostatin.
In addition we also analyzed memory CD4 T-cell treated with AZD5582 and Ingenol B. Treatment with Ingenol B induced a total of 39 DE TEs (21 L1 (55%)and 17 HERV (45%)). About AZD5582 treatment, we found a total of 753 DE TEs (406 HERV (54%) and 347 L1 (46%)). Eight HERV families (Harlequin, HERVE, HERVI, HERVL, HERVS, HUERS, LTR, PAB) were exclusively regulated by AZD5582 treatment. PRIMA41_19q13.2a and PRIMA41_19q13.2b loci were upregulated in both AZD5582 and Ingenol B treatment.
Conclusions: Our findings suggest that new LRAs may have off-target effects on the expression of TEs and impact the T-CD4 phenotype, which may be used as a biomarker to eliminated target HIV reservoir.

EPA060
Off-target effects on retroelement expression in T-cells Treated with Histone deacetylase inhibitors

G. Curty[1], L.P. Iniguez[2], D.F. Nixon[2], M.A. Soares[1], M. de Mulder Rougvie[2,3]
[1]Instituto Nacional de Cancer, Oncovirology Program, Rio de Janeiro, Brazil, [2]Weill Cornell Medicine, Division of Infectious Diseases, New York, United States, [3]Weill Cornell Medicine, Department of Genetic Medicine, New York, United States

Background: A wide spectrum of drugs have been assessed as latency reversal agents (LRA) to reactivate HIV-1 from cellular reservoirs and aid in viral eradication strategies. Histone deacetylase inhibitors (HDACis) have been studied *in vitro* and *in vivo* as potential candidates for HIV-1 latency reversion. Suberoylanilide hydroxamic acid (SAHA) and romidepsin (RMD) are two HDACis able to reverse HIV latency, however studies of potential off-target effects on retroelement expression have been limited.
Methods: In this study, we analyzed differential expression of retroelements using public RNA-seq datasets obtained from uninfected CD4+, and HIV-1 latently infected CD4+ T-cells treated with HDACis (SAHA and RMD). Datasets were downloaded from the Gene Expression Omnibus and filtered for length and quality. Filtered reads were aligned to the human genome using Bowtie2 and analyzed to retroelements expression using Telescope. Differential expression analysis was performed with DESeq2 and retroelements with adjusted p-values < 0.05 and absolute log2FoldChange > 1.5 were considered differentially expressed.
Results: We found a total of 712 and 1,380 differentially expressed retroelements in HIV-1 latently infected cells following a 24-hour SAHA and RMD treatment, respectively. Furthermore, we found that 531 retroelement sequences (HERVs and L1) were differentially expressed under both HDACi treatments, while 1,030 HERV/L1 were exclusively regulated by each drug.
Furthermore, we analyzed the link between differentially expressed retroelements and nearby immune genes. TRAF2 (TNF receptor) and GBP5 (inflammasome activator) were upregulated in HDACis treated samples and their expression was correlated with nearby HERV (MERV101_9q34.3) and L1 (L1FLnI_1p22.2k, L1FLnI_1p22.2j, L1FLnI_1p22.2i).
Conclusions: Our findings suggest that HDACis have an off-target effect on the expression of retroelements and on the expression of immune associated genes in treated CD4+ T-cells.
Furthermore, our data highlights the importance of exploring the interaction between HIV-1 and retroelement expression in LRA treated samples to understand their role and impact on "shock and kill" strategies and their potential use as reservoir biomarkers.

Nanoparticle delivery of romidepsin to reverse HIV latency

A. Ali[1], M. Roche[1], C. Jugo-Cortez[2], P. Cevaal[1], D. Purcell[1], F. Caruso[2], J. Symons[1,3], S. Lewin[1]
[1]The University of Melbourne / The Peter Doherty Institute for Infection & Immunity, Department of Infectious Diseases, Melbourne, Australia, [2]The University of Melbourne, Department of Chemical Engineering, Melbourne, Australia, [3]Utrecht University / University Medical Center Utrecht, Department of Medical Microbiology, Utrecht, Netherlands, the

Background: One strategy to eliminate latently infected CD4+ T cells in people living with HIV on antiretroviral therapy (ART) is to reactivate virus expression using latency-reversing agents (LRAs). However, this strategy (often called „shock and kill") has demonstrated limited efficacy both *in vitro* and *in vivo* based on high toxicity combined with low potency and the failure to reduce reservoir size. One approach to increase the potency and reduce toxicity of LRAs is to use a nanoparticle (NP) delivery system.
Methods: We developed a biopolymer nanocarrier system using polymethacrylic acid (PMA_{SH}) to encapsulate the hydrophobic LRA romidepsin (RMD) (RMD-NPs). The

Oral abstracts

latency reversal potential and toxicity profile of RMD-NPs was compared to free RMD in T cell-line models of HIV latency, including J-Lat A2 and J-Lat 10.6. Activation of the LTR was measured by green fluorescent protein (GFP) expression using flow cytometry. Cell viability was quantified using an ATP-based chemiluminescent assay.

Results: In the J-Lat A2 cell line, RMD-NPs compared to free RMD displayed a similar potency [mean GFP expression = 73 and 82% respectively] and toxicity profile [mean viability = 36 and 29% respectively].

In contrast, in the HIV J-Lat cell line 10.6, which contains near full length HIV, RMD-NPs compared to free RMD significantly enhanced potency of LTR activation [mean GFP expression = 53 and 22% respectively, p= 0.0253 unpaired t test] and markedly reduced toxicity [mean viability = 100% and 1.4%, respectively, p= 0.0001 unpaired t test].

Conclusions: We have demonstrated in a T cell line model of HIV latency that encapsulation of the LRA romidepsin can lead to enhanced latency reversal with reduced toxicity.

Further studies are necessary to investigate the mechanism behind this effect and whether similar results are found in CD4+ T cells from people living with HIV *ex vivo.*

EPA062

Gamma/Delta T cells target latently HIV-infected non-T cell reservoirs

M. Sanz-Perez[1], A. Chitrakar[1], B. Mann[1], S. Maggirwar[1], N. Soriano-Sarabia[1]

[1]*George Washington University, Microbiology, Immunology, and Tropical Medicine, Washington DC, United States*

Background: The "shock and kill" strategy for HIV cure requires approaches to induce immune responses against reactivated latently HIV-infected cells. The most abundant peripheral gamma/delta (γδ) T cell population (Vδ2 cells) can be expanded *in vitro* using aminobisphosphonates that induce their specific activation.

We previously demonstrated Vδ2 cell ability to recognize and kill reactivated CD4 T cell reservoirs. HIV-infected monocytes may exhibit an intrinsic resistance to apoptosis, although their susceptibility to Vδ2 cells killing is unknown. We hypothesized that *in vitro*expanded Vδ2 cells will clear non-T cell reservoirs.

Methods: We used aminobisphosphonate and IL-2 to expand Vd2 cells from 6 uninfected donors for 14 days. Cells were then FACS-sorted to high purity (>99%). Cytotoxic phenotype of expanded Vδ2 cells (CD16 and CD56) and Granzyme production was analyzed.

U1 cells (Latently HIV-infected monocytic cell line) were exposed to phorbol myristate acetate (PMA) to reverse latency and were cocultured with or without expanded Vδ2 cells at 1:1 and 1:5 [Effector:Target] ratios for 18 hours. Vδ2 cell-mediated U1 cell killing was analyzed by measuring intracellular HIV-p24 production and viability by flow cytometry.

Results: Mean basal CD3+Vδ2 cell frequency was 2.3% compared to 26.8% post-expansion (p=0.002). Expanded Vδ2 cells displayed increased expression of cytotoxic markers CD16 and CD56 and GrzB production. Upon reactivation, mean HIV-p24 in U1 cells cultured alone was 68.3% and was reduced to 34.6% when Vδ2 cells were co-cultured at a 1:1 ratio (p=0.004). Viability of U1 cells was 81.9% and was reduced to 42.1% in the presence of Vδ2 cells (p=0.004). No difference was detected at 1:5 ratio (Mann Whitney U-test). The decrease in HIV-p24 production from reactivated U1 cells (%DHIVp24 (U1 alone - U1+Vδ2 cells) inversely correlated with the frequency of Vδ2+CD16+ cells (r=-0.9, p=0.02, Spearman's correlation).

Conclusions: *In vitro*expansion of Vδ2 cells induced expression of cytotoxic markers and increased Granzyme B production. Vδ2 T cells targeted and killed reactivated U1 cells, as demonstrated by decrease in both intracellular HIV-p24 production and survival.

Our study shows the capacity of Vδ2 cells to clear non-T cell HIV reservoirs and expands on their role as an alternative immunotherapy option for HIV cure.

Background: Immune exhaustion is a major cause for the failure of Shock & Kill strategy in people with HIV (PWH). In vivo treatment with tyrosine kinase inhibitors (TKIs) induce functional cytotoxic populations that are able to control residual cancer cells in individuals with chronic myeloid

leukemia (CML). PWH with CML on ART and dasatinib or imatinib show a very small reservoir size. Our objective was to determine whether TKIs may induce the development of responsive cytotoxic cell populations in PWH.

Methods: 34 PWH on ART and 6 PWH with CML on ART and dasatinib (n=3) or imatinib (n=3) were recruited for this study. Ten healthy donors were also recruited as controls. Cell proliferation was measured with CFSE for 6 days with or without dasatinib (75nM) or imatinib (10µM). Direct cellular cytotoxicity (DCC) was measured using K562 as target. IFNγ, TNFα, and granzyme-B (GZB) secretion was measured after Hsp70 (NK) or CD28/CD49D (CD8) stimulation.

Results:

1. Most PWH were males in ART and ART+TKI groups (78.6% and 100%, respectively).
2. Dasatinib in vitro induced a potent cytostatic effect on CD4 from PWH on ART and healthy donors, whereas NK cells were expanded and large granular cell populations with cytotoxic phenotype (CD3±CD56+; CD3+CD8±TCRgd+) were developed after 24h in both groups. Imatinib did not modify cell proliferation in vitro.
3. PBMCs from PWH on ART+TKI showed CD56+ NK cells increased 1.7-fold, whereas the expression of inhibitory receptors KIR2DL5 and NKG2A was reduced 7.4-(p=0.0005) and 2.7-fold (p=0.0350), respectively, in comparison with PWH on ART. NK cells with memory phenotype (CD56+CD57+) were also increased (1.3-fold;p=0.0047).
4. DCC against NK-target K562 cells was increased (1.4-fold;p=0.0424) in PWH on ART+TKI.
5. IFNγ, TNFα, and GZB secretion was increased 14.0-(p=0.0043), 1.3-(p=0.043), and 1.2-fold, respectively, in NK from PWH on ART+TKI, whereas TNFα secretion by Hsp70-stimulated NKT cells was increased 3.0-fold (p=0.0476) in PWH on ART+TKI

Conclusions: Despite immune exhaustion characteristic of chronic HIV infection, PWH on ART+TKI showed increased levels of functional cytotoxic cells with NK and TCRgd phenotypes that support using TKIs as adjuvants of ART during Shock & Kill to advance towards an HIV cure.

EPA064

Broadly neutralizing HIV-1 antibodies as a PrEP modality among young sexual minority men: a conjoint experiment

J. Bauermeister[1], W. Lin[1], P. Valente[2], R. Drab[1], D. Teixeira da Silva[3], L. Hightow-Weidman[4], K. Mayer[5], K. Biello[2]

[1]University of Pennsylvania, Family and Community Health, Philadelphia, United States, [2]Brown University, Providence, United States, [3]University of Pennsylvania, Philadelphia, United States, [4]University of North Carolina - Chapel Hill, Chapel Hill, United States, [5]Fenway Health & Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, United States

Background: End-user perspectives are vital to the design and implementation of emergent Pre-Exposure Prophylaxis (PrEP) modalities. ATN 141a (Next Choices) used a conjoint experiment to evaluate young men who have sex with men's (YMSM; ages 15-24) hypothetical acceptability of broadly neutralizing HIV-1 antibodies (bnAb) as a PrEP formulation.

Methods: We enrolled 150 HIV-negative YMSM in the U.S. into in an online conjoint experiment. YMSM completed the bnAb experiment, selecting between random sets of product profiles using 6 features (delivery time: 30 minutes, 1 hour, 2 hours, and 3 hours; duration of protection: 1, 2, 3, 6 and 12 months; prevention efficacy: 50%, 65%, 80%, 95%, and 99% efficacious; potential side effects: none, soreness at injection site, fever, fatigue, nausea, and weight gain; cost per month in US dollars: $0, $25, $50, $100, $150). A subset of participants completed a follow-up in-depth-interview (IDI; n=10) to discuss their product preferences.

Feature	Level	Preference Share
Time for Delivery	3 hours	14%
	2 hours	24%
	1 hour	30%
	30 minutes	33%
Duration of protection	1 month	3%
	2 months	3%
	3 months	8%
	6 months	21%
	12 months	66%
Efficacy	50%	1%
	65%	1%
	80%	4%
	95%	23%
	99%	71%
Side Effects	None	46%
	Soreness at injection site	13%
	Fever	10%
	Fatigue	17%
	Nausea	9%
	Weight gain	6%
Average cost per month (in $US)	$0	64%
	$25	21%
	$50	9%
	$100	4%
	$150	2%

Table 1. YMSM preference for PrEP bnAb by feature.

Note. Preference share indicates the probability of choosing a level of the feature over another, after adjusting for all other components in the conjoint model.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Results: YMSM's most desired bnAB package would be delivered in 30 mins, confer 12 months of protection and have 99% efficacy, and result in no side effects. However, when asked to assign value across attributes, participants rated efficacy as the most important feature in a PrEP bnAb (40%), followed by cost (20%), side effects (19%), duration of protection (18%), and delivery time (3%). We then estimated YMSM's preference within each feature (see Table 1).

In IDIs, participants' assessment of PrEP bnAb acceptability was informed by the aforementioned features, personal considerations (e.g., income), and social context (e.g., access to care, stigma).

Conclusions: YMSM weighed the features of a bnAb differentially, offering insights into how product characteristics may affect its potential as a PrPE formulation for YMSM. While efficacy is the most valued component for bnAb, behavioral considerations regarding cost and side-effects should inform bnAb development given their potential impact on acceptability and future uptake.

Background: On demand pre-exposure prophylaxis (PrEP) in msm has not been evaluated in Africa and the dosing requirement for insertive sex is unknown. The CHAPS trial (NCT03986970) aims to optimize on-demand PrEP dosing for insertive sex for young men.

Methods: Phase 2 open-label, randomised controlled trial (RCT) in Uganda and South Africa of 144 HIV negative men aged 13-24yrs, randomized to one of 9 arms receiving F/TDF, F/TAF or no PrEP at 1 (2 tablets) or 2 (2+1 tablets) consecutive days, with final dose 5 or 21h prior to voluntary medical male circumcision. Foreskins explants were exposed to HIV-1_{BaL} at a high (HVT) or a more biological relevant, low viral titre (LVT); and dosed using the same oral PrEP drug 20h post-challenge. Infection was assessed in culture supernatants by p24 ELISA. TFV-diphosphate (TFV-DP) and emtricitabine-triphosphate (FTC-TP) levels were measured using LC-MS methods. Parallel PK/PD evaluation was performed in isolated PBMCs at VMMC. PrEP effect on foreskin tight junctions was assessed by western blot evaluation of claudin-1, occludin and zonula occludens-1. We present data from South Africa.

Results: Tissue TFV-DP concentrations were ~2-fold higher with F/TAF vs. F/TDF dosing (p=0.02). FTC-TP levels were ~10-fold higher than TFV-DP, and no significant differences were seen between regimens. TFV-DP levels were ~40% higher with 2+1 vs. 2 tablets F/TDF dosing. No TFV-DP dose accumulation was evident for F/TAF. Following *ex vivo* HIV-1_{BaL} challenge, greater decrease of p24 relative to control arm was observed with 2+1 than with 2 PrEP tablets dosing (F/TDF dosing: p=0.24 for HVT; 0.62 LVT; F/TAF dosing: p=0.12 for HVT; 0.39 LVT).

Further decrease was observed in PBMCs (F/TDF dosing: p=0.20 for HVT; 0.57 LVT; F/TAF dosing: p=0.07 for HVT; 0.57 LVT). Protection against LVT with F/TDF and F/TAF was similar. Tight junction proteins were not significantly affected.

Conclusions: Oral on demand PrEP dosing with 2 tablets of F/TDF or F/TAF from 5-21h before HIV-exposure provides *ex vivo* protection of foreskin tissue which increases with 2+1 dosing. PrEP efficacy should be evaluated in blood and mucosally. *Ex vivo* challenge studies in human foreskin explants may facilitate dosing requirements and evaluation of new drugs for PrEP.

EPA066

Mode of interaction of CD4-CD4i antibody hybrids to HIV-1 envelope glycoproteins

S.Y. Gong[1,2], D. Vézina[1,3], D.N. Nguyen[4], W.D. Tolbert[4], J. Richard[1,3], M. Pazgier[4], A. Finzi[1,2,3]

[1]*Centre de Recherche du CHUM, Montréal, Canada,* [2]*McGill University, Department of Microbiology and Immunology, Montréal, Canada,* [3]*Université de Montréal, Département de Microbiologie, Infectiologie et Immunologie, Montréal, Canada,* [4]*Uniformed Services University of the Health Sciences, Department of Medicine, Bethesda, United States*

Background: The human-immunodeficiency virus-1 (HIV-1) envelope glycoprotein (Env) trimer [$(gp120/gp41)_3$] is the only viral protein expressed on the surface of infected cells and virions. Env is a metastable complex sampling multiple conformations – the ground state, State 1, is a "closed" conformation resistant to antibodies (Abs) commonly present in infected individuals. Interaction with its

primary receptor CD4, present on the surface of host cells, triggers an intermediate conformation (State 2), which allows downstream rearrangement for engaging the co-receptors to "open" the Env (State 3) and mediate viral fusion. A conformation outside of the entry pathway (State 2A) has been recently described.

This conformation is susceptible to antibody-dependent cellular cytotoxicity (ADCC) and is stabilized in the presence of small molecule CD4 mimetics (CD4mc) together with two families of non-neutralizing Abs (nnAbs) recognizing CD4-induced (CD4i) epitopes of Env: the co-receptor binding site (CoRBS) and the Cluster A families.

We recently developed single Ab-based molecules using prototypic Abs from these families of CD4i Abs and extracellular domain of CD4 receptor (d1d2 domains), which recognize the "closed" Env and have neutralizing activity against different HIV-1 clades; but most importantly, they mediate potent ADCC against HIV-1-infected cells.

Methods: To gain a better understanding on how these conjugates engage the "closed" trimer, we used a "trimer mixing" approach by combining wild-type (wt) subunits with subunits impaired for CD4 or CoRBS Ab binding. Env recognition by Ab-CD4 hybrids was evaluated by flow cytometry.

Results: We found that the soluble-CD4 moiety of the hybrid molecules is responsible for triggering the conformational changes, which allows the subsequent exposure of the otherwise occluded vulnerable epitopes. These new molecules mediate ADCC against infected primary CD4+ T cells and are more potent than the combination of the different moieties (i.e. sCD4 and the respective CoRBS or Cluster A Abs).

Conclusions: Our study provides valuable information on the mode of action of this new family of molecules that represents a promising avenue for eradication strategies.

Small-molecule CD4-mimetic compounds expose vulnerable HIV-1 Env epitopes and contact the highly conserved aspartic acid 368

S. Ding[1], X. Zhao[2], D. Nguyen[3], T. Higgins[2], W.D. Tolbert[3], S.Y. Gong[1,4], R. Sherburn[3], D. Vézina[1,5], J. Richard[1,5], G.-G. Lepage[1], H. Medjahed[1], M. Mohammadi[6], C. Abrams[6], M. Pazgier[3], A.B. Smith III[2], A. Finzi[1,4,5]

[1]Centre de Recherche du CHUM, Montreal, Canada, [2]University of Pennsylvania, Department of Chemistry, School of Arts and Sciences, Philadelphia, United States, [3]Uniformed Services University of the Health Sciences, Infectious Disease Division, Department of Medicine, Bethesda, United States, [4]McGill University, Department of Microbiology at Immunology, Montreal, Canada, [5]Université de Montréal, Département de Microbiologie, Infectiologie et Immunologie, Montreal, Canada, [6]Drexel University, Department of Chemical and Biological Engineering, Philadelphia, United States

Background: The HIV-1 envelope glycoprotein (Env) trimer mediates virus entry into cells. The "closed" conformation of Env is resistant to non-neutralizing antibodies (nnAbs). Small-molecule CD4 mimetics (CD4mc) such as BNM-III-170 and MCG-IV-210 sensitize HIV-1-infected cells to antibody-dependent cellular cytotoxicity (ADCC) mediated by nnAbs present in plasma from infected individuals.

Structural studies revealed that the new family of MCG-IV-210 CD4mc derivatives bind within the CD4 receptor-binding, Phe43 cavity in close proximity to the highly-conserved Asp^{368} residue in HIV-1 Env but without establishing a direct contact to the α-carboxylic acid group.

We speculated that further optimized MCG-IV-210 analogs capable of forming H-bonds with Asp^{368} could gain breadth and ADCC potency.

Methods: We optimized MCG-IV-210 piperidine nitrogen substituent to develop new CD4mcs. High resolution structures of complexes formed by new analogs and a $gp120_{CRF01_AE}core_{e}$ were solved by X-Ray crystallography to provide insight into interactions within the CD4-binding cavity and Asp CD4-binding cavity in close proximity to the highly-conserved Asp^{368}. Their capacity to neutralize viral particles or sensitize infected cells to ADCC was measured.

Results: A set of CD4Mc analogs was developed and tested for neutralization and ADCC activities. The best performing analogs were subjected to structural analyses that confirmed their binding within the Phe43 cavity in a manner similar to MCG-IV-210.

In addition, several modifications of the piperidine core improved the position of the new CD4mcs in the Phe43 pocket and surrounding vestibule.Interestingly, two analogs (ZXC-I-090 and ZXC-I-092) exhibitdirect H-bonding with the α-carboxylic acid group of Asp368. This enhanced proximity to Asp368 resulted in improved neutralization and ADCC activities.

Metformin acts on HIV reservoirs to facilitate their recognition by the immune system

A. Fert[1,2], J. Richard[1,2], L. Raymond Marchand[2], D. Planas[2,1], E. Cohen[3], J.-P. Routy[4,5], N. Chomont[2,1], A. Finzi[1,2], P. Ancuta[2,1]
[1]*Université de Montréal, Microbiologie, Infectiologie et Immunologie, Montréal, Canada,* [2]*Centre de Recherche du CHUM, Immunopathologie, Montréal, Canada,* [3]*Institut de Recherches Cliniques de Montréal, Montréal, Canada,* [4]*McGill University Health Center, Montréal, Canada,* [5]*Division of Hematology, McGill University Health Center, Montréal, Canada*

Background: The persistence of viral reservoirs in people living with HIV (PLWH) receiving antiretroviral therapy (ART) is associated with chronic inflammation and non-AIDS comorbidities. Our group demonstrated that Th17 cells are selectively targeted by HIV-1 for infection and viral persistence *via* Mechanistic Target Of Rapamycin (mTOR)-dependent mechanisms. Others groups reported that mTOR positively regulates HIV-1 reactivation from latency.

Given this knowledge, we aimed to explore the molecular mechanisms by which metformin, an indirect mTOR inhibitor commonly used to treat type 2 diabetes, interferes with Th17 functions, HIV replication and viral outgrowth in memory $CD4^+$ T cells from ART-treated PLWH.

Methods: Memory $CD4^+$T cells from HIV-uninfected donors were stimulated with anti-CD3/CD28 antibodies in the presence/absence of metformin and infected with NL4.3Bal HIV-1. HIV release in supernatant was measured by HIV-p24 ELISA.

The frequency of productively infected cells (HIV-$p24^+CD4^{low}$) was measured by flow cytometry. HIV reactivation was assessed by viral outgrowth assay (VOA) in memory $CD4^+$ T cells from ART-treated PLWH in the presence/absence of metformin.

The recognition by broadly neutralizing antibodies (bnAbs) of HIV-$p24^+CD4^{low}$cells from ART-treated PLWH was measured by flow cytometry.

Results: As expected,metformin reduced mTOR pathway activity. Also, metformin reduced HIV-p24 level in the supernatant after *in vitro* infection (Fold Change: 0,69). Surprisingly, it increased the frequency of productively infected HIV-$p24^+CD4^{low}$ cells, as well as the frequency of HIV-$p24^+$ $CD4^{high}$cells after *in vitro* infection (FC: 5,15 and 5,2 respectively) and HIV outgrowth assay (FC: 1,55 and 1,38 respectively).

At the single-cell level, metformin, upon*in vitro* infection, amplified intracellular HIV-p24 accumulation (FC: 1,76) and upregulated the expression of CD4 (FC: 4,24) and BST2 (FC: 1,47), two molecules typically downregulated by HIV. Most importantly, metformin, upon HIV reactivation, enhanced the recognition of productively infected cells by bnAbs, particularly by PGT126 (FC: 2.41) and 101074 (FC: 1.15).

Conclusions: Despite a robust inhibitory effect on HIV release/outgrowth, metformin caused intracellular accumulation of HIV-p24 and facilitated the recognition of infected cells by neutralizing HIV antibodies.

Future clinical trials should explore whether metformin acts on HIV reservoirs *in vivo* to reverse latency and facilitate their recognition by the immune system.

EPA069

Dual antiretroviral loaded nanoparticles for long-acting suppressive HIV therapy

J. Fofana[1], B. Eshaghi[2], S. Nodder[1], B. Reinhard[2], S. Gummuluru[1]
[1]*Boston University School of Medicine, Microbiology, Boston, United States,* [2]*Boston University, Chemistry and The Photonics Center, Boston, United States*

Background: Viral persistence in secondary lymphoid tissues (SLTs) in patients on combination antiretroviral therapy (cART) has been linked to low SLT penetration of antiretrovirals (ARVs).

Furthermore, commitment to daily antiretrovirals causes poor adherence that can lead to drug failure and rapid viral rebound from these SLTs. Therapeutic strategies that enhance ARV concentrations in SLTs are essential.

Hence, we have designed membrane-wrapped poly-lactic acid nanoparticles (GM3-NPs) expressing the CD169 ligand, GM3 ganglioside, to achieve selective targeting of CD169+ macrophages in SLTs.

We constructed long-acting rilpivirine (RPV) and cabotegravir (CAB) loaded GM3-NPs and hypothesized that NP retention within CD169+ CD81+ non-degradative compartments in macrophages will lead to establishment of long-term cell-associated drug-depots for sustained antiviral potency in SLTs.

Methods: GM3-NPs were formulated by one-step nano-precipitation of lipids, poly-lactic acid, RPV and CAB. Intracellular ARV retention in CD169+ monocyte-derived macrophages (MDMs) was quantified by liquid chromatography (HPLC).

Intracellular trafficking of GM3-NPs in MDMs was determined by confocal microscopy. Antiviral efficacy of GM3-NPs (IC_{50}) was determined in single cycle HIV-infected TZM/bl cells by quantifying luciferase expression in cell lysates.

Long-acting antiviral potency of GM3-NPs was assessed in $CD169^+$ MDMs pre-treated with ARV containing GM3-NPs or NP-free ARVs and maintained in culture for 35 days. MDMs were infected at 7-day intervals with luciferase expressing single cycle HIV-1, and antiviral potencycy was determined by quantifying luciferase expression in infected cell lysates.

Results: IC_{50} of GM3-NPs was comparable to that of free ARVs, suggesting that ARVs retained antiviral potency upon encapsulation in GM3-NPs. Temporal HPLC analysis of MDM lysates revealed that exposure to GM3-NPs, but not NP-free ARVs, resulted in maintenance of inhibitory intracellular ARV concentration (mean ng ±SEM for RPV, 10.4 ± 0.8 and CAB, 14.6 ± 3.7) at day 28 post drug treatment, which correlated with persistent localization of GM3-NPs in non-degradative CD169+ CD81$^+$ compartments.

Importantly, GM3-NPs retained sustained efficacy in MDMs, with robust viral suppression up to 35 days post NP addition.

Conclusions: These results suggest that GM3-NPs maintain ARV-depots and continued suppression of HIV-1 in CD169+ macrophages. Ongoing *in vivo* studies will confirm their antiviral potency in SLTs and potential as a long-acting platform for HIV treatment and prevention.

Background: People living with HIV (PLWH) have a higher risk of cardiovascular disease (CVD) compared with age-matched HIV uninfected persons. Most PLWH are also human cytomegalovirus (CMV) co-infected. CMV infection drives the expansion of a population of adaptive NKG2C$^+$CD57$^+$natural killer (adapNK) cells. We questioned whether the frequency of adapNK cells was associated subclinical CVD.

Methods: This cross-sectional study included194 participants aged ≥40 yrs enrolled in the Canadian HIV and Aging Cohort Study (CHACS). Of these, 128 were CMV$^+$PLWH, 8 CMV$^-$PLWH, 37 CMV mono-infectedand 21 were negative for both HIV and CMV infection.

All participants were free of clinical CVD. All underwent a cardiac computed tomography (CT) scan to measure total coronary atherosclerotic plaque volume (TPV) in mm^3. Participants were classified as free of or having coronary atherosclerosis if their TPV was "0"and >"0", respectively. The frequency of NKG2C$^+$CD57$^+$adapNK cells were categorized as low, intermediate, and high if they constituted <4.6%, between 4.6% and 20% and >20%,respectively, of the total frequency of CD3$^-$CD56^{dim}NK cells.

The association between adapNK cell frequency and TPV was assessed using an adjusted Poisson regression analysis. The concentration of plasma anti-CMV-specific antibodies was assessed in a subset of 76 CMV$^+$PLWH and 28 CMV mono-infected individuals.

Results: A greater proportion of CMV$^+$PLWH had high adapNK cell frequencies in those with TVP=0 than TPV>0 (61.90% versus 39.53%, p = 0.03, Chi-square) with a similar non-significant trend in CMV mono-infected participants [46.15% versus 34.78%]. In the adjusted Poisson regression analysis, ahigh frequency of adapNK cells had a relative risk of 0.75 (95% CI 0.58, 0.97, p= 0.03) for presence of coronary atherosclerosis.

The concentration of anti-CMV-specific antibodies and frequency of adapNK cells was positively correlated in CMV$^+$individuals (p=0.04, Spearmans).

The concentration of these antibodies positively correlated with TPV in CMV$^+$PLWH and negatively correlated with TPV in CMV-mono-infected persons, though neither correlation achieved statistical significance.

Conclusions: High frequencies of adapNK cells was associated with a reduced risk of atherosclerosis in CMV$^+$PLWH and CMV mono-infected individuals. This observation suggests that adapNK cells protect against the development of coronary atherosclerotic plaques.

EPA071

Scaling-up HPV testing for cervical cancer screening in WLHIV in Zambia

M.J. Chaila[1,2], E. Mwewa[1], P. Choonga[1], P. Kamfwa[1], A. Shibemba[1]

[1]Ministry of Health, Lusaka, Zambia, [2]Catholic Relief Services, Lusaka, Zambia

Background: Zambia has an estimated cervical cancer (CaCx) incidence rate of 66.4/100,0000. CaCx remains the most common cancer accounting for nearly 25% of all cancers diagnosed and causing more cancer deaths

in Zambia. The Ministry of Health (MOH) established the national CaCx screening program in 2006 using Visual Inspection with Acetic Acid (VIA) enhanced with digital cervicography. Recently, WHO made a call to eliminate CaCx through the 90-70-90 approach. The 70 target demands that 70% of eligible women are screened with a high-precision test at 35 and 45 years of age. We present Zambia's progress in scaling-up HPV testing for CaCx screening in WLHIV.

Methods: Through PEPFAR funding, the Ministry of Health procured 50,000 HPV test kits and were distributed across the country in 2021. Through the support of Hologic, we held a country-wide orientation in September 2021 to improve the uptake of HPV testing for CaCx screening in WLHIV.

Results: A team of 24 facilitators, distributed across 8 of the 10 Zambian provinces trained a total of 133 health care workers. This included 38 staff from the laboratory, 82 nurse providers, and 13 medical doctors. The orientation included basics of CaCx and available screening methods and why the country was moving towards HPV testing. Other key topics included sample correction, courier systems, and testing on the Hologic Panther.

This orientation showed an immediate increase in the utilization of HPV testing from a monthly average of 531 to 2,765 before and after the training respectively. The HPV positivity rate was 31% (4,762/15,303).

Month	Tests Done	Negative	Positive	Positivity Rate
Jan	216	161	55	25%
Feb	74	49	25	34%
Mar	64	48	16	25%
Apr	-	-	-	0%
May	618	383	235	38%
Jun	1,272	913	359	28%
Jul	270	190	80	30%
Aug	1,730	1,209	521	30%
Sep	3,700	2,719	981	27%
Oct	1,996	1,304	692	35%
Nov	2,922	1,896	1,026	35%
Dec	2,441	1,669	772	32%
Total	15,303	10,541	4,762	31%

Table 1. HPV testing & positivity rate among WLHIV

Conclusions: These orientations are expected to improve the utilization of HPV testing for CaCx screening. Support from PEPFAR and HPV testing kits manufacturers such as Hologic is key in the integration of HPV testing in Low- and Middle-Income Countries.

EPA072

Association of HIV viremia with pro-inflammatory fatty acid signatures in pregnancy

S.A. Fisher[1], J. Jao[2], L.M. Yee[1], E.G. Chadwick[2], D.L. Jacobson[3], Pediatric HIV/AIDS Cohort Study

[1]Northwestern University Feinberg School of Medicine, Department of Obstetrics and Gynecology, Chicago, United States, [2]Northwestern University Feinberg School of Medicine, Ann & Robert H. Lurie Children's Hospital of Chicago, Department of Pediatrics (Infectious Diseases), Chicago, United States, [3]Harvard T.H. Chan School of Public Health, Department of Biostatistics, Boston, United States

Background: Omega-6 (n-6) and omega-3 (n-3) polyunsaturated fatty acids (PUFAs) are vital for fetal metabolic programming and immunomodulation. Arachidonic acid (AA), an n-6 PUFA, is a precursor of pro-inflammatory eicosanoids. The n-3 PUFAs eicosapentaenoic acid (EPA) and docosahexaenoic acid (DHA) are precursors to anti-inflammatory eicosanoids. Higher n-6:n-3 ratios are harmful to human health.

We assessed associations of HIV immune status and viremia with PUFA signatures in pregnant persons living with HIV (PLHIV).

Methods: We included pregnant PLHIV enrolled from 2009-2011 in the Nutrition sub-study of the Pediatric HIV/AIDS Cohort Study's Surveillance Monitoring for ART Toxicities Study.

We measured 3rd trimester plasma PUFA levels (6 n-6 PUFAs, AA; 4 n-3 PUFAs, EPA, DHA), each as a percent of total fatty acid content, via esterification and gas chromatography. PUFA ratios (n-6:n-3, AA:EPA+DHA) were calculated to evaluate PUFA inflammatory signatures.

Exposures assessed were 1st/2nd trimester CD4 count (<200 vs. ≥200 cells/mm^3) and HIV viral load (VL≥400 vs. <400 copies/mL).

We fit linear regression models using generalized estimating equations to evaluate differences (95% confidence intervals [CI]) in n-6:n-3 and AA:EPA+DHA ratios by each exposure.

Results: Of 264 eligible pregnant PLHIV, 69% were Black, 69% had used antiretroviral therapy (ART) prior to pregnancy, and 94% received ART by the 2nd trimester, predominately protease inhibitor (PI)-based (84%). In the 1st/2nd trimesters, 12% had CD4 counts <200 cells/mm^{3}and 56% had VL ≥400 copies/mL. PUFA concentrations and ratios were similar by CD4 count. VL ≥400 was associated with lower median n-3 concentrations (2.8% vs. 3.0%, p<0.01) and EPA+DHA (1.8% vs. 2.0%, p<0.01). Median PUFA concentrations were 37.9% vs. 36.5% (p=0.09) for n-6 and 6.8% vs. 6.4% (p=0.23) for AA (VL ≥400 vs. <400, respectively).

In models adjusted for age, education, tobacco use, body mass index, and PI vs. non-PI based ART, VL ≥400 was associated with higher n-6:n-3 and AA:EPA+DHA ratios (mean difference in ratio: 1.6 [95% CI 0.79-2.5] for n-6:n-3 and 0.51 [95% CI 0.26-0.76] for AA:EPA+DHA ratios).

Conclusions: PUFA signatures in viremic pregnant PLHIV exhibit a pro-inflammatory milieu. Future studies should evaluate effects of pro-inflammatory PUFA signatures on adverse maternal, neonatal, and childhood outcomes in pregnant PLHIV.

EPA073
MiRNAs as cardiovascular risk biomarkers in people living with HIV (PWH)

M. Martinez-Velasco[1], P. Velli[1], M. Cairó[2], Á. Jaén[2], R. Font[2], X. Martinez-Lacasa[2], J. Royo[2], L.F. Cortés[3], V. Asensi[4], J. Muñoz[5], J. Olalla Sierra[6], R. Muga[7], D. Dalmau[2]
[1]Fundació Docència i Recerca Mútua Terrassa, HIV, Terrassa, Spain, [2]Hospital Universitari Mútua Terrassa, HIV, Terrassa, Spain, [3]Hospital Universitario Virgen del Rocío, HIV, Sevilla, Spain, [4]Hospital Universitario Central de Asturias, HIV, Oviedo, Spain, [5]Hospital Universitario Basurto, HIV, Bilbao, Spain, [6]Hospital Costa del Sol, HIV, Marbella, Spain, [7]Hospital Universitari Germans Trias i Pujol (Can Ruti), HIV, Badalona, Spain

Background: PWH have higher cardiovascular (CV) risk than healthy population (HP), associated with chronic inflammatory processes linked with HIV infection. miRNAs have been studied in HP as biomarkers to facilitate earlier detection of diseases.
The aim of this study was to ascertain if miRNAs could be associated with CV risk in PWH, allowing their use as biomarkers.
Methods: Atherosclerosis, evaluated by the presence of atheroma plaque (AP) as surrogate marker was assessed by eco-doppler ultrasonography (2010 and 2018). PWH with and without AP were considered as high CV (HCVr) and low CV risk (LCVr), respectively. Demographic, clinic-epidemiological and viro-immunological data were collected as well as peripheral blood, stored as peripheral blood mononuclear cells (PBMCs). 72 PBMCs samples were selected for the exploratory assay (N=36 HCVr and N=36 LCVr in 2010). miRNA array was performed to ascertain miRNAs differentially expressed (DE) between groups. Data was normalized and adjusted and DE analyses were performed. Six miRNAs were selected for replication (N=289) and follow-up (N=124) using qRT-PCR. Non-parametric test was applied and results were reproduced by limma.
Results: DE analyses were performed between both groups (HCVr-LCVr). 44 miRNA were identified fulfilling the fold change cutoff ([FC>1.2]) and pvalue < 0.05 (not adjusted) (Fig1). 4 miRNAs were selected, based upon functional/pathway enrichment analysis (miR-140-5p, miR-4668-3p, miR-3613-5p and miR-638) and 2 based in current literature (miR-146a and miR-27b). Replication phase -N=289- and follow-up -N=124- of miRNAs expression was assessed by RT-qPCR. None of them showed significant differences among HCVr and LCVr groups and no association with clinical variables was found.

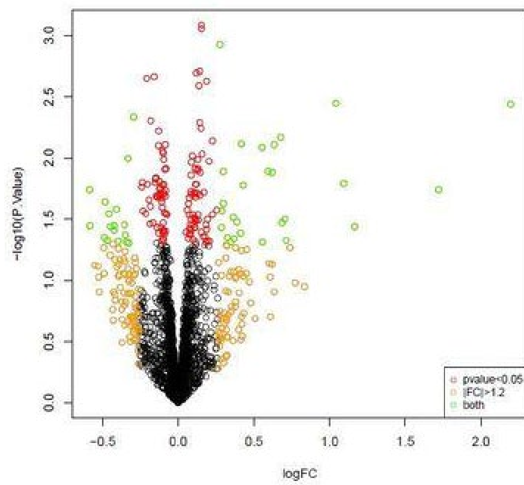

Figure 1. Results of miRNA array normalized by RMA. In green, those 44 miRNAs candidates with p-value <0.05 and |FC|>1.2 (not adjusted).

Conclusions: Although miRNAs can be involved in numerous pathologies based on sequence analysis, data published to date appear contradictory. Our results corroborate the assumption, into a well characterized HIV longitudinal cohort, that miRNAs are not reliable biomarkers for CV risk. More stable biomarkers should be explored in this setting.

EPA074
Youth HIV-associated neurocognitive disorders: a longitudinal cohort study

N. Phillips[1,2], M. Buttacharjee[2], L. Schrieff[2], K. Thomas[2], L. Myer[2], H. Zar[2], D. Stein[2], J. Hoare[2]
[1]University of Cape Town, Psychiatry and Mental Health, Cape Town, South Africa, [2]University of Cape Town, Cape Town, South Africa

Background: Milder forms of HIV-associated neurocognitive disorders (HNCD) remain of major concern even with ART, but there are few longitudinal data in changes in subdomains of cognition during adolescence.
This exploratory study investigates if there are significant changes in cognitive performance across a 36-month follow-up period among a sample of South African youth living with HIV (YLH).
Methods: A subset of 151 participants (121 YLH + 30 controls) of the Cape Town Adolescent Antiretroviral Cohort (CTAAC) completed the same comprehensive neuropsychological test battery for baseline and 36-month follow-up. Cases were perinatally HIV-infected adolescents well-established on ART; controls were age matched HIV-uninfected adolescents from similar communities.
Fluid cognition was assessed across 8 composite cognitive domains and General Intellectual Functioning was assessed as a measure of crystalized cognition. To determine mean differences between YLH and controls for each composite cognitive domains we performed a series

of Mann-Whitney U tests for baseline data and follow-up data separately. To determine if there were any changes in cognitive impairment between baseline and follow-up, we performed a series of Kruskal-Wallis tests for the YLH and control groups separately.

Results: YLH and controls did not differ significantly with regards sex, age, home language, ethnicity, education and repeated grades. With regards to crystalized intelligence, YLH were significantly more impaired than controls at baseline (U=961.5, p=0.000) and follow-up (U=851.5, p=0.000). Regarding change in cognitive impairment between baseline and follow-up, YLH and controls both show significant improvement in the domains of attention (YLH: H=7.308, p=0.007. control: H=5.509, p=0.019), language (YLH: H=74.295, p=0.000. control: H=16.369, p=0.000) and executive function (YLH: H=16.458, p=0.000. control: H=12.804, p=0.000). YLH also significantly improved in the domains of visual memory, visual spatial ability, and motor coordination. Controls also significantly improved in the domain of verbal memory.

Conclusions: YLH showed significant improvement in six cognitive domains and showed no significant improvement or deterioration in the other domains. Cognitive changes as a function of age are well-documented, however, in the context of YLH questions remain regarding the rate of maturation as compared to controls.

Further to this exploratory study, our next steps will include in-depth statistical models to investigate the HIV-time-cognition interaction.

EPA075

What can we learn from the 2021 Aids Healthcare Foundation-Eswatini mortality profile after meeting the UNAIDS 95-95-95 target?

Y. Mafulu[1], S. Khumalo[1], L. Buzaalirwa[2], N. Ndlovu[1], S. Ndabezitha[1], C. Magagula[1], S. Gwebu[1], N. Dube[3], N. Dube[1]

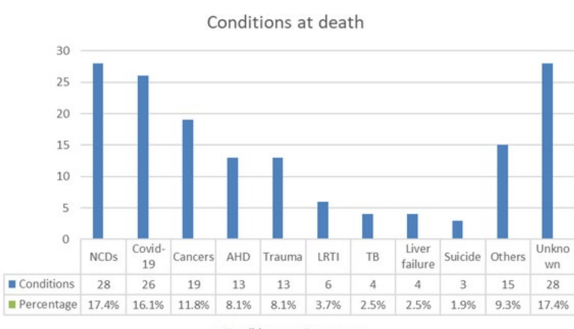
[1]AIDS Healthcare Foundation Eswatini, Manzini, Eswatini, [2]Aids Healthcare Foundation, Nairobi, Kenya, [3]AIDS Healthcare Foundation-Africa Bureau, Johannesburg, South Africa

Background: Eswatini has one of the world's highest adult HIV prevalence rates at 27%. Around 200,000 people were living with HIV in 2019. AIDS-related deaths in Eswatini dropped from 400/100,000 in 2010 to about 200/100,000 in 2019. This coincided with the introduction of universal ART coverage.

Additionally, Eswatini is one of the first countries to meet the UNAIDS 95-95-95. We give a descriptive analysis of mortality in a post-UNAIDS 95-95-95 target attainment at AIDS Healthcare Foundation (AHF)-Eswatini from January to October 2021.

Methods: We performed a retrospective data analysis on HIV positive patients whose death was reported between January 2021 and October 2021 at five AHF facilities in Eswatini. Data from the Antiretroviral therapy Patient Monitoring and Reporting system and physical files were analysed using an Excel spreadsheet.

Results: A total of n = 161 patients died in the period under review. The average age was 47.1 (6-87), majority were 40-59 years. 54% had a CD4 count > 350 cells/mm3, 34.1% had a CD4 count < 350. Of the 161 deaths, only 4 (2.5%) had a Viral load > 1000. Majority (64.6%) of the deaths had spent > 36 months on Antiretroviral therapy (ART) while 1.2% died before ART initiation.



The known conditions at death were mostly Non-Communicable Diseases (NCDs) (Diabetes, Hypertension, related complications including chronic kidney diseases) at 17.4%, next was Covid-19 accounting for 16.1% and all types of cancers at 11.8%. 9.3% of clients (n=15) died with Advanced HIV Disease (AHD) related conditions.

Conclusions: Our study shows that while the introduction of universal ART coverage has contributed to reducing AIDS-related mortality, non-AIDS causes of death such as NCDs, cancers and new epidemics (Covid-19) are becoming more frequent. These figures highlight the importance of further efforts and resources towards prevention and early diagnosis of those conditions.

HIV and co-infections (TB, viral hepatitis, SARS-CoV2, other)

EPA077

Active tuberculosis co-infection is associated with broad HIV-1 antibody responses

B. Adeoye[1]

[1]Boston University School of Medicine, Microbiology, Boston, United States

Background: Mycobacterium tuberculosis (TB) has been shown to enhance antibody responses against diverse viruses in animal models. Thus, we hypothesized that active TB co-infection enhances the development of HIV-1 specific neutralizing antibodies (nAbs).

Methods: We compared humoral responses among plasma samples from 15 HIV-1 participants with TB (HIV-1/TB) and 16 HIV-1 participants without TB. Neutralization and antibody-dependent cellular cytotoxicity (ADCC) against

12 and 10 HIV-1 isolates were used to estimate breadth and potency scores. HIV-1 envelope diversity was compared among 341 single genome amplified sequences. Plasma cytokines and antibody levels were measured using the flow and Luminex-based assay respectively.

Results: HIV-1/TB and HIV-1 infected participants had similar baseline plasma virus levels (p= 0.3) and CD4 counts (p= 0.4). Anti-HIV-1 neutralization (p = 0.02), but not ADCC (p = 0.7) was broader and more potent in HIV-1/TB group than in HIV group. Plasma IgG titer, CD4 count, viral load, and envelope diversity did not associate with plasma neutralizing and ADCC capacity. Some plasma markers, such as APRIL and IL-6, were higher in HIV-1/TB individuals and associated with enhanced HIV-1 neutralizing antibody (nAb) responses.

Conclusions: Tuberculosis co-infection enhances HIV-1 nAbs but not ADCC, and this may be due to changes in pathways important for antibody production but not increased virus level or antigen diversity. Dissecting mechanisms that account for the enhanced HIV-1 neutralization in HIV-1 individuals with active TB could be used to boost immune responses as part of a functional cure approach in chronic HIV-1 infection.

EPA078

Role of PD-1, TIGIT and TIM3 on NK cell exhaustion and function in HIV/HCV coinfection, and the impact of HCV elimination in the long term

A.A. Osegueda Peña[1], A. Perbeils[1], A. Urioste[1,2], S. Paz[3], G. Turk[1,2], M.F. Quiroga[1,2], Y. Ghiglione[1,2], M.L. Polo[1,2], N.L. Laufer[1,4]

[1]Instituto de Investigaciones Biomédicas en Retrovirus y SIDA UBA-CONICET, Buenos Aires, Argentina, [2]University of Buenos Aires. Faculty of Medicine, Buenos Aires, Argentina, [3]Francisco Javier Muñiz Hospital. Hepatology Service, Buenos Aires, Argentina, [4]University of Buenos Aires. Faculty of Medicine. Department of Microbiology, Parasitology and Immunology, Buenos Aires, Argentina

Background: NK cells negatively modulate liver fibrosis (LF), therefore, playing an important role in liver pathologies. Previously, we demonstrated that NK cells from cirrhotic HCV/HIV-coinfected individuals (HCV/HIV+) displayed impaired functionality and high PD-1 expression.

Here, we aimed to study PD-1, TIGIT and Tim3 as potential exhaustion markers in NK cells from HCV/HIV+ with mild and advanced LF. Also, to evaluate the role of PD-1 on NK cell function in HCV/HIV+ after HCV clearance by direct-acting antivirals (DAA).

Methods: PBMCs were isolated from 37 HCV/HIV+ under ART (20 METAVIR F0/F1, 55% Females and 18 F4, 39% Females, evaluated by transient elastography), 6 HIV-monoinfected (HIV+, 67% Females) and 8 HCV-monoinfected (HCV+, 38% Females) individuals. In 24 individuals, samples were collected before (BSL), end (EOT) and 12 months (12MPT) after successful DAA treatment. NK-cell percentage, immunophenotype (PD-1, TIGIT and Tim3 expression) and degranulation capacity (CD107a assay) were determined by flow cytometry. Non-parametric tests were used to analyze data.

Results: Mean CD4 count: 740±293, 577±339, 944±274 cells/µL for F0/F1, F4 and HIV+, respectively; all with undetectable VL. Unlike PD-1, neither TIGIT nor Tim3 were expressed differently in F0/F1 and F4.

Degranulation of NK/PD-1+ cells was reduced in F4 (p=0.039), while NK/TIGIT+ cells showed diminished CD107a expression in both groups (F0/F1: p=0.016/F4: p=0.023). Tim3 did not affect NK cell degranulation.

After DAA, F4 NK cell frequency was improved between BSL-12MPT (p=0.039) reaching similar levels of HIV+ and HCV+, %NK/PD-1+ diminished at EOT and 12MPT (p=0.015, p=0.03), with no change in CD107a expression.

In F0/F1, no changes in NK cell frequency or %NK/PD-1+ were observed, however, CD107a expression increased between BSL and 12MPT (p=0.03).

Conclusions: PD-1 was the only exhaustion marker expressed differentially between F0/F1 and F4 groups. TIGIT emerged as a marker of lower NK cell functionality.

Although DAA improved exhaustion and frequency of NK cells in cirrhotic individuals, functionality was only reverted in mild LF, remarking the importance of an early DAA treatment.

Results suggest that addition of biological agents (eg. anti-PD-1) might boost this effect and modify LF progression.

EPA079

Maternal HIV status and risk of infant *M. tuberculosis* infection

J. Mecha[1], J.N. Escudero[2], B.A. Richardson[2], E.M. Obimbo[3], D. Matemo[1], J. Kinuthia[1,2,3], G.J. Stewart[2], S.M. LaCourse[2]

[1]Kenyatta National Hospital, Nairobi, Kenya, [2]University of Washington, Seattle, WA, United States, [3]University of Nairobi, Nairobi, Kenya

Background: The effect of maternal HIV on infant *M. tuberculosis* (Mtb) infection risk is not well-characterized. Young children with Mtb infection are at high risk of developing active tuberculosis (TB).

Methods: Pregnant women with and without HIV and their children were enrolled in a longitudinal cohort in western Kenya. Mothers had interferon gamma-release assays (IGRA, QFT-Plus) and tuberculin skin tests (TST) during enrollment in pregnancy; children underwent TST at 12 and 24 months of age (TST+ = ≥5mm for HIV+, ≥10mm for HIV-). We estimated incidence and correlates of 24-month cumulative infant Mtb infection (TST positivity) using Cox proportional hazards regression.

Results: Among 322 infants with TST, 170 (53%) were HIV-exposed and 152 (47%) were HIV-unexposed. Median infant age at enrollment was 6.6 weeks (IQR 6.1-10.0); most received BCG vaccination (320, 99%). Thirty-nine (12%)

Oral abstracts

Late-breaker abstracts

Author Index

mothers were TST+ and 102 (32%) were QFT-Plus+. Among 170 HIV-exposed infants, 154 (95%) received ARVs for PMTCT and 141 (83%) of their mothers had ever received isoniazid preventive therapy (IPT).

Twenty-two (6.8%) infants had at least one positive TST for a 24-month cumulative Mtb infection incidence of 3.6/100 PY (95%CI 2.4-5.4/100 PY). Ten percent (17/170) of HIV-exposed and 3.3% (5/152) HIV-unexposed children had at least one positive TST for a 24-month cumulative incidence of 5.3 among HIV-exposed vs. 1.7/100PY for unexposed children (HR 3.1 [95%CI 1.2-8.5], p=0.024).

The majority of TST conversions occurred in the first year of life (12 months 5.1 vs. 12-24 months 2.0/100 PY, HR 2.5 [95%CI 0.9-8.8], p=0.06). Infant Mtb infection was associated with maternal TST positivity (HR 2.9 [95%CI 1.1-7.4], p=0.03), but not QFT-Plus positivity (HR 1.2 [95%CI 0.5-2.7], p=0.74).

Among HIV-exposed children, Mtb infection incidence was similar regardless of maternal IPT (IPT 4.5 vs. no IPT 6.3/100PY, HR 0.7 [95%CI 0.2-2.1], p=0.48).

Conclusions: Infant Mtb infection incidence (as measured by TST) by 24 months of age was ~3.1-fold higher among HIV-exposed children, despite high levels of maternal IPT. Overall, there was a trend for higher incident TST conversions in the first compared to the second year of life, which was similar among both HIV-exposed and unexposed infants.

EPA080

Impact of chronic HCV infection on CD4-T cells permissiveness to HIV infection and viral reservoir persistence

S.T. Gobran[1,2], J. Dion[2], L.R. Marchand[2], A. Pagliuzza[2], N. Chomont[1,2], M. Klein[3,4], J. Bruneau[5], P. Ancuta[1,2], N.H. Shoukry[6,2]

[1]*Université de Montréal, Faculté de Médecine, Département de Microbiologie, Infectiologie et Immunologie, Montréal, Canada,* [2]*Centre de Recherche du Centre Hospitalier de l'Université de Montréal, Montréal, Canada,* [3]*McGill University Health Centre, Division of Infectious Diseases, Department of Medicine, Montréal, Canada,* [4]*McGill University, Faculty of Medicine and Health Sciences, Department of Medicine, Montréal, Canada,* [5]*Université de Montréal, Faculté de Médecine, Département de Médecine de Famille et de Médecine d'Urgence, Montréal, Canada,* [6]*Université de Montréal, Faculté de Médecine, Département de Médecine, Montréal, Canada*

Background: Hepatitis C virus (HCV) co-infection is a serious co-morbidity in people living with HIV (1), as reflected by higher HIV-DNA reservoir size in CD4-T cells in HCV/HIV co-infected individuals as compared to HIV mono-infected subjects (2).

Reports that HCV cure with Directly Acting Antivirals (DAA) leads to an increase in HIV-DNA/RNA levels raised new questions on the relationship between the two viruses (3).

Methods: We aim to investigate the permissiveness of CD4-T cells from chronic HCV patients to HIV infection *in Vitro and*to characterize changes in the HIV reservoir in HCV/HIV co-infected patients receiving antiretroviral therapy (ART) for HIV, before and after DAA-induced HCV cure. Memory CD4-T cells from chronic HCV patients and negative controls (n=20 per group) were infected with HIV-1 (NL4.3BaL, THRO) *in vitro*. HIV integration and replication were measured by real-time nested PCR and HIV-p24 ELISA/flow cytometry analysis, respectively.

The Carboxy Fluorescein Succinimidyl Ester (CFSE)-based T-cell proliferation assay was used to examine the susceptibility of HCV-specific CD4 T-cells to HIV infection; *Staphylococcus aureus* lysates, CMV-pp65 peptide, and Staphylococcal Enterotoxin B (SEB) were used as controls.

Results: We observed that CD4-T cells from chronic HCV-infected individuals compared to HCV-negative controls are more susceptible to NL4.3BaL HIV-1 infection *in vitro,* as demonstrated by intracellular (p = 0.0332) and soluble HIV-p24 expression (p = 0.0298), and integrated HIV-DNA levels (p = 0.0559). These high levels of HIV-1 replication coincided with superior expression of the HIV co-receptor CCR5 (p=0.007) and positively correlated with HCV plasma viral loads (r= 0.5; p= 0.046). The CFSE-based T-cell proliferation assay combined with HIV exposure *in vitro* indicated that a fraction of HCV-specific CD4 T cells supports productive HIV infection.

Real-time nested PCR and RT-PCR are currently used to examine HIV-DNA reservoir size and the HIV-RNA/DNA ratio in CD4+ T-cells of HCV/HIV co-infected patients (n=10) before DAA,at the end of DAA, and three months post-DAA.

Conclusions: Our data support a model in which chronic HCV infection is associated with increased CD4-T cells activation and permissiveness to HIV infection and that HCV-specific CD4 T-cells are targeted by HIV for infection *invitro*thus, supporting their potential contribution to viral reservoir persistence during ART.

EPA081

HPV circulating tumoural DNA as a potential biomarker to monitor anal lesions in HIV-infected men who have sex with men (MSM)

N. Robillard[1], D. Veyer[2], C. Badoual[2], J. Pavie[3], L. Weiss[2], H. Pere[2]

[1]*Université de Paris, Paris, France,* [2]*Université de Paris/APHP, Paris, France,* [3]*APHP, Paris, France*

Background: Human papillomavirus (HPV) is the principal cause of anal squamous cell carcinomas (ASCC). Recent studies have already showed the prognostic value of HPV circulating tumoral DNA (HPVctDNA) to monitor treatment response in advanced ASCC. Recently, our team has reported the potential interest of HPVctDNA to monitor post-treatment high grade anal intraepithelial neoplasia in HIV infected patient.

No study has been conducted to evaluate HPVctDNA as a non-invasive biomarker to monitor patients with low grade/high grade anal intraepithelial neoplasia (LGAIN/HGAIN) potentially at risk to develop ASCC particularly in exposed HIV infected MSM. We proposed to evaluate HPVctDNA as a predictive and prognostic biomarker in HIV MSM patients with LGAIN/HGAIN or ASCC.

Methods: A cohort of 55 HIV MSM with anal lesion has been enrolled (16 LGAIN, 32 HGAIN and 7 ASCC) in European Georges Pompidou Hospital. First of all, oncogenic HPV genotype was characterized in anal lesion biopsies. Specific HPVctDNA detection and quantification by droplet-based digital PCR (ddPCR) was performed on plasma samples collected at the time of diagnosis. So far, we have developed ddPCR to detect the most prevalent oncogenic HPV namely HPV16, -18, -31 and -33.

Results: As expected HPV16 was the most prevalent (27/55, 49.09%) in all biopsies tested. Multiple infections have been detected for about half of the patients (27/55).

Finally, regarding HPV16/18/31/33 genotype, corresponding HPVctDNA could have been performed on 30 plasmas. No HPVctDNA was detected in plasma of LGAIN/HGAIN patients. For 7 patients presenting ASCC, 5 have undetectable HPVctDNA.

For the 2 other positive patients, a longitudinal retrospective analysis corresponding to plasma collected before and after diagnosis has been performed. In one case, HPVctDNA was already detected in anterior plasma before ASCC diagnosis and in both, HPVctDNA became negative following treatment, correlating with a clinical cure.

Conclusions: Our result confirmed the capacity of HPVctDNA as a non-invasive biomarker to detect ASCC and its specificity regarding anal lesion stages.

Moreover, the possibility to early detect HPVctDNA before anal cancer diagnosis leads the way for specific HPVctDNA as a complementary tool to monitor ASCC development and to optimize medical care of such at risk population of HIV MSM.

Neuropathogenesis

EPA082

Machine learning prediction and phyloanatomic modeling of viral neuroadaptive signatures in the macaque model of human immunodeficiency virus-mediated neuropathology

A. Ramirez-Mata[1], S. Marini[1], M. Salemi[1], B. Rife Magalis[1]
[1]*University of Florida, Gainesville, United States*

Background: In human immunodeficiency virus (HIV) infection, virus replication in the brain can result in HIV-associated neurocognitive deficits in approximately 25% of patients with unsuppressed viremia and is thought to be characterized by evolutionary adaptation to this unique microenvironment. While no single unique mutation has distinguished this neuroadapted population from virus in patients without neuropathology, earlier studies have demonstrated that a machine learning approach could be applied to identify a collection of mutational signatures that can be used to predict this disease.

Methods: The translatability of a machine learning approach to the widely used animal model of HIV neuropathology – the SIV-infected macaque – has not yet been tested, however. We applied a similar machine learning approach to predict simian immunodeficiency virus (SIV)-mediated encephalitis (SIVE) using envelope gene sequences obtained from the central nervous system (CNS), as well as various tissues when available from rhesus macaques infected with the SIVmac251 viral swarm. CNS tissues from four distinct macaque cohorts were used as training datasets, comprised of varying models of neuropathology (e.g., virus- and immune-mediated progression).

Results: The model presented 83% of accuracy in SIVE prediction. SIVE signatures were present at earlier time points of infection and in non-CNS tissues, though not distinguishing SIVE from SIVnoE animals. Lung macrophages in particular were observed to harbor a large proportion (35-100%) of SIVE-classified sequences in both SIVE and SIVnoE animals regardless of time point, suggesting an association between the neuroadaptive signature and macrophage tropism.

Further phyloanatomic analysis corroborated hypothesis, revealing the source of virus in the brain of SIVE animals to be lung macrophages and T cells in SIVnoE animals.

Conclusions: Additional studies investigating model specificity for entry versus replication in the brain are underway, though results also encourage additional studies of the role of lung macrophages as the potential driving force behind neuroAIDS and of a solution for prevention of colonization of the CNS by neurovirulent HIV strains.

SARS-Cov2 Viral origins, evolution and diversity

EPA083

Evidence of recurrent selection of mutations commonly found in SARS-CoV-2 variants of concern in viruses infecting immunocompromised patients

J. Siqueira[1], L. Goes[1,2], M. Garrido[3], B. Alves[1], C. Cicala[2], J. Arthos[2], J. Viola[4], M. Soares[1,5]

[1]*Brazilian National Cancer Institute, Oncovirology Program, Rio de Janeiro, Brazil,* [2]*National Institute of Allergy and Infectious Diseases, Laboratory of Immunoregulation, Bethesda, United States,* [3]*Brazilian National Cancer Institute, Hospital Infection Control Committee, Rio de Janeiro, Brazil,* [4]*Brazilian National Cancer Institute, Immunology and Tumor Biology Program, Rio de Janeiro, Brazil,* [5]*Federal University of Rio de Janeiro, Department of Genetics, Rio de Janeiro, Brazil*

Background: SARS-CoV-2 novel variants emerge throughout the COVID-19 pandemic and represent a public health problem. Recent reports have shown that prolonged SARS-CoV-2 infections in immunocompromised patients lead to viral diversification and cancer patients have a higher intrahost viral genetic diversity compared to non-cancer subjects. These viral changes could play an important role in the emergence of SARS-CoV-2 variants.

Here we report a case of a subject with acute myeloid leukemia and persistent SARS-CoV-2 infection after a bone marrow transplantation and characterize the viral genome over time.

Methods: SARS-CoV-2^{+} swabs from a 31-yr old male patient were collected at six different timepoints during SARS-CoV-2 infection between 18 May and 01 July, 2020. Complete viral genomes were amplified using ARTIC-network primers and sequenced in a MiSeq platform. Viral genomes were assembled using Geneious R11. Nucleotide variations identified between the genomes from different timepoints were evaluated for minor nucleotide frequency using LoFreq.

Results: The first SARS-CoV-2^{+} test was on day 53 post bone marrow transplant when the patient reported respiratory symptoms, fever and a ground-glass profile chest tomography. The following positive tests were performed 14, 22, 28, 37 and 44 days after the first SARS-CoV-2^{+}test. Three genome variations were found comparing the longitudinal samples.

All three changes were in low or no frequency in the first timepoint, S:144del was first detected at the second timepoint and increased in frequency overtime. The nsp6:L37F and nsp6:del106-108 mutations fluctuated over time and in the last timepoint, L37F was predominant and the deletion was not detected. Nsp6 is involved in immune evasion, while L37F has been associated with reduced activation of inflammasomes and pyroptosis and with asymptomatic SARS-CoV-2 infections. Nsp6:del106-108 is found in multiple variants of concern (alpha, beta and gamma) and its impact is unclear. S:144del is present in alpha and omicron variants, is located in the NTD antigenic-supersite and is associated with immune evasion.

Conclusions: Our data suggest that immunocompromised hosts are central to the genesis and emergence of SARS-CoV-2 genomic variations that impact viral immune evasion and are present in VOCs throughout the COVID-19 pandemic, a phenomenon that requires continuous monitoring.

Immune responses to SARS-Cov2

Effects of COVID-19 on the cytokine background in chronic controlled HIV infection

R. Emilova[1], Y. Todorova[1], M. Aleksova[1], R. Dimitrova[2], L. Grigorova[2], I. Alexiev[2], N. Yancheva[3], N. Kapincheva[3], M. Nikolova[1]

[1]*National Center of Infectious and Parasitic Diseases (NCIPD), Department of Immunology, Sofia, Bulgaria,* [2]*National Center of Infectious and Parasitic Diseases, National Reference Confirmatory Laboratory of HIV, Sofia, Bulgaria,* [3]*Specialized Hospital for Active Treatment of Infectious and Parasitic Diseases, Sofia, Bulgaria*

Background: Although the available retrospective studies have not reported an increased COVID-19 prevalence and mortality among HIV+ individuals with undetectable HIV viral load (VL), the possible effects of SARS-CoV-2 co-infection on immune restoration and low-level immune activation in those patients are still scarce.

Aim: To evaluated plasma cytokine balance as a major indicator of immune response potential in HIV+ART+ patients after convalescence from COVID-19, in comparison to non-coinfected controls.

Methods: Two groups of HIV+ART+ patients with undetectable HIV VL were studied: A, n=20, aged 44 (28-68), 40 (11 - 91) days after mild/moderate COVID-19 and B, n=18, aged 37.8 (22 - 74), without data of previous SARS-CoV-2 infection. Peripheral blood samples were collected during the routine follow-up.

Ex vivo plasma cytokine concentrations (IFNγ, TNFα, IL-12p70, IL-13, IL-1α, IL-1β, IL-5, IL-6, IL-18, IL-10, IL-17A, IL-21, IL-22, IL-23, IL-15, IL-1RA, IL-7) were measured with Luminex technology (ProcartaPlex, ThermoFischer Scientific). CD4 T-cell absolute counts (CD4AC), and CD4/CD8 ratio were determined by flow cytometry using lysis-no-wash procedure and TRUCount tubes (BD Biosciences).

Results: CD4AC and CD4/CD8 ratio in group A did not change significantly after SARS-CoV-2 infection (826 vs. 894 and 1.03 vs. 0.96, p>0.05 for both), and were not significantly different from group B (894 vs.753 and 1.03vs.1.04, p>0.05 for both). However, the post-COVID19 cytokine background was characterized with an important decrease of: (mean,

pg/ml) IFNγ (2.8 vs. 19, p<0.001), IL-18 (14.3 vs. 531, p<0.001), IL-13 (2.6 vs. 8.6, p<0.05), IL-10 (0.23 vs. 6.9), and IL-1RA (672 vs. 10581, p<0.05). The total Th1 (IFNγ+TNFα+IL-2) production was also significantly lower in group A (12.1 vs. 53.5, p<0.01), while the sum of pro-inflammatory (IL-1α, IL-1β, IL-6) cytokines remained comparable (8.9 vs. 13.4, p>0.05).

Conclusions: Although CD4AC and residual inflammation do not seem to be affected in HIV+ART+ patients immediately after SARS-CoV-2 infection, the significant decrease of IL-18, IL-13 and Th1 cytokine levels may impact both the effector and immuno-modulatory potential of those patients in the long term.

Acknowledgments: The study is supported by theEuropean Fund for regional development through Operational Program Science and Education for Smart Growth, Grant BG05M2OP001-1.002-0001-C04

Vitamin D supplementation enhances cytotoxic response in patients with severe COVID-19

M. Torres[1], G. Casado[1], L. Vigón[1], S. Rodríguez-Mora[1], J. García-Pérez[1], E. Mateos[1], F. Ramos-Martín[1], D. López-Wolf[2], J. Sanz-Moreno[3], P. Ryan-Murua[4], M.L. Taboada-Martínez[5], M.R. López-Huertas[1], M. Cervero[6], M. Coiras[1]

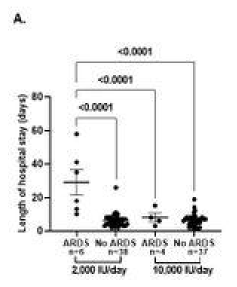
[1]*Instituto de Salud Carlos III, Immunopathology Unit, Majadahonda, Spain,* [2]*Hospital Universitario Fundación Alcorcón, Internal Medicine Service, Alcorcón, Spain,* [3]*Hospital Universitario Príncipe de Asturias, Internal Medicine Service, Alcalá Henares, Spain,* [4]*Hospital Universitario Infanta Leonor, Internal Medicine Service, Madrid, Spain,* [5]*Hospital Universitario de Cabueñes, Internal Medicine Service, Gijón, Spain,* [6]*Hospital Universitario Severo Ochoa, Internal Medicine Service, Leganés, Spain*

Background: Main cause of severe illness and death in patients with COVID-19 is an excessive inflammatory response derived from a massive cytokine storm.

The objective was to evaluate the effect of high doses of vitamin D on the exacerbated immune response during COVID-19.

Methods: Multicenter, randomized clinical trial with 85 patients hospitalized with respiratory failure due to COVID-19 and serum levels of 25-hydroxyvitamin D [25(OH) D] <30ng/mL. Patients were assigned randomly (1:1) to receive one daily dose of 10,000IU (n=41) or 2,000IU (n=44) of cholecalciferol for 14 days. Peripheral blood samples and clinical data were collected at baseline, 7 and 14 days.

Results: Median age of participants was 65.2 years (IQR 53.0-74.0), most patients (70.6%) were men and mean baseline serum 25(OH)D level was 15ng/mL (SD:6.0). Vitamin D levels increased 1.5-fold in the group receiving 10,000IU/day (p<0.0001) after 14 days, in comparison with 2,000IU/day group. Mean length of hospital stay (LOS) in patients with acute respiratory distress syndrome (ARDS) was significantly different between 10,000IU/day group (8.0 days [SD:4.4]) and 2,000IU/day group (29.2 days [SD: 17.1]) (p<0.0001) *(Figure 1A)*. No significant overall benefit was observed for reducing the inflammatory response, but high doses of vitamin D increased plasma levels of the anti-inflammatory cytokine IL-10 and antiviral cytokine IFNγ. After 14 days of supplementation, cytotoxic response was increased 4.3-fold (p=0.0205) in the 10,000IU/day group, in comparison with the 2,000IU/day group *(Figure 1B)*.



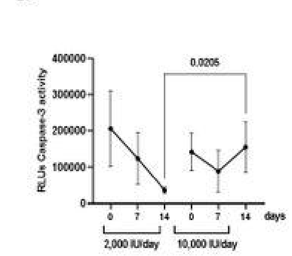


Figure 1.

Conclusions: This is the first study that describes the effect of high doses of vitamin D on the inflammatory and cytotoxic response in patients with severe forms of COVID-19. Due to the exacerbated but ineffective inflammatory response that occurs in some patients, the administration of vitamin D could shorten LOS and prevent the progression to ARDS and the most critical forms of the disease, mostly by increasing the cytotoxic response against the infected cells.

EPA086

T cell immunity to natural SARS-CoV2 infection in virally suppressed HIV infection

S. Pallikkuth[1], R. Pahwa[2], M. Alcaide[3], S. Pahwa[4,4]

[1]*University of Miami, Microbiology and Immunolology, Miami, United States,* [2]*University of Miami, Miami, United States,* [3]*University of Miami, Medicine, Miami, United States,* [4]*University of Miami, Microbiology and Immunology, Miami, United States*

Background: Immune response to SARS-CoV2 among Persons with HIV (PWH) have not been described in details. In this cross-sectional study, we investigated the SARS CoV2 antigen (Ag)-specific T cell responses in a group of PWH after COVID-19, and the association with age, humoral immunity, and T cell immune activation.

Methods: Participants with documented SARS-CoV2 infection: 17 virally suppressed PWH (4F/13M, median age 55 years and 17 HIV-uninfected (9F/8M, median age 39 years) were included. All had mild/moderate symptoms without hospitalization.

Median days from COVID-19 diagnosis to study entry was 44 days in both groups. Ag-specific CD4, CD8 and pTfh responses were analyzed by flow-cytometry using activation induced marker (AIM) assay after 24 hrs stimulation of PBMC with SARS-CoV2 peptides. Spike IgG response was

analyzed by COVID-SeroIndex Kantaro Quantitative IgG ELISA. Results compared by non-parametric Kruskal-Wallace test and by Spearman correlation.

Results: Days from diagnosis to study entry inversely correlated with total Ag-specific CD4 (p=0.02; r= -0.57) and pTfh (p=0.001; r= -0.75) response. CD4 T cell immune activation (IA) measured as frequencies of HLA-DR+CD38+ cells did not differ by HIV status while CD8 IA was significantly higher in HIV+ (p = 0.012).

Age did not correlate with total CD4 and CD8 responses in both groups. Spike IgG responses at study entry did not differ by HIV status (HIV+,12,789±9567 AU/ml: HIV-, 10,341.5±9142 AU/ml). Ag-specific CD4 and pTfh responses analyzed as frequencies of AIM+ (CD40L+CD69+) cells specific to spike (S), non-spike (R) peptides and total response calculated as S+R responses were not significantly different by HIV status.

Frequencies of AIM+ CD8 (CD69+CD137+) were also not different between groups. Spike IgG response directly correlated with AIM+ CD4 (HIV+: p=0.03; r=0.52, HIV-: p=0.027; r=0.52) and pTfh (HIV+: p=0.01; r=0.62, HIV-: p=0.02; r=0.52) in both groups.

Conclusions: Ag-specific CD4 and pTfh responses are associated with humoral response to SARS-CoV2 in HIV following COVID-19. Humoral and cell mediated immunity to SARS-CoV2 were not compromised in PWH and age and T cell IA did not influence the response.

How COVID vaccination in PWH influences these immune determinants and whether vaccine specific immunity is different than the natural infection needs investigation.

SARS-Cov2 vaccines

EPA087

Limited immunogenicity of SARS-CoV-2 vaccine in people living with HIV (PWH) and low nadir CD4 counts

P. Vizcarra[1], A. Vallejo[1,2], A. Cortés[3], S. Martín-Colmenarejo[1], J. del Pino[1], J.J. Serrano[3], H. Velasco[2], A. Martín-Hondarza[2], A. Abad[1], F. Longo[3], M.J. Vivancos[1], A. Moreno[1], J.L. Casado[1]
[1]*Ramon y Cajal University Hospital, Infectious Diseases, Madrid, Spain,* [2]*Ramon y Cajal University Hospital, Laboratory of Immunovirology, Madrid, Spain,* [3]*Ramon y Cajal University Hospital, Oncology, Madrid, Spain*

Background: Data regarding SARS-CoV-2 vaccine immunogenicity among PWH is conflicting. We assessed immune responses to a primary immunization schedule among PWH compared with healthcare workers (HCWs) and individuals with cancer (CA).

Methods: Blood samples from PWH, HCWs, and CA participating in a single-center cohort study were collected 21-30 days after the second SARS-CoV-2 vaccine dose. SARS-CoV-2-spike-specific IgG (IgG-S) was measured using CLIA, and percentages of SARS-CoV-2-spike INF-γ-producing CD4/CD8 were measured using *in vitro* stimulation of PBMCs and flow cytometry.

Results: Overall, 231 individuals (83 PWH, 60 HCWs, and 88 CA) were included. Mean age was 52 years (range, 26-80), and 114 (49.4%) were females. Among PWH, median nadir and current CD4 counts were 226 (interquartile range, IQR, 55-379) and 605 (IQR 466-981) cells/mm3, all were on ART, and 79 (95.2%) were virologically suppressed. Median time since HIV infection diagnosis was 15 (IQR 8-22) years, and 28 (35%) had prior AIDS.

Ninety-five and 89% of PWH developed humoral and cellular responses after second dose, respectively. Compared with HCWs and CA, PWH had significantly lower titers of IgG-S. CD4/CD8 responses among PWH with nadir CD4<=200 cells/mm3 were comparable to that of CA (Figure).

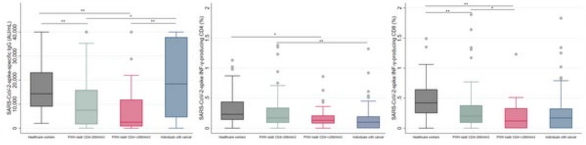

*Figure. SARS-CoV-2-spike-specific IgG titers (AU/mL), and percentages (%) of SARS-CoV-2-spike INF-γ-producing CD4 and CD8 T-cells after vaccination by groups of participants. *p<0.05; **p<0.001.*

In multiple linear regression analysis adjusted by age and sex, nadir CD4<=200 cells/mm3 was significantly associated with lower IgG-S titers and cellular responses (Table).

Multivariate analysis adjusted by age and sex	SARS-CoV-2-spike IgG titers Coef. (95% CI) p-value		SARS-CoV-2-spike INF-γ-producing CD4 Coef. (95% CI) p-value		SARS-CoV-2-spike INF-γ-producing CD8 Coef. (95% CI) p-value	
PWH, nadir CD4 <=200 cells/mm3	reference		reference		reference	
PWH, nadir CD4 >200 cells/mm3	4490.10 (-1387.15-10367.30)	0.134	0.12 (0.01-0.24)	0.037	0.15 (0.00-0.30)	0.056
Healthcare workers	7222.40 (1283.09-13161.65)	0.017	0.17 (0.05-0.28)	0.005	0.34 (0.19-0.49)	<0.001
Individuals with cancer	9796.50 (4083.49-15509.57)	<0.001	-0.04 (-0.15-0.07)	0.475	0.07 (-0.07-0.22)	0.327

Table.

Conclusions: Humoral and cellular immune responses were elicited in almost all PWH after SARS-CoV-2 vaccination, whereas the magnitude was affected by nadir CD4 counts. Blunted cellular immunogenicity was observed in PWH with nadir CD4<=200/mm3 and CA, which may impact vaccine effectiveness.

EPA088

Adverse events following COVID-19 vaccination among people with HIV: review of available vaccine safety literature

S. Kiplagat[1], E. Blau[1], J. Gidudu[1]

[1]*Centers for Disease Control and Prevention, Global Immunization Division, Center for Global Health, Atlanta, United States*

Background: Vaccines used in national immunization programs undergo scientifically rigorous, multi-stage randomized clinical trials and robust post-licensure studies for safety and efficacy. However, they are not risk-free, and adverse events following immunization (AEFI) may occur. While people with HIV (PWH) have an increased risk for severe COVID-19 disease, there are limited COVID-19 vaccine safety data among this population.

We conducted a literature review to summarize published safety data and describe reported AEFIs of COVID-19 vaccinations among PWH.

Methods: This systematic review included published literature from January 1 2019–December 3, 2021. We searched MEDLINE, Embase, CINAHL and Global Health without any geographic restrictions. Grey literature sources including medRXIV were also reviewed. The keywords and search terms included HIV and COVID-19 and vaccine.

Eligibility criteria included vaccine safety outcomes among PWH published in English in peer-reviewed journals. Data on vaccine platforms, products, study design, sample size and AEFIs were compiled. AEFIs were classified into serious or non-serious: non-serious AEFIs could be local (e.g., pain or swelling) or systemic (e.g., fatigue, headache). Serious adverse events (SAEs) were defined as events that were life-threatening or resulted in hospitalization or death.

Results: A total of 3,005 unduplicated articles were identified. After title and abstract screening, 52 were further assessed for full-text review. A total of 12 articles met the inclusion criteria. The majority of the included articles (75%) described randomized controlled trials or prospective cohort studies using mRNA, inactivated vaccine, and adenovirus vector COVID-19 vaccine platforms. The reported AEFIs were predominantly non-serious (99%) local and systemic adverse events. SAEs were rare (0.1%–0.4% of recipients), and included Bell's palsy, myocardial infarction, thrombocytopenia; 4 SAEs were among PWH. Overall, there was a lack of reported AEFI data stratified by special populations, including PWH.

Conclusions: A small number of studies reported on COVID-19 vaccine safety among PWH. Most of the reported AEFIs were non-serious and few occurred among PWH. Potential contributing factors to AEFIs, such as immunosuppression and antiretroviral drug interactions may be considered for future reviews. COVID-19 vaccines and other newly introduced vaccines should continue to be monitored for safety among general and special populations, including PWH.

EPA089

Potent cytotoxic activity against SARS-CoV-2 of CD8+ T cells from individuals with HIV who received complete schedule of COVID-19 vaccines

G. Casado[1], J. Cantón[2], L. Vigón[1], M. Manzanares[1], F. Ramos Martín[1], M. Torres[1], S. Domínguez-Mateos[3], S. Pérez-Santos[3], M. Aranzazu Murciano Antón[3], R. Torres Perea[2], S. Rodríguez Mora[1,4], M. Cervero[2], M. Coiras[1,4]

[1]*Instituto de Salud Carlos III, AIDS Immunopatology Unit, National Center of Microbiology, Madrid, Spain,* [2]*Hospital Universitario Severo Ochoa, Internal Medicine Service, Leganés, Spain,* [3]*Centro de Salud Doctor Pedro Laín Entralgo, Family Medicine, Alcorcón, Madrid, Spain,* [4]*Biomedical Research Center Network in Infectious Diseases (CIBERINFEC), Madrid, Spain*

Background: COVID-19 vaccination is recommended for people with HIV (PWH) but low CD4 count and immune system exhaustion may affect the quality of the immune response.

Our objective was to evaluate the humoral and cellular immune responses in PWH after receiving complete schedule of currently approved vaccines against SARS-CoV-2.

Methods: Blood samples of 23 PWH who did not have passed COVID-19 were collected before and 4-6 weeks after receiving two doses of COMIRNATY or Spikevax, or one dose of Ad26.COV2-S. Fourteen healthy donors with similar vaccination patterns were recruited as controls. Direct cellular cytotoxicity (DCC) was analyzed by measuring caspase-3 activity in Vero E6 cells infected with pseudotyped SARS-CoV-2_Renilla after co-culture with PBMCs (1:1). DCC against HIV-1 was analyzed in NL4.3_Renilla-infected TZM cells. Cell subpopulations were analyzed by flow cytometry. IgG titers were quantified by Euroimmun-Anti-SARS-CoV-2.

Results: 1. Most participants (78%) were vaccinated with COMIRNATY. CD4 count in PWH was 864 (IQR 631-1035) cells/mm3 and CD4/CD8 ratio was 0.97 (IQR 0.69-1.2).

2. DCC against SARS-CoV-2 increased 3.86-fold (p=0.0255) in PBMCs from PWH before vaccination and 1.65-fold (p=0.0434) after vaccination, in comparison with healthy donors. Viral replication was reduced 1.67- (p=0.0229) and 1.53- (p=0.0251) fold after co-culture with PBMCs from PWH before and after vaccination, respectively.

3. CD8 count increased 1.43-fold (p=0.0408) in PWH before vaccination and it was maintained after vaccination. CD8+CD107a+ subpopulation increased 1.3-fold (p=0.0408) in PWH but remained unchanged in healthy donors.

4. CD3+CD8-TCRγδ+ subpopulation increased 6.55-fold (p<0.0001) in PWH after vaccination, with CD107a expression increased 8.84-fold (p=0.0016). CD3+CD8+TCRγδ+CD107a+ subpopulation increased 2.08-fold (p=0.0050) in PWH.

5. We found no differences in NKs or NKTs between groups.

6. The response against HIV-infected TZM monolayer was not modified after vaccination.

7. IgG levels against SARS-CoV-2 increased 43.78-fold ($p<0.0001$) after vaccination, similarly to healthy donors ($p=0.0156$).
Conclusions: PBMCs from ART-treated PWH with >500 CD4/mm3 showed a good cellular and humoral response to SARS-CoV-2 one month after receiving complete schedule of COVID-19 vaccines. DCC was higher than in PBMCs from healthy donors and it was mostly based on a potent memory CD8±TCRgd+ response. Vaccination did not modify the immune response against HIV.

EPA090

Factors associated with SARS-CoV2 vaccination acceptance in people with HIV participating in the SCAPE-HIV study

F. Burns[1,2], T.J. Barber[2,1], J.R.G. Brown[3], C. Smith[3], N. Hemat[2], S. Madge[2], A. Hunter[2], M. Lipman[2], S. Bhagani[2], T. Mahungu[2], D. Peppa[4,2], M.A. Johnson[2]
[1]University College London, Institute for Global Health, London, United Kingdom, [2]Royal Free London NHS Foundation Trust, Ian Charleson Day Centre, London, United Kingdom, [3]University College London, London, United Kingdom, [4]University College London, Institute of Immunity & Transplantation, London, United Kingdom

Background: The high prevalence of comorbidities and social inequity, coupled with regular contact with heath care services experienced by people with HIV (PWH), are likely to influence vaccine uptake as well the risk of SARS-CoV2 infection and severity. This analysis aims to determine factors associated with SARS-CoV2 vaccine uptake.
Methods: The SCAPE-HIV study (SARS CoV2 Antibody PrevalencE in a London HIV cohort) is an ongoing cross-sectional study within a London HIV clinic outpatient adult cohort. Interim analysis was performed on 515 participants recruited between July-September 2020. Participants completed questionnaires about their sociodemographic, clinical and SARS CoV2 vaccine status.
Results: 493/515 (89.6%) reported they had been offered a SARS-CoV2 vaccine. Median age offered vaccination was 53 years, 18.1% self-identified as female, 72.4% white, 17.3% black.Over half (57%) had a university degree, 62.5% were in employment (24.6% as keyworkers), but 95/483 (19.7%) reported they did not always have enough money to cover basic needs.
All were on antiretroviral therapy (ART), median CD4 627 (IQR 471, 802; range 20-1969); median nadir CD4 237 (IQR 111, 372; range 2-1048); 96.4% had an undetectable HIV viral load (<50 copies/ml). Almost all (95.7% (472/493)) participants accepted the vaccination offer.
Acceptance of SARS-CoV2 vaccination offer among PWH was not associated with age, education, employment status, numbers living in household or any HIV related factors (see table). Those more likely than others to refuse SARS-CoV2 vaccination included women, PWH who did not identify as white or black ethnicity (OR 3.12 (95%CI 1.05-9.25)), those did not always have enough money to cover basic needs (OR 2.65 (95%CI 1.07-6.60)), and those who do get seasonal influenza vaccinations (OR 4.32 (1.77-10.51)). History of COVID19 was also associated with vaccine refusal (OR 3.46 (1.43-8.38)).
Conclusions: SARS-CoV2 vaccine acceptance in this cohort of PWH was extremely high. Although participation in the study may be more likely in those accepting vaccination, the study recruited a substantial proportion of people with social disadvantage.
These findings suggest a history of declining influenza vaccination may be a marker of SARS-CoV2 vaccine hesitancy. Better understanding of the psychosocial factors influencing vaccination uptake will enable effective intervention.

EPA091

Immunogenicity of mRNA-1273 COVID-19 vaccination in PLWH after inadequate primary vaccination response

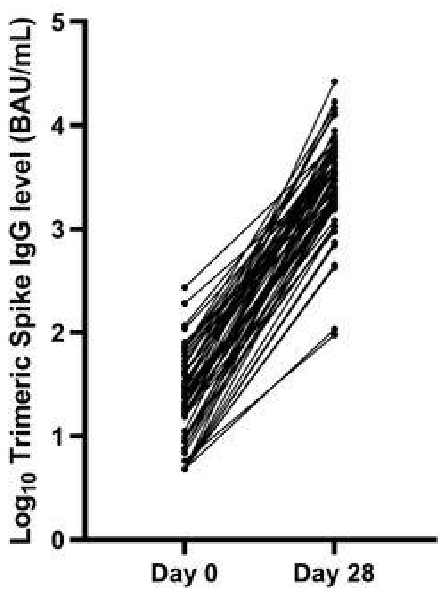
Background: A single prime-boost COVID-19 vaccination cycle led to lower antibody levels in people living with HIV (PLWH) compared to healthy controls, with a substantial proportion of inadequate responders. Here, we evaluated whether an extra vaccination could induce measurable immune responses in this population.

Methods: In a nationwide prospective cohort study (COVIH, n=1148) all PLWH with inadequate antibody response to primary vaccination (≤300 BAU/mL Trimeric Spike IgG, Liaison) were invited for an mRNA-1273 (100mcg) vaccination (n=165). The anti-SARS-CoV-2 Trimeric Spike IgG response 4 weeks later was assessed as primary endpoint. Secondary endpoints include clinical biomarkers for antibody responses, reactogenicity and the induction of SARS-CoV-2-specific neutralizing antibodies and T-cell responses targeting circulating variants.

Results: Seventy PLWH with inadequate antibody responses (41 after primary vaccination with ChAdOx1-S, 25 after BNT162b2, 4 after Ad26.COV2.S) were included. The mean antibody level directly pre-vaccination was 34.2 BAU/mL (95% CI 24.0-77.5), including 7 with undetectable serological responses. Their median age was 64 years [IQR 61-67], 87.1% was male, median current and nadir CD4+ T-cells were 650/µL [IQR 454-933] and 230/µL [IQR 160-350], and 94.3% had HIV-RNA <50 copies/ml on cART. Median time between completing the primary vaccination schedule and the extra vaccination was 170 days [IQR 153-187].

In total, 97.1% (66/68) of the PLWH responded well to extra vaccination (>300 BAU/ml). The mean increase in antibody level was 4428 BAU/ml (95% CI 3369-5487). The responses were comparable after primary vaccination with ChAdOx1-S and BNT162b2, 3890 BAU/ml (95% CI 2974-4806) and 4939 BAU/ml (95% CI 7384-2493) respectively, p=0.36. We found no significant differences in antibody responses in relation to baseline CD4+ T-cell count (<500, >500/mm3), age groups (<65, >65 years) or time post-primary vaccination.



Conclusions: An additional mRNA-1273 vaccination substantially increased antibody levels in PLWH with inadequate antibody response to primary vaccination, regardless of initial vaccine type or HIV characteristics.

[1]Centre de Recherche du CHUM, Department of Microbiology, Infectiology and Immunology, Québec, Canada, [2]University of Montreal, Département de Microbiologie, Infectiologie et Immunologie, Montreal, Canada, [3]McGill University, Department of Microbiology and Immunology, Montreal,, Canada, [4]University of Ottawa, Department of Biochemistry, Microbiology and Immunology, and Center for Infection, Immunity, and Inflammation, Ottawa, Canada, [5]Héma-Québec, Affaires Médicales et Innovation, Québec, Canada, [6]Laboratoire de Santé Publique du Québec, Institut Nationale de Santé Publique du Québec, Sainte-Anne-de-Bellevue, Canada, [7]Institut National de Santé Publique du Québec, Quebec, Canada, [8]Université de Montréal, Département de Médecine, Montreal, Canada

Background: Continuous emergence of SARS-CoV-2 variants of concern (VOC) is fueling the COVID-19 pandemic. Omicron (B.1.1.529) is rapidly spreading worldwide. The large number of mutations in its Spike raised concerns about a major antigenic drift that could significantly decrease vaccine efficacy and infection-induced immunity. A long interval between BNT162b2 mRNA doses was shown to elicit antibodies that efficiently recognize Spikes from different VOCs.

Here we evaluated the recognition of Omicron Spike by plasma from a cohort of SARS-CoV-2 naïve and previously- infected individuals that received their BNT162b2 mRNA vaccine 16-weeks apart. These responses were compared to those elicited in individuals receiving a short dose interval regimen (4-weeks).

Methods: Plasma binding to the full-length Spike from different VOCs (D614G, Alpha, Beta, Gamma, Delta and Omicron) expressed at the cell surface was evaluated by flow cytometry. The capacity of plasma to neutralize the different VOCs was evaluated with a well-established pseudoviral assay.

Results: The Omicron Spike was recognized less efficiently than D614G, Alpha, Beta, Gamma and Delta Spikes. Plasma from individuals of the long interval cohort recognized and neutralized significantly better the Omicron Spike compared to those that received a short interval.

Conclusions: In summary, our results suggests that the delayed boosting in naïve individuals facilitates antibody maturation resulting in enhanced breadth able to provide detectable levels of recognition and neutralization against Omicron. Epidemiological studies will determine if the vaccine interval advantage, as measured by these*in vitro*parameters, confers any clinical benefit against Omicron.

EPA093

Detection of pre-existing neutralizing antibodies against Ad26 in HIV-1-infected Individuals not responding to the Ad26.COV2.S vaccine

K. Schmidt[1], E. Harrer[1], V. Schönau[1], D. Simon[1], A. Kleyer[1], P. Steininger[2], K. Korn[2], K. Nganou-Makamdop[2], T. Harrer[1]

[1]Universitätsklinikum Erlangen, Medizin 3 - Rheumatologie und Immunologie, Erlangen, Germany, [2]Institut für Klinische und Molekulare Virologie, Erlangen, Germany

Background: The Ad26.COV2.S COVID vaccine is a replication-incompetent human adenovirus type 26 vector encoding the SARS-CoV-2 spike protein. In clinical trials, a single dose of AD26.CoV2.S induced SARS-CoV-2-neutralizing antibodies in 96% of healthy adults. In the Erlangen HIV cohort, failure to develop SARS-CoV-2 specific antibodies was observed in 9 out of 13 HIV-1-infected subjects after vaccination with Ad26.COV2.S.

To investigate pre-existing anti-vector immunity as a potential cause for poor vaccine response towards Ad26.COV2.S, we analyzed neutralizing antibodies against the Ad26.COV2.S vaccine in stored serum and plasma samples obtained from time points before and after vaccination with Ad26.COV2.S.

Methods: Investigation for pre-existing A26-antibodies could be performed in 6 of 9 HIV-1-infected subjects who did not develop SARS-CoV-2 specific antibodies after Ad26.COV2.S vaccination.

Furthermore, 8 subjects (4 HIV-1-infected, 4 HIV-1-uninfected) with antibody responses after Ad26.COV.2.S vaccination were included as controls. Serum or plasma samples were collected 33-738 days before and 18-147 days post Ad26.COV2.S vaccination. SARS-CoV-2 specific antibodies were measured by IgG ELISA.

Anti-Ad26 neutralizing antibody responses were investigated by flow cytometric evaluation of spike and adenoviral protein expression in co-cultures of HEK293T cells, Ad26.COV2.S and serial dilutions of pre- or post-vaccination sera. The ChAdOx1-S vaccine that is based on a chimp adenovirus served as control.

Results: Both Ad26.COV2.S and the ChAdOx1-S vaccines induced high expression rates of up to 98% of spike and adenoviral protein in HEK293T cells 24h after *in-vitro* transduction. Of the 6 vaccine non-responders 3 showed strong neutralizing activity towards Ad26 in 1:50 diluted pre-vaccination sera that significantly decreased the Ad26.COV2.S-induced spike expression and even more pronounced the expression of the adenoviral protein. In contrast, the spike and adenoviral protein expression stayed at high levels in the group of vaccine responders. All but two subject developed neutralizing antibod-

ies after vaccination. Neutralizing activity towards the ChAdOx1-S vaccine could not be observed except for one of the vaccine responders.

Conclusions: Ad26.COV2.S vaccination was associated with a high failure rate in HIV-1- infected patients in our cohort. Pre-existing immunity against Ad26 could be an important reason for poor vaccine efficacy in a subgroup of patients.

EPA094

Characterization of serum and mucosal SARS-CoV-2-antibodies in HIV-1 infected subjects after BNT162b2 mRNA vaccination or SARS-CoV-2 infection

K. Schmidt[1], E. Harrer[1], K. Nganou-Makamdop[2], B. El Kenz[2], T. Harrer[1]

[1]Universitätsklinikum Erlangen, Medizin 3 - Rheumatologie und Immunologie, Erlangen, Germany, [2]Institut für Klinische und Molekulare Virologie, Erlangen, Germany

Background: Limited data are available regarding the immunogenicity of the BNT162b2 mRNA vaccine in HIV-1 infected patients. Here, we report on the humoral immune responses to BNT162b2 mRNA vaccination. In HIV-1 infected patients on antiretroviral therapy (ART) in comparison to HIV-1-uninfected subjects.

Methods: For this study, 27 HIV-1 infected patients on ART and 23 HIV-1 uninfected subjects were recruited. Of the total cohort consisting of 50 subjects, 27 subjects were vaccinated with the BNT162b2 mRNA SARS-CoV-2 vaccine (12 HIV-1 infected, 15 HIV-1-uninfected).

17 of the 50 study participants had recovered from asymptomatic to severe COVD-19 infection (9 HIV-1 infected, 8 HIV-1 uninfected). 6 HIV-1 infected subjects served as SARS-CoV-2 non-immune controls. Serum and saliva samples were collected 8-119 days after the second BNT162b2-mRNA vaccination or 38-119 days after SARS-CoV-2 infection and analyzed using SARS-CoV-2 spike-specific IgG and IgA ELISAs and a surrogate neutralization assay.

Results: While all subjects showed anti-spike IgG and IgA in serum after two doses of BNT162b2 mRNA vaccine, HIV-1 infected subjects displayed significantly less anti-spike IgG and lower serum neutralizing capacity compared to HIV-1 uninfected subjects. Serum levels of anti-spike IgG and IgA as well as neutralizing activity were significantly higher in vaccinees compared to SARS-CoV-2 convalescents irrespective of HIV-1 status.

Among SARS-CoV-2 convalescents, there was no significant difference in the spike-specific antibody response between HIV-1 infected and uninfected subjects. In saliva, anti-spike IgG and IgA antibodies were detected both in vaccinees and convalescents albeit at lower frequencies compared to serum and only rarely with detectable neutralizing activity.

Conclusions: In summary, our study demonstrates that the BNT162b2 mRNA vaccine induces SARS-CoV-2-specific antibodies in HIV-1 infected patients on antiretroviral therapy. However, lower vaccine induced IgG and neutralization activity indicate a lower functionality of the humoral vaccine response in HIV-1 infected patients.

Track B - Clinical science

Impact of co-factors (e.g., viral clade, tropism, genetic factors) on disease progression

EPB001

Factors influencing immune restoration in people living with HIV/AIDS

B. Aksak-Wąs[1], A. Urbańska[1], K. Scheibe[1], K. Serwin[1], M. Leszczyszyn-Pynka[1], M. Rafalska-Kosior[1], J. Gołąb[1], D. Chober[1], M. Parczewski[1]
[1]*Pomeranian Medical University in Szczecin, Department of Infectious, Tropical Diseases and Acquired Immunodeficiency, Szczecin, Poland*

Background: Immune restoration is a key clinical aspect that is pursued in the care of human immunodeficiency virus (HIV)-infected patients. Despite effective antiretroviral treatment and undetectable viremia, immune recovery is often incomplete.

Furthermore, it may be influenced by an array of clinical and genetic factors. Patients lacking immune recovery, despite the suppression of viral replication, have a higher risk of cardiovascular diseases; acquired immunodeficiency syndrome-defining events, including malignancies; and severe infections due to persistent immune activation and inflammation.

The aim of this study was to assess the impact of selected genetic variants and clinical variables on immune reconstruction in HIV-positive individuals.

Methods: Longitudinal data were collected from 311 Caucasian patients followed up at Pomeranian Medical University, Szczecin, Poland. Single nucleotide polymorphisms in *CCR2* (rs1799864), *CX3CR1* (rs3732378), *HLAC-35* (rs9264942), and *CCR5* (promoter, rs1799988); a 32 bp deletion (Δ32) in *CCR5*; and *HLA-B**5701 genotypes were correlated with clinical data and selected endpoints reflecting immune reconstruction (increase in $CD4^+$ lymphocyte count to > 500 cells/µL and > 800 cells/µL and the reconstitution of the $CD4^+/CD8^+$ cell ratio to > 0.8 and > 1.0). Kaplan-Meier and Cox proportional hazards models were used to analyze the effects of genetic factors over time.

Results: A notable influence of genetic variants, *HLA-B**5701, *CCR2*, and *CCR5*-Δ32, on immune reconstruction was observed for the first year from the initiation of cART. These effects were lost within 1-4 years. For *HLA-B**5701, the effect on the $CD4^+/CD8^+$ cell ratio was lost within 48 months (hazard ratio [HR]=2.04, 95% confidence interval CI:1.04–4.03) and the effect on $CD4^+$cell count was lost within 12 months (HR=2.12, CI:1.11–4.04).

The effect of *CCR2*-GG on the $CD4^+/CD8^+$ cell ratio was lost within 36 months (HR=1.7, CI:1,05–2,75). For *CCR5*-wt/Δ32, the effect on the $CD4^+/CD8^+$ cell ratio was lost within 24 months (HR=2.0, CI:1.08–3.69) and the effect on $CD4^+$cell count was lost within 18 months (HR=1.98, CI:1.14–4.73).

Conclusions: Selected genetic polymorphisms, namely *CCR2*-GG and *CCR5*-Δ32, and the presence of the*HLA-B**5701 allele positively influenced immune restoration in cART-treated patients with HIV/AIDS. These results indicate that host genetics plays an important role in early immunological treatment responses.

EPB002

Reduced selection of unfavourable HLA-I in mother-to-child HIV transmission in KwaZulu Natal, South Africa

G.Z.L. Cromhout[1], T. Ndung'u[2], P. Goulder[3]
[1]*University of KwaZulu Natal, HIV Pathogenesis Programme, Durban, South Africa,* [2]*African Health Research Institute, Durban, South Africa,* [3]*University of Oxford, Paediatrics, Oxford, United Kingdom*

Background: Combination antiretroviral therapy (cART) has transformed HIV disease outcomes and reduced transmission risk. In addition, in the pre-cART era, HLA class I genes associated with high viraemia and rapid disease progression were more prevalent in infected children and their mothers. Now in the cART era, mother-to-child-transmission (MTCT) arises principally in association with maternal seroconversion during pregnancy, and not with poor maternal immune control of HIV. Using MTCT as a model, we examine whether cART has altered the specific transmission pairs most at risk of transmission.

Methods: We studied HLA-I types in a current cohort of mother-child pairs enrolled in the setting of cART availability in 2015-2020 in KwaZulu-Natal, South Africa, and compared these with a historical (2000-2005) cohort enrolled in the same locality, when cART was unavailable to mothers during pregnancy.

Results: In the historical cohort, the frequency of HLA-I alleles associated with high viraemia (HLA-B*18/45:01/58:02) was higher in HIV-infected mothers and children than in non-transmitting mothers (43.9% and 47.4%, respectively, versus 26.5%; p=1.3x10-5 and p=0.0003) whilst the frequency of HLA-I alleles associated with low viraemia (HLA-B*27/57/58:01/81:01) was lower (16.8% and 17.5%, respectively, versus 30.7%; p=0.002 and p=0.002).

By contrast, in the current cohort, high viraemia-associated HLA-I alleles (HLA-B*18/45:01/58:02) are not significantly more frequent than in non-transmitter mothers but are significantly less frequent than in the historical cohort of transmitter mother-child pairs (31.9% and 33.3% versus 43.9%;47.4%, in mothers and children, respectively; p=0.01, comparing current with historical children).

Similarly, protective HLA-I alleles (HLA-B*27/57/58:01/81:01) are more frequent in the current than the historical cohort of transmitter pairs and do not differ significantly in frequency from the historical non-transmitter mothers.

Conclusions: It has been proposed that the best opportunity to achieve functional cure may be in early-cART-treated children. The data here suggest that children,

no longer burdened by unfavourable HLA-I, may benefit particularly from cure interventions such as therapeutic vaccines that aim to boost immune control of HIV.

Morbidity, mortality and life expectancy in clinical research

EPB003

Sex-stratified analyses of trends and risk of all-cause mortality among patients living with HIV with different at-risk populations in a country with a universal health-care system and free access to cART

C.-Y. Lee[1,2,3], Y.-P. Lin[2], H.-P. Tu[4], S.-F. Wang[5], P.-L. Lu[2,6,7]
[1]Kaohsiung Medical University, Department of Medicine, Kaohsiung, Taiwan, Province of China, [2]Kaohsiung Medical University Hospital, Department of Internal Medicine, Kaohsiung, Taiwan, Province of China, [3]Kaohsiung Medical University, Graduate Institute of Medicine, Kaohsiung, Taiwan, Province of China, [4]Kaohsiung Medical University, Department of Public Health and Environmental Medicine, Kaohsiung, Taiwan, Province of China, [5]Kaohsiung Medical University, Department of Medical Laboratory Science and Biotechnology, Kaohsiung, Taiwan, Province of China, [6]Kaohsiung Medical University, School of Post-Baccalaureate Medicine, Kaohsiung, Taiwan, Province of China, [7]Kaohsiung Medical University, Center for Liquid Biopsy and Cohort Research, Kaohsiung, Taiwan, Province of China

Background: We aim to assess at-risk population differences in the trend and risk of all-cause mortality of patients living with HIV (PLWH) by sex in Taiwan from 1984 to 2016.

Methods: We performed a retrospective, nationwide cohort from a nationwide HIV/AIDS database. We used Cox proportional hazard models to assess the effect of the different at-risk populations on all-cause mortality overall and by each sex. We also tested for interactions between HIV acquisition and sex in separate Cox proportional hazard models.

Results: We enrolled 33,142 PLWH: 61.25% in MSM, 14.37% in men who have sex with women (MSW), 18.32% in male intravenous drug users (M-IDU), 3.30% in women who have sex with men (WSM), and 2.74% in female IDU (F-IDU).

The overall reduction of all-cause mortality from 1984-1996 to 2012-2016 for MSM, MSW, M-IDU, WSM, and F-IDU was 91.1%, 87.5%, 34.2%, 71.8%, and 80.9%, respectively.

The trends in all-cause mortality evolved distinctly in different HIV acquisition populations: the all-cause mortality substantially decreased from 1984-1996 to 1997-2006, and then declined slowly to 2007-2011; between 2007-2011 and 2012-2016, the mortality decreased by 33.6% for MSM, 34.0% for MSW, 24.3% for WSM, and increased by 54.8% for M-IDU and 25.8% for F-IDU.

Among male PLWH, MSM (aHR 0.35, 95% CI 0·32-0.39) and MSW (aHR 0.51, 95%CI 0.45-0.57) had a lower risk of all-cause mortality compared to M-IDU. In female PLWH, WSM had a lower risk of all-cause mortality (aHR 0.45, 95% CI 0.33-0.62) compared to F-IDU. We found no significant interaction between sex and HIV acquisition on all-cause mortality.

Conclusions: A better understanding of the differences in all-cause mortality for each mode of HIV acquisition across each sex, could help enhance investigation into the different etiologies of mortality, and thus more precisely address the disparities or health inequities for patients with each mode of HIV acquisition.

EPB004

The relationship between infant mortality, survival rates, and HIV status among Ethiopian infants born to HIV-positive mothers within their first year

T. Legesse[1], B. Asale[2], T. Anjulo[3], A. Lencha[4]
[1]Shanto Zone Higher Clinic, Nursing, Shanto, Ethiopia, [2]Boditi Primary Hospital, Social Work, Boditi, Ethiopia, [3]Hope in Every Person Inc., Health Promotion, Sodo, Ethiopia, [4]Wolaita Sodo University Teaching and Referral Hospital, Psychiatric and Pediatric Department, Wolaita Sodo, Ethiopia

Background: Few studies have been conducted on the survival of newborns delivered to HIV-positive mothers. The goal of this study was to find out what variables impact infant survival in HIV-infected and HIV-exposed but infected newborns.

Methods: At birth and 2, 6, and 12 months of age, z-scores in body mass index, weight, age, and head circumference were calculated using data from 400 babies (50 HIV-infected and 350 HIV-exposed but uninfected) and their HIV-infected mothers.

Mixed-effects models were used to examine how z-scores changed over time due to HIV infection status, maternal age, co-morbidities, maternal HIV disease status, and other variables.

Results: From birth to 6 months, age, BMI, weight, and head circumference all increased, but after eight months, they all decreased significantly. Infant HIV infection was associated with significant weight, age, and head circumference losses, but not with body mass index. In HIV-exposed but uninfected newborns, repeated diarrhea episodes were related to reduced weight (-0.40) and body mass index (-0.75).

Mixed-fed infants regularly weighed less than breastfeeding infants. Lower z-scores have also been linked to premature births and low birth weight.

Infants born to mothers with less than a high school diploma (vs. college degrees), who were 18-22 years old (vs. 35+), and who had a viral load at delivery of >100,000 copies/ml (vs. 100,000) had worse z-scores at all periods. The mother's viral load at the time of birth was a significant

Oral abstracts

Poster exhibition

E-posters

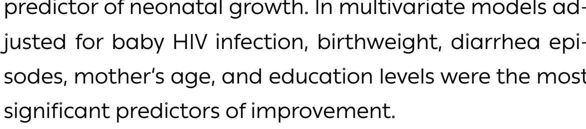
Author Index



predictor of neonatal growth. In multivariate models adjusted for baby HIV infection, birthweight, diarrhea episodes, mother's age, and education levels were the most significant predictors of improvement.

Conclusions: The findings on the negative impact of diarrhea episodes and mixed feeding on infant development suggest that HIV-positive mothers exclusively breastfeed their kids. Early infant growth is significantly predicted by HIV infection in the newborn, mother's age, education, and viral load.

EPB005

The CIHR Canadian HIV Trials Network: 32 years strong in improving prevention, treatment and management for people living with HIV in Canada through the implementation of high-quality research

S. Walmsley[1], M. Klein[2], A. Anis[3], D. Tan[1], E. Cherban[4]
[1]University of Toronto, Department of Medicine, Toronto, Canada, [2]McGill University, Department of Medicine, Montreal, Canada, [3]University of British Columbia, School of Population and Public Health, Vancouver, Canada, [4]CIHR Canadian HIV Trials Network, Vancouver, Canada

Background: Since 1990, The CIHR Canadian HIV Trials Network (CTN) has been a partnership of researchers, people living with HIV, governments, health advocates, and industry committed to advancing prevention, treatment, and management of HIV, HCV, and STTBIs. We will provide an overview of CTN's successes, lessons learned, challenges and future opportunities as Canada works diligently to reach all of our 90-90-90 targets.

Description: By conducting trials on the treatments of HIV, the Network developed research cores to address immunotherapy and vaccines; comorbidities; coinfections; and HIV prevention. This includes community-based and culturally appropriate treatment.

The CTN address research gaps and priorities by: funding pilot studies; developing research with community; scientific and community review of studies; accountable resource allocation; meeting semi-annually; an international External Advisory Committee; providing research support services; and employing virtual technologies.

Lessons learned: Lessons learned include:

1. Training: The Postdoctoral Fellowship Program has now trained over 100 fellows, many of whom lead the Network and continue to conduct research.
2. Community Engagement: The Community Advisory Committee is an embedded that became a model for community engagement for other networks. We have community led Community Engagement Teams.
3. Funding Innovation: An inclusive research agenda to develop and Supporting investigator-initiated studies.
4. Funding for Pilot Studies: We provide junior investigators with funding for high-risk, preliminary studies to build skills, generate data, and make them more competitive in national funding competitions.
5. Guidelines and Long-Term HIV Management: The Network supports guideline development (e.g. PrEP) and studies focused on managing comorbidity, coinfections, and aging.
6. Enhancing Infrastructure: As studies complexity increases, the Network supports investigators with experts to file Health Canada trials and trial monitors.

Conclusions/Next steps: Next steps include:

1. Embracing international collaborations for larger sample size clinical trials and building expertise in implementation science particularly around coinfections, comorbidities, and a broader STBBI mandate.
2. Concentrate populations with less favourable outcomes, such as Indigenous communities, people who use drugs, and people aging with HIV to reach our 90:90:90 goals.
3. Using decentralized trials, virtual appointments, and in-home procedures introduced by COVID-19 to co-create participant-centric and trauma-informed research studies.
4. A commitment to anti-racism/anti-colonialism Network policies and structures.
5. Increasing support to investigators to eliminate study administrative burden.

EPB006

Improving short-term mortality of people living with HIV admitted to the intensive care unit: a 20-year study (2000-2019)

T. Kanitkar[1], O. Dissanayake[1], N. Bakewell[2], S. Rimmer[1], M. Symonds[1], M. Lipman[1], S. Bhagani[3], A. Adlakha[4], C. Sabin[2], B. Aggarwal[4], R.F. Miller[1]
[1]Royal Free Hospital, HIV Services, London, United Kingdom, [2]University College London, Institute for Global Health, London, United Kingdom, [3]University College London, Research Department of Infection, London, United Kingdom, [4]Royal Free Hospital, Intensive Care Medicine, London, United Kingdom

Background: Intensive care unit (ICU) survival outcomes have markedly improved in people living with HIV (PLWH), due to the widespread use of effective combination antiretroviral therapy (cART), critical care advances and changing reasons for ICU admission.

We retrospectively reviewed records of PLWH admitted to ICU in an HIV-referral centre to study trends in short-term mortality between 01/01/2000 and 31/12/2019.

Methods: Short-term outcomes were in-ICU and in-hospital mortality. The odds of in-ICU/in-hospital mortality were modelled using logistic regression, considering only a patient's first ICU admission.

Univariable models including ICU admission calendar year as a linear term were used to explore trends in in-ICU/in-hospital mortality over the study period.

Multivariable models were fitted to further explore the calendar year effect adjusting for sex, age, APACHE-II score and CD4+ T-cell count.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Results: There were 221 PLWH (71% male, median [Interquartile range (IQR)] age 45 years [38-53]) admitted to ICU with median [IQR] ICU-stay length of 5 days [2-12], APACHE-II score 19 [14-25] and CD4+ T-cell count 122 cells/mm3 [30-297]; 46% (94/221) had an undetectable viral load (<50 copies/mL).

Of admission diagnoses, 48% (106/221) were advanced HIV-related; the most common admission diagnosis category was lower respiratory tract infection (30%).

Overall, in-ICU mortality was 29% (64/221) and in-hospital mortality was 38% (85/221); median [IQR] time to death from ICU admission was 4 [1-12] and 7 [2-19] days, respectively.

The odds of in-ICU and in-hospital mortality significantly decreased over the 20-year period, with an estimated decrease of 11% per year (95% Confidence Interval (CI): 0.84-0.94, p<0.001) and 14% per year (95% CI: 0.82-0.91, p<0.001), respectively.

After adjusting for patient demographics and clinical factors, there was no evidence of a decreasing trend in ICU mortality (adjusted Odds Ratio: 0.96, 95% CI: 0.89-1.04, p=0.36), however, there was evidence of a decreasing trend in in-hospital mortality, with an estimated decrease of 10% per year (95% CI: 0.84-0.97, p=0.008).

Conclusions: Our study found that short-term mortality of critically ill PLWH admitted to ICU has continued to decline in the cART era; this may partly be due to changing reasons for ICU admission as well as improvements in critical care.

EPB007

Mortality disparities by gender and sexual behavior in PWH in Rio de Janeiro, Brazil

L.E. Coelho[1], P.M. Luz[1], E.M. Jalil[1], S.W. Cardoso[1], R.I. Moreira[1], G. Calvet[1], A.G. Pacheco[2], L. Monteiro[1], B.F. Nascimento[1], T.S. Torres[1], V.G. Veloso[1], B. Grinsztejn[1]
[1]*Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz, Rio de Janeiro, Brazil,* [2]*Programa de Computação Científica, Fundação Oswaldo Cruz, Rio de Janeiro, Brazil*

Background: The introduction of combination antiretroviral therapy (cART) has been associated with a decline in HIV-related mortality. However, mortality hazard may differ by gender and sexual behavior.

In this study, we estimated mortality hazards in people living with HIV (PLWH) according to gender and sexual behavior in Rio de Janeiro, Brazil, over the past 33 years.

Methods: In this observational cohort study, we included PLWH ≥18 years enrolled at INI/Fiocruz between 1986-2019. Study population was categorized according to self-report gender and sexual behavior as cis-women, trans-women, cis-men who have sex with men (cis-MSM), cis-men who have sex only with women (cis-MSW), and cis-men with unknown sexual behavior (cis-Munk). Vital status information was complemented through linkage with Rio de Janeiro State Death registry. Cox proportional hazards models assessed risk factors for death since HIV diagnosis. Covariates were gender and sexual behavior, age, CD4 count and viral load at HIV diagnosis, education, race, cART use, year of HIV diagnosis and history of opportunistic illnesses.

Results: Among 7,185 PLWH, 30% were cis-women; 43% cis-MSM, 23% cis-MSW, 5% trans-women and 5% cis-Munk. Median age at HIV diagnosis was 32 years (interquartile range 26-40), 19% were black and 34% mixed race; 47% had <12 years of education.

A total of 1508 deaths occurred in 76,110 persons-year of follow-up. Cis-Munk had the highest mortality adjusted hazard ratio (aHR 2.24, 95%CI 1.80, 2.79), followed by cis-MSW (aHR 1.31, 95%CI 1.14, 1.51), cis-MSM (aHR 1.10, 95%CI 0.96, 1.26), cis-women (reference) and trans-women (aHR 0.59, 95%CI 0.36, 0.97) (Figure).

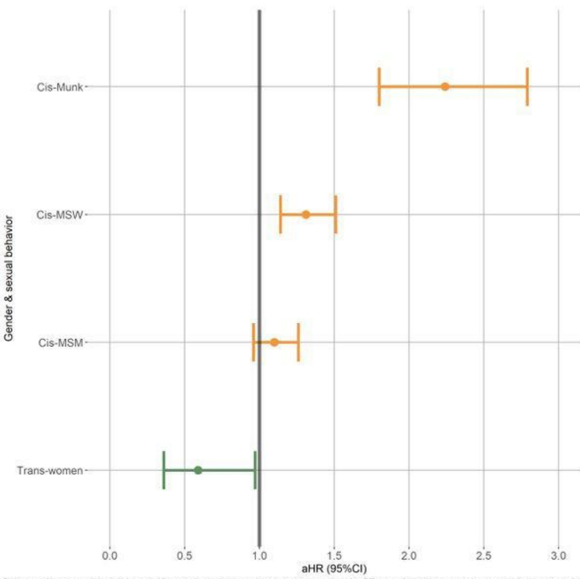


Figure.

Conclusions: We observed existing disparities in mortality hazard by gender and sexual behavior in PLWH. Trans-women had the lowest mortality hazard ratio, which may be explained by trans-specific strategies implemented in our service to reach, engage, retain and support trans-women. Further studies are needed to better understand cis-Munk and their morality hazard.

DHIVAx: a novel HIV-1 antibody test unaffected by vaccine-induced seroreactivity

O. Lagatie[1], D. Lauwers[1], H. Singh[1], F. Vanroye[2], K. Vercauteren[2], D. Stieh[3], J. Vingerhoets[1], L. Lavreys[1], V. Oriol-Mathieu[3], W. Colon[1], C. Verhofstede[4], D. Van den Bossche[2], M. Grazia Pau[3]
[1]Janssen Research and Development, Beerse, Belgium, [2]Institute of Tropical Medicine, Antwerp, Belgium, [3]Janssen Vaccines and Prevention, Leiden, Netherlands, the, [4]University Ghent, Ghent, Belgium

Background: HIV vaccine development faces multiple challenges. For most investigational HIV vaccines, antibodies are produced in vaccine recipients, and these antibodies are often detectable by currently available HIV infection screening and confirmatory assays. Hence, vaccinees may be misclassified as seropositive, a condition known as vaccine-induced seroreactivity (VISR).
Nucleic acid testing (NAT) allows discrimination of a true HIV infection in vaccinees but is not always part of diagnostic algorithms and may not always be available, accessible, or affordable in resource-limited countries.
Methods: We investigated whether internal HIV proteins could be used to overcome VISR and discovered a set of 4 proteins (gp41 endodomain, p31 integrase, p17 matrix protein, and Nef) that are recognized by antibodies produced in HIV-infected individuals but not in vaccinated individuals. The 4 proteins were recombinantly produced in *E. coli*, and a multiplex double-antigen bridging ELISA based on these 4 markers was developed.
Results: The DHIVAx prototype assay was tested in a cohort of 600 treatment-naïve HIV-infected individuals and 109 vaccine trial participants, sampled pre- and 12 weeks post-vaccination. Specificities of 98.1% and 97.1% were observed pre- and post-vaccination, respectively, demonstrating the assay is minimally impacted by vaccine-induced antibodies (Chi^2 p=0.61). A sensitivity of 98.5% was observed, further increasing to 99.7% when p24 antigen testing was included.
The analysis of seroconversion and longitudinal follow-up panels of HIV-infected individuals demonstrated reactivity in the DHIVAx assay as soon as or before p24 antigen became undetectable and showed the signal further increased over time.
Additional assay accuracy testing using the WHO HIV specimen reference panel (450 HIV-positive and 736 HIV-negative samples) demonstrated a specificity of 93.5% and sensitivity of 94.9% (increasing to 95.3% when p24 antigen testing was included).
Conclusions: Despite the need for more technical advancements, our work has provided the groundwork for the development of new fourth-generation HIV tests unaffected by VISR. The proteins that were used in the ELISA can readily be transferred to established platforms, such as lateral flow assays and electro-chemiluminescence immunoassays. A novel HIV serological test insensitive to VISR is essential for the rollout of future HIV vaccines.

EPB009
Comparison of different methods for the detection of HLA 57:01 allele in people living with HIV (PLWHIV) Easter Uttar Pradesh, India

T.K. Rai[1], S. Srivastva[2], P. Kumari[2], J. Chakravarty[2]
[1]Institute of Medical Sciences, Banaras Hindu University, Department of Medicine, Varanasi, India, [2]Institute of Medical Sciences, Banaras Hindu University, Department of General Medicine, Varanasi, India

Background: Abacavir (ABC) is known to cause fatal hypersensitivity reactions (HSR) in 5-8% patients. This HSR is linked to the HLA-B*57:01 allele. The current gold standard methodology for detecting the HLA-B*57:01 allele is the sequence-based method, which is difficult and expensive in programmatic conditions. HLA complex P5 gene (HCP5) shows single nucleotide polymorphism (SNP) (T/G). In different populations HCP5-G (minor) allele has been shown to be 99.9% predictive of the presence of the HLA-B*57:01 allele, with a perfect linkage Disequilibrium (LD).
Therefore, in this study we have compared different methods like direct PCR followed by nested PCR, HCP-5 PCR and a sequence-based method to develop simple and cost-effective method for detection of HLA-B*57:01 allele.
Methods: We collected whole blood cells from 366 PLHIV in the EDTA vials and buffy coat was separated by centrifugation followed by DNA isolation by QIAamp DNA Blood Mini Kit (QIAGEN, Hilden, Germany). Direct PCR followed by nested PCR and HCP5 PCR were used to detect HLA-B*57:01 allele and a sequence-based technique was used to confirm the results.
Results: Out of 366 samples, 25 (6.83%) were found positive for HLA-B*57 gene by direct PCR. All positive samples were subsequently analysed for HLA-B*57:01 using Nested PCR and sequenced and were found to be positive. All 366 subjects were also tested for the T/G Polymorphism (rs2395029) by PCR.
25 patients were found to be positive for (T/G) heterozygous (mutant) and they were also positive by nested PCR and Sequencing and suggests 100% LD between HCP5 and HLA-B*57:01 allele.
Conclusions: Although nested PCR followed by direct PCR was a reliable and easy procedure for the detection of HLA-B*57:01 allele but it requires two PCR steps, which is time consuming.
So, we concluded that detection of HCP5 gene by PCR is a simple and cost-effective way for identifying the HLA-B*57:01 in Indian population.

Novel approaches to assess viral load and ARV resistance/tropism

EPB010

"I feel drug resistance testing was giving us an informed decision": qualitative insights on HIV drug resistance testing among children and pregnant women living with HIV in western Kenya

A. Scallon[1], S. Hassan[2], S.R. Qian[3], P. Oyaro[4], E. Brown[5], J. Wagude[6], I. Mukui[7], J. Gao[3], E. Kinywa[8], F. Oluoch[9], F. Odhiambo[10], B. Oyaro[11], L. Kingwara[12], N. Yongo[5], E. Karauki[5], L. Otieno[10], G.C. John-Stewart[2], L.L. Abuogi[13], R.C. Patel[2]

[1]University of Washington, Jackson School of International Studies, Seattle, United States, [2]University of Washington, Department of Medicine, Seattle, United States, [3]University of Washington, School of Public Health-Global Health, Seattle, United States, [4]Health Innovations Kenya (HIK), Nairobi, Kenya, [5]University of Washington, UW Kenya, Nairobi, Kenya, [6]Siaya County, Department of Health, Siaya, Kenya, [7]Kenya Ministry of Health, Nairobi, Kenya, [8]Department of Health-Kisumu, Kisumu, Kenya, [9]Department of Health-Siaya County, Siaya, Kenya, [10]Kenya Medical Research Institute, Family AIDS Care and Education Services, Kisumu, Kenya, [11]Kenya Medical Research Institute-CDC, Kisian, Kenya, [12]Kenya Ministry of Health, National HIV Reference Laboratory, Nairobi, Kenya, [13]University of Colorado, Department of Pediatrics, Denver, United States

Background: Achievement of viral suppression (VS) is critical in both pregnant women and children living with HIV. While many factors contribute to virologic failure, the acquisition and development of HIV drug resistance mutations (DRMs) are a contributing factor. Drug resistance testing (DRT) is, unfortunately, limited, particularly in resource-limited settings. However, optimal ways to operationalize, from provider and participant perspectives, and scale up DRT in such settings remain open questions.

Methods: We conducted a mixed methods study, with qualitative data collection focused on attitudes, facilitators, and barriers towards current DRT approaches, among children and pregnant women on antiretroviral therapy (ART) in five HIV treatment facilities in western Kenya. We conducted 68 key informant interviews (KIIs) from December 2019 to December 2020 with adolescents and pregnant women living with HIV, child/adolescent caregivers, and other stakeholders such as providers, laboratory/facility leadership, and county- or national-level policy makers. Our KII guides addressed the following domains pertaining to DRT:

1. Experiences with DRT in routine care and
2. Experienced or anticipated barriers and facilitators regarding routine and point-of-care (POC) DRT scale up.

We used inductive coding and thematic analysis to identify dominant themes with convergent and divergent subthemes.

Results: We highlight the following three main themes emerging from our analysis.

1. DRT and DRT counselling were valuable to providers for optimal clinical decision-making and participants for reassurance, respectively.
2. Providers strongly desired an amended DRT process that incorporates quicker sample-to-results turn-around-time, less burdensome protocols to request DRT, interpret results, and make clinical decisions, and greater participant and provider "empowerment" to feel more comfortable with current national DRT protocols.
3. Lastly, facility-level delays, deriving from overworked staff and the mishandling of DRT results,were highlighted as areas of improvement.

Conclusions: Providers and participants desired a more simplified, time-efficient, and potentially decentralized DRT process that builds provider comfort and confidence with DRT protocols.

Further investigating the implementation, endurance, and effectiveness of DRT training are critical to DRT scale-up, as DRT has the potential to considerably improve patient health outcomes and longevity of existing ART options.

HIV testing, self-testing and retesting (e.g., point-of-care diagnostics)

EPB011

HIV self-test: high acceptability and diagnostic performance among key populations in Argentina

J.A.E. Barletta[1], M. Nadal[1], M. Orlando[1], J. Recchi[1], A. Adaszko[1], N. Cochon[1], D.S. Bouchet[2], M.G. Barbás[3], M. Balangero[4], N. Altamirano[5], L. Caporaletti[6], J. Millan[7], M. Vila[8], M. Ceriotto[1], Argentine Study Group on HIV Self-Test

[1]National Ministry of Health, National HIV/STI Program, Buenos Aires, Argentina, [2]Provincial Program for HIV/STI, Viral Hepatitis and Tuberculosis, Córdoba, Córdoba, Argentina, [3]Secretariat for Health Promotion and Prevention, Ministry of Health, Córdoba, Argentina, [4]Health Integration Directorate, Córdoba, Argentina, [5]Provincial Central Laboratory, Córdoba, Argentina, [6]Provincial HIV/STI Program, Salta, Argentina, [7]Provincial HIV/AIDS Program, San Luis, Argentina, [8]Panamerican Health Organization, Buenos Aires, Argentina

Background: In Argentina, 17% of PLHIV do not know that they are infected; and HIV prevalence is high among key populations (KP) such as cisgender men who have sex with men (MSM) transgender women (TGW) and sex workers (SW). Implementation of HIV self-test in testing programs is recommended by the WHO.

The aim of this study was to explore the acceptability and diagnostic performance of an HIV self-test in KP.

Methods: This is a pilot cross-sectional study, eligible individuals aged ≥18 years self-identified as transgender men(TGM), TGW, MSM and/or SW with unknown HIV status who attended the local community-based testing centers in 3 districts in Argentina were offered a finger-prick HIV self-test (SURE CHECK® HIV 1/2 Assay, Chembio Diagnostics), in addition to the standard POC HIV tests (Alere Determine® HIV-1/2).

A survey was used to assess HIV infection risk and self-test acceptability. The study had the technical cooperation of the PAHO and was approved by local IRBs. Funding: National Ministry of Health.

Results: Recruitment was affected by COVID-19 pandemic. A total of 321 individuals with a median age of 29 years were included (66.4% cisgender men, 14.3% cisgender women, 14.3% TGW,2.2% TGM, 2.8% non-binary/other), 30% were SW. Global HIV prevalence was 3.7%; 22% of the study population had not been tested for HIV ever before. Concordance between HIV self-test and conventional POC test was 97.8%, acceptability among the participants was high (Table).

The main advantages of the self-test mentioned by the participants included: privacy(42%), easiness(33%) and possibility to do it accompanied or alone(16%); 54% did not find any disadvantages and 91% would seek medical attention if the test was positive.

The self-test was easy to perform —N (%)	311 (96%)
I felt that the waiting time to get the self-test result was too long—N (%)	63 (20%)
I found easy to interpret the self-test result —N (%)	283 (88%)
I consider the self-test results reliable/trustworthy —N (%)	285 (89%)
I would definitely use the self-test again if it available free of charge (i.e. pick it up from a clinic or pharmacy) —N (%)	303 (94%)
I would test for HIV more often if self-test were available at pharmacies and/or clinics. —N (%)	295 (92%)
I would recommend the HIV self-test to others (i.e. friends, partners) —N (%)	302 (94%)
I would prefer to get the self-test done with someone else (i.e. a friend) rather than alone/by myself —N (%)	167 (52%)

Table.

Conclusions: In this study, a finger-prick HIV self-test was highly accepted by KP in a LMIC and showed good diagnostic performance. Implementing this strategy could significantly contribute to improve access to HIV diagnosis among KP (particularly hard-to-reach KP) and closing the gap towards UNAIDS 95-95-95 targets.

EPB012

"After viral load testing, I get to know which path my life is taking me": qualitative insights on routine and point-of-care viral load testing in western Kenya

S.R. Qian[1], S. Hassan[2], A. Scallon[3], P. Oyaro[4], E. Brown[5], J. Wagude[6], I. Mukui[7], E. Kinywa[8], F. Oluoch[6], F. Odhiambo[9], B. Oyaro[10], L. Kingwara[11], N. Yongo[5], E. Karauki[2], L. Otieno[9], J. Gao[2], G.C. John-Stewart[12], L.L. Abuogi[13], R.C. Patel[12]

[1]University of Washington, Seattle, United States, [2]University of Washington, School of Public Health-Global Health, Seattle, United States, [3]University of Washington, Jackson School of International Studies, Seattle, United States, [4]Health Innovations Kenya (HIK), Nairobi, Kenya, [5]University of Washington-Kenya, Nairobi, Kenya, [6]Department of Health - Siaya County, Siaya, Kenya, [7]Ministry of Health - Kisumu County, Kisumu, Kenya, [8]Department of Health, Kisumu, Kenya, [9]Kenya Medical Research Institute, Family AIDS Care and Education Services, Kisumu, Kenya, [10]Kenya Medical Research Institute-CDC, Kisian, Kenya, [11]Kenya Ministry of Health, National HIV Reference Laboratory, Nairobi, Kenya, [12]University of Washington, Department of Medicine, Seattle, United States, [13]University of Colorado, Department of Pediatrics, Denver, United States

Background: Viral suppression (VS) is a vital goal of effective HIV therapy, and viral load (VL) testing is critical for treatment monitoring, especially in high-risk groups such as children and pregnant/postpartum women.

Although routine VL testing, via centralized laboratory networks, was implemented in Kenya starting in 2014, optimal approaches to scale up VL testing remains unclear.

Methods: We conducted a mixed methods study to evaluate the impact of point-of-care (POC) VL testing in optimizing VS among children and pregnant/postpartum women on antiretroviral treatment (ART) in five HIV treatment facilities in western Kenya in the Opt4Kids and Opt4Mamas studies.

We conducted 68 key informant interviews (KIIs) from December 2019 to December 2020 with adolescents and pregnant women living with HIV, child/adolescent caregivers, providers, laboratory/facility leadership, and county- or national-level policy makers.

Our KII guide covered the following domains:

1. barriers and facilitators to ART use and VS,
2. literacy and experiences with VL in routine care and via study, and
3. opinions on how to scale up VL testing for optimal programmatic use.

We used inductive coding and thematic analysis to identify dominant themes with convergent and divergent subthemes.

Results: Three main themes regarding VL testing emerged from our analysis.

1. Participants uniformly contrasted POC VL testing's faster results turnaround, higher accessibility and likely cost-effectiveness against routine VL testing.

2. Key informants also identified areas of improvement for POC VL testing in Kenya, such implementing robust quality control measures, better human resource allocation, and integrating POC VL testing into existing VL monitoring systems.
3. To enable successful scale-up of VL testing, including for POC, participants proposed conducting quality checks and validations, training more staff, and developing strong partnerships between key stakeholders.
Conclusions: The more accessible, decentralized model of POC VL testing was deemed capable of overcoming critical challenges associated with routine VL testing and was considered highly desirablefor optimizing VS for children and pregnant/postpartum women living with HIV.
While POC VL testing has the potential to improveVS rates among these populations, additional research is needed to develop strategies for ensuring the sustainability of POC VL testing programs.

Diagnosis of HIV disease in paediatric and adolescent populations

EPB013

Performance evaluation of home-based caregiver-assisted oral HIV screening of children compared to facility-based confirmatory testing using the national algorithm in Uganda

N.M. Tumwesigye[1], C. Stecker[2], C. Biribawa[1], A. Mukose[1], C. Namanda[1], J. Kagaayi[1], S. Kagongwe[1], A. Nabuduwa[1], M. Kaakyo[1], M. Nsenga[1], C. Pounds[1], D. Oliver[2], C. Mwangi[3], D. Mabirizi[2], A.C. Awor[3], E. Nazziwa[3], F. Okello[4], M.G. Alwano[4], M. Hast[5], J. Gross[5], K. Parris[5], G. Taasi[6], B. Parekh[5]
[1]Makerere University School of Public Health, Epidemiology and Biostatistics, Kampala, Uganda, [2]Catholic Relief Services, Baltimore, United States, [3]Centers for Disease Control and Prevention, Kampala, Uganda, [4]Catholic Relief Services, Kampala, Uganda, [5]Centers for Disease Control and Prevention, Atlanta, United States, [6]Ministry of Health, HIV Testing Services, Kampala, Uganda

Background: Uganda has an estimated 26,727 children living with HIV (CLHIV) not on treatment. CLHIV depend on caregivers facing logistical and societal barriers, limiting testing uptake. Caregiver-assisted oral HIV self-testing (HIVST) offers a convenient and timely opportunity to expand pediatric testing options.
This analysis aims to identify factors associated with discrepant results between reactive at-home caregiver-assisted oral HIVST and subsequent facility-based HIV-positive confirmatory testing.
Methods: This investigation focused on caregiver-assisted HIVST among children 18 months-14 years, using OraQuick Advance© Rapid HIV-1/2 Antibody screening from April-October 2021. Counselors received pre-study and refresher trainings on how to instruct caregivers to correctly conduct HIVST screening and report results. Children with reactive HIVST results received blood-based confirmatory testing following the national testing algorithm. Firth's logistic regression was used to explore factors associated with the discrepant results, including counselor trainings/refreshers and background characteristics of HIVST reactive cases.
Results: A total of 2,318 index parents/caregivers of 4,865 children were recruited and 4,766 were screened with caregiver-assisted HIVST with 4 (0.1%) invalid and 98 (2.1%) reactive results. All 98 children (100.0%) received confirmatory testing with 32 (32.7%%) confirmed HIV-positive and 66 (67.3%) HIV-negative (HIV prevalence, 0.67%). Assuming all nonreactive HIVST results (n=4,664) were true negatives, HIVST specificity was 98.6% (positive predictive value, 32.7%).
Discrepant reactive HIVST and HIV-negative confirmatory results were associated with a period between full site activation and the second refresher training [OR=2.75, 95% CI: 2.75 (1.10-6.87)], but did not vary by rural/urban residence, child's biological status, or age/sex of child or caregiver.

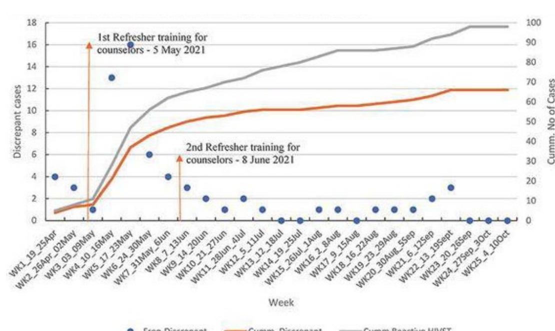

Figure 1. Time and distribution of discrepancy test results by week.

Conclusions: Caregiver-assisted HIVST performed well and is an effective pediatric screening tool. The lower positive predictive value and number of false-positive results were not unexpected in this low prevalence population. Intensive counselor training on how to instruct caregivers to correctly administer HIVST and read results are critical for reliable caregiver-assisted pediatric oral HIVST.

Viral load and CD4 monitoring

EPB014

Performance evaluation of the point-of-care m-PIMA HIV-1/2 Viral Load assay in two South African clinics

J. Dorward[1,2], F. Sayed[2], J. Naidoo[2], P. Moodley[3,4], N. Samsunder[2], Y. Sookrajh[5], N. Naicker[2], P.K. Drain[6,7,8], R.J. Lessells[2,9], H. Ngobese[5], G. Hayward[1], C.C. Butler[1], N. Garrett[2,10]

[1]University of Oxford, Nuffield Department of Primary Health Care, Oxford, United Kingdom, [2]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa, [3]University of KwaZulu-Natal, Department of Virology, Durban, South Africa, [4]Inkosi Albert Luthuli Central Hospital, Department of Virology, Durban, South Africa, [5]eThekwini Municipality, eThekwini Municipality Health Unit, Durban, South Africa, [6]University of Washington, Department of Global Health, Seattle, United States, [7]University of Washington, Department of Medicine, Seattle, United States, [8]University of Washington, Department of Epidemiology, Seattle, United States, [9]University of KwaZulu-Natal, KwaZulu-Natal Research and Innovation Sequencing Platform (KRISP), Durban, South Africa, [10]University of KwaZulu-Natal, Discipline of Public Health Medicine, Durban, South Africa

Background: The m-PIMA HIV-1/2 Viral Load (VL) (Abbott, Chicago, USA) is a point-of-care assay that provides quantitative VL results between 800 and 1,000,000 copies/mL, and could help increase VL testing coverage.

We aimed to assess its performance in a clinic-based setting.

Methods: We compared the analytic performance of the m-PIMA in two South African clinics with the reference laboratory Cobas 6800 (Roche, Basel, Switzerland) assay, using plasma samples.

We determined accuracy to detect viraemia ≥1000 copies/mL, agreement using Bland-Altman plots, and Pearson correlation co-efficients.

Results: We tested 118 samples from 92 participants receiving antiretroviral therapy (ART) between July 27, 2020 and September 13, 2021. 63/92 (68.4%) were women, with median age 38.5 (interquartile range [IQR] 35-43.5) years, median time on ART 4.6 years (IQR 2.9-6.0) and median CD4 count 502 (IQR 311-744) cells/mm^3.

After excluding two invalid m-PIMA results, 116 valid paired results were compared. The m-PIMA was 92% (95%CI 72 to 99) sensitive and 99% (95%CI 93 to 100) specific to detect a viral load ≥1000 copies/mL (Table). When restricted to the 25 paired samples that were both quantifiable ≥800 copies/mL, the mean difference between m-PIMA and Cobas 6800 was -0.26 log copies/mL (95% limits of agreement -0.83 to 0.31), and the Pearson correlation co-efficient was 0.93 (95%CI 0.85 to 0.97, p <0.001, Fig 1).

Trained nurses conducted 23 of the m-PIMA tests and results were broadly similar (Table).

		m-PIMA HIV 1/2 VL: technician & nurse testing			m-PIMA HIV 1/2 VL: nurse testing only		
		<1000	≥1000	Total	<1000	≥1000	Total
Roche Cobas 6800	<1000	90	1	91	16	0	16
	≥1000	2	23	25	1	6	7
	Total	92	24	116	17	6	23
		Sensitivity: 0.92 (0.72-0.99)			Sensitivity: 0.86 (0.42-0.99)		
		Specificity: 0.99 (0.93-1.00)			Specificity: 1.00 (0.76-1.00)		

Table: Sensitivity & specificity of the m-PIMA HIV 1/2 VL

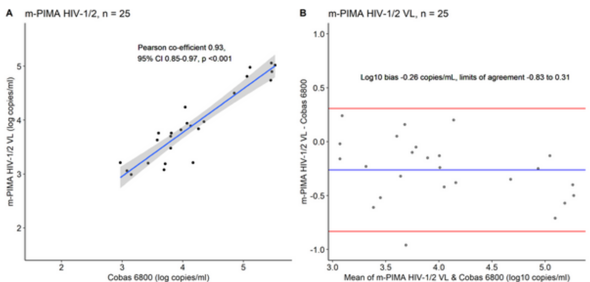

Figure 1. Correlation & Bland Altman plot of m-PIMA HIV-1/2 VL vs Cobas 6800

Conclusions: The analytic performance of the quantitative m-PIMA HIV-1/2 VL was good in these South African clinics.

EPB015

Effectiveness of Dried Blood Spot in achieving optimal viral load coverage for Key Populations in hard-to-reach areas of North-East Nigeria

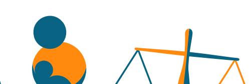
A. Ukaere[1], A. Salihu[1], J. Anyanti[1], M. Katbi[2], H. Meri[2]

[1]Society for Family Health, Abuja, Nigeria, [2]United States Agency for International Development, Abuja, Nigeria

Background: Despite efforts invested towards optimizing viral load coverage, performance has remained suboptimal for Key Populations in hard-to-reach terrains where client movement for viral load sample collection and sample movement have been greatly hindered by poor, inaccessible roads networks. Long-distance journeys are made routinely to hard-to-reach areas with no cold chain facilities and access to electricity to ensure viral load testing of Key Populations. The plasma samples which are time-sensitive and temperature-dependent for separation are collected at the communities and transported to the pre-analytical labs for separation under harsh conditions. The integrity of the samples is compromised, and samples lysed with resultant increased sample rejection at PCR laboratories. This often leads to longer analytical turn-around-time (TAT) and delayed initiation of client treatment plans.

Due to challenges associated with plasma method, the viral load coverage for the USAID-funded HIV KP project for KPs, KP CARE-2, has since remained suboptimal.

Description: In July 2020, the Dried Blood Spot method of viral sample collection was introduced to mitigate the challenges associated with sample collection in hard-to-



reach terrains. Following its introduction, the program recorded the highest number of sample collections since inception in 2019.

A total of 1,890 samples were collected in the post-intervention period (July-Sept 2020) as against 967 samples collected in three months pre-intervention (April-June 2020). DBS sample collection method allowed community workers room to extend viral load services to the Key Populations in hard-to-reach terrains and collect a large number of samples without fear of sample compromise.

Lessons learned: A significant improvement in viral load coverage using the DBS method, prior(April-June 2020) to which the viral load coverage rate was 34% with a 28-day TAT. However, the viral load coverage performance skyrocketed to 100% between July-September 2020 after deployment of this strategy with a significant reduction of the TAT to 9 days.

Conclusions/Next steps: DBS for viral load has shown to improve coverage rates for viral load in hard-to-reach geographical terrains because it requires less equipment for the pre-analytic processing and can stay potent for days at room temperature.

This method should be scaled up in resources-constrained settings as part of efforts towards achieving HIV epidemic control by 2030.

EPB016

Improved HIV viral load suppression among Tanzanian children attending caregiver support groups

E. Mgeyi[1], K. McKenzie[1,2,3], L. Mwita[1], N. Myenzi[1]

[1]Baylor College of Medicine Children's Foundation, Mbeya, Tanzania, The United Republic of, [2]Baylor College of Medicine-Houston, TX, United States, [3]Baylor International Pediatric AIDS Initiative (BIPAI) at Texas Children's Hospital, Baylor College of Medicine-Houston, TX, United States

Background: Viral suppression in children living with HIV (CLHIV) in Tanzania is a challenge due to multiple factors including complex treatment regimens and difficult socioeconomic environments. Since the majority of CLHIV are reliant on treatment support from caregivers (CG), we strengthened the Caregiver Support Group (CSG) model to combat the issue of viral failure.

Description: A program review was performed involving all CSGs held between January to December, 2021. Inclusion criteria included CLHIV below 14 years old who had a failing HIV viral Load (VL) (≥1000 copies/ml).

Each CSG involved 20 CGs, and included three sessions, held over 3 months. During the sessions, CGs shared their challenges and had opportunities to provide their own experiences to help their peers. Clinic staff were available to add information or answer any technical questions.

Lessons learned: Three CSGs were completed with a total of 52 CLHIV (29 (56%) were female). The median age of CLHIVs was 7 years old and those <5 years numbered 19 (37%). Two (3.8%) CLHIV were malnourished and 36 (69%) were classified as WHO stage III/IV. Fifty (96.3%) of the CLHIV were active in care, one (2%) transferred out during the intervention, and one (2%) died. One (2%) CLHIV had TB and one (2%) had a CD4 count <200 cells/mm^3.

Per enrolment criteria, 52 (100%) CLHIV had VL >1000 copies/ml at baseline. On post-CSG VL, 48 (92%) VLs were suppressed with 34 (65%) <50 copies/ml and 14 (27%) 50-999 copies/ml, and 4 (8%) continued to be unsuppressed. However, among the four unsuppressed, 3 (75%) demonstrated a significant log drop (average=1.09) and the fourth died between the first and second sessions.

Conclusions/Next steps: This study shows that our CGS model is successful with 92% of participants achieving viral suppression and 98% having a significant reduction in their VL.

The program will be enlarged to reach more CLHIV with high VLs at the clinic and eventually expanded to outreach sites as well. To better address CG challenges, CSG will be split into two groups, <5 and 5-13 years old.

EPB017

Near point-of-care HIV viral load testing: an essential tool to combat HIV/AIDS in Myanmar

N.N. Tun[1,2], F. Smithuis[3,4], N.L. Tun[2], M. Min[5], M.M.M. Hlaing[6], T. Gils[7], J.v. Olmen[8], L. Lynen[9]

[1]Medical Action Myanmar, HIVTB, Yangon, Myanmar, [2]Myanmar Oxford Clinical Research Unit, HIV TB, Yangon, Myanmar, [3]Medical Action Myanmar, Coordination, Yangon, Myanmar, [4]Myanmar Oxford Clinical Research Unit, Coordination, Yangon, Myanmar, [5]Myanmar Oxford Clinical Research Unit, Data, Yangon, Myanmar, [6]Medical Action Myanmar, Data, Yangon, Myanmar, [7]Institute of Tropical Medicine, Clinical Science, Antwerp, Belgium, [8]University of Antwerp, Faculty of Medicine, Antwerp, Belgium, [9]Insitute of Tropical Medicine, Clinical Science, Antwerp, Belgium

Background: Access to viral load (VL) testing is critical to control HIV. In Myanmar, VL testing was centralized in two cities from late 2012-2017. In January 2017, Medical Action Myanmar (MAM), a medical organization, introduced near point-of-care (near-POC) VL testing in 3 clinics in sub-urban Yangon: testing close to, but not inside, clinics to improve VL testing and adequate VL management in adults (≥15years) living with HIV (PLHIV).

Methods: Blood samples were collected at the clinics and sent daily to a laboratory at 30 minutes' drive, where trained lay workers performed VL testing. Same-day results were sent by phone. WHO guidelines were used for VL monitoring. We performed cross-sectional analysis for annual VL uptake among PLHIV enrolled on anti-retroviral therapy (ART) between 2009-2019. VL management after near-POC VL testing was analysed among PLHIV enrolled on ART between 2009-2018. Predictors of confirmed virological failure were assessed using logistic regression.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Results: VL uptake increased significantly after 2017 (chi-squared, p<0.001) (Fig-1). Among 3205 patients, eligible for first VL testing after near-POC VL, 99% were between 15-59 years and 50% were male. 2945/3205 (92%) patients received a first VL test. 2796/2945 (95%) had VL ≤1000 copies/ml. Among 149/2945 (5%) with VL >1000 copies/ml, 125 (84%) received enhanced counselling and second VL testing. 84/125 (67%) had confirmed VL failure, of whom 69 (82.1%) were switched to second-line ART.
Among those with a second VL after a first high VL, having a first VL of ≥5000 copies/ml was significantly associated with confirmed VL failure (adjusted odds ratio 2.75, 95% confidence interval: :1.11-6.79).

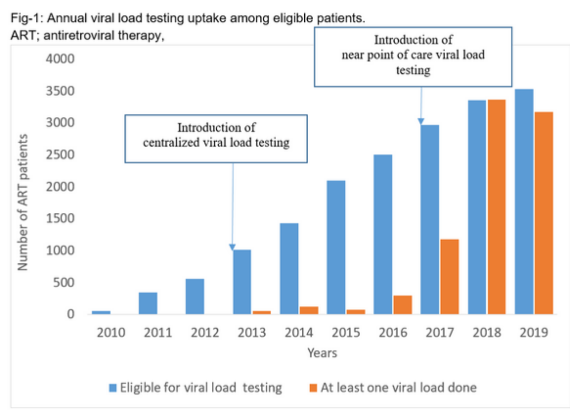


Figure 1. Annual viral load testing uptake among eligible patients. ART; antiretroviral therapy.

Conclusions: Near-POC VL testing increased VL uptake significantly and allowed adequate VL management. The stakeholders should be advocated to scale up near-POC testing for better patients care in resource limited settings. A first VL of >5000 copies/ml was a positive predictor for confirmed virological failure.

EPB018

Evaluation of low-level viraemia detection across three automated HIVVL assays in Johannesburg, South Africa

L. Hans[1,2], S. Sarang[2], S. Ndlovu[2], K. Peloakgosi-Shikwabani[3], M. Moloi[4,5], P. Da Silva[1,2], W. Stevens[1,2]
[1]University of the Witwatersrand, Department of Molecular Medicine and Haematology, Johannesburg,, South Africa, [2]National Health Laboratory Service, Johannesburg, South Africa, [3]Wits Health Consortium, Johannesburg, South Africa, [4]Sefako Makgatho Health Sciences University, Department of Virology, Pretoria, South Africa, [5]National Health Laboratory Service, Pretoria, South Africa

Background: Virological suppression indicates a successful response to anti-retroviral therapy. Generally determined by the lower limit of detection (LLOD) of HIV viral load (HIVVL) assays, suppression is currently defined at <50 copies/ml. However, HIVVL assays demonstrate increased variability at the low-level viraemia (LLV) range (50 -999 copies/mL) which may misdiagnose of failure or suppression. We evaluated the variability of LLV detection on the Abbott *m*2000 and Alinity m, and Roche cobas 6880/8800 HIVVL assays in Johannesburg, South Africa
Methods: Five replicates of a fresh panel of HIV Subtype C viral supernatant serially diluted to concentrations of 50, 200, 500, 1000 and 10000 copies/ml were tested on all three instruments including on an older and an upgraded version of the cobas software. T
he mean, standard deviation (SD) and percentage coefficient of variation (%CV) were calculated. Ninety frozen remnant clinical plasma samples of low HIVVL were tested on the cobas in an inter-laboratory comparison following significant differences in clinical suppression rates between the laboratories. The samples underwent one freeze-thaw cycle in both laboratories. Bland-Altman and correlation analyses were performed.
Results: For the 50 copies/mL, the lowest mean concentration was 60 copies/ml (Alinity m), the highest was 108 copies/mL (cobas new software). The means for the m2000 and the older cobas software were 80 and 89 copies/mL, respectively.
The *m*2000 reported two samples as <40 copies/mL and one undetectable result for the <50 copies/mL samples and consistently reported means lower than the nominal value for all other dilutions, including reporting one 100 copies/ml as undetected.
The highest SD was 0,13 (Alinity m) and %CV was 5.61% (cobas). For the inter-laboratory comparison, the mean bias was 0.04 copies/mL and R^2= 0.96.
Conclusions: There is variability in the detection of low-level viraemia amongst assays but acceptable precision. The *m*2000 under-detected all dilutions which has implications for laboratories upgrading from this assay. The acceptable inter-laboratory comparison indicates the need for investigating non-assay related reasons for variability.
Guidelines may need to take assay variability into account when determining strict cut-offs for more intensive interventions at LLV.

EPB019

Adherence and resistance to ART among postpartum women with HIV in KwaZulu-Natal, South Africa

S. Bosman[1], A. Stanton[2], J. Smit[3], N. Mosery[3], A. Bedoya[2], A. Blyler[4], L. Matthews[5], C. Psaros[2]
[1]Human Science Research Council, Centre for Community Based Research, Sweetwaters, South Africa, [2]Massachusetts General Hospital, Boston, United States, [3]Wits MRU, Durban, South Africa, [4]Harvard Medical School, Boston, United States, [5]University of Alabama at Birmingham, Department of Medicine, Birmingham, United States

Background: Postpartum women with HIV (WWH) are at increased risk for antiretroviral therapy (ART) interruptions, virologic failure, and development of HIV drug resistance. To explore the impacts of adherence on viral suppression in postpartum WWH, we assessed ART adherence and drug resistance patterns in a subset of women enrolled in a cohort study examining factors associated with postpartum attrition from HIV care.

Methods: Pregnant WWH aged 18-45 and currently accessing ART were enrolled in the parent study between August 2019 and February 2021 in KwaZulu-Natal, South Africa. At 12 months post-enrolment, self-reported adherence was measured using a visual analogue scale (VAS), and HIV Viral Load testing was conducted.

Tenofovir-diphosphate (TFV-DP) levels in dried blood spots (DBS) and HIV drug resistance mutations were assessed in participants with HIV-RNA ≥ 1000 copies/mL.

Results: At enrolment, participants (N=170) had a mean age of 28.9 years, 164 (96%) had a suppressed viral load, and most were taking TDF/FTC/EFV (99.4%). At 12 months post-enrolment, 20 (12%) had an unsuppressed VL of which 4 (2%) remained unsuppressed from enrolment, and 16 (9%) were virally suppressed at enrolment. None of the participants with unsuppressed VL switched ART regimen from baseline to 12 months.

Of the 20 unsuppressed WWH at 12 months, 16 (80%) reported no missed doses and rated their adherence to be > 95% on a VAS. Four (20%) of the 20 WWH with unsuppressed viral loads had detectable TFV-DP levels (> 0.1ng/ml), while 16 (80%) had no detectable TFV-DP. Drug resistance mutations were detected in 13 (65%) of the 20 samples.

Characteristics	Total (n=20)	TFV-DP detected (>0.1ng/ml) (n=4)	TFV-DP not detected (n=16)
Self-reported adherence*			
> 95%	16	2	14
60 – 90%	3	2	1
HIV Drug Resistance pattern			
No resistance detected	7	0	7
NNRTI resistance	10	1	9
NNRTI + NRTI resistance	3	3	0

Table 1: ART adherence and drug resistance patterns
**self-report data not available for 1 participant*

Conclusions: While self-reported adherence was high, TFV-DP levels, an objective measure of adherence, demonstrated that 80% of women with viremia had undetectable tenofovir. Adherence to ART needs to be addressed to prevent failure of newer first line regimens, including Dolutegravir containing regimens, and second line regimens. Self-reported adherence tools may have limited benefit in assessing adherence to ART showing the need for early treatment support for all WWH.

EPB020

Know your numbers: a catalyst to improve viral load coverage in Western Region of Ghana

D.T. Nartey[1], E. Adiibokah[1], J.E. Ayetey[1], H. Tagoe[1], T.A. Ayoumah[2], Y.A.A. Rahman[1], H. Nagai[1]
[1]JSI Research & Training Institute, Inc., USAID Ghana Strengthening the Care Continuum Project, Takoradi, Ghana, [2]Ghana Health Service, Effia Nkwanta Regional Hospital, Sekondi-Takoradi, Ghana

Background: A critical pillar in achieving HIV epidemic control is ensuring patient-centered services to all clients on ART Yet, as of 2019, viral load (VL) coverage for persons on ART was only 48%, with 68% of those clients achieving viral suppression, according to the Global AIDS Monitoring 2019 report.

Challenges faced nationally include frequent breakdown of VL testing machines, reagent shortages, low demand generation, poor access to VL tests, VL sample transportation and delays in receiving test results.

Description: The USAID Strengthening the Care Continuum Project (Care Continuum), led by JSI Research & Training Institute, Inc., implemented enhanced VL demand generation activities in the Western Region to increase VL testing. These include the "Know Your Numbers" campaign where VL literacy messages were developed promoting Undetectable=Untransmittable (U=U) messaging.

The Project trained case managers (CMs) to support newly-diagnosed clients with HIV to navigate and start ART treatment. CMs provide motivational counselling on adherence to PLHIVs, track clients due for VL testing using Google calendar reminder alerts prompted by the client monitoring mechanism in GHS DHIS2 eTracker at all sites providing ART services.

Additionally, a VL Monitoring System (VLMS) was piloted to interface with the Laboratory Information Management System (LIMS) to enable electronic transmission of VL results to facilities. Advocacy meetings with key stakeholders were also held to discuss practical solutions to addressing the VL testing gaps.

Lessons learned: VL coverage, which includes clients receiving timely results, increased from 59% (6331 /10,663) in December 2019 to 92% (13,995 / 15282) by September 2021. Western Region has reduced VL result turnaround time by integrating the LMIS and VLMS so that VL requests and VL test results are electronically transmitted to health facili-

ties through the public sector eTracker system. Stakeholders suggested synchronizing dates of VL samples collection and ART refill appointments dates. This approach enhanced VL sample collection.

Conclusions/Next steps: VL literacy and demand creation efforts should be replicated in other regions of Ghana to improve VL coverage. Greater involvement of PLHIV as champions advocating U=U campaign in their communities will catalyze improving the third 95. Ensuring reliable logistics for VL testing is also critical.

EPB021
Pilot of HIV viral load testing using plasma samples in poor resources settings in Malawi: challenges and lessons learned

P.S. Kamudumuli[1], N.B. Herrera[2], M. Msukwa[1], T. Ndundu[1], T. Croxton[2], V. Harawa[1], J. Bitilinyu-Bangoh[3], E. Kampira[4], M. Kaba[4], L. Kim[4], L. Kim[5], R. Mwenda[3], B. Chiwandira[6], T. Msikuwanga[3], T. Kalua[1], A. Abimiku[2]

[1]University of Maryland Global Initiative Corporation, Lilongwe, Malawi, [2]University of Maryland, Baltimore, United States, [3]Ministry of Health, Health technical support services, Lilongwe, Malawi, [4]Centers for Disease Control and Prevention, Lilongwe, Malawi, [5]US Public Health Service, Rockville, Maryland, Malawi, [6]Ministry of Health, Department of HIV and AIDS, Lilongwe, Malawi

Background: Plasma viral load (VL) testing is the recommended method for monitoring treatment in people living with HIV. However, dried blood spot (DBS) remains the most used sample for VL testing in low-resource settings, including Malawi. The detection threshold of DBS VL testing on m2000 Abbott machine is 839 copies/ml, as such classifying clinically-relevant low-level viremia as "below detection limit".

In response, the University of Maryland (UMB), collaborated with the Ministry of Health and Centers for Disease Control and Prevention Malawi to implement a pilot to identify the feasibility and challenges of switching to plasma VL testing.

This abstract aims to describe the experience of this pilot, the challenges identified and lessons learned.

Description: First, we established a readiness baseline assessment of facilities, where facilities located closer to molecular laboratories with Hologic VL machines were the first to be considered.

Second, we mapped sample transportation routes and added additional routes and pick-ups to improve efficiency. UMB supported plasma sample collection training, provided sample collection materials and a dedicated transport system. From April 2020 to October 2021, 20 facilities from Lilongwe and Blantyre started collecting VL plasma samples, collecting a total of 38,400 samples.

Lessons learned: The process has led to a reduction in turn-around time. The pilot also identified implementation barriers, including:

1. the lack of dedicated phlebotomists to avoid relying on nurses and physicians;
2. limited stock of materials and equipment necessary to collect, store and process plasma samples;
3. lack of timely sample transportation that maintains cold chain; and
4. lack of or intermittent electricity.

In response, UMB and MoH are collaborating with the government health teaching institution to offer short trainings for phlebotomists. UMB is also procuring plasma separation tubes and refrigerators to facilitate plasma separation and storage.

Conclusions/Next steps: UMB has demonstrated that plasma VL testing is feasible to implement in limited-resource settings; however, it is necessary to address the identified challenges.

The pilot will continue to expand to facilities further away from the molecular labs, developing a sample transportation strategy and VL testing network across Malawi.

Adherence testing

EPB022
Molecular epidemiologic characteristics of HIV-1 cases diagnosed in Mongolia between 1997 and 2016

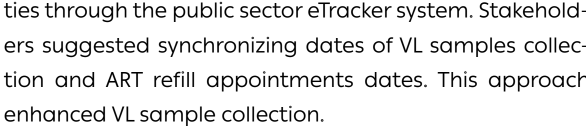
O. Bayandorj[1], S. Zayasaikhan[2], D. Jagdagsuren[1], B. Chimeddorj[3], H Tsunefusa[4], N Kanayama[4], M Takano[4], K Tsuchiya[4], O Shinichi[4]

[1]National Center for Communicable Disease, HIV/STI Surveillance and Research Department, Ulaanbaatar, Mongolia, [2]Youth for Health Center NGO, SKPA Program, Ulaanbaatar, Mongolia, [3]Mongolian National University of Health Science, Department of Microbiology, Infection Prevention and Control, School of Bio-Medicine, Ulaanbaatar, Mongolia, [4]National Center for Communicable Disease, AIDS/STI Surveillance and Research Department, Tokyo, Japan

Background: Information on molecular epidemiology of Mongolian HIV cases only available for 1997-2009 and 2005-2016 timeframe. There is no specific information available for 1997-2016 on HIV-1 molecular epidemiology.

Methods: Thus, we investigated subtype distribution and population group involvement and did phylogenetic tree analysis on the information of 160 HIV-1 cases diagnosed between 1997-2016 in Mongolia. Subtype distribution was compared between cases diagnosed in 1997-2012 and those in 2013-2016.

Results: Subtype B was dominant with 66.6%. CRF51_01B was 13.8% and CRF02_AG was 10.1%. CRF01_AE, A, C and G subtypes also present in Mongolia. On phylogenetic tree, two main clusters determined, one for subtype B – Cluster 1, another one for subtype CRF51_01B – Cluster 2. Among



Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

gay and bisexual male participants, 83% had subtype B infection and 16% had subtype CRF51_01B infection. This related higher percentage of this population group in the clusters (79.6% in Cluster 1 and 81.8% in Cluster 2).

Prevalence of subtype CRF51_01B is significantly higher among 2013-2016 cases with 23.4% than among 1997-2012 cases which is 5.5% while subtype B was lower. Despite that, previously identified cluster of subtype B continues to grow. HIV-1 subtype distribution differs by sexual orientation groups and the difference is statistically significant (X2= 134.20 6a df=7; p<0.0005).

Conclusions: In this investigation, most prevalent HIV-1 subtypes were B followed by CRF51_01B among people who were diagnosed between 1997-2016. HIV-1 subtype distribution varies by sexual orientation of people with HIV. Majority of CRF51_01B cluster members were bisexual men. It may be a key factor for further increase in percentage of heterosexual men and women in the cluster.

Background: Kaposi sarcoma (KS) remains one of the most common HIV-associated cancers with high burden in sub-Saharan Africa. Accurate diagnosis of KS requires tissue confirmation; clinical exam alone is insufficient. However, capacity for tissue-based diagnosis is often limited. In this study, predictors of tissue biopsy availability at HIV treatment centers were identified using the 2020 site assessment survey of the International epidemiology Database to Evaluate AIDS (IeDEA).

Methods: The IeDEA site assessment data were collected through a cross-sectional survey conducted among 238 HIV treatment facilities across 43 countries in 7 geographic regions in 2020. For 226 facilities that completed the KS survey, descriptive statistics were used to characterize availability of KS diagnostics. Multivariable logistic regression was used to identify predictors of KS biopsy capacity, defined as availability to perform punch biopsy

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

or surgical wedge/excision. We excluded 31 sites in low-KS-incidence countries (incidence rate <0.21/100,000 person-years, GLOBOCAN 2020) that did not diagnose KS in the previous year and did not answer follow-up questions on diagnostics.

Results: Of 195 (86%) included sites, 68(35%) had biopsy capacity. Of the sites in sub-Saharan Africa, 20% reported tissue biopsy availability compared to 82% of sites in Asia-Pacific and 61% of sites in North America. Multivariable logistic regression showed that predictors of tissue biopsy availability were regional/provincial/university hospital (RR 1.70; 95%CI [1.13-2.57], p=0.011), and high or upper-middle income World Bank country income status (RR 3.46; 95%CI [1.53-7.84], p=.003 and RR 2.61; 95%CI [1.08–6.29], p=0.032, respectively).

Characteristic (n)	n (%) with available tissue biopsy†	Unadjusted Risk Ratio (95% CI)	Unadjusted P value	Adjusted* Risk Ratio (95% CI)	Adjusted* P value
Setting					
Rural (64)	4 (6)	Ref.		Ref.	
Urban (127)	63 (50)	7.94 (3.02 - 20.83)	<0.001	2.51 (0.92 - 6.82)	0.072
Clinic Level					
Health center (109)	24 (22)	Ref.		Ref.	
District hospital (15)	3 (20)	0.91 (0.31 - 2.65)	0.861	1.42 (0.72 - 2.79)	0.315
Regional, provincial, or university hospital (63)	38 (60)	2.74 (1.83 - 4.11)	<0.001	1.70 (1.13 - 2.57)	0.011
Country income designation					
Low-income (51)	8 (16)	Ref.		Ref.	
Lower-middle-income (80)	17 (21)	1.35 (0.63 - 2.91)	0.436	1.34 (0.57 - 3.16)	0.499
Upper-middle-income (24)	14 (58)	3.72 (1.81 - 7.64)	<0.001	2.61 (1.08 - 6.29)	0.032
High-income (40)	29 (72)	4.62 (2.38 - 8.98)	<0.001	3.46 (1.53 - 7.84)	0.003

*The adjusted model included all other variables in the left-most column.
†Percentage represents portion of sites with that characteristic who have available tissue biopsy, for example, 4/64 (6%) rural sites had tissue biopsy available.

Figure 1: Unadjusted and adjusted logistic regression factors associated with availability of tissue biopsy for the diagnosis of Kaposi sarcoma in HIV treatment settings.

Conclusions: In a global sample of ambulatory HIV treatment centers, skin biopsy was not routinely available for diagnosis of KS. This was most pronounced in lower-income countries, rural settings, and lower-level facilities. Investment in cancer diagnostics in HIV care settings, de-centralization of biopsy capability, and investment in point-of-care diagnostics may reduce the global burden of advanced-stage cancers.

EPB024

Evaluation of a rapid multiplex assay based digital screening strategy in Canada: what's the verdict?

A. Karellis[1,2], D. Webster[3], J. Boulanger[4], K. Harland[3], P. Feltmate[3], G. Daunais-Laurin[4], C. Mesa[5], J. Kim[5], N. Pant Pai[1,2]

[1]McGill University, Medicine, Montreal, Canada, [2]Research Institute of the McGill University Health Centre, Montreal, Canada, [3]Center for Research, Education & Clinical Care of At-Risk Populations (RECAP), Saint John, Canada, [4]REZO, Montreal, Canada, [5]National Laboratory for HIV Reference Services, Winnipeg, Canada

Background: During the COVID-19 pandemic, screening for human immunodeficiency virus (HIV) and associated sexually transmitted blood-borne infections (STBBIs) has fallen behind. To fill screening gaps and meet STBBI elimination objectives, rapid multiplex point-of-care (POC) tests/assays can help screen/detect multiple HIV/STBBIs and triage to confirmatory testing and treatment, with a short turnaround time and ideally within one-two visits. However, real-life diagnostic accuracy of these promising tests, against lab-based confirmatory standard assays, has not yet been determined.

We evaluated the diagnostic performance of two assays for HIV, hepatitis C virus (HCV) and syphilis in a digitally App-connected rapid multiplex screening strategy. The AideSmart! app, designed for health aide use, facilitates training, result documentation and communication, and pre/post-test counselling.

Methods: We report results from an ongoing cross-sectional study, conducted during the COVID-19 pandemic, in key at-risk Canadian populations (injection drug users, immigrants, and MSM) in Quebec and New Brunswick.

This interim analysis focuses on the diagnostic accuracy of two multiplex POC tests against lab-based test protocols:

(i) Chembio's Dual Platform Pathway (DPP) test that screens for HIV/syphilis using a reader, and

(ii) an investigational MedMira test for HIV/HCV/syphilis screening.

Results: This interim analysis presents diagnostic accuracy results of 184 participants (Table 1).

1. Specificity remained high (>98.0%) for both tests and for all pathogens (HIV, syphilis, HCV).

2. Sensitivity was higher for Chembio's DPP test, that screens for HIV and syphilis. While for MedMira, the sensitivity was high for HIV [100.0 (95% CI: 76.8-100.0)%] and HCV [95.2 (83.8-99.4)%], though lower for syphilis [77.3 (54.6-92.2)%].

3. Due to the antibody-based nature of these POC tests, past HCV or syphilis infections were occasionally detected where there was no active infection, though they were confirmed with lab tests.

POC Test	Measure	Human Immunodeficiency Virus	Syphilis	Hepatitis C
Chembio	Sensitivity, % (95% CI)	100.0 (76.8-100.0)	95.5 (77.2-99.9)	Not applicable
Chembio	Specificity, % (95% CI)	98.8 (95.8-99.9)	100.0 (97.7-100.0)	Not applicable
MedMira	Sensitivity, % (95% CI)	100.0 (76.8-100.0)	77.3 (54.6-92.2)	95.2 (83.8-99.4)
MedMira	Specificity, % (95% CI)	100.0 (97.9-100.0)	100.0 (97.7-100.0)	99.3 (96.1-100.0)

Table 1: Diagnostic Accuracy of Chembio and MedMira POC Tests

Conclusions: During this COVID-19 pandemic, rapid multiplex assays offer a high potential to rapidly screen and triage participants to confirmatory testing and treatment pathways.

These tools are essential in our diagnostic repertoire to screen/treat and prevent transmission of undiagnosed HIV/STBBIs in the community.

EPB025

Syndemics in people newly diagnosed with HIV in Manitoba, Canada. Importance of coinfections and comorbidities

Z. Rueda[1], M. Sorokopud-Jones[2], A. Sharp[2], C. Boodman[2], L. Ireland[3], K. Kasper[2], L. MacKenzie[2], J. Bullard[4], M. Payne[3], L. Larcombe[1], S. Shaw[5], J. Schellenberg[1], K. Templeton[6], M. Haworth-Brockman[5], Y. Keynan[2]

[1]University of Manitoba, Medical Microbiology and Infectious Diseases, Winnipeg, Canada, [2]University of Manitoba, Internal Medicine, Winnipeg, Canada, [3]Nine Circles Community Health Centre, Winnipeg, Canada, [4]Cadham Provincial Laboratory, Winnipeg, Canada, [5]University of Manitoba, Community Health Sciences, Winnipeg, Canada, [6]Manitoba HIV Program, Winnipeg, Canada

Background: The demographic composition of persons who are newly diagnosed with HIV (PLHIV) infection in Manitoba has changed dramatically in recent years.

This study aims to describe the drivers of new HIV infections in Manitoba, the associated comorbidities of newly diagnosed PLHIV, and identify gaps in routine testing for co-infections.

Methods: Retrospective cohort study. Clinical charts of all PLHIV in Manitoba, Canada between 2018 to 2021 are being reviewed. Variables collected include sociodemographic data (race, gender, age, housing status, sexual orientation), past medical history clinical and laboratory findings at the time of admission into the HIV program concurrent sexually transmitted infections and blood borne infections (STBBI) and substance use. This abstract contains preliminary results, and the full results will be presented at the conference.

Results: In the preliminary results (n=82), 57.8% were male, and the median age was 37 years (P25: 30, P75: 48). 62.2% reported substance use: 45.8% were people who inject drugs (PWID), with intravenous methamphetamine use reported by 96.7% of PWID, either alone or in combination with opioids. Sixty two percent reported alcohol consumption, 47.6% were current smokers, and 84% reported to have at least one additional comorbid condition or infection at the time of entry into HIV care. Mental health conditions, cardiovascular disease, and STBBI were the most common concurrent conditions. 61.9% had prior history of STBBI and 51.2% had an additional STBBI diagnosed at presentation to the HIV program: 61.9% had positive syphilis serology, 33% had HCV antibodies or RNA detected. Opportunistic infection was identified in 18.2% at entry. Only 52% were screened for latent tuberculosis and only a half of cis-female and trans-male were screened with pap smear. The most common HIV clades were B (55.1%) and C (29.5%).

Conclusions: Improved linkage to primary care may allow for opportunities to improve diagnosis and management of concurrent conditions, as well as decreasing missed opportunities for early diagnosis of STBBIs by application of routine testing. Substance use is overrepresented with crystal methamphetamine identified as the most common injected substance.

This preliminary study also highlights the need for improved harm reduction programming to prevent further amplification of HIV in Manitoba.

EPB026

Low utilization of TB-LAM for TB screening among children under five with advanced HIV disease in Uganda: a descriptive analysis of surveillance data

M. Nakanwagi[1], P. Namuwenge[1], I. Arinaitwe[1], C. Mulowoza[1], E. Nyamugisa Ochora[2], E. Nazziwa[3], E. Namusoke Magongo[1]

[1]AIDS Control Program, Ministry of Health - Uganda, HIV Care and Treatment, Kampala, Uganda, [2]UNICEF, HIV, Kampala, Uganda, [3]U.S. Centers for Disease Control and Prevention, Health Services Branch, Kampala, Uganda

Background: WHO classifies all children living with HIV (CLHIV) aged <5 years, at diagnosis, as having advanced HIV disease (AHD). CLHIV with AHD and/or those with CD4 counts of 100 – 200 cells/mm^3 are eligible for TB screening using lateral flow urine lipoarabinomannan assay (TB-LAM).

We analyzed data on TB screening using TB-LAM (Determine™ TB LAM Ag) in CLHIV <5 years in Uganda to understand TB-LAM utilization in relation to current WHO recommendations on AHD.

Description: We determined the number and proportion of CLHIV aged <5 years active in care (new and old) with: baseline CD4 counts, 'confirmed' AHD (CD4 count <200 cells/mm^3), and TB-LAM tests conducted, deaths during treatment and reported causes of death, during October 2020–September 2021, from Uganda's District Health Information Software (DHIS2). There was no data on patient history and chest X-rays in DHIS2.

Lessons learned: There were 9,840 CLHIV aged <5 years in HIV care, and 33% (3,304/9,840) newly initiated ART. Of the 3,304 newly ART initiated, 40% (1,310/3,304) were designated as AHD and 29% (946/3,304) had baseline CD4-counts. TB-LAM results were available for 11% (105/946) of children with baseline CD4 counts (105 had CD4<200cells/mm^3) of whom 30% (32/105) tested positive and 88% (28/32) started TB treatment.

There was no significant difference in TB-LAM positivity between children aged <1 year (8/18, 44%) and children aged 1–4 years (24/87, 28%) (P=0.113).

Mortality was 3% (301/9,840) of all CLHIV aged <5 years in care. TB contributed 20% (20/100) to reported causes of death, and TB-related mortality was higher in children aged <1 year compared to children aged 1– 4 years (35% versus 13%) (P=0.009).

Conclusions/Next steps: Two-fifths of CLHIV <5 years initiating ART were designated as AHD despite guidance that all should be AHD. This, coupled with low baseline CD4-

count testing, led to low TB-LAM utilization for children <5 years despite high TB related morbidity and mortality in this age-band.
Considering the high yield on TB-LAM testing, explicit guidance on TB-LAM screening for TB in AHD for children aged <5 years newly tested HIV positive is critical to improve TB indicators in this age-band.

EPB027

Diagnostic performance of HbA1c, fasting blood glucose, and the oral glucose tolerance test among people with HIV

A. Garrib[1], S. Kivuyo[2], K. Bates[3,4], E. van Widenfelt[3], S. Mfinanga[2], K. Ramaiya[5], S. Jaffar[3], on behalf of the Research Partnership for the Control of Chronic Diseases in Africa (RESPOND-AFRICA)

[1]Liverpool School of Tropical Medicine, Clinical Sciences, Liverpool, United Kingdom, [2]National Institute for Medical Research, Muhimbili Research Centre, Dar es Salaam, Tanzania, The United Republic of, [3]Liverpool School of Tropical Medicine, International Public Health, Liverpool, United Kingdom, [4]Medical University Innsbruck, Medical Statistics, Informatics and Health Economics, Innsbruck, Austria, [5]Shree Hindu Mandal Hospital, Dar es Salaam, Tanzania, The United Republic of

Background: Rates of diabetes have risen sharply including among people with HIV but how screening for and management of diabetes should be done is unclear. We compared the diagnostic accuracy of HbA1c, FBG and OGTT among patients with HIV and on anti-retroviral therapy.

Methods: A cross sectional study of 975 patients with HIV was done between November 2019 and July 2020 in 4 hospitals in Tanzania. Patients were eligible if aged ≥18 years, on antiretroviral therapy for ≥6 months, did not have a prior diagnosis of diabetes, or ongoing acute illness, liver or renal conditions. OGTT was measured 2-hours after drinking a 75g anhydrous glucose solution.
Tests used point of care devices (Haemocue HbA1c 501 system, Hemocue Glucose 201 RT-Hemocue AB, Angelholm-Sweden). Diagnostic accuracy of HbA1c and FBG were compared to OGTT using sensitivity, specificity and ROC-AUC. Youden's Index determined optimal cut-points.

Results: Among the 971/975 patients who completed screening, 728 (75.0%) were female and median age was 47.0 years (IQR 42.0-54.0). Using WHO OGTT 6.7% of patients were diabetic and 25.1% prediabetic (Table 1).
Both FBG and HbA1c prevalence for diabetes were more than double OGTT, prevalence for prediabetes were comparable. Both FBG and HbA1c had low sensitivity for both diabetes and prediabetes, specificity high for both and comparable. For diabetes ROC-AUC was higher for FBG (0.89) than HbA1c (0.81, p 0.025). ROC-AUC for prediabetes was low for both FBG and HbA1c (0.44 and 0.48, respectively).

		Diabetes Thresholds			Prediabetes Thresholds		
		OGTT ≥11.1 mmol/L	FBG ≥7.0 mmol/L	HbA1c ≥ 6.5%	OGTT 7.8 - <11.1 mmol/L	FBG 6.1-<7.0 mmol/L	HbA1c 5.7 - <6.5%
Prevalence n/N (%)		65/971 (6.7)	142/971 (14.6)	129/971 (13.3)	244/971 (25.1)	267/971 (27.5)	232/971 (23.9)
Diagnostic Accuracy compared to OGTT	Sensitivity (95% CI)	Gold Standard	31.0 (23.5,39.2)	27.1 (19.7,35.7)	Gold Standard	47.9 (41.8,54.1)	31.0 (25.1,37.4)
	Specificity (95% CI)	Gold Standard	95.5 (96.2,98.4)	96.4 (95.0,97.6)	Gold Standard	83.5 (80.6,86.2)	76.7 (73.5,79.7)
	ROC AUC (95% CI)	Gold Standard	0.89 (0.83,0.94)	0.81 (0.75,0.87)	Gold Standard	0.44 (0.40,0.47)	0.48 (0.44,0.52)
Optimal cut-point analysis	Optimal cut-point	Gold Standard	6.3	5.9	Gold Standard	5.5	5.5
	Sensitivity	Gold Standard	87.7	73.8	Gold Standard	73.8	55.3
	Specificity	Gold Standard	26.7	24.9	Gold Standard	24.9	47.5

Table 1: Results of Diagnostic Accuracy Tests for FBG and HbA1c compared with OGTT

Conclusions: Compared to OGTT, FBG performs better on sensitivity, specificity and ROC-AUC than HbA1c. Our study indicates further research is needed to establish optimal thresholds for FBG and HbA1c for people living with HIV.

EPB028

Health related quality of life is impaired in people living with HIV and hepatic steatosis

M. Michel[1], C. Labenz[1], M. Anders[1], A. Wahl[1], L. Girolstein[1], L. Kaps[1], W.M. Kremer[1], Y. Huber[1], P.R. Galle[1], M. Sprinzl[1], J.M. Schattenberg[1]

[1]University Medical Centre Mainz, I. Department of Medicine, Mainz, Germany

Background: People living with HIV (PLWH) show a high prevalence of hepatic steatosis and non-alcoholic fatty liver disease (NAFLD). NAFLD has been linked to impaired health-related quality of life (HRQL) and therefore could be an aggravating factor in PLWH.
The aim of this study was to determine differences in HRQL between PLWH presenting with and without hepatic steatosis and to identify predictors associated with impaired HRQL.

Methods: A total of 245 PLWH were prospectively enrolled at an outpatient clinic. Hepatic steatosis was assessed using vibration controlled transient elastography (VCTE) and defined as a controlled attenuation parameter (CAP) of > 275 dB/m. The cohort was then divided into two groups: no steatosis and steatosis. The generic EQ-5D-5L questionnaire was used to determine differences in the HRQL. It consists of an overall value (UI-value) and five dimensions, each addressing different aspects of an individual HRQL. Univariable and multivariable linear regression models were applied to identify predictors with impaired HRQL in both groups.

Results: In this cohort of PLWH, the prevalence of hepatic steatosis was 35% (n = 85) of whom 76.5% (n = 65) had NAFLD and 16.5% (n = 14) alcoholic liver disease. The median age was 52 years (IQR 42; 58) and the majority

of PLWH were male (n = 174, 71%). The mean UI-value in the total cohort was 0.90 (± 0.15). The HRQL (UI-value) was significantly lower in PLWH and steatosis in comparison to no steatosis (p = 0.013). The most strongly affected dimensions were mobility (p = 0.016) and pain/discomfort (p = 0.012) in the steatosis group, and the dimension anxiety/depression was equally impaired in both groups (p = 0.629) (Figure 1).
Unemployment (p = 0.025) and waist circumference (p = 0.017) remained independent predictors of a poor HRQL in the steatosis subgroup.
In turn, age (p = 0.045), female sex (p = 0.030), BMI (p = 0.010) and arterial hypertension (p = 0.025) were independent predictors of a low HRQL in the subgroup without steatosis.
Conclusions: Hepatic steatosis and metabolic comorbidities negatively affect HRQL. Addressing these factors may improve patient reported and liver-related outcomes in PLWH.

EPB029
Improved tuberculosis case finding among patients with Advanced HIV Disease in Nigeria through the deployment of a point of care tuberculosis diagnostic test

W. Eigege[1], B. LevyBraide[1], N. Otubu[1], O. Abudiore[1], O. Sowale[1], A. Inyang[1], D. Rathakrishnan[2], J. Conroy[2], I. Amamilo[2], F. Lufadeju[1], C. Amole[2], O. Wiwa[1], C. Adesigbin[3], P. Nwaokenneya[3], A. Ikpeazu[3], R. Oladele[4,5], O. Agbaji[6], S. Akanmu[4]
[1]Clinton Health Access Initiative, HIV Access Program, Abuja, Nigeria, [2]Clinton Health Access Initiative, HIV Access Program, Boston, United States, [3]Federal Ministry of Health, National AIDS and STI Control Programme, Abuja, Nigeria, [4]Lagos University Teaching Hospital, Lagos, Nigeria, [5]Medical Mycology Association of Nigeria, Lagos, Nigeria, [6]Jos University Teaching Hospital, Jos, Nigeria

Background: Nigeria recently rolled out a package of care (PoC) to manage Advanced HIV Disease (AHD) among people living with HIV (PLHIV). The AHD PoC recommends screening for opportunistic infections and use of tuberculosis lateral flow urine lipoarabinomannan assay (TB-LAM), a point of care test, to complement the Xpert MTB/RIF test for prompt identification of Tuberculosis (TB) in AHD patients. We documented early lessons from the deployment of TB-LAM in Nigeria.
Description: Facility implementation of AHD PoC commenced in February 2021 and involved 28 health facilities across 4 high-burden states (Lagos, Akwa-Ibom, Rivers and Anambra). Healthcare workers (HCWs) conducted TB-LAM tests for AHD patients regardless of TB symptoms, and those with positive results were referred for Xpert MTB/RIF, the gold standard for TB diagnosis in-country. Diagnosed TB patients were managed for TB and commenced on antiretroviral therapy after 2-weeks of TB treatment.

Lessons learned: By September 2021, 80% (1719 of 2160) of newly enrolled PLHIV with AHD received TB-LAM test and 35% (606 of 1719) tested positive. Of those positive, 70% (426 of 606) had a documented Xpert MTB/RIF result. 75% (320 of 426) of confirmed TB cases commenced treatment.
The proportion of AHD patients who received TB-LAM test increased across the quarters with 56%, 81% and 90% recorded in Q1, Q2 and Q3 2021 respectively. In Q3 2021, 78% (166 of 214) of TB-LAM positive patients received an Xpert MTB/RIF, and 55% (91 of 166) of these patients tested positive with Xpert MTB/RIF.
Some HCWs did not conduct Xpert MTB/RIF for TB-LAM positive patients without TB symptoms and also did not treat Xpert negative TB-LAM positive patients as there was no clear guidance from the TB program. Limited availability of urine sample cups in Q1 impacted TB-LAM testing. Ensuring availability of all commodities required for TB-LAM testing and enhanced collaboration between TB and HIV programs at facility and national levels will improve AHD patients' outcomes.
Conclusions/Next steps: Introduction of TB-LAM test as part of the AHD PoC has improved TB case identification among PLHIV. Using these lessons, clear guidance recommending treatment for TB-LAM positive patients was developed for use across the HIV and TB programs

Biomarkers for the prediction of morbidity and mortality

EPB030
Adopting a Continuous Quality Improvement (CQI) platform as a real-time performance tracker for improving HIV care and treatment outcomes in Botswana

O. Makgabana[1], M. Thero[2], R. Marima[2], M. Montebatsi[2], P. Memiah[3], V. Makokha[4], N. Ndwapi[2]
[1]University of Maryland- Baltimore, Programmes, Gaborone, Botswana, [2]Botswana-University of Maryland School of Medicine Health Initiative, Programmes, Gaborone, Botswana, [3]University of Maryland, CQI, Baltimore, United States, [4]University of Maryland-Baltimore, Programmes, Nairobi, Kenya

Background: In Botswana, there was a lack of a formal electronic real-time platform for documenting and sharing quality improvement initiatives geared towards closing the performance gaps identified from the generated data. Botswana-University of Maryland School of Medicine Health Initiative (Bummhi) in collaboration with Botswana Ministry of Health and Wellness (MoHW) and support from PEPFAR has since adopted the use of the Continuous Quality Improvement (CQI) Digital Platform which tracks CQI projects for clinical HIV/TB pathways and provides users real-time tracking data. The CQI projects

Author Index

captured electronically seek to improve health care and performance gaps through the Plan-Do-Study and Act (PDSA) approach which has been adopted in the Botswana CQI Framework.

Description: CQI teams across 53 Bummhi supported facilities and all other government facilities within the 12 districts were trained on the use of CQI digital platform. A total of 332 log-in credentials were created.

Additionally, teams were also trained on conducting HIV Site Assessments to identify a baseline for performance improvement.

Lessons learned: As of September 2021, 9 months of use of the CQI digital platform a total of 204 projects across the HIV cascade have been initiated, including projects on increasing HIV testing among elicited partners, improving patient management and retention, increasing viral load coverage and critically on new indicators like Determined Resilient Empowered AIDS-Free Mentored and Safe (DREAMS), HIV self-testing and Pre-exposure Prophylaxis (PrEP) implementation.

Conclusions/Next steps: The successful implementation of the CQI digital platform provided Botswana an opportunity to capture, monitor, and virtualize CQI initiatives from one centralised and standard place. The CQI digital platform provides an archive which is easy to use, flexible, expandable, and interoperable with other existing systems, e.g., The District Health Information Software 2 (DHIS2) and can be optimized through digitalised processes. Intensified mentoring and support to users is ongoing for expanded utilization, ownership, and sustainability by the MoHW. We are currently collecting user feedback on acceptability and feasibility to use to further enhance development of the CQI platform.

EPB031

Soluble CD27 predicts progression of kidney dysfunction in people living with HIV

J. Diaz-Martinez[1], J.A. Tamargo[1], I. Delgado-Enciso[2], C. Bejar[3], K.E. Sherman[4], J. Bastida[1], A. Johnson[1], H.R. Martin[1], L. Seminario[1], J. Jasmin[1], M.K. Baum[1]
[1]Florida International University, Miami, United States, [2]University of Colima, Colima, Mexico, [3]The Kidney and Hypertension Group of South Florida, Fort Lauderdale, United States, [4]University of Cincinnati, Cincinnati, United States

Background: Chronic kidney disease (CKD) is a considerable global public health issue that disproportionately impacts people living with HIV. Biomarkers can provide information on the mechanisms of kidney disease, improve clinical practice, and/or predict cardiovascular and renal endpoints in CKD patients. We investigated whether biomarkers detect the progression of kidney dysfunction in the Miami Adult Studies on HIV (MASH) cohort.

Methods: Available data on 30 biomarkers of oxidative stress, immune activation, pro-inflammation, interleukins, cytokines, growth factors and tumor necrosis factors were analyzed.The receiver operating characteristic (ROC) curve confirmed the ability of the serum biomarkers to predict an outcome of a 30% loss or more of estimated glomerular filtration rate (eGFR). Binary logistic regression analyses were performed to determine predictors of a 30% loss of eGFR at 24 months.

Results: The analysis included 481 HIV-infected (HIV+) on HAART and 549 HIV-uninfected (HIV-) participants from the MASH cohort. HIV+ participants were more likely than HIV- to suffer a 30% loss in eGFR over 24 months (7.3% vs. 3.1%, P=0.049). The area under the ROC curve (auROCc) showed that, from the analyzed battery of serum biomarkers, only serum tissue inhibitor of metalloproteinase 1 (TIMP-1; auROCc 0.68, 95% CI 0.55-0.80, P=0.005, cut-off point 53.25 ng/mL) and soluble CD27 (sCD27; auROCc 0.75, 95% CI 0.65-0.86, P<0.001, cut-off point 8.4ng/mL) were able to predict 30% loss of eGFR in 24 months.

Multivariate analyses revealed that after adjustment for covariates only sCD27 (>8.4ng/mL) remained an independent risk factor for the progression of kidney dysfunction (relative risk [RR] 3.93, 95% CI 1.05-14.74, P=0.042). Among HIV+ participants, sCD27 >8.4 ng/mL remained a significant risk factor for a 30% loss of eGFR at 24 months (RR 4.59, 95% CI 1.29-16.27, P=0.018) after adjustments.

Conclusions: Higher circulating levels of sCD27 at baseline stand out as an independent predictor of a 30% loss of kidney function during a 24-month period. Soluble CD27 may be particularly useful as a predictor of eGFR decline among people living with HIV.

Tuberculosis: Prevention, diagnosis, treatment

EPB032

Integrating 3HP-based tuberculosis preventive treatment (TPT) into Zimbabwe's fast track HIV model: aligning TPT and HIV visits, multi-month dispensing, and telephone follow-up were feasible and acceptable

M.P. Mapingure[1], J. Zech[2], Y. Yael Hirsch-Moverman[2], M. Msukwa[3], A.A. Howard[2], C. Gwanzura[4], T. Apollo[4], C. Sandy[4], G.N. Musuka[1], M. Rabkin[2]
[1]ICAP at Columbia University, Harare, Zimbabwe, [2]ICAP at Columbia University, New York, United States, [3]ICAP at Columbia University, Pretoria, South Africa, [4]Ministry of Health and Child Care, Harare, Zimbabwe

Background: Tuberculosis (TB) causes one-third of HIV-related deaths worldwide, making TB preventive treatment (TPT) a critical element of HIV programs. Approximately15% of people living with HIV (PLHIV) on antiretroviral therapy (ART) in Zimbabwe are enrolled in the Fast Track (FT) differentiated service delivery model, which includes multi-month dispensing (MMD) of ART and quarterly health facility (HF) visits.

We assessed the feasibility and acceptability of utilizing FT to deliver 3HP (three months of once-weekly rifapentine and isoniazid) for TPT by aligning TPT and HIV visits, providing MMD of 3HP, and using phone-based monitoring and adherence support.

Methods: We recruited a purposive sample of 50 PLHIV enrolled in FT at a high-volume HF in urban Zimbabwe. At enrollment, participants provided written informed consent, were seen by a HF-based provider, completed a baseline survey, and received counseling, education, and a three-month supply of 3HP and vitamin B6. A study nurse called participants at weeks two, four, and eight to assess and support adherence and monitor side effects.

When participants returned for their routine three-month FT visit, they completed another survey and study staff conducted a structured medical record review.

Results: Participants were enrolled between April and June 2021 and followed through September 2021and were in FT for a median of 1.83 years (IQR0.75,2.67); median age=32 years (IQR24,41); 50% were female. Forty-eight participants (96%) completed 3HP in 12 weeks; one completed in 16 weeks, and one stopped due to jaundice. Most participants (94%) reported always or almost always taking 3HP correctly. All reported they were very satisfied with the counseling, education, support, and quality of care they received from providers. Almost all (98%) said they would recommend it to other PLHIV.

Challenges reported include pill burden (12%) and tolerability (24%), but none had difficulty with phone-based counseling or wished for additional HF-based visits.

Conclusions: Using the FT model to deliver 3HP was feasible and acceptable to participants. Some reported tolerability challenges but 98% completed 3HPand all appreciated the efficiency of aligning TPT and HIV HF visits, MMD, and phone-based counseling. Scaling up this approach could expand TPT coverage in Zimbabwe.

EPB033

Tolerability of Isoniazid and 3HP among opioid dependent people in a Malaysian prison

A. Ahmad[1,2], S. Shenoi[1], F. Altice[3], S. Dhaliwal[2], A. Kamarulzaman[2]

[1]Yale University School of Medicine, Infectious Diseases, New Haven, United States, [2]University of Malaya, Kuala Lumpur, Malaysia, [3]Yale University, New Haven, United States

Background: Prisons are high-risk environments for TB transmission, yet data on the feasibility of TB preventive treatment (TPT) is lacking. We report on early findings of TPT completion rates and tolerability from a randomized control trial comparing 26-week daily isoniazid (26H) and 12-week 3HP in people in prison with opioid use disorder (OUD) and LTBI.

Methods: People with OUD living with and without HIV and/or Hepatitis C (HCV) entering Kajang men's prison in Kuala Lumpur, Malaysia August 2017-January 2022, underwent screening for active TB. Individuals with latent TB (negative chest-X-ray, negative sputum culture and GeneXpert, and a positive Tuberculin Skin Test (TST) (HIV negative, TST≥10mm, HIV+, TST≥5mm) were randomized to receive 3HP (900 mg Rifapentine, 900 mg Isoniazid, 50 mg Pyridoxine weekly for 12 weeks) or 26H (300 mg Isoniazid, 50 mg Pyridoxine daily for 26 weeks).

All received medications via directly observed therapy, monthly liver function tests (LFTs) and clinical evaluation at 3 and 6 months. Treatment tolerability and completion were assessed. Grade 2, 3, 4, hepatotoxicity was defined as <2.5-5, 5-10x, and >10x upper limit of normal (ULN).

Results: Among 103 participants, the median age was 43 (IQR 37-50), all were men, 55 (53.4%) had HCV, 28 (27.2%) had HIV with 18 (64.3%) taking ART, and 20 (19.42%) had both HCV and HIV.Among the 26H group (n=50), 25 (50%) completed TPT to date, and 26 (52%), 17 (34%), and 6 (12%) participants experienced grade 2, 3, and 4 toxicity, respectively. Among 53 randomized to 3HP, 38 (71.7%) completed treatment to date, and 19 (35.8%), 7 (13.2%), and 1 participant experienced grade 2, 3, and 4 toxicity, respectively.

Overall hepatotoxicity was significantly greater in the 26H group compared to the 3HP group (p<0.001). One (1.9%) participant did not complete TPT due to hepatotoxicity, from the 26H group. HIV and Hep C were not associated with hepatotoxicity.

Conclusions: TB preventive therapy for people in prison with OUD in a highly Hepatitis C and HIV prevalent context is feasible and well tolerated. People in prison should be prioritized for TB preventive therapy.

Background: There are limited data describing the incidence and risk factors associated with Liver Enzyme Elevation (LEE) among patients co-infected with HIV and tuberculosis (TB) receiving antiretroviral therapy (ART).
This study aimed to describe the incidence, severity and risk factors associated with LEE in patients enrolled in Reflate TB2 trial.

Methods: ANRS 12300 Reflate TB2 was a multicenter, open-label, phase 3, non-inferiority randomized trial where ART-naïve adult HIV1-infected patients on standard TB treatment received either raltegravir 400 mg BID or efavirenz 600 mg QD both in association with tenofovir and lamivudine. Alanine aminotransferase (ALT) levels were assessed at weeks 0, 2, 4, 8, 12, 24, and 48. LEE was defined as any grade 2 or more ALT [≥2.5 upper limit of normal (ULN)] during follow-up visits.
The Overall incidence of LEE [per 100 persons-year (PY)] over the trial duration and baseline risk factors for LEE using univariate and multivariate cox proportional-hazards models [HR (95%CI)] were assessed.

Results: A total of 453 patients [median age=35 years (IQR: 29-43), median baseline CD4 count=102 /µL (IQR: 38-239), median ALT level=24 IU/L (IQR: 15-38), 31% with disseminated Extrapulmonary TB were included in the analysis.
Overall, 11% of patients (n=48) experienced LEE, corresponding to an incidence of 13.42 (95% CI: 9.89-17.79) events per 100 PY. Of 48 patients with LEE, 63% (n=30) were male, 58% (n=28) were from Vietnam, 65% (n=31) were younger than 35 years, 40% (n=19) had ALT elevation grade ≥3. Additionally, among those, 34 subjects (71%) had a baseline Karnofsky score above 80%, 32 (67%) declared current or past alcohol consumption, 35 (75%) had baseline CD4 counts ≤100/µL and their median baseline HIV RNA was 5.6 $\log_{10}$ copies/mL, 23 individuals (48%) had baseline ALT≥ 40 IU/L. Inclusion in Vietnam [vs Ivory Coast, HR=3.16 (95%CI: 1.51-6.61), ALT≥ 40 IU/L [vs <40 IU/L, HR=2.35 (95%CI: 1.27-4.37)] and Neutrophils ≤ 1500/mm3 [Vs Neutrophils >1500. mm3, HR= 1.901 (95%CI: 1.002-3.605)] at baseline were independently associated with LEE.

Conclusions: The incidence of LEE was relatively high in HIV/TB co-infected patients receiving anti-TB treatment and ART, particularly among those from Vietnam and those with higher baseline ALT levels.

EPB035

Early culture conversion among people with HIV and drug resistant tuberculosis in Uganda

J.B. Baluku[1,2], M. Nabwana[3], S.B. Mwanahamisi[4], G. Kansiime[4], E. Nuwagira[4], S. Turyahabwe[5], B. Kirenga[2]
[1]Kiruddu National Referral Hospital, Division of Pulmonology, Kampala, Uganda, [2]Makerere University Lung Institute, Kampala, Uganda, [3]Makerere University John Hopkins University Research Collaboration, Kampala, Uganda, [4]Mbarara University of Science and Technology, Mbarara, Uganda, [5]Ministry of Health, Uganda, National Tuberculosis and Leprosy Control Programme, Kampala, Uganda

Background: Culture conversion is useful in evaluating the efficacy of drug resistant tuberculosis (DRTB) regimens. We determined associations of early (≤ 2 months) culture conversion among people with HIV (PWH) and DRTB in Uganda. We further compared the frequency of early culture conversion among PWH and people without HIV.

Methods: This was a countrywide retrospective cohort of people with bacteriologically confirmed DRTB at 16 centres in Uganda between 2013 – 2019. Data were abstracted from treatment files and unit DRTB registers. Monthly sputum cultures were performed using the Lowenstein-Jensen medium.
The month of culture conversion was determined to be the first of two months with consecutive negative sputum cultures following a positive baseline culture. Associations of early culture conversion were determined using logistic regression analysis.

Results: There were 664 people with DRTB and a positive baseline culture of whom 353 (53.4%) were PWH. Among the PWH, 225 (63.7%) were male, 331 (94.3%) were on antiretroviral therapy and the median (interquartile range, IQR) age was 36.0 (30.0 – 43.0) years. The median (IQR) month of culture conversion was 2 (1 – 3). Early culture conversion was observed among 226 PWH (64.0%, 95% confidence interval (CI) 58.9 – 68.9%). In a multivariable model, a DRTB treatment regimen of >5 drugs was associated with early culture conversion among PWH (adjusted odds ratio (aOR) = 3.82, 95% CI 1.06 – 13.82, p = 0.041).
Cure and overall treatment success were observed among 232 (65.7%) and 269 (76.2%) PWH respectively. However, early culture conversion was neither associated

with cure (odds ratio (OR) = 0.97, 95% CI 0.61 – 1.54, p = 0.901) nor overall treatment success (OR = 1.29, 95% CI 0.78 – 2.13, p = 0.326) among PWH. The frequency of early culture conversion was higher among PWH than people without HIV (226 (64.0%) vs. 177 (56.9%), p = 0.061) although this was not statistically significant.

Early culture conversion was not associated with cure or treatment success among people without HIV as well.

Conclusions: Majority of PWH and DRTB achieve early culture conversion. However early culture conversion does not predict cure or treatment success. Moreover, it may require ≥6 drugs to achieve early culture conversion.

EPB036

Evaluating two tuberculosis preventive therapy treatment modalities in an HIV treatment program: 3HP versus 6H

T. Mudzviti[1,2], B. Kasimonje[1], T. Chatindo[1], T. Shamu[1,3], C. Chimbetete[1], S. Makhaza[2], S. Gavi[4]

[1]*Newlands Clinic, Harare, Zimbabwe,* [2]*University of Zimbabwe, Department of Pharmacy and Pharmaceutical Sciences, Harare, Zimbabwe,* [3]*University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland,* [4]*University of South Carolina, Department of Epidemiology and Biostatistics, Arnold School of Public Health, Columbia, United States*

Background: Tuberculosis preventive treatment (TPT) can reduce the risk of individuals developing Tuberculosis (TB) by treating latent tuberculosis infection (LTBI). This study was conducted to evaluate completion rates for 2 different TPT modalities in HIV infected patients.

Methods: This was a retrospective cohort study conducted at Newlands Clinic, Harare, Zimbabwe. Patients were either receiving 6 months of daily isoniazid (6H) or 3 months of weekly rifapentine/isoniazid (3HP) for LTBI treatment. Routinely collected patient level data, for patients receiving TPT was abstracted from an electronic medical record. Descriptive statistics were used to evaluate the data.

A marginal structural model analysis using inverse probability weight estimators to assess the causal relationship between prophylaxis regimen (6H or 3HP) and completion of treatment was conducted.

Results: A total of 502 patients received 3HP whilst 1672 patients received 6H. All patients were HIV infected. The median ages for patients receiving 3HP and 6H were 37 (IQR: 22-49) and 24 (IQR: 16-46) years respectively.

One hundred and eighty (35.9%) and 774 (46.3%) participants on 3HP and 6H respectively were male. Discontinuation rates were 3.4% for 3HP and 5.7% for 6H.

Of the discontinuations in the 3HP arm 7(1.6%) were caused by an adverse reactions (2 developed a rash, 2 developed nausea and vomiting, 1 developed facial oedema, 1 developed impaired renal function and 1 of the adverse reactions was undocumented) and one discontinued as a result of a drug interaction. Of the 95 discontinuations in the 6H arm, 64(3.8%) were as a result of an adverse reaction (AR) or drug interaction.

Variable	6H, N = 1,672	3HP, N = 502
Age, Median (IQR)	23.5 (14.0-45.0)	37.0 (22.0 - 48.8)
Gender, n(%)		
Male	774 (46.5)	180 (35.9)
Female	898 (53.5)	322 (64.1)
Completed, n(%)	1,053 (63.0)	483 (96.2)
Still on treatment, n(%)	386 (23.1)	2 (0.4)
ARs leading to discontinuation, n(%)	**64 (3.8)**	**7 (1.4)**
Liver toxicity	47 (2.8)	0 (0)
Rash	6 (0.4)	2 (0)
Other	11 (0.7)	5 (1.0)
Developed TB whilst on TPT, n(%)	4 (0.2)	0 (0)
Deceased/Lost to follow up/ Transferred out	16 (1)	0 (0)
Median Time to discontinuation, weeks(IQR)	10 (4 - 15)	2 (0 - 6)

Table.

In a marginal structural model analysis regression analysis between treatment regimen and completion of treatment, using 6H result in lower completion of treatment compared to isoniazid alone (RR=0.974, CI: 0.957 - 0.991, p < 0.003).

Conclusions: Completion rates were higher with 3HP compared to 6H. Use of 3HP had better retention in TPT whilst having less toxicity.

EPB037

Traditional healers are "part & parcel" on fight against TB". Lesson learnt, Ruvuma region, Tanzania

A. Kiravu[1], J. Minde[1], D. Sando[1], N. Sam[1], E. Aris[1], F. Ntogwisangu[1], G. Lyatuu[1], M. Kihongole[2], W. Socky[2], A. Kumbukila[2], M. Xavier[2], S. Meta[1]

[1]*Management and Development for Health, Dar es Salaam, Tanzania, The United Republic of,* [2]*Regional Municipal office of Health, Ruvuma, Tanzania, The United Republic of*

Background: Worldwide, TB is the leading cause of death among people living with HIV. Tanzania ranks 6th among 30 highest TB burdened countries in the world and in Africa. The 2020 WHO model estimates that the incidence of TB in Tanzania is 237 cases per 100,000. TB case detection rates is at 59%. Reports show that most of the TB cases remains undiagnosed in the community. MDH through support from Global Fund have been working with the government to implement TB services in the communities in 7 regions including Ruvuma using different approaches such as engagement of traditional healers (THs).

Description: MDH engaged THs through local authorities responsible for regulating their activities and through their unions. We mapped and identified 70 THs in the region. They were oriented on TB screening and how to

Oral abstracts

Author Index

identify and refer individuals with TB symptoms to diagnostic facilities. In addition, they were linked with trained CHWs for sputum sample collection and transport to nearest facility with GeneXpert. CHWs also supported referrals and ensured results are returned to TH clinic site. The District TB & Leprosy Coordinators were contacted for initiating TB treatment to all confirmed cases. TH were also involved to supervise their patients' treatments.

Lessons learned: From January to November, we observed a steady increase in TB case detection largely contributed by THs. Out of 1,458 TB cases in the region during this period, 25 (1.3%) came from THs.

Interestingly among the 25 cases, 10 including 2 MDR TB came from one champion TH clinic site. Four patients tested HIV+ and were initiated on ART.

Conclusions/Next steps: Community TB identification strategy with involvement of TH has shown positive impact whereby TB presumptive cases are now notified from TH clinics. This minimizes possibilities of missing cases in the community. MDH proved that TH are the important group who plays a great role on TB case notification on its implementation regions. Engagement of THs have been scaled up in other regions where similar support is provided.

EPB038

Integration of TB-LAM and Xpert MTB/RIF (Xpert) testing to improve TB case detection and shorten time to treatment initiation among People Living with HIV (PLHIV) in Harare City, Zimbabwe

B. Mushangwe[1], T. Maphosa[2], G. Gonese[1], B. Makunike-Chikwinya[1], P. Chonzi[3], T. Apollo[4], K. Thomson[5], R. Weber[6], S. Wiktor[5]

[1]Zimbabwe Technical Assistance, Training & Education Center for Health (ZimTTECH), Care and Treatment Program, Harare, Zimbabwe, [2]Centers for Disease Control (CDC), Harare, Zimbabwe, [3]City of Harare, Health Department, Harare, Zimbabwe, [4]Ministry of Health and Child Care, HIV/AIDS and STIs, Harare, Zimbabwe, [5]University of Washington, Seattle, United States, [6]Centers for Disease Control (CDC), Harare, Zimbabwe

Background: The Abbott Determine TB LAM Ag (TB-LAM) assay is a urine-based point of care diagnostic test. In October 2020 the Zimbabwe Ministry of Health and Child Care (MOHCC) introduced TB-LAM test for concurrent use with Xpert among asymptomatic PLHIV with advanced disease (CD4<200cells/mL or stage 3 or 4 disease) and symptomatic PHLIV regardless of CD4 cell count or stage of disease at selected high-volume sites.

We describe TB case detection, time-to-treatment before and during implementation of TB-LAM testing and acceptability and value of TB-LAM testing at 2 sites in Harare.

Description: Prior to implementing TB-LAM testing, we conducted on the job training for laboratory technicians and sensitized clinicians on identification of eligible clients for testing, sample collection and client management. We reviewed TB program records from October 2020 to September 2021 for two high-volume sites in Harare. We abstracted data from MoHCC registers and patient files using Excel. Health workers were interviewed to determine acceptability and ease of administration of the test.

Lessons learned: Health workers described TB-LAM as acceptable, simple to administer and shortens results turnaround time. Prior to LAM implementation (duration 8 months),161 symptomatic clients were tested using Xpert and 12% (20) were positive.

Post implementation (duration 4 months), 82 clients were tested with TB-LAM and 22% (18) were positive. In the absence of TB-LAM testing 15 cases of asymptomatic TB would have remained undiagnosed among 72 PLHIV who were considered negative based on question-based symptom screening alone.

Before implementation of TB-LAM testing median time from diagnosis to initiation on treatment was 2 days (IQR:1-6) and during implementation median time was 1 day (IQR:1-2).

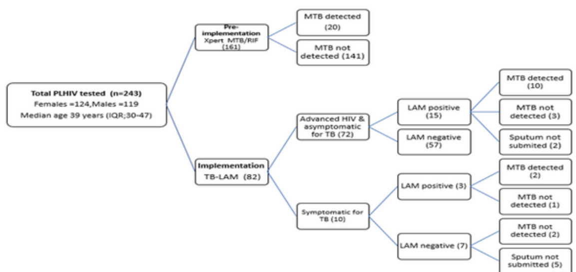

Figure. TB testing at facilities implementing TB LAM in Harare City, October 2020 - September 2021

Conclusions/Next steps: Our experience demonstrates TB-LAM testing as an acceptable and simple tool to integrate into routine HIV care. Scale-up of TB-LAM can improve TB diagnosis among PLHIV co-infected with TB and may facilitate timely treatment initiation.

EPB039

Safety and pharmacokinetic of daily isoniazid/rifapentine (1HP) in adults with HIV on standard dose of dolutegravir

A. Avihingsanon[1,2], S. Gatechompol[1,2], T. Ueaphongsukkit[1,2], J. Sophonphan[1], S. Ubolyam[1,2], H.M.S. Lwin[1], W.M. Han[1], P. Kadeelok[1], S.J. Kerr[1,3,4], Y.S. Cho[5], J.G. Shin[5], LTBI/HIV-NAT 255
[1]HIV-NAT, Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]Centre of Excellence in Tuberculosis, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [3]Biostatistics Excellence Centre, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [4]The Kirby Institute, University of New South Wales, Sydney, Australia, [5]Center for Personalized Precision Medicine of Tuberculosis, Inje University College of Medicine, Busan, Korea, The Republic of

Background: People living with HIV (PLWH) has 20 times greater risk of developing active TB than those without HIV infection and tuberculosis preventive therapy (TPT) is recommended. A 28-day regimen of daily isoniazid (H) 300mg and rifapentine (P) 450-600 mg (1HP) is a novel, effective, ultra-short regimen for TPT. Rifapentine may decrease dolutegravir (DTG) concentrations via inducer of drug-metabolizing enzymes. We evaluated the effect of 1 HP on DTG exposure among PLWH in Thailand.

Methods: Adult PLWH on DTG-based ART with undetectable HIV viral loads were recruited at HIV-NAT, Thailand during 2021. All received DTG 50 mg once daily (TDF/3TC/DTG: TLD 1 pill a day) for at least 4 weeks, then 1 HP (300/600mg) was initiated on Day 1. All participants were followed until week 24, and HIV-1 RNA, liver, and renal function tests were monitored.

Intensive PK for DTG was performed at Day 0 (before 1HP) and at day 28 (last dose of 1HP). Plasma samples were collected pre-dose, 1, 2, 4, 8, 12 and 24 hours post-DTG dose. DTG concentrations were determined by validated LC-MS/MS. PK parameters were estimated (nonparametric; WinNonLin).

Results: Thirteen participants (84.6% males) completed 24 hours intensive PK. The median age was 32 years, and the median body weight was 70.5 kg. The geometric mean (GM) with 95%CI of DTG (with HP) of maximum concentration (C_{max}), area under curve ($AUC_{0-\tau}$), and minimal concentration (C_{min}) were 3 (2.4-3.8) ug/mL, 25.1 (19.7-32) ug.hr/mL, and 0.2 (0.1-0.5) ug/mL, respectively.

Overall, HP decreased DTG C_{max}, AUC and C_{min} concentrations by 8%, 51.2%, and 24.9%, respectively. Only 1 participant had C_{min} less than protein-binding-adjusted IC_{90} of DTG (0.064 ug/mL). Median ALT changed during 1 HP was 27 (23-34) U/L. At week 24, 92% of participants had HIV-RNA <40 copies/mL. The study regimen was well-tolerated, only 1 participant had mild rash and 1 HP was prematurely terminated. No serious adverse events were reported.

Conclusions: Although there were substantial reductions in DTG concentrations when co-administered with 1HP, C_{min} levels were still above the protein-binding-adjusted IC_{90} of 0.064 µg/mL and majority of them (>90%) remained virologically suppressed. Future large studies are warranted to confirm the findings.

EPB040

Treatment outcome of rifampicin-resistant tuberculosis among people with HIV in South Africa: a nested prospective cohort study

J.E. Farley[1,2], K. Lowensen[1], A. Patil[1], K. Geiger[1], A. Bergman[1], K. McNabb[1], C. Budhathoki[1], N. Mthimkhulu[1], N. Ndjeka[3]
[1]Johns Hopkins University School of Nursing, Center for Infectious Disease and Nursing Innovation, Baltimore, United States, [2]Johns Hopkins University School of Medicine, Center for AIDS Research, Baltimore, United States, [3]National Department of Health, South Africa, National TB Program, Pretoria, South Africa

Background: South Africa has high rates of rifampicin-tuberculosis (RR -TB), which disproportionately affects people living with HIV (PWH). Treatment outcomes in PWH are poorer with death and loss to follow-up (LTFU) consistently greater. Newer all-oral RR-TB treatment regimens offer hope to improve outcomes, yet may require ART substitution.Little is known about whether real-world use of oral regimens and their impact on outcome in PWH.

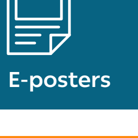
Methods: We evaluated a prospective, nested cohort of PWH within the control arm of a cluster randomized nurse case management trial in 10 public hospitals, 2013-2020. Baseline demographics, RR-TB regimen type, and HIV clinical data were included. Multinomial logistic regression models were used to compare treatment success against failure, LTFU and death.

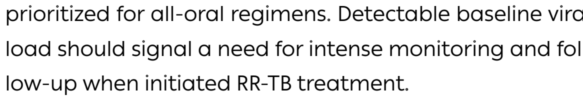
Results: Among 603 participants, 426 (70.6%) were PWH whose mean age was 36.6 years, 53.1% female, 68.8% did not complete high school, 61.7% unemployed. On intake, median CD4 was 192; 61.2% on ART with 66.4% with a detectable viral load. Of those starting oral regimens (n=78), 39.7% required ART substitution. Outcomes remain poor with 55.2% success; 5.2% failure; 23.5% LTFU; 16.2% death. Oral regimens reduced odds of LTFU by 90% and death by 67%. Those without viral suppression at intake had 2.7-fold greater odds of death. Increased household number increased odds of failure by 25%, while living in town increased odds of LTFU 3-fold and death 3.4-fold. For each unit increase in BMI, odds of death decreased 22% and completing high school decreased failure by 85%.

	Failure a(OR)	95% CI	LTFU a(OR)	95% CI	Death a(OR)	95% CI
Oral regimen (ref. injectable)	0.33	0.06 – 1.68	**0.10**	**0.04 – 0.28**	**0.33**	**0.13 – 0.85**
BMI	0.93	0.81 – 1.06	0.98	0.92 – 1.04	**0.88**	**0.80 – 0.98**
Baseline viral load > 50 (ref. undetectable)	0.53	0.14 – 2.02	1.218	0.60 – 2.47	**2.67**	**1.02 – 6.99**
Peri-urban hospital site (ref. Rural Hospital)	0.33	0.09 – 1.15	**0.31**	**0.16 – 0.61**	**0.27**	**0.11 – 0.65**
Living in town/city/suburb (ref. village)	0.96	0.20 – 4.63	**2.95**	**1.44 – 6.03**	**3.37**	**1.38 – 8.26**
Number in household	**1.25**	**1.07 – 1.46**	1.06	0.97 – 1.16	1.01	0.90 – 1.14
Completion, high school (ref. primary school)	**0.15**	**0.03 – 0.77**	0.71	0.37 – 1.36	0.99	0.43 – 2.25
Legend: a(OR), adjusted odds ratio; CI, confidence interval; LTFU, loss to follow-up; ref., reference; BMI, body mass index (continuous); adjusting for sex, government financial assistance, employment, CD4 categorical < 200 and > 200.						

Table 1. Predictions of negative RR-TB treatment outcomes among people with HIV (N=426)

Conclusions: PWH receiving all oral regimens demonstrated dramatic improvements in LTFU and death compared to older injectable-based regimens and should be





prioritized for all-oral regimens. Detectable baseline viral load should signal a need for intense monitoring and follow-up when initiated RR-TB treatment.
Treatment adherence programs should target patients who travel outside of town for treatment, crowded homes and those with lower education.

EPB041
Clinical and virologic outcomes of TB/HIV co-infected patients treated with dolutegravir-based HIV antiretroviral regimens: programmatic experience from Nigeria

O. Ajayi[1], O. Olajide[2], E. Osayi[3], O. Olaniyi[4], J. Ekere[5], P. Jwanle[6], O. Ogunsola[1], I. Onwuatuelo[7], P. Okonkwo[7]
[1]APIN Public Health Initiatives, Prevention and Community Services, FCT, Nigeria, [2]APIN Public Health Initiatives, Clinical Service Directorate, Ibadan, Nigeria, [3]APIN Public Health Initiatives, Clinical Services, Jos, Nigeria, [4]APIN Public Health Initiatives, Clinical Services, Abeokuta, Nigeria, [5]APIN Public Health Initiatives, Clinical Services, Makurdi, Nigeria, [6]APIN Public Health Initiatives, Clinical Services, FCT, Nigeria, [7]APIN Public Health Initiatives, Program, FCT, Nigeria

Background: Globally, there has been concerns about clinical and virologic outcomes of TB/HIV co-infected patients on Dolutegravir based (DTG) antiretroviral therapy (ART) as rifampicin reduces dolutegravir bioavailability.
This study hopes to assess HIV and TB treatment success among TB/HIV patients on DTG-based HIV drug and rifampicin-based TB drugs.
Methods: Retrospective analysis of data of TB/HIV co-infected patients managed between October 2017 and December 2021 in 96 ART sites in Nigeria. TB data were extracted from the presumptive TB register and TB treatment register in DOTs unit, while HIV data were extracted from facility ART electronic monitoring records. Data were analyzed using SPSS. Association between exploratory variables and study outcomes "TB treatment outcome and viral load suppression status" were examined using binary logistic regression at p value of 0.05.
Results: The mean age of respondents was 39.0 ± 13.0 years. About half (53.8%) were on DTG-based antiretroviral drug, Viral load suppression rate was 89.1%. Major site for tuberculosis (TB) presentation was pulmonary (98.0%). A larger percentage of the respondents had favorable TB outcome i. e completed or TB cured (84.7%). There was statistically significant association between DTG-based therapy and favourable TB treatment outcome (Crude OR = 1.383, Adjusted OR = 1.600).
Other findings included lower likelihood of favorable TB outcome among patients with extrapulmonary TB (AOR = 0.114), and higher likelihood of favorable TB outcome in patients with CD 4 count more than 500 cells/ml (AOR = 1.925) and those who commenced INH before TB diagnosis (AOR = 1.689). No significant association was found between DTG-based therapy and patient viral load suppression.
Conclusions: Use of DTG-based antiretroviral therapy with rifampicin based anti-TB drugs in TB/HIV patients has better TB treatment outcome than non-DTG based therapy. Effort should be geared towards transitioning all TB-HIV co-patients to DTG-Based ART except if contra-indicated.

EPB042
Identifying gaps in the tuberculosis care cascade in sub-Saharan Africa

N. Shah[1], S. Cavanaugh[1], M. Iroezindu[1,2], E. Bahemana[1,3], H. Kibuuka[4], J. Owuoth[5,6], J. Maswai[1,7], V. Singoei[5,6], A. Parikh[1,8], A. Esber[1,8], T. Crowell[1,8], C. Polyak[1,8], J. Ake[1], AFRICOS Study Group
[1]Walter Reed Army Institute of Research, U.S. Military HIV Research Program, Bethesda, United States, [2]HJF Medical Research International, Abuja, Nigeria, [3]HJF Medical Research International, Mbeya, Tanzania, The United Republic of, [4]Makerere University Walter Reed Project, Kampala, Uganda, [5]U.S. Army Medical Research Directorate – Africa, Kisumu, Kenya, [6]HJF Medical Research International, Kisumu, Kenya, [7]HJF Medical Research International, Kericho, Kenya, [8]Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, United States

Background: People living with HIV (PLWH) who do not have active tuberculosis (TB) are candidates for TB preventive treatment (TPT), which reduces TB-associated mortality. TB screening in PEPFAR-supported countries suggests about 2.3% of PLWH have active TB, although literature suggests screening positivity should be closer to 5%., TPT has been initiated in only 12% while the goal is to ensure all PLWH have had TPT.
Methods: The African Cohort Study (AFRICOS) enrolls PLWH who are engaged in care at 12 PEPFAR-supported clinics in Uganda, Kenya, Tanzania and Nigeria.Semiannual evaluations include medical examinations, medical history-taking, and TB symptom screening. Self-report of any fever, night sweats, weight loss or cough in the past week is considered a positive TB screen.
Molecular testing, smear and/or chest x-ray were used to confirm or exclude active TB. TPT is administered according to World Health Organization guidance.
Results: Of 3077 PLWH enrolled from January 2013 through August 2021, 698 (23%) were newly engaged in HIV care (≤1 month). Of these, 296 (42%) screened positive for TB and 26 (8.8%) were confirmed cases.
An additional 8 were confirmed without symptoms. Of 2379 PWLH engaged in care for >1 month prior to enrollment, 760 (32%) screened positive and 25 (3.3%) were confirmed cases.
An additional 41 were confirmed without symptoms. Of 2977 without active TB, 1693 (57.0%) initiated TPT, of whom 1430 (83.9%) (n=1430) completed treatment, and 26 (1.5%) were still on treatment. (Figure).

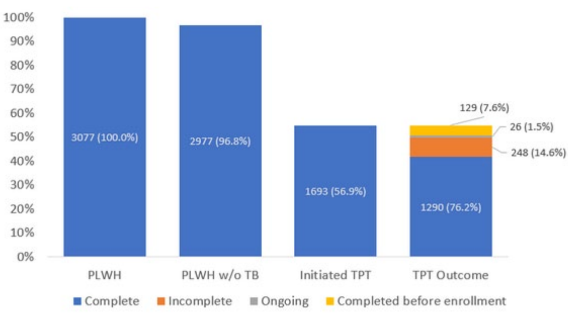


Figure. TPT care cascade among those enrolled PLWH in AFRICOS, 2013-2021

Conclusions: A structured cohort setting with routine TB symptom screening yielded higher TB screening positivity than program data, even in participants who had previously been engaged in HIV care.

These data underscore the importance of symptom screening at every visit and demonstrate opportunities to optimize TB screening and TPT administration to improve TB/HIV outcomes.

EPB043

Trends in QGIT positivity among newly diagnosed people living with HIV in South Africa: results from the TEKO trial

M. Billingsley[1], B. Jarrett[2], K. Shearer[3], N. Martinson[3,4,5], J. Golub[3,1,2]

[1]*Johns Hopkins Bloomberg School of Public Health, Department of International Health, Baltimore, United States,* [2]*Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States,* [3]*Johns Hopkins University, Center for Tuberculosis Research, Department of Medicine, Baltimore, United States,* [4]*University of the Witwatersrand, Perinatal HIV Research Unit (PHRU), Johannesburg, South Africa,* [5]*University of the Witwatersrand, Klerksdorp Tshepong Hospital Complex, Department of Internal Medicine, Klerksdorp, South Africa*

Background: In South Africa, TB preventive therapy (TPT) is recommended for people living with HIV (PLHIV) regardless of TB infection (TBI) status, partially because tests are a barrier to maximizing TPT implementation. The intervention arm of the TEKO trial utilized QuantiFERON-TB gold in-tube (QGIT) testing linked to the baseline blood draw among newly diagnosed PLHIV to identify TBI status. Here we describe TBI prevalence as QGIT positivity among PLHIV in TEKO.

Methods: 1,365 newly diagnosed PLHIV were enrolled across seven QGIT clinics between November 2014 and May 2017, with 1,166 included in this analysis.

Participants were excluded if they had a missing or out-of-date CD4 count or were retrospectively found ineligible for study participation. We present crude TBI prevalence stratified by age (18-24, 25-34, 35-44, 45+ years) and baseline CD4 count (≥500, 499-350, 349-200, <200 cells/mm^3).

Results: The median (interquartile range [IQR]) age at enrolment was 32 years (26,39), 33% were men, and the median (IQR) baseline CD4 count was 321 cells/mm^3 (172,506). Overall TBI prevalence was 40% (n=468/1,166). Ninety (8%) indeterminate results were recorded; most (n=51/90; 57%) among individuals with a CD4 <200 cells/mm^3. We observed little variability in TBI prevalence across age categories (18-24: 49%; 25-34: 43%; 35-44: 39%; 45+: 45%). However, TBI prevalence increased with increasing CD4 count: (CD4 <200: 34%, 200-349: 39%, 350-499: 48%, ≥500: 54%). Increasing QGIT positivity by age was observed only in the 350-499 cells/mm^3 group (Fig 1).

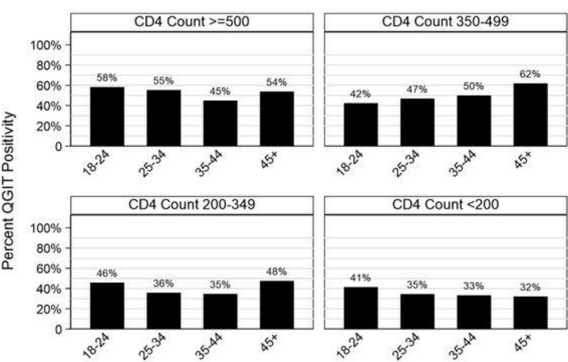

Fig 1. QGIT positivity by age and CD4 count

CD4 count is measured as cells/mm^3, age as measured in years at date of enrollment

Conclusions: Our results show that less than half of newly diagnosed PLHIV in NW province have TBI. Although those without documented TBI are eligible to receive TPT under current guidelines, data are limited regarding the benefit of TPT for PLHIV who are TBI negative by QGIT.

Thus, an integrated strategy of TBI testing via CD4/viral load-linked QGIT could be a cost-effective way to target TPT.

EPB044

Applying Quality Improvement methodology using DMAIC for process-based strengthening of TB case finding among PLHIV at ART clinic in the University of Nigeria Teaching Hospital, Enugu, Nigeria

C.G. Orji[1], B.A. Adeyemo[2], O. Ezeobi[3], B.O. Ozonweke[4], E. Onu[5], G. Onyedike[6], F. Bassey[7], I. Tony-Monye[8], C.U. Onyegbado[1], O. Olayiwola[5], A. Effiong[5], J.O. Oko[9], S. Balogun[10]

[1]Caritas Nigeria, Care and Treatment, Enugu, Nigeria, [2]Caritas Nigeria, Quality Improvement Unit, Enugu, Nigeria, [3]Caritas Nigeria, Monitoring and Evaluation Unit, Enugu, Nigeria, [4]Caritas Nigeria, Laboratory Unit, Enugu, Nigeria, [5]Caritas Nigeria, Care and Treatment, Abuja, Nigeria, [6]Caritas Nigeria, Laboratory Unit, Abuja, Nigeria, [7]Caritas Nigeria, Programme Unit, Enugu, Nigeria, [8]Caritas Nigeria, Quality Improvement Unit, Abuja, Nigeria, [9]Caritas Nigeria, Programme Unit, Abuja, Nigeria, [10]Caritas Nigeria, Surveillance Unit, Abuja, Nigeria

Background: Tuberculosis (TB) continues to be the highest cause of mortality from infectious diseases among PLHIVs. Between 10% and 20% of already on treatment and new PLHIV are expected to be presumptive TB cases. Poor implementation of provider-initiated TB symptom screening, incomplete documentation of findings, and poor transmission of results have been identified as significant contributors to the low TB case-finding gap in ART clinics. Using the Diagnostic Cascade Evaluation (DiCE) entry assessment tool, baseline analysis shows that 10% of GeneXpert MTB/RIF positive results were returned between February and April 2021.

This project uses the quality improvement principle to understand the bottle-necks and improve GeneXpert result documentation from the baseline to at least 70% by November 2021.

Methods: A multi-disciplinary team applied the DMAIC (Define, Measure, Analyze, Improve and Control) methodology using fishbone analysis to identify issues affecting the poor transmission of results from laboratory to clinic. Issues identified include low clinical screening, poor knowledge of best practices, incomplete documentation, and poor tracking of GeneXpert results.

Proffered change ideas were prioritized for implementation in Plan Do Study Act (PDSA) cycles between May and November 2021. Implemented solutions included capacity training, the constitution of TB champions, and job aids provision. Monthly reports of TB screening and cases were collected from TB registers. Monthly meetings after each PDSA cycle to review the intervention and record possible improvement were held.

Results: There was a significant improvement in result transmission rate from the baseline of 10% to a median of 93% during the implementation. Within the period of this intervention, 26 active TB cases were identified and placed on treatment

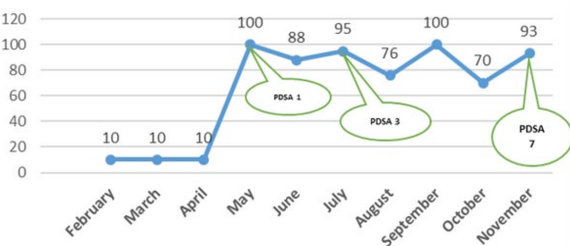

Figure. Trends analysis of transmitted results.

Conclusions: The project successfully increased TB screening and results documentation among PLHIV from a baseline of 10% to 89% within seven months of implementation. The successes have been integrated into routine operations and will be monitored for sustainability.

Opportunistic infections (excluding TB): Bacterial, non-TB mycobacterial, viral and parasitic infections

An estimate of the global burden of HIV-associated cryptococcal infection in adults in 2020

R. Rajasingham[1], N. Govender[2], A. Jordan[3], A. Loyse[4], A. Shroufi[3], D. Denning[5,6], D. Meya[7], T. Chiller[3], D. Boulware[1]

[1]University of Minnesota, Medicine, Minneapolis, United States, [2]National Health Laboratory Service and Faculty of Health Sciences, University of the Witwatersrand, National Institute for Communicable Diseases, Johannesburg, South Africa, [3]Centers for Disease Control and Prevention, Atlanta, United States, [4]St. George's University of London, Centre for Global Health, Institute and Infection and Immunity, London, United Kingdom, [5]University of Manchester, Faculty of Biology, Medicine and Health, Manchester Academic Health Science Centre, Manchester, United Kingdom, [6]Global Action Fund for Fungal Infections, Geneva, Switzerland, [7]Makerere University, Kampala, Uganda

Background: In 2014, an estimated 223,100 persons developed cryptococcal meningitis globally, resulting in 181,100 deaths and accounting for 15% of AIDS-related deaths. Since the last estimate of the global burden of HIV-associated cryptococcal infection in 2014,[1]

Global AIDS-related deaths among adults have decreased from 950,000 in 2014 to 580,000 in 2020. By 2020, ART coverage had increased to 27.5 million adults, up from 15 million in 2014, and integrase inhibitors are now first-line therapy in many large HIV programs.

Here we present an updated estimate of the global burden of HIV-associated cryptococcal infection (antigenemia), cryptococcal meningitis, and cryptococcal-associated deaths using data through 2020.

Methods: We used Joint UN Programme on HIV and AIDS estimates (2019 to 2020) and population-based HIV impact assessment (PHIA) surveys from 2016 to 2018, conducted by the International Center for AIDS Care and Treatment Program (ICAP) and Centers for Diseases Control and Prevention (CDC) to estimate the number of adults with CD4 <200 cells/mcL at risk for cryptococcal infection, by country and region. Secondly, we summarized cryptococcal antigenemia (CrAg) prevalence in CD4<200 by reviewing published literature.

Thereafter we calculated the number of CrAg-positive people by country and region by multiplying the number with advanced HIV disease at risk for cryptococcal infection by the CrAg prevalence of the respective country or region.

We estimated progression from CrAg-positive status to meningitis and/or death based on estimates from the published literature.

Results: We estimate an average global cryptococcal antigenemia prevalence of 4.4% (95%CI 1.6% to 7.4%) among people with CD4 counts of <200 cells/mL, corresponding to 182,000 (95% CI 67,000 to 292,000) cases of cryptococcal antigenemia globally per year.

Annually, we estimate 152,000 (95% CI 55,000 to 247,000) cases of cryptococcal meningitis, resulting in 112,000 cryptococcal-related deaths (95% CI 38,000 to 183,000).

Globally cryptococcal disease results in 19% (95%CI, 6 to 38%) of AIDS-related mortality. Sixty-two percent of deaths occur in sub-Saharan Africa.

Conclusions: Although there has been a reduction in the absolute global burden of HIV-associated cryptococcal infection, likely due to ART expansion, cryptococcal disease still accounts for 19% of AIDS-related deaths.

EPB046

Hematological toxicity of amphotericin B deoxycholate-based induction therapy in patients with HIV-associated talaromycosis

Y. Zhou[1,2], T. Lu[2], Y. Li[2], Y. Qin[1], Y. Lu[1], Q. Tian[3], K. Lan[4], G. Zhou[5], Y. Qin[6], V. Harypursat[1], S. Lin[2], Y. Chen[1,2]

[1]Chongqing Public Health Medical Center, Chongqing, China, [2]Zunyi Medical University, Zunyi, China, [3]the Third People's Hospital of Guilin, Guilin, China, [4]Longtan Hospital of Guangxi Zhuang Autonomous Region, Liuzhou, China, [5]the First Hospital of Changsha, Changsha, China, [6]the Fourth People's Hospital of Nanning, Nanning, China

Background: This study's objective was to investigate the predictors for severe anemia, severe leukopenia, and severe thrombocytopenia when amphotericin B deoxycholate-based induction therapy is used in HIV patients with talaromycosis.

Methods: This was a prospective, multi-center, observational study. A total of 170 HIV patients with talaromycosis were enrolled at 11 hospitals located in 9 cities from January 1st, 2019 to September 30th, 2020. Patients received treatment for 14 days with amphotericin B deoxycholate at a dose of 0.5 to 0.7 mg per kilogram per day. Multivariate logistic regression was used to analyze.

Results: Among these 170 patients, 24 (14.1%) were female. Approximately 42.9%, 20.6%, and 10.6% of the enrolled patients developed severe anemia, severe leukopenia, and severe thrombocytopenia, respectively.

Baseline lower hemoglobin levels (OR=0.938, 95% CI: 0.913~0.965), higher serum creatinine levels (OR=1.023, 95% CI: 1.003~1.044), higher AST/ALT ratios (OR=1.543, 95% CI: 1.170~2.036), lower sodium levels (OR=0.922, 95% CI: 0.855~0.995), and a dose of amphotericin B deoxycholate >0.58 mg/kg/d (OR=2.504, 95% CI:1.066~5.882) were independent risk factors associated with the development of severe anemia.

Co-infection with tuberculosis (OR = 3.313, 95% CI:1.052 ~ 10.439), and lower platelet levels (OR = 0.995, 95% CI: 0.990 ~ 0.999) at baseline was shown to be independent risk factors associated with the development of severe leukopenia. A lower platelet level (OR = 0.991, 95% CI: 0.984 ~ 0.998) at baseline was the independent risk factor found to be associated with the development of severe thrombocytopenia.

Conclusions: The preceding findings reveal risk factors for severe anemia, severe leukopenia, and severe thrombocytopenia, which will favor prevention and timely treatment of hematological toxicity, improvement of patient outcomes, shorter hospital stays, and a reduction of the requirement for blood transfusion.

EPB047

Voriconazole or amphotericin B deoxycholate: which is the preferred induction therapy in HIV-infected patients with talaromycosis?

Y. Zhou[1], Y. Qin[1], J. Ouyang[1], Y. Lu[1], J. Yuan[1], J. Nie[1], M. Liu[1], Q. Tian[2], K. Lan[3], G. Zhou[4], Y. Qin[5], K. He[6], J. Yu[7], Z. Jiang[8], J. Liu[9], S. Liu[10], V. Harypursat[1], Y. Chen[1]

[1]Chongqing Public Health Medical Center, Chongqing, China, [2]the Third People's Hospital of Guilin, Guilin, China, [3]Longtan Hospital of Guangxi Zhuang Autonomous Region, Liuzhou, China, [4]the First Hospital of Changsha, Changsha, China, [5]the Fourth People's Hospital of Nanning, Nanning, China, [6]Guangzhou Eighth People's Hospital, Guangzhou, China, [7]Xixi Hospital of Hangzhou, Hangzhou, China, [8]Liuzhou General Hospital, Liuzhou, China, [9]Kunming Third People's Hospital, Kunming, China, [10]Guiyang Public Health Clinical Center, Guiyang, China

Background: To compare the efficacy and safety of voriconazole and amphotericin B deoxycholate as induction therapy for talaromycosis in people living with HIV.

Methods: In this open-labelled, multicenter, prospective controlled trial, we enrolled patients at 15 hospitals in China from 2019 to 2020. Participants received treatment with either intravenous amphotericin B deoxycholate or voriconazole.

The primary endpoint was all-cause mortality during the first 2 weeks after baseline. Secondary endpoints were mortality at week 48, clinical resolution of talaromycosis, and fungal clearance at week 2.

Results: We observedno difference in the risk of death at weeks 2, at weeks 24 or at week 48 after multivariable logistic regression and multivariable Cox proportional-hazards modelling. Logistic regression analysis revealed a significantly lower odds ratio of clinical resolution (aOR=0.543, 95% CI: 0.338-0.872) and fungal clearance (aOR= 0.605, 95% CI: 0.377-0.972) over the course of 2 weeks in voriconazole users than in amphotericin B deoxycholate users.

A significantly lower odds ratio of hemoglobin levels <74 g/L (aOR= 0.507, 95% CI: 0.310-0.828) over the course of 48 weeks in voriconazole users than in amphotericin B deoxycholate users.

Conclusions: Induction therapy using voriconazole had a similar efficacy in terms of all-cause mortality rate to induction therapy using amphotericin B deoxycholate in HIV-infected patients with talaromycosis over a 48-week observation period. Amphotericin B deoxycholate contributed to earlier fungal clearance and clinical resolution of symptoms but was more likely to induce myelosuppression.

EPB048

Immunogenicity and safety of yellow fever vaccination in people living with HIV

E. Motta[1], L. Camacho[2], A. Filippis[3], S. W. Cardoso[1], L. Pedro[4], M. Costa[4], F. Cortes[5], C. Gripp[5], M. Morata[1], S. Lima[6], M.C. O. Souza[6], Y. S. Mendes[6], A. S. A. Soares[6], N. S. Alves[6], B. Grinsztejn[1], L. E. Coelho[1]

[1]*FIOCRUZ, Instituto Nacional de Infectologia Evandro Chagas - LAPClin, Rio de Janeiro, Brazil,* [2]*FIOCRUZ, Escola Nacional de Saúde Pública - ENSP, Rio de Janeiro, Brazil,* [3]*FIOCRUZ, Laboratório de Flavivírus do Instituto Oswaldo Cruz - IOC, Rio de Janeiro, Brazil,* [4]*FIOCRUZ, Instituto Nacional de Infectologia Evandro Chagas - CRIE, Rio de Janeiro, Brazil,* [5]*FIOCRUZ, Instituto Oswaldo Cruz - IOC, Rio de Janeiro, Brazil,* [6]*FIOCRUZ, Biomanguinhos, Rio de Janeiro, Brazil*

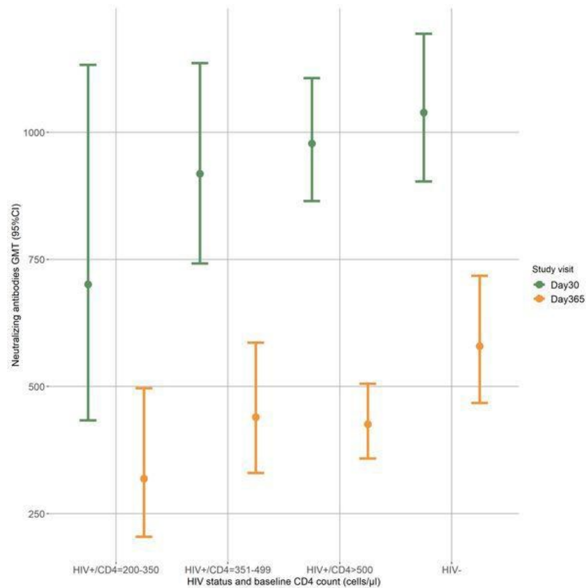
Background: There is a paucity of information regarding immunogenicity and safety of Yellow Fever (YF) vaccine in people living with HIV (PLWH). We evaluated the immunogenicity and safety of YF vaccine in PLWH compared to HIV-negative participants.

Methods: A prospective study enrolled PLWH with CD4 ≥200 cells/µl and HIV-negative participants, without previous YF vaccine.Participants received a standard dose of 17DD vaccine at baseline and were evaluated at Days 5, 30 and 365 after vaccination.

Immunogenicity was measured at Days 30 and 365 using micro plaque reduction neutralization test (µPRN50%, cut off ≥1:100); geometric mean titers (GMT) were calculated according to HIV status and baseline CD4. Adverse events (AE) and serum YF virus detection (PCR and plaque-forming units [PFU]) were measured at Days 5 and 30.Linear regression evaluated factors associated with neutralization titers.

Results: 218 PLWH and 82 HIV-negative were included. All PLWH were using antiretroviral therapy (ART); at baseline, 93% had undetectable viral load (VL); median CD4 was 630 cells/µl (IQR 463-888). Seroconversion was observed in 99% (95%CI 97%-100%) and in 95% (95%CI 91%-97%) of the participants at Days 30 and 365, respectively, with similar between PLWH and HIV-negative.

Figure shows neutralization GMT at Days 30 and 365. Among PLWH, longer use of ART, undetectable VL and higher CD4 were associated with higher neutralization titers. YF vaccine was safe and there was no serious AE. AE incidence was 6% in PWH vs. 12% in HIV-negative (p=0.05). YF virus was detected in 18% and 6% of PWH and 7% and 5% of HIV-negative, by PCR and PFU, respectively.



Conclusions: YF vaccine is immunogenic and safe in PLWH using ART. Neutralization titers were lower among PLWH with CD4 < 350 cells/µl and decreased over time.

Studies with longer follow-up are required to evaluate vaccine immunogenicity duration and the need for a booster dose in PLWH.

EPB049

Epidemiology of pneumonia in a multicenter cohort of people living with HIV

M. Berruti[1], R. Pincino[1], L. Taramasso[2], A. Vena[2], M. Giacomini[3], S. Mora[3], M. Bassetti[4], G. Cenderello[5], A. Di Biagio[4]

[1]Borea Hospital ASL-1 Imperiese, University of Genoa, Infectious Diseases Department, Sanremo, Italy, [2]Policlinico San Martino Hospital, Infectious Diseases Department, Genoa, Italy, [3]University of Genoa, Department of Informatics, Bioengineering, Robotics and System Engineering (DIBRIS), Genoa, Italy, [4]Policlinico San Martino Hospital, University of Genoa, Infectious Diseases Department, Genoa, Italy, [5]Borea Hospital ASL-1 Imperiese, Infectious Diseases Department, Sanremo, Italy

Background: Pneumonia is an important cause of infection in people living with HIV. The aim of our study is to define characteristics and outcome of hospitalized people living with HIV with pneumonia in modern antiretroviral therapy era.

Methods: We conducted a two-centre retrospective study between January 01 2015 and December 31 2020 in San Martino Hospital and Borea Hospital in Liguria region, Italy. Patients were selected using hospital database through ICD-9 discharge codes of HIV and pneumonia. Patients' demographic, clinical and microbiological records were collected through analysis of clinical charts and online regional database "Liguria HIV Network".

Results: We registered 90 cases of pneumonia during the study period. Study participants had median age of 51 years (IQR 44-58), 71.1% (64/90) were male, the main risk factor for HIV transmission was intravenous drug use (41/90, 45.6%), 25.6% (23/90) had HCV co-infection.

Median T CD4+ cell count was 100 cells/mmc (IQR 33-360), 53.3% (48/90) people living with HIV had HIV-RNA>50 copies/ml, 68.9% (662/90) were on antiretroviral therapy. History of smoking was present in 58.8% (53/90) of participants.

Only 2.2% (2/90) of participants were vaccinated for *S. pneumoniae*. The aetiologic pathogens were identified in 56/90 (62.2%) cases, 30 were opportunistic. Pneumonia was caused by *Pneumocystis jirovecii* in 24/90 (26.7%) of cases, by *S. pneumoniae* in 15/90 (16.7%), by *S. aureus*or SARS-CoV-2 in 4/90 (4.4%), by citomegalovirus in 3/90 (3.3%), by atypical mycobacteria or influenza virus or metapneumovirus in 2/90 (2.2%), by *Hemophilus influenzae*or*Legionella pneumophila*or*Aspergillus spp* in 1/90 (1.1%).

About 10% (9/90) of cases had septic shock, 12.2% (11/90) required intensive care unit admission and 17.8% (16/90) mechanical ventilation or continuous airways positive pressure.

Overall mortality was 17.8% (16/90) while mortality due to opportunistic infections was 6.6% (2/30). At univariate analysis, HIV-RNA>50 copies/ml (OR 3.47, 95% CI 1.13-10.67 p 0.03) was associated with increase mortality while being on ART (OR 0.12, 95%CI 0.01-0.928, p 0.04) was protective. At multivariable analysis none of the considered variables retained significant association with the outcome.

Conclusions: Further efforts are needed to improve screening of high-risk population and vaccination programs in PLWHIV.

EPB050

Prevalence and determinants of asymptomatic *Leishmania* infection in HIV-positive people and progression to symptomatic visceral leishmaniasis in Bihar, India

R. Mahajan[1], S. Owen[2], S. Kumar[3], S. Kazmi[4], K. Pandey[3], N. Verma[3], V. Kumar[1], A. Harshana[1], E. Lasry[5], L.M. Planas[5], E. Adams[2], S. Burza[1]

[1]Médecins Sans Frontières, New Delhi, India, [2]Liverpool School of Tropical Medicine, Liverpool, United Kingdom, [3]Rajendra Memorial Research Institute of Medical Sciences, Patna, India, [4]Médecins Sans Frontières, Patna, India, [5]Médecins Sans Frontières, Barcelona, Spain

Background: In the leishmaniasis-endemic region of Bihar, India, the detection of asymptomatic *Leishmania* infection (ALI) among People living with HIV (PLHIV) can potentially identify those at risk of developing visceral leishmaniasis (VL).

This study investigates the prevalence and determinants of *ALI* and the risk of developing symptomatic VL in PLHIV with *ALI*.

Methods: We conducted a cross-sectional survey of PLHIV ≥18 years of age with no history of VL at four anti-retroviral therapy centers within VL endemic regions of Bihar, India. *ALI* was defined as a positive rK39 ELISA, rK39 RDT, and/or qPCR result.

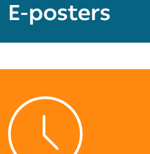
In addition, the Leishmania antigenELISA on urine was evaluated as a non-invasive alternative. Asymptomatic individuals were followed-up at three-month intervals over 18 months to assess conversion from asymptomatic to symptomatic infection. All non-asymptomatic patients were followed up telephonically.

Results: A total of 1,296 PLHIV (females: 53.6%) were included in the analysis. The baseline prevalence of *ALI* was 7.4% (n=96). All 96 (7.4%) were positive by rK39 ELISA, while 0.5% (n=6) and 0.4% (n=5) were positive by qPCR and rK39 RDT, respectively. A total of 2.2% (n=28) patients were positive by *Leishmania* antigen ELISA. Independent risk factors for asymptomatic *Leishmania* infection were a CD4 count <100 (odds ratio (OR) 3.1), a CD4 count between 100-<200 (OR=2.1) compared to a CD4 count ≥ 300, and household size ≥ 5 (OR=1.8).

The risk of all-cause mortality in the asymptomatic cohort was 2.6 times higher than in non-asymptomatic participants. A total of 109 asymptomatic patients were followed up prospectively. Overall, 3.7% (n=4) of patients converted from asymptomatic to symptomatic infection. The conversions rate of participants who were positive with rK39 ELISA, rK39 RDT, qPCR, and *Leishmania* antigen

Oral abstracts

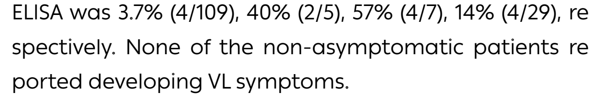
Poster exhibition



E-posters

Late-breaker abstracts

Author Index



ELISA was 3.7% (4/109), 40% (2/5), 57% (4/7), 14% (4/29), respectively. None of the non-asymptomatic patients reported developing VL symptoms.

Conclusions: PLHIV living in highly VL-endemic areas have a relatively high prevalence of ALI. Although progression rates to symptomatic infection appear low, all-cause mortality rates are higher and may reflect the impact of sub-clinical infection on HIV outcomes. The results may justify further studies investigating the early treatment of ALI in PLHIV.

Viral hepatitis C and other viral hepatitis (e.g., A, B, D, E)

EPB051

Understanding unsuccessful direct-acting antiviral hepatitis C treatment among people living with HIV from the International Collaboration on Hepatitis C Elimination in HIV Cohorts (InCHECH)

Background: Historically, hepatitis C virus (HCV) was difficult to treat among people with HIV, however treatment with direct-acting antivirals (DAA) results in 90-95% of people being cured. There is a need to further understand why 5-10% are not successfully cured in order to ensure no one is left behind in HCV elimination efforts.

Methods: Data were drawn from InCHECH and included data from Australia, Canada, France, the Netherlands, Spain, and Switzerland. People who had interferon-free DAA HCV treatment data recorded between 2014 & 2019 were included in analyses.

Among people with at least one HCV RNA test 12 or more weeks after end of treatment (EOT), we used mixed-effects logistic regression to examine factors at treatment

start associated with unsuccessful treatment, defined as a positive RNA test at their first test 12+ weeks after EOT. Factors included in univariable analyses were key population (gay and bisexual males, males with a history of injecting drug use, females with a history of injecting drug use, heterosexual or other exposure males and heterosexual or other exposure females), years since HIV diagnosis, HIV viral load, CD4 cell count, HCV genotype, cirrhosis, and previous interferon-based HCV treatment). Factors significant at 90% in univariable analyses, and age, were included in multivariable analyses.

Results: Overall, 4554 people had DAA treatment data; the majority of whom were gay or bisexual males (46%) or had a history of injection drug use (37%). Of these people, 4509 (99%) had any HCV RNA data recorded, and 3844 (85%) had a test 12 or more weeks following EOT, ranging from 84% to 87% across key population groups.

Unsuccessful treatment was 5.5% (212/3844) overall, ranging from 4% to 8% among key population groups. Adjusted for age and key population group, a CD4 cell count between 200-350 cells/mm^3 was the only factor associated with unsuccessful treatment (aOR 1.78, 95%CI 1.20-2.63) compared to a CD4 cell count >350 cells/mm^3.

Conclusions: We found that 5.5% of people with an SVR12+ test were unsuccessfully treated with minimal difference across key populations.

Extra support through HCV treatment may be warranted among people with markers of sub-optimal HIV treatment.

EPB052

Acute HCV infection followed by spontaneous clearance impact on telomere shorting

C. Crespo-Bermejo[1], V. Lara-Aguilar[1], D. Valle-Millares[1], L. Martín Carbonero[2], L. Domínguez-Domínguez[3], P. Ryan[4], I. de los Santos[5], M. Llamas-Adán[1], S. Grande-García[1], A. Fernández Rodríguez[1], V. Briz[1]

[1]*Institute of Health Carlos III (ISCIII), Laboratory of Reference and Research on Viral Hepatitis, National Center for Microbiology, Majadahonda, Spain,* [2]*Instituto de Investigación Sanitaria Hospital de la Paz (IdiPAZ), Madrid, Spain,* [3]*Instituto de Investigación Biomédica del Hospital Doce de Octubre (imas12), Unidad VIH, Servicio de Medicina Interna, Madrid, Spain,* [4]*Infanta Leonor Hospital, Department of Infectious Diseases, Madrid, Spain,* [5]*Hospital Universitario de La Princesa, Servicio de Medicina Interna-Infecciosas, Madrid, Spain*

Background: Human Immunodeficiency Virus (HIV)-mediated inflammation and immune activation is associated with an immunesenescence status that accelerate telomere shorting. Coinfection with Hepatitis C (HCV) is related to a decreased telomere length in cirrhotic patients. HCV exposure is also associated to a higher HIV reservoir size and viral splicing in resting CD4 T-cells (rCD4), the main HIV reservoir.

However, it is unknown the impact of HCV exposure in telomere length of patients without cirrhosis, and its relation with HIV reservoir in rCD4 cells.

Methods: Prospective study of 71 HIV patients under antiretroviral therapy (ART) stratified by HCV status:

a) 28 without previous HCV infection (HIV+);

b) 18 with spontaneous HCV clearance (HIV+/HCV-);

c) 25 patients who previously eliminated HCV with Direct-acting Antivirals (DAAs) (HIV+/HCV- DAAs).

All patients displayed no advance fibrosis (F<2). The relative telomere length (RTL) was assessed by real-time multiplex PCR (MMqPCR) and reservoir size by Alu-LTR qPCR on rCD4

T-cells. Differences between groups were analysed using a generalized linear model. Linear correlations between telomere length and viral reservoir size were determined.

Results: HIV patients had a median age of 49 years, 94.4% were Caucasians and 66% were men. Median HIV infection time was 14 years. Lower CD4 nadir was found in HCV exposed individuals [425 (HIV+), 220 (HIV+/HCV-) and 280 (HIV+/HCV- DAAs), p= 0.004]. Our results showed similar RTL among patients HIV+/HCV- and HIV+/HCV- DAAs (AMR=1.032, p=0.569) and a lower significant RTL between previously exposed HCV patients (HIV/HCV- and HIV+/HCV- DAAs) and HIV+ subjects [(AMR=0.862, p=0.010) and (AMR=0.890, p=0.039), respectively] *(Figure 1a)*.

Additionally, we detected a significant negative correlation between RTL and the viral reservoir size (r=-0.531; p=0.028) in HIV+/HCV- patients *(Figure 1b)*.

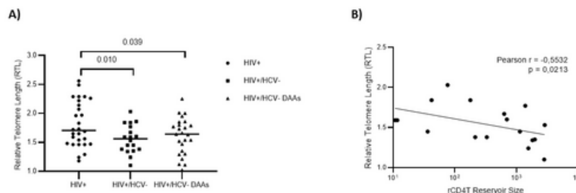

Figure 1. a) The RTL in rCD4 T-cells. b) Negative correlation between rCD4T reservoir size and RTL.

Conclusions: Exposure to HVC decreases the telomere length in rCD4 T-cells. In addition, lower telomere length in spontaneous clarifiers is associated with a larger reservoir size in rCD4 T-cells.

EPB053

A cluster randomized controlled studyofsecondary distribution of HCV self-test to support micro-elimination in Karachi, Pakistan

A. Hasnain[1], S. Shilton[2], W. Shah[1], J. Markby[2], N. Luhmann[3], M.S. Jamil[3], E.I. Reipold[2], S. Hamid[1]

[1]*Aga Khan University, Medicine, Karachi, Pakistan,* [2]*FIND, Geneva, Switzerland,* [3]*WHO, Geneva, Switzerland*

Background: Pakistan has a nationwide HCV prevalence of 6% with majority of cases undiagnosed due to lack of comprehensive screening programmes. Self-testing has shown to increase testing uptake and acceptability in

HIV due to its convenience and privacy advantages. This study aims to evaluate the acceptability and impact of a program enabling home delivery of HCV self-testing using the oral-based OraQuick® HCV rapid antibody test. It is nested within a community-based micro elimination project in an HCV endemic district of Karachi, Pakistan.

Methods: This ongoing cluster randomized control study targets persons missed during house-to-house screening done as part of the micro-elimination study in two Union Councils in district Malir of Karachi. During house visits, individuals not found at home are eligible for participation. Target sample size is 1000 participants each in the intervention and control group. In the intervention group, an HCV self-test is left with instructions for use explained to a senior household member.

In the control group, a pamphlet is left with directions to visit the nearest clinic for HCV screening. Both groups are followed up within 4 weeks to inquire if testing was completed and a brief survey is conducted. Results reported are incentivized and individuals with positive tests are linked for further management.

Results: 728 participants have been recruited from 29th Nov 2021 to 22ndDec 2021 with 431 in the intervention group and 297 in the control group from rural and peri-urban clusters of the district. Mean age across both groups is 36 years with 85% male participants.

The proportion of participants who reported completing the HCV antibody test was 89% in the intervention group compared to 15% in the control group.

Over half (54%) of the participants who completed self-testing had received no formal education. Nearly all (96%) participants who reported completing the test demonstrated willingness to perform HCV self-test in the future.

Conclusions: Preliminary results of this study demonstrate that HCV self-testing is acceptable in this setting and population with potential of self-testing to increase the uptake of testing compared to standard HCV testing services while ensuring confidentiality and convenience especially in hard to reach populations.

EPB054

Hepatitis B prevalence and risk factors among adults living with HIV in South Africa

M. Shivakumar[1], C. Moe[2], M. Krows[1], S. Govere[3], M.Y.S. Moosa[4], C. Celum[5], P. Drain[6]

[1]University of Washington, Global Health, Seattle, United States, [2]University of Washington, Epidemiology, Seattle, United States, [3]AIDS Healthcare Foundation, Durban, South Africa, [4]University of KwaZulu-Natal, Infectious Diseases, Durban, South Africa, [5]University of Washington, Global Health, Medicine, Seattle, United States, [6]University of Washington, Global Health, Medicine, Epidemiology, Seattle, United States

Background: Globally, about 10% of people living with HIV (PLHIV) also have concurrent Hepatitis B virus (HBV) infection. Without routine screening for Hepatitis B, the choice of antiretroviral therapy can be more difficult to manage, as not all medications treat both infections.

The objective of this research was to identify risk factors that put PLHIV at higher risk of Hepatitis B infection.

Methods: We conducted a prospective clinic-based cohort from 2013 – 2017 in Durban, South Africa. Participants were enrolled into the cohort if they tested positive for HIV, and all PLHIV were subsequently tested for Hepatitis B after enrollment.

Follow up assessments were conducted at 3, 6, and 12 months after enrollment. Patients completed questionaries pertaining to sociodemographic status, medical history, clinical symptoms, and mental health and stigma pertaining to their diagnosis at each visit.

Alcohol use was measured as used within the last 30 days, used within the last year but not the last month, used but not within the last year, or never used.

We compared prevalence of HBV between age groups using a chi squared test. Univariate and multivariate logistic regression models were conducted on co-variates of the data set using the 'dplyr' and 'stats' packages in R. We measured adjusted odds ratios (aORs) for each covariate to compare the risk factors for those with HBV and HIV compared to PLHIV.

Results: A total of 3105 PLHIV were enrolled, with a mean age of 33 years and 43% (n=1331) were male. Of those, 196 (6%) individuals tested positive for HBV, with a mean age of 33 years and 62% (n=121) were male. Participants aged >25, who were born before South Africa implemented routine infant vaccination for HBV in 1995, were more likely to have HBV (p=0.043). HBV diagnosis was associated with drinking alcohol over the past year (aOR = 1.17), lack of condom use (aOR = 1.10), and income >10,000 ZAR/month (aOR = 1.63).

Conclusions: Implementing routine Hepatitis B testing for adults born before 1995 can help prevent the further increase of Hepatitis B infection rates.

These study findings also provide additional support for enhanced Hepatitis B screening among PLHIV.

EPB055

Behavioral factors associated with HCV viremia among HIV-positive men who have sex with men

M.-H. Huang[1], Y.-T. Chen[2], L.-H. Su[2], S.-H. Huang[3], Y.-C. Huang[3], W.-D. Liu[2], Y.-S. Huang[2], G.-J. Chen[4], W.-C. Liu[2], Y.-C. Su[2], S.-Y. Chang[5], H.-Y. Sun[2], C.-C. Hung[2]
[1]Hualien Tzu Chi Hospital, Buddhist Tzu Chi Medical Foundation, Internal Medicine, Hualien, Taiwan, Province of China, [2]National Taiwan University Hospital, Internal Medicine, Taipei, Taiwan, Province of China, [3]National Taiwan University Hospital Hsin-Chu Branch, Internal Medicine, Hsin-Chu, Taiwan, Province of China, [4]Min-Sheng General Hospital, Internal Medicine, Taoyuan, Taiwan, Province of China, [5]National Taiwan University College of Medicine, Clinical Laboratory Sciences and Medical Biotechnology, Taipei, Taiwan, Province of China

Background: Sexually acquired HCV infection contributes to the epidemics of incident HCV infection and reinfection among people living with HIV (PLWH) in recent decades. To achieve the goal of HCV microelimination, identification of the modifiable factors associated with HCV viremia is crucial to prevent onward HCV transmission.
Our study aimed to identify the behavioral factors associated with HCV viremia in high-risk HIV-positive men who have sex with men (MSM).
Methods: HIV-positive MSM who had documented free of HCV viremia at screening and met at least one of the following criteria were invited to participate in this prospective cohort study:
1. Having had sexually transmitted infections in the past six months;
2. Presence of elevated aminotransferases in the past six months; and,
3. Having had prior HCV viremia and achieved viral clearance either spontaneously or via antivirals.
Face-to-face questionnaire interviews about the behavioral factors associated with HCV acquisition for each participant was completed at enrollment. All participants underwent regular HCV RNA testing every 12 weeks with the use of 3-stage pooled-serum HCV RNA testing methods and were followed till detection of HCV viremia or completion of 48-week follow-up.
Results: Among the 735 participants, all had been receiving antiretroviral therapy with a mean CD4 count of 643 cells/mm^3 and plasma HIV RNA <200 copies/ml in 96.7%. High rates of recreational drug use (39.5%) and sexualized drug use ("chemsex") (34.0%) were reported.
After 48 weeks of follow-up, 674 participants (91.7%) remained HCV RNA-negative and 61 (8.3%) had HCV viremia detected. In the multivariable analysis, we found that recreational drug use (adjusted odds ratio [AOR], 2.13; 95% confidence interval [CI], 1.00-4.57], sharing injecting equipment (AOR, 19.9; 95% CI, 1.60-248.4), and having group sex (AOR, 2.5; 95% CI, 1.20-5.06) in the past 12 months were significantly associated with HCV viremia.
Conclusions: Recreational drug use, sharing injecting equipment, and having group sex were risk behaviors associated with HCV viremia in PLWH.
In addition to improving access to DAA testing and treatment, risk modification is imperative to prevent HCV acquisition in our endeavor to achieve HCV microelimination among high-risk PLWH who are MSM.

EPB056

Prospective liver fibrosis assessment in hepatitis B-positive individuals with and without HIV-coinfection in Senegal

J.M. Tine[1], A. Ramirez Mena[1,2,3], K. Ndiaye[4], L. Fortes[1], O. Ndiaye[5], D. Ka[1], N.F. Ngom[4], M. Fall[1], M. Seydi[1], G. Wandeler[1,2,6], SEN-B Study Group
[1]University Hospital Fann, Service de Maladies Infectieuses et Tropicales, Dakar, Senegal, [2]Bern University Hospital, University of Bern, Department of Infectious Diseases, Bern, Switzerland, [3]University of Bern, Graduate School of Health Sciences, Bern, Switzerland, [4]University Hospital Fann, Centre de Traitement Ambulatoire, Dakar, Senegal, [5]University Hospital Dakar, Centre de Recherche et Formation Clinique, Dakar, Senegal, [6]University of Bern, Institute of Social and Preventive Medicine, Dakar, Senegal

Background: Hepatitis B virus (HBV) infection is the first cause of liver cancer in West Africa. Although >10% of the general population is affected by chronic HBV infection in the region, only few large-scale research efforts have been undertaken to date.
Here, we present prospective data on liver fibrosis from a cohort of HBV-monoinfected and HIV/HBV-coinfected individuals (SEN-B) in Dakar, Senegal.
Methods: We included all persons living with HIV and HBV-coinfection, as well as HBV-monoinfected individuals presenting after October 2019 at two HIV-clinics in Dakar, Senegal. We measured HBV_DNA using the COBAS/TaqMan® platform and liver fibrosis (liver stiffness [LS]≥7.1 kPa) and cirrhosis (LS≥11.1 kPa) using transient elastography (TE).
TE results were compared between groups using descriptive statistics, and the association between HIV infection and liver fibrosis was assessed using multivariable with logistic regression adjusted for age, sex, HBV DNA, and body mass index.
We evaluated the proportion of individuals who experienced regression of cirrhosis or significant fibrosis during 6-12 months of follow-up.
Results: We included 581 HBsAg-positive individuals, of whom 110 were HIV/HBV-coinfected and on antiretroviral therapy. The median age was higher in HIV/HBV-coinfected compared to HBV-monoinfected participants (45 vs. 33years, p<0.001).
Among HIV/HBV-coinfected participants 89/107 (83%) had a suppressed HBV DNA. The prevalence of significant fibrosis at enrolment was 13% in HBV-monoinfected and

6% in HIV/HBV-coinfected individuals (p=0.07), whereas the proportion of cirrhosis was 4% in both groups. In multivariable analyses, male sex (adjusted odds ratio 3.83, 95% confidence interval 1.72-8.53) and HBV DNA >2,000 IU/mL (2.86, 1.41-5.83) were associated with liver fibrosis.

Overall, 288 (50%) individuals had follow-up TE results available at the time of analyses. Among individuals on tenofovir, 6/11 (54.5%) participants with significant fibrosis and 5/11 (45.4%) with cirrhosis had a regression of their fibrosis stage. No patient with untreated HBV-monoinfection developed liver cirrhosis during follow-up.

Conclusions: SEN-B is one of the first prospective cohorts of HBV-infected individuals in sub-Saharan Africa. The prevalence of liver fibrosis was low, and no association with HIV infection was found. Liver fibrosis regression was observed in one-half of patients on tenofovir during 12 months of follow-up.

EPB057

Long-term serologic responses to different combinations of inactivated hepatitis A virus vaccines among people living with HIV

K.-Y. Lin[1], H.-Y. Sun[1], G.-J. Chen[1,2], W.-D. Liu[1], C.-C. Hung[1], S.-C. Chang[1]

[1]*National Taiwan University Hospital, Taipei, Taiwan, Province of China,* [2]*Min-Sheng General Hospital, Taipei, Taiwan, Province of China*

Background: PLWH are at increased risk for hepatitis A virus (HAV) infection. However, serologic responses and durability of HAV vaccination are reduced among PLWH. We aimed to compare the long-term serologic responses to different 2-dose combinations of the inactivated HAV vaccines and to identify the factors associated with seroreversion among PLWH.

Methods: This retrospective study included adult PLWH who had achieved seroconversion after completing 2-dose vaccination against HAV during an outbreak of acute hepatitis A between 1 June 2015 and 31 December 2017. PLWH included in the study received either Havrix for both doses (Havrix-Havrix group), Havrix as the first dose followed by Vaqta as the second dose (Havrix-Vaqta group), or Vaqta for both doses (Vaqta-Vaqta group). The antibody persistence was evaluated 5 years after vaccination and compared between different groups.

Results: The study comprised 1025 PLWH with a median age of 34 years and CD4 count of 584 cells/mm^3. Of them, 643 (62.7%) were in the Vaqta-Vaqta group, 363 (35.4%) were in the Havrix-Vaqta group, and 19 (1.9%) were in the Havrix-Havrix group. The peak anti-HAV IgG titers within 12 months after HAV vaccination were 10.5, 9.4, and 7.2 signal-to-cutoff (S/CO) in the Vaqta-Vaqta, Havrix-Vaqta, and Havrix-Havrix groups, respectively.

The proportion of PLWH with persistent seroprotection remained more than 96% over time, from 96.2% at months 24-36 to 96.0% at months 48-60. After a median follow-up of 3.9 years, 81 of the 1025 patients (7.9%) seroreverted. The seroreversion rate was much higher for the Havrix-Havrix group (10.5%) and the Havrix-Vaqta group (11.6%) than for the Vaqta-Vaqta group (5.8%) (P=0.001).

In the multivariable analysis, seroreversion was significantly associated with peak anti-HAV IgG titers (AOR, 0.60; 95% CI, 0.54-0.66), receiving 2 doses of Havrix (AOR, 2.47; 95% CI, 1.34-4.54), receiving immunosuppressants (AOR, 39.96; 95% CI, 1.11-1434.46), and weight (per 1-kg increment, AOR, 1.03; 95% CI, 1.00-1.05).

Conclusions: The seroprotection against HAV remained high in the long-term follow-up among PLWH on antiretroviral therapy who had undergone 2-dose HAV vaccination. The higher peak anti-HAV IgG titers and lower seroconversion rate among PLWH receiving 2 doses of Vaqta may provide potential benefits in conferring long-term protection against HAV.

EPB058

Integrating hepatitis services into community based opioid substitution therapy in three South African cities: interim findings on feasibility and HIV and viral hepatitis C prevalence

L. Casey[1], A. Scheibe[2], M. Mahaso[3]

[1]*NACOSA, Pretoria, South Africa,* [2]*Community Oriented Primary Care Research Unit, Department of Family Medicine, University of Pretoria, Pretoria, South Africa,* [3]*NACOSA, Cape Town, South Africa*

Background: There are an estimated 82500 people who inject drugs (PWID) in South Africa. Among whom, the prevalence of HIV and hepatitis C virus (HCV) infection is high; 21% and 55%, respectively. Access to harm reduction and HIV services is increasing, however HCV diagnosis and treatment with direct acting antivirals (DAAs), remains limited.

We aimed to assess the feasibility of integrating HCV care into community-based opioid substitution therapy (OST) services in three South Africa cities and assess the HIV and HCV prevalence among clients.

Methods: PWID taking or initiated on OST were offered HIV antibody and HCV antibody testing using rapid point of care tests. HCV infection was confirmed using laboratory-based molecular testing. PWID with confirmed HCV infection were initiated onto DAAs.

Results and data on gender and age disaggregation were extracted from a centralised database and analysed in Stata v14.2 using descriptive statistics.

Results: Between June 2021-January 2022, 319 PWID were screened for HCV and HIV (83 in Cape Town; 68 in Durban, 168 in Johannesburg). Eighteen percent of clients were female. Most clients (58% of males and 57% of females) were aged between 25 – 35 years old.

Overall HIV prevalence was 30% (n=96), ranging from 8% (n=7) in Cape Town to 41% (n=69) in Johannesburg. Overall HCV prevalence was 83% (n=265), ranging from 69% (n=46) in Durban to 93% (n=156) in Johannesburg. 88 PWID

(28%) had HIV-HCV co-infection. The highest HIV-HCV co-infection prevalence was in Johannesburg among clients aged 25 – 35 (14% (n=6) of females and 86% (n=37) of males). To date, 95% (40/42) of clients with reactive HCV antibody tests have confirmed HCV infections and 30 clients have started DAAs.

Conclusions: A high prevalence of HCV and HIV and HCV-HIV co-infection was identified among PWID on OST in these cities. Interim findings demonstrate the feasibility of integrating HCV screening, lab-based molecular testing and DAA treatment in community-based OST services in South Africa.

STIs (including HPV)

EPB059
Impact of methamphetamine use and rectal STIs on systemic and rectal mucosal inflammation

C. Blair[1], J. Fulcher[1], G. Cho[1], P. Gorbach[2], S. Shoptaw[3], J. Clark[1]

[1]David Geffen School of Medicine at UCLA, Department of Medicine, Division of Infectious Diseases, Los Angeles, United States, [2]UCLA Fielding School of Public Health, Department of Epidemiology, Los Angeles, United States, [3]David Geffen School of Medicine at UCLA, Department of Family Medicine, Los Angeles, United States

Background: Rectal gonorrhea and chlamydia (GC/CT) are associated with increased risk for HIV acquisition resulting from mucosal inflammation. In addition to promoting sexual risk behavior, methamphetamine (MA) use is associated with systemic and mucosal inflammation, suggesting parallel biological and behavioral mechanisms for HIV transmission among MA-using men who have sex with men (MSM). Data evaluating the combined biological effects of MA use with rectal GC/CT on inflammation are limited.

Methods: This is a cross-sectional analysis of stored rectal sponge and plasma specimens from 100 MSM in a NIDA-funded longitudinal cohort to evaluate markers of systemic and rectal inflammation under two conditions:

1. Recent MA use (measured by urine drug screen) and;
2. Rectal GC/CT infection (via nucleic acid testing).

The study consisted of 50 participants with recent MA use (25 with and 25 without rectal GC/CT) and 50 non-substance using controls (NSUC) (25 with and 25 without rectal GC/CT). NSUC had negative urine drug screens for opiates, cocaine, MA, amphetamines, ecstasy, and cannabis.

Luminex assays were used to measure cytokine concentrations from plasma and rectal samples as well as markers of immune activation (CD14, -163, -27) from plasma. Log-transformed immune markers were regressed on MA exposure and rectal GC/CT, controlling for HIV status, age, and, for rectal samples, receptive anal intercourse in past week. The Benjamin-Hochberg procedure with a false discovery rate of <0.2 was used to adjust for multiple comparisons.

Results: Study visits occurred from October 2014 to December 2017. Median age was 32 (range 19-45). 58% of participants identified as Latinx, 33% Black, and 9% non-Black/non-Latinx. 58% were living with HIV. Increased plasma levels of tumor necrosis factor (TNF)-α, interleukin (IL)-6, IL-8, IL-1ß, and rectal levels of IL-6 were associated with MA use and rectal GC/CT, independent of HIV status. Increased rectal levels of TNF-α, IL-1ß, and IL-17a were associated with rectal GC/CT.

Conclusions: Markers of systemic and rectal inflammation were positively associated with both MA use and rectal GC/CT. Condomless sex in the setting of MA- and GC/CT-induced immune activation may provide the basis for synergistic bio-behavioral mechanisms that promote HIV/STI transmission among MA-using MSM.

EPB060
Sexually transmitted infection testing and case rates before and during COVID-19 pandemic in a United States HIV cohort

G. Simoncini[1], Q. Hou[2], K. Buchacz[3], C. Armon[2], K. Chargaris[2], K. Carlson[2], J. Fuhrer[4], D. Ward[5], C. Mayer[6], C. Firnhaber[7], M. Durham[3], J. Li[3]

[1]AIDS Healthcare Foundation, Medicine, Los Angeles, United States, [2]Cerner Corporation, Kansas City, United States, [3]Centers for Disease Control and Prevention, Atlanta, United States, [4]Stony Brook Medicine, Stony Brook, United States, [5]Dupont Circle Infectious Disease Specialists, Washington DC, United States, [6]Infectious Disease Associates of Tampa Bay, Tampa, United States, [7]University of Colorado Anschutz Medical Campus, Aurora, United States

Background: The COVID-19 pandemic affected sexually transmitted infection (STI) testing and case (positive lab test) rates in the United States but testing and case rates among people with HIV (PWH) during this period have not been well characterized.

Methods: We analyzed medical records data of HIV Outpatient Study (HOPS) participants who were in HIV care from 1/1/2019-3/31/2021, with at least one CD4+ cell count and HIV viral load recorded.

We calculated STI (gonorrhea, chlamydia, and syphilis) testing, diagnosed STI case rates, and rate ratios (RR) comparing pre- and during pandemic periods (1/1/2019-2/29/2020 and 3/1/2020-3/31/2021) respectively.

Results: A total of 2,311 patients had 14,185 STI tests during the study window: 4,991 gonorrhea tests with 157 cases, 4,978 chlamydia tests with 135 cases, and 4,216 syphilis tests with 114 cases. Of the 2,311 pts, 10% were under 30 years of age, 53% were older than 50 years old, 76% were men, 56% were men who have sex with men (MSM), 39%

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

were non-Hispanic/Latino (NH) Black, 40% were NH white, and 17% were Hispanic/Latino people.Overall STI testing RR for pandemic vs. pre-pandemic periods was 0.78 (95% Confidence Interval [CI] 0.73-0.82) for gonorrhea, 0.78 (CI 0.73-0.83) for chlamydia, and 0.93 (CI 0.88-0.99) for syphilis. Overall STI case RR for pandemic vs. pre-pandemic periods was 0.99 (CI 0.76-1.28) for gonorrhea, 0.84 (CI 0.61-1.14) for chlamydia, and 1.08 (CI 0.98-1.19) for syphilis.

In univariate analyses, those with any diagnosed STI tended to be ≤40 years of age, MSM, patients who entered the HOPS in 2019 or later, antiretroviral-naïve, and without an AIDS diagnosis. In univariate analyses for syphilis, RR of diagnosed syphilis between pandemic and pre-pandemic was significantly higher for MSM (1.11, CI 1.10-1.23), those who entered the HOPS during 2019-2021 (1.39, CI 1.08-1.80), those with baseline HIV viral loads > 200 copies/mL (1.43, CI 1.12-1.81), and antiretroviral-naïve patients (1.54, CI 1.06-2.25).

Conclusions: STI testing rates in the HOPS cohort decreased during the pandemic. STI case RRs for pandemic vs. pre-pandemic were similar, except for increases in diagnosed syphilis among some subgroups, highlighting the need for continued vigilance of syphilis, especially among PWH.

EPB061
The burden of genital discharge causing sexually transmitted infections over time starting from acute HIV infection among a cohort of women in South Africa

K. Asare[1,2,3], F. Osman[2], A. Mindel[2], A. Vandormael[4], N. Naicker[2], M. Khanyile[2], A. Tomita[5,6], N. Garrett[1,2]
[1]*University of KwaZulu Natal, School of Nursing and Public Health, Durban, South Africa,* [2]*Centre for the AIDS Programme of Research in South Africa, Durban, South Africa,* [3]*Health Economics and HIV and AIDS Research Division (HEARD), University of KwaZulu-Natal, Durban, South Africa,* [4]*Heidelberg Institute of Global Health, Heidelberg, Germany,* [5]*Centre for Rural Health, School of Nursing and Public Health, University of KwaZulu-Natal, Durban, South Africa,* [6]*KwaZulu-Natal Research Innovation and Sequencing Platform (KRIPS), College of Health Sciences, University of KwaZulu-Natal, Durban, South Africa*

Background: Many curable sexually transmitted infections (STIs) co-occur with HIV infection, adversely affecting women and HIV prevention efforts. However, limited longitudinal studies exist to understand temporal associations. We determined factors associated with discharge-causing STIs over time among a cohort of acutely HIV-infected women in South Africa.

Methods: We analysed data from the CAPRISA 002 study in South Africa, which included STI testing at enrollment and 6-12 monthly thereafter up to 15 years.

We estimated incidence as new cases per 100 person-years (PYs) and characterized all subsequent cases over time as re-infections. We used Cox-proportional-hazard and generalised estimation equation analyses to determine factors associated with STI incidence and prevalence over time, respectively.

Results: The median age at enrollment was 25 years (IQR=22-29) among 235 women. Total follow-up was 7.5 median years (IQR=5.7-10.8), within which 84.3% (n=198) started antiretroviral-therapy (ART) at 3.3 median years (IQR=1.2-5.6) after enrollment.STI incidence and re-infections per 100 PYs respectively, were *Neisseria gonorrhoeae* (NG) (5.1 and 9.5), *Chlamydia trachomatis* (CT) (7.4 and 14.7), *Trichomonas vaginalis* (TV) (8.0 and 26.6), *Mycoplasma genitalium* (MG) (7.7 and 16.7) and at least one STI (25.2 and 37.3).

STI incidence overtime was associated with Log_{10} viral load (aHR=1.3, 95%CI=1.1-1.5), Syphilis (aHR=16.7, 95%CI=7.7-36.3), HSV2 PCR (aHR=1.6, 95%CI=1.1-2.4), Bacterial vaginosis (aHR=1.5, 95%CI=1.0-2.2), baseline steady sexual partners (One versus none: aHR=3.2, 95%CI=1.8-5.6; two plus versus none: aHR=3.5, 95%CI=1.9-6.5), increasing age (5-year fold: aHR=0.8, 95%CI=0.7-0.9) and being married at baseline (aHR=0.3, 95%CI=0.1-0.8). STI prevalence before and after ART respectively, were NG (6.3% and 5.7%), CT (10.6% and 8.7%), TV (14.0% and 13.4%), MG (10.5% and 7.1%) and at least one STI (34.0% and 29.5%). STI prevalence overtime was associated with increasing age (5-year fold: aHR=0.8, 95%CI=0.7-0.9), baseline steady sexual partners (One versus none: aOR=4.3, 95%CI=2.0-9.2; two plus versus none: aOR=5.1, 95%CI=1.7-14.8) and being married at baseline (aOR=0.4, 95%CI=0.2-0.8).

Conclusions: The burden of curable STI co-infection with HIV remained high over time among women, underscoring the implications for HIV transmission risk and the need for integrated HIV and other STI care.

EPB062
What will it take to control the syphilis epidemic among gay, bisexual and other men who have sex with men (MSM) in British Columbia (BC), Canada?

V.D. Lima[1], J. Zhu[1], B. Takeh[2], J.F. David[3], J. Toy[1], P. Sereda[1], M. Hull[4], T. Grennan[5], R. Barrios[1], J.S.G. Montaner[4]
[1]*BC Centre for Excellence in HIV/AIDS, Epidemiology and Population Health Program, Vancouver, Canada,* [2]*University of British Columbia, School of Population and Public Health, Vancouver, Canada,* [3]*York University, Department of Mathematics and Statistics, York, Canada,* [4]*BC Centre for Excellence in HIV/AIDS, AIDS, Vancouver, Canada,* [5]*BC Centre for Disease Control, HIV/STI Program, Vancouver, Canada*

Background: In BC, due to the fast expansion of the Treatment as Prevention and pre-exposure prophylaxis (HIV-PrEP) programmes, the HIV burden among MSM has been substantially decreased. However, the syphilis epidemic continues to affect this population disproportionately. We developed an HIV and syphilis co-infection mathematical model to evaluate whether syphilis epidemic control in BC can be achieved in 15 years.

Methods: We designed a comprehensive deterministic compartmental model that combines the complex individual-based knowledge of clinical, behavioural and epidemiological aspects of the HIV and Syphilis epidemics among MSM in BC. We sub-divided the MSM population by HIV status and PrEP usage. The scenarios investigated included increasing syphilis testing and treatment rates and the use of doxycycline as PrEP for syphilis (Doxy-PrEP).
We measured the intervention impact by the World's Health Organization (WHO) target for ending the syphilis epidemic (90% reduction in syphilis incidence compared to 2018) and by the number of syphilis infections averted per 1000 tests/Doxy-PrEP. We also evaluated the impact of the HIV-PrEP program on the syphilis epidemic.
Results: The WHO's target can be achieved as early as 2027 by targeting MSM not on HIV-PrEP with increased testing and treatment and use of Doxy-PrEP (Figure). However, targeting MSM diagnosed with HIV (in comparison to the previous group) can be >5 times more effective in averting new syphilis infections if testing or Doxy-PrEP is increased by ≥10%.
Our model also showed the importance of HIV-PrEP programs in decreasing the burden of the syphilis epidemic (74% decrease in syphilis incidence rate), since MSM in these programs are regularly tested for syphilis.
Conclusions: Our results suggest that increasing access to syphilis tests and Doxy-PrEP among MSM with HIV diagnosis will effectively reduce the number of syphilis infections. However, faster achievement of WHO's target will require additional interventions among MSM not on HIV-PrEP.

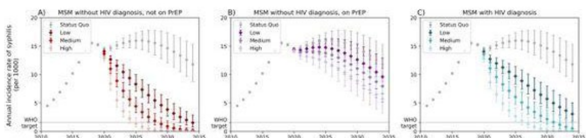

Figure. Intervention scenarios for improveents on syphilis testing, treatment and Doxy-PrEP coverage among MSM in different subgroups during 2020-2034 (Low: 10%, Medium: 20%, High: 40%)

EPB063
Serologic response after syphilis treatment among Thai adults living with HIV: a longitudinal cohort study

A. Hiransuthikul[1,2], T. Apornpong[2], S. Gatechompol[2,3], H. Mar Lwin[2], T. Wichiensan[2], K. Woratanarat[2], W. Min Han[2], S. Ubolyam[2], K. Ruxrungtham[2,3], A. Avihingsanon[2,3], HIV-NAT 006 study team
[1]Chulalongkorn University, Preventive and Social Medicine, Bangkok, Thailand, [2]HIV-NAT, Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [3]Center of Excellence in Tuberculosis, Department of Medicine, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand

Background: Despite straightforward treatments, post-treatment serologic monitoring and interpretation are challenging, particularly for people living with HIV (PLWH), who may have a slow serologic response and a higher risk of advanced-stage syphilis.
To add to the limited data of syphilis monitoring among PLWH, we aimed to determine the proportion and time interval of PLWH with a serologic response after syphilis treatment.
Methods: Data from the HIV-NAT 006 cohort which prospectively enrolled and followed Thai adults (aged ≥18 years) living with HIV who had reactive pretreatment RPR, at least one follow-up RPR within 1 year for primary/secondary syphilis and 2 years for latent/other syphilis after treatment, and documented syphilis stage was included in the analysis.
Adequate response (AR) was defined as ≥4-fold decrease or seroreversion within 12 months for primary/secondary syphilis and within 24 months for latent/other syphilis.
Delayed response was defined as ≥4 fold decrease or seroreversion beyond the time of an adequate response. Kaplan-Meier was used to determine the probability of achieving serologic response at month 12 and 24.
Results: Among 172 eligible PLWH, all were male (88.8% identified themselves as homosexual), median (IQR) age was 34.5 (26.5-41.6) years, 2.0% (3/152) reported using intravenous recreational drugs, CD4 cell count was 440 (294-597) cells/µL, 66.3% were taking antiretroviral therapy (ART), and 82.4% (98/119) had viral suppression at the time of syphilis diagnosis. Eight (4.7%) participants had primary, 59 (34.3%) had secondary, 103 (59.9%) had latent, and 2 (1.2%) had neuro/ocular syphilis. A total of 127 (73.8%) had AR (76.6% of primary/secondary and 72.2% of latent/other syphilis) and 13 (7.6%) had delayed response.
The probability of achieving serologic response at 12 and 24 months was 0.81 (95%CI 0.70-0.90) and 0.98 (95%CI 0.72-0.92) for primary/secondary, and 0.59 (95%CI 0.50-0.69) and 0.77 (95%CI 0.68-0.85) for latent/other syphilis, respectively.
Using a multivariable Cox regression, primary/secondary was the only significant predictive factor for achieving AR (adjusted hazard ratio: 1.73, 95%CI 1.10-2.73, p=0.019).

Conclusions: Most Thai PLWH with syphilis had a serologic response after treatment. Primary/secondary syphilis was more likely to respond and respond earlier than latent/other syphilis. Long-term monitoring is warranted for PLWH with syphilis.

EPB064

Cytomegalovirus viremia during pregnancy among women living with HIV in Canada

E. McClymont[1], A.Y. Albert[2], H.C. Côté[1], A.B. Diallo[3], C. Elwood[1], F. Kakkar[4], D. Money[1], L. Sauvé[1], H. Soudeyns[4], S. Gantt[4], I. Boucoiran[4], The CARMA-PREG (CIHR CTN 291) Cohort Study

[1]University of British Columbia, Vancouver, Canada, [2]Women's Health Research Institute, Vancouver, Canada, [3]Université du Québec à Montréal, Montreal, Canada, [4]Université de Montréal, Montreal, Canada

Background: Congenital cytomegalovirus (CMV) infection is the leading cause of non-genetic childhood hearing loss and neurodevelopmental delay worldwide, and occurs disproportionately often in infants born to the 20 million women living with HIV (WLWH).

We aimed to quantify the frequency and viral load of CMV detected in blood collected from WLWH during pregnancy, and their association with parameters of HIV infection.

Methods: Pregnant WLWH enrolled in a Canadian multicentre prospective cohort study provided clinical data and biological specimens throughout pregnancy (at approximately 16-20, 24-28, 32-36 weeks), as well as at delivery and 4-16 weeks postpartum. CMV serostatus was determined by CMV IgG ELISA at 12-20 weeks, and CMV viral load was measured by qPCR in whole blood from all study visits. Associations between CMV viremia, antiretroviral therapy (ART), CD4+ T cell count, and HIV viral load were explored using logistic regression models.

Results: Of 298 pregnant WLWH, 216 were eligible for this analysis, having provided ≥1 blood specimen during pregnancy and being CMV seropositive.

At study entry (during pregnancy), median age was 33 years (IQR: 29-37), median CD4 count was 531 cells/mm^3(IQR: 390-723), 114 (53%) had a suppressed HIV viral load, and 40 (18.5%) initiated ART during pregnancy.

Of 932 total blood specimens tested, 34 specimens obtained from 28 (13%) women were positive by CMV qPCR, most with a viral load between 100-1000 (n=16) or >1000 IU/mL (n=14).

Two participants had CMV viremia at 2 visits; two had viremia at 3 visits. Women with CMV viremia during pregnancy/postpartum were not different from those without viremia in regards to maternal age, baseline CD4 count, baseline HIV viral load suppression, CD4 nadir, and proportion naïve to ART at the beginning of pregnancy.

Conclusions: In this cohort of pregnant CMV-seropositive WLWH in Canada, 13% had detectable CMV viremia during pregnancy, compared to ~0.5% among CMV-seropositive women without HIV as reported in the literature. No specific HIV parameters were associated with the detection of CMV viremia during pregnancy. The association between CMV replication and congenital CMV infection should be investigated.

EPB065

Cluster-randomized trial of routine syphilis screening among men attending HIV outpatient clinics in Ontario, Canada

A. Burchell[1,2], D. Tan[1,2], R. Grewal[1,2], A. Kroch[3], P. MacPherson[4,5], S. Walmsley[6,2], A. Rachlis[2,7], N. Andany[7,2], S. Gardner[2], J. Raboud[2], S. Mishra[1,2], C. Cooper[4,5], D. Fisman[2], K. Gough[1,2], I. Salit[6,2], T. Mazzulli[2,8], R. Rousseau[2], J. Maxwell[9], V. Allen[2,8]

[1]Unity Health Toronto, Toronto, Canada, [2]University of Toronto, Toronto, Canada, [3]Ontario HIV Treatment Network, Toronto, Canada, [4]The Ottawa Hospital, Ottawa, Canada, [5]University of Ottawa, Ottawa, Canada, [6]University Health Network, Toronto, Canada, [7]Sunnybrook Hospital, Toronto, Canada, [8]Sinai Health, Toronto, Canada, [9]ACT, Toronto, Canada

Background: The Enhanced Syphilis Screening Among HIV-positive Men (ESSAHM) Trial was a stepped wedge cluster-randomized trial that paired opt-out syphilis tests with routine HIV bloodwork to improve early syphilis case detection (https://doi.org/10.1093/cid/ciab582). Few patient covariates were collected given the pragmatic trial approach.

We re-analysed intervention effects using data from a concurrent cohort study that ascertained sociodemographic characteristics and sexual histories.

Methods: Population: HIV-positive men; intervention: standing orders for syphilis testing with HIV viral loads; control: usual syphilis testing practice; outcomes: case detection, proportion screened ("coverage"), and screening frequency; time: 01/02/2015 to 31/07/2017.

Trial clinics were also sites for the Ontario HIV Treatment Network Cohort Study (OCS); annual interviews measure income, education, sexual orientation, and number of sexual partners in the past 3 months.

We quantified intervention effects among OCS participants using time-adjusted generalized linear mixed-effect models to estimate odds ratios (OR) and rate-ratios (RR) with 95% confidence intervals (CI) and explored evidence for confounding and effect modification by sociodemographic and sexual history covariates.

Results: 34% (1325/3895) of trial participants were also OCS participants (mean 52.0 years old, 86% men who have sex with men). At baseline, 25% (n=316) reported 2+, 30% (n=365) reported 1, and 45% (n=556) reported 0 sex partners.

Comparing intervention to control periods, there were increases in case detection (OR 1.83, CI 0.85, 3.93), the proportion screened (OR 2.81, CI 2.20, 3.59), and number of tests per year (RR 1.73, CI 1.51, 1.97). There was no evidence

of confounding by sociodemographic characteristics. However, intervention effects were modified by number of sex partners (Table).

	Early syphilis	Screening coverage	Screening frequency
	OR (CI)	OR (CI)	RR (CI)
0 - 1 partner	1.46 (0.53, 4.00)	3.58 (2.71, 4.72)	2.05 (1.76, 2.39)
2 or more partners	3.05 (1.14, 8.12)	2.01 (1.39, 2.92)	1.30 (1.09, 1.56)
P-value for interaction	0.1629	0.0018	<0.0001

Table. Time-adjusted ratios for early syphilis case detection, syphilis screening coverage, and syphilis screening frequency comparing intervention to controls periods, by number of sex partners self-reported in past 3 months at baseline.

Conclusions: Routine screening tripled detection of early syphilis among men more likely to have had sexual exposure. Although the magnitude of increases in screening coverage and frequency were less among men with multiple partners compared to men without, there was still improvement compared to usual care.

EPB066
HPV DNA testing for women living with HIV visiting the women's health program(WHP), Cameroon Baptist Convention Health Services(CBCHS) clinics

N. Calvin[1,1], M. Florence[2], S. Manga[3], N. Kathleen[4], T. Pius[5], M. Eveline[6]

[1]*Cameroon Baptist Convention Health Services, Women's Health Program, Bamenda, Cameroon,* [2]*Cameroon Baptist Convention Health Services, Women's Health Program, Yaounde, Cameroon,* [3]*Cameroon Baptist Convention Health Services, Deputy Director CBCHS, Bamenda, Cameroon,* [4]*Cameroon Baptist Convention Health Services, Women's Health Program, Mutengene, Cameroon,* [5]*Cameroon Baptist Convention Health Services, Director CBCHS, Bamenda, Cameroon,* [6]*Cameroon Baptist Convention Health Services, HIV Free Project Manager South West Region Cameroon, Mutengene, Cameroon*

Background: It is a well-established fact that HPV is about six times more prevalent in HIV patients than their HIV negative counterparts. Due to immunosuppression, high risk HPV infections persist in women living with HIV population and would often progress to cervical neoplasia. WHO recently instituted oncHPV DNA testing as primary test for cervical cancer based on evidence from well-designed large randomized controlled trials and meta-analyses.

Novel tests for oncogenic subtypes of HPV has improved cervical cancer screening efficacy to about 95%; hence making predictability of cervical cancer risk higher.

Description: We summarize the findings and lessons learnt from screening women living with HIV for cervical cancer using oncHPV DNA from January 1 to December 31, 2021 at the Women's Health Program (WHP) of the CBCHS.

Lessons learned: Within CBCHS-WHP clinics, a total of 3,468 women were tested for HPV in 2021, 620 (17.9%) were women living with HIV and receiving ART treatment in various care and treatment centers across the country.

Of these 620 women living with HIV, 320 (52.6%) were positive for oncHPV types. 2690 women were HIV negative with 792 (29.4%) testing positive for oncHPV types.

Women with unknown HIV status (158) were excluded from the analysis. HIV positive women had a 2 fold higher rate of oncHPV positive than their HIV negative counterparts.

These results indicate the need for HIV-cervical cancer screening integration into HIV care so as to facilitate identification and treatment of women with cervical disease to prevent cervical cancer.

Conclusions/Next steps: Efforts need to be made to ensure HPV DNA testing is made systematic in the HIV population. It will be necessary to evaluate barriers as well as enhancers for uptake of oncHPV DNA testing in the HIV population.

EPB067
Prevalence of viral and bacterial STIs in patients with PrEP testing

D. Curanovic[1], C. Walworth[1]

[1]*Monogram Biosciences, South San Francisco, United States*

Background: The DHHS HIV treatment guidelines recommend evaluation of HIV-1, HCV, HBV, and bacterial sexually transmitted infections (STIs) prior to prescription of HIV pre-exposure prophylaxis (PrEP). Diagnostic panels were developed to facilitate guideline-recommended baseline evaluations and monitoring on PrEP.

We investigated the prevalence of STIs among patients for whom PrEP panels were ordered in the United States.

Methods: This was a retrospective database analysis of results reported for PrEP panels ordered from Aug 2019 through Dec 2021. PrEP Baseline panels tested for HIV-1, syphilis, chlamydia, gonorrhea, HBV, and HCV infections, while PrEP Monitoring panels tested for HIV-1, syphilis, chlamydia, and gonorrhea.

Tests with valid results were interpreted per CDC and treatment guidelines. Prevalence of infection was determined using combined data from Baseline and Monitoring panels.

Results: PrEP panels were ordered for 2,316 patients and were ordered more than once for 332 patients; average patient age was 43 years, and most (71%) were male. Laboratory evidence consistent with HIV-1 infection was seen in 2.7% of patients.

Syphilis infection was seen in 9.7% and evidence of previously treated or early syphilis in 7.1% of patients.

Chlamydia and gonorrhea were seen in 4.1% and 2.2% of patients, respectively.

Active HCV infection was seen in 1.3% and past HCV infection in 7.2% of patients.

Author Index

Most patients (47%) had no evidence of HBV exposure or immunity; 38% had evidence consistent with HBV vaccination, and 13% with recovery from HBV infection; 1% had biomarkers consistent with active HBV infection.

Among patients with more than one test, acquisition of HIV-1 infection was seen in one patient; syphilis was acquired by 1.8%, chlamydia by 2.2%, and gonorrhea by 0.6% of patients; no patients acquired HCV or HBV.

The most frequent coinfection with HIV-1 was syphilis (1.2% of patients), followed by chlamydia and gonorrhea (0.3% of patients, each), active HCV (0.2% of patients) and HBV (0.06% of patients).

Conclusions: The prevalence of STIs in patients with PrEP testing was high compared to the general population.

These findings may reflect a bias toward testing symptomatic individuals and/or high-risk behavior in this patient group. Continued vigilance for STIs, even among asymptomatic PrEP users, is warranted.

Neurologic disorders (e.g. CNS malignancies)

A 2-year longitudinal examination of dosage of speed of processing training on Useful Field of View performance in adults 40+ with HIV-associated neurocognitive disorder: findings from the ThinkFast Study

D. Vance[1], K.K. Ball[2], A. Azuero[1], V.G. Wadley[3], C.N. Pope[4], J.L. Raper[5], A.E. Jacob[2], S. Haase[2], A.R. Long[1], J.Y. Byun[1], P.L. Fazeli[1]

[1]University of Alabama at Birmingham, School of Nursing, Birmingham, United States, [2]University of Alabama at Birmingham, Department of Psychology, Birmingham, United States, [3]University of Alabama at Birmingham, Center for Healthy Aging, School of Medicine, Birmingham, United States, [4]University of Kentucky, Department of Health, Behavior & Society, Lexington, United States, [5]University of Alabama at Birmingham, School of Medicine, Birmingham, United States

Background: Approximately 40% of adults with HIV experience HIV-Associated Neurocognitive Disorder (HAND). Neurocognitive strategies are needed to protect cognitive reserve in adults with HAND, especially as they age. Fortunately, speed of processing (SOP) training, a computerized cognitive training program, has demonstrated neurocognitive benefit in older adults without HIV.

The aim of this study was to examine if adults with HAND administered different doses of SOP training would experience improved performance in their rate of visual information processing over a 2-year period.

Methods: Examining the efficacy of SOP training in a clinical trial, HIV+ adults 40 years and older were administered a cognitive battery to determine if they had HAND or borderline HAND. If so, they were randomized to one of three-treatment groups: 1) 10 hours of SOP training (n=70; M_{age}=51.62 years); 2) 20 hours of SOP training (n=73; M_{age}=51.36 years); or 3) 10 hours of Internet (control) training (n=74; M_{age}=50.01 years).

Participants were assessed at baseline, posttest, year 1, and year 2 to determine their rate of visual processing using the Useful Field of View (UFOV®) test (lower scores=faster processing).

Results: No significant group differences in UFOV® performance at baseline was detected.Controlling for baseline UFOV® performance, posttest comparisons revealed significant dosage effects with the 10-hour group performing better than the control group (p=0.002, d=0.28), and the 20-hour group performing better than the 10-hour group (p=0.087, d=0.15) and the control group (p<0.001, d=0.43).

Effect sizes waned over the 2-year period; yet, compared to the control group modest effect sizes were observed in the 10-hour group (d=0.10) and 20-hour group (d=0.32) over time.

Conclusions: There was a significant improvement on UFOV® for participants in the training groups, with improvement observed with a higher dose of SOP training.

Other studies in older adults without HIV have also observed improvements in locus of control, driving safety, health-related quality of life, and self-rated health after receiving SOP training.

As it is hypothesized that this cognitive training provides wide-spread neural activation in the brain that provides these transfer effects, clinical and research implications are provided.

Mental health (including depression and psychiatric manifestations) and HIV

Jackson Foundation for the Advancement of Military Medicine, Inc., Bethesa, United States, [13]University of Washington, Psychiatry and Behavioral Sciences, Seattle, United States

Background: Depression is a common comorbidity among people living with HIV (PLWH) in sub-Saharan Africa. Depression can threaten HIV treatment effectiveness, though its relationship with mortality among PLWH in this context requires further characterization.

We described the prevalence and chronicity (i.e., accumulation) of depressive symptoms among PLWH in four sub-Saharan African countries and estimated the effects of depressive symptom chronicity on all-cause mortality.

Methods: The African Cohort Study (AFRICOS) is an ongoing prospective cohort of people receiving care at twelve clinics in Kenya, Tanzania, Uganda, and Nigeria. Every six months from January 2013 to May 2020, participants underwent laboratory monitoring, structured surveys, and assessment of depression symptom severity using the Center for Epidemiologic Studies Depression Scale (CES-D). PLWH with at least two consecutive CES-D assessments within one year were included in this analysis.

All-cause mortality was the outcome of interest. The predictor of interest was a time-updated measure of the percentage of days lived with depression (PDD).

Marginal structural Cox proportional hazards regression models were used to estimate hazards ratios (HRs) and 95% confidence intervals (CIs), adjusting for time-invariant and time-variant confounders including alcohol use, drug use, and viral load. Inverse probability of exposure weights and inverse probability of censoring weights were used.

Results: Among 2520 eligible participants, 1479 (59%) were women and the median age was 38 (interquartile range [IQR]: 32-46). At enrollment, 1438 (57%) were virally suppressed (<200 copies/mL) and 457 (18%) had possible depression (CES-D ≥ 16).

Across 9093 observed person-years, the median PDD was 0.7% (interquartile range: 0-5.9%). The observed mortality rate was 0.8 deaths per 100 person-years. Causes of mortality were not ascertained for 39% of deaths; leading ascertained causes included cancer (18% of deaths) and accidents (14%). Models suggested that each 25% increase in PDD was associated with a 69% increase in the risk of all-cause mortality (HR: 1.69; 95% CI: 1.18-2.43).

Conclusions: Cumulative exposure to depressive symptoms substantially increased the risk of mortality in this cohort of PLWH in sub-Saharan Africa.

Systematic screening for and treatment of depression and associated common mental health conditions in sub-Saharan Africa may improve health outcomes in PLWH.

EPB070

Management of depression in people living with HIV in Senegal: acceptability and feasibility of group interpersonal therapy

C. Bernard[1], H. Font[1], I. Mané[2], S. Ziadeh[3,4], J.M. Tine[5], A. Diaw[6], I. Ndiaye[7], O. Samba[7], T. Bottai[8], L. Jacquesy[9], H. Verdeli[10], N.F. Ngom[6], F. Dabis[1], M. Seydi[5], N. de Rekeneire[11]

[1]University of Bordeaux, National Institute for Health and Medical Research (INSERM), Research Institute for Sustainable Development (IRD), Bordeaux Population Health Research Centre, UMR 1219, Team GHiGS, Bordeaux, France, [2]CNRS, Université de Pau et des Pays de l'Adour, Pau, France, [3]Université Libanaise, University of Public Health, Sidon, Lebanon, [4]WellCore Consulting & Intervention, USA, New-York, United States, [5]Service des Maladies Infectieuses et Tropicales, CHNU de Fann, Dakar, Senegal, [6]Centre de Traitement Ambulatoire, CHNU de Fann, Dakar, Senegal, [7]Service de Psychiatrie, CHNU de Fann, Dakar, Senegal, [8]Pôle de Psychiatrie, CH de Martigues, Martigues, France, [9]Psychiatre Indépendant, Président de CREATIP, Annecy, France, [10]Teachers College, Columbia University, New York, United States, [11]Fondation Mérieux, Lyon, France

Background: Depression is highly prevalent in people living with HIV (PLHIV), with significant consequences for patient care. In resource-limited settings, the World Health Organization (WHO) recommends group interpersonal therapy (IPT-G) for its management. In the IeDEA West Africa Cohort Collaboration, we evaluated the feasibility and acceptability of IPT-G in depressed PLHIV in Senegal.

Methods: After screening for depression with the Patient Health Questionnaire (PHQ-9), PLHIV with a score ≥ 5 consulted a psychiatrist to confirm their diagnosis of depression. Post confirmation and in accordance with the WHO manual on the implementation of IPT-G, each patient received an individual session followed by 8 weekly group sessions. IPT-G sessions were led by trained social or community workers.

A double approach (i.e. quantitative and qualitative) was used to evaluate the IPT-G experience. Refusal rate, drop-out and attendance levels were assessed, as well as changes in the severity of depressive symptoms.

Results: Of the 75 PLHIV with a diagnosis of depression, five patients (6%) declined to participate in IPT-G. Among the 70 participants, 13% dropped out, often for specific reasons (hospitalization, moving, flooding, etc.).

The majority of patients who completed IPT-G (97%) attended ≥7 sessions; missed sessions were justified (i.e. death in the family, illness, work constraints). Improvement in depressive symptoms (from start to end of therapy), was significant (83% ± 23%, t=19, paired series, p<0.001).

Qualitative data showed positive benefits at different levels: 1) for patients, with immediate and long term positive effects (i.e., improved social and professional lives, skills to prevent relapse); and 2) for facilitators (i.e., skills to support patients). The main barrier to attending IPT-G sessions was transportation cost.

Conclusions: To our knowledge, this study constituted the first time IPT-G was used in West Africa. It appears to be well accepted, feasible and effective in treating depression in PLHIV in Dakar, Senegal. The group modality provides an opportunity to break patient isolation and enable peer-to-peer exchanges.

With a task-shifting approach, IPT-G is also helpful in closing the mental health treatment gap. Bringing services closer to those patients, by making IPT-G available beyond Dakar, needs to be considered.

EPB071

Potential health benefits of integrated screening strategies for alcohol, tobacco, and other substance use, and depression, anxiety, and chronic pain among PLHIV in the United States

A. Bershteyn[1], E.L. Richard[2], M.R. Khan[1], J.D. Scheidell[1], Q. Zhou[1], K. Ban[1], P. Manandhar-Sasaki[1], D.L. Charles[1], A.C. Justice[3], E.J. Edelman[3], R.S. Braithwaite[1]

[1]NYU Grossman School of Medicine, Department of Population Health, New York, United States, [2]HealthCore, Inc, Wilmington, United States, [3]Yale School of Medicine, New Haven, United States

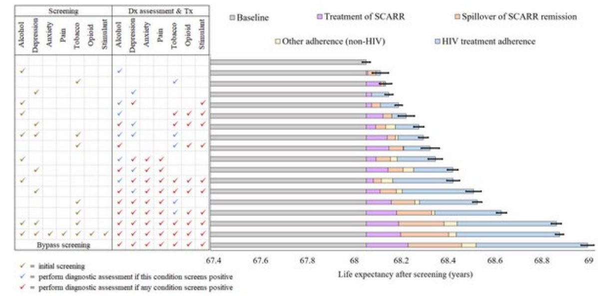
Background: Substance use often co-occurs with depression, anxiety, and chronic pain due to common determinants and dysregulations of the mesolimbic reward system. These syndemic conditions of abnormal reward response (SCARR) disproportionately affect people living with HIV (PLHIV). Current guidelines suggest individually screening for each of these conditions followed by diagnostic assessment for conditions that screened positive. We used a microsimulation model to compare alternative screening strategies that account for interrelationships among SCARR.

Methods: We augmented a microsimulation model previously validated to predict life expectancy in US adults with and without HIV. Using analyses of a large HIV-positive veterans cohort (98.4% male, median age 49), we specified the prevalence and co-occurrence of SCARR and causal inferences for how treating each condition impacts other SCARR ("spillover"), HIV treatment adherence, and preventative care.

We simulated PLHIV receiving alternative SCARR screening strategies (Figure), ranging from usual care (individual screening for alcohol/tobacco/depression, with diagnostic assessments only for conditions screening positive) to integrated care (screening alcohol/tobacco/depression with diagnostic assessments for additional conditions beyond those screening positive) to a "saturation strategy" (diagnostic assessments for all SCARR).

Results: The saturation strategy increased life expectancy by 0.95 years (95% CI: 0.93 – 0.98 years) compared to no screening. Usual care provided a small fraction of this benefit: 0.06 years gained for alcohol (95% CI: 0.03 – 0.09 years), 0.08 years for tobacco (95% CI: 0.06 – 0.11 years), 0.10 years for depression (95% CI: 0.08 – 0.11 years), or 0.25 years for all three (95% CI: 0.22 – 0.27 years).

However, one integrated strategy (screening alcohol, tobacco, and depression, with diagnostic assessment for all SCARR if any screened positive) approached the benefit of the saturation strategy (0.82 years, 95% CI: 0.80 – 0.84 years) with far lower diagnostic burden.



Conclusions: Primary care providers for PLHIV should consider comprehensive diagnostic assessment of SCARR if any conditions screen positive.

EPB072

Depressive symptoms among women by gender identity and HIV status participating in three multisite cohorts in the United States

A. Rich[1], H. Jiang[1], A. Wirtz[2], A. Adimora[1], G. Wingood[3], C. Cannon[4], A. Wawrzyniak[5], A. D'Souza[2], K. Mayer[6], P. Tien[7], D. Konkle-Parker[8], S. Reisner[9], S.J. Haw[10], J. Schnieder[10], E. Cooney[2], M. Malik[1], K. Althoff[2], S. Kassaye[11], T. Poteat[1]

[1]University of North Carolina at Chapel Hill, Chapel Hill, United States, [2]Johns Hopkins University, Baltimore, United States, [3]Columbia University, New York, United States, [4]Whitman Walker Health System, Washington, D.C., United States, [5]University of Miami, Miami, United States, [6]The Fenway Institute, Boston, United States, [7]University of California San Francisco, San Francisco, United States, [8]University of Mississippi Medical Center, Jackson, United States, [9]Harvard University, Boston, United States, [10]Emory University, Atlanta, United States, [11]Georgetown University, Washington, D.C., United States

Background: Depression is a risk factor for HIV acquisition and a common HIV co-morbidity. Few studies have examined depression prevalence among a diverse cohort of women, allowing comparisons across race, gender identity, and HIV status.

Methods: We combined 2019-2020 data from 3 cohorts of adult women: LITE (transgender women of mixed HIV serostatus), LITE Plus (Black and Latina transgender women living with HIV) and WIHS (cisgender women of mixed HIV serostatus). Multivariable logistic regression models estimated crude (OR) and adjusted (aOR) odds ratios and 95% confidence intervals (95%CI) associated with correlates of depression symptoms (Center for Epidemiologic Studies-Depression score≥10; Kessler score>5).

Results: The study sample included 113 transgender women living with HIV (TWLH), 1470 cisgender women living with HIV (CWLH), 819 HIV seronegative transgender women (TW), and 621 HIV seronegative cisgender women (CW). Among women with HIV, mean CD4 count was similar by gender identity, with TWLH reporting lower viral suppression prevalence (<200 copies/mL).

Depressive symptom prevalence was high across groups (TWLH: 60%; both CWLH and CW: 72%; TW: 85%) and elevated for transgender (TW+TWLH) compared to cisgender (CW+CWLH) women in bivariable analyses (OR=1.62 95%CI=1.33-1.98).

In multivariable analyses, American Indian/Alaskan Native (aOR: 5.0, 95%CI: 1.4-17.7), White (aOR: 2.0, 95%CI: 1.5-2.7), and multiracial identity (aOR: 1.8, 95%CI: 1.3-2.4), Alcohol Use Disorder (aOR: 1.3 95%CI: 1.0-1.7), and substance use (aOR 1.65, 95%CI: 1.3-2.1) were associated with increased odds of depressive symptoms while gender identity (reference=cisgender; aOR: 0.6, 95%CI: 0.4-0.9) and Hispanic/Latina ethnicity (aOR: 0.6, 95%CI: 0.5-0.9) were associated with lower odds of depression. HIV status was not significant in adjusted analyses.

Conclusions: The unexpected association of transgender identity with lower odds of depression may relate to common requirements for mental health engagement before accessing gender-affirming hormones. It may also relate to CW sample selection criteria, as those at risk of HIV acquisition may experience heightened depression as well as drivers of poor mental health, reducing variability by gender identity.

Findings point to the need for combination interventions to address mental health and substance use, particularly given known links between poor mental health, substance use treatment discontinuation, and suboptimal antiretroviral and PrEP adherence.

EPB073

Does HIV compound maternal mental health challenges among adolescent mothers in South Africa?

K. Roberts[1], C. Smith[1], E. Toska[2], L. Cluver[3,2], K. Haag[1], C. Wittesaele[4], N. Langwenya[3], J. Jochim[3], W. Saal[2], Y. Shenderovich[5], L. Sherr[1]

[1]University College London, Institute for Global Health, London, United Kingdom, [2]University of Cape Town, Cape Town, South Africa, [3]University of Oxford, Oxford, United Kingdom, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom, [5]Cardiff University, Cardiff, United Kingdom

Background: Adolescent pregnancy and HIV are prominent global health challenges within South Africa and, both-independently and combined-may compound mental health difficulties for adolescents. There is an absence of knowledge regarding risk and protective factors for mental health difficulties among adolescent mothers affected by HIV in sub-Saharan Africa.

This study aims to identify the prevalence, risk and protective factors associated with common mental disorder among adolescent mothers (comparing those living with and not living with HIV.

Methods: Data are drawn from 1002 adolescent mothers (10-19 years) with 272 27.1% living with HIV and 730 (72.9%) not living with HIV) enrolled in a cohort study of young mothers and their children residing in the Eastern Cape Province, South Africa. All mothers completed a detailed interviews consisting of standardised measures of sociodemographic characteristics, mental health scored on a validated inventory, HIV management (if appropriate), and hypothesised risk and protective factors.

Logistic regression models were utilised to explore associations between hypothesised risk, protective factors, and common mental disorder. Interaction effects with maternal HIV status were additionally explored.

Results: Prevalence of common mental disorder among adolescent mothers was 12.6% overall, 16.2% ALHIV and 11.2% no HIV. Adolescent mothers living with HIV were significantly more likely report common mental disor-

Author Index

der compared to adolescent mothers not living with HIV (16.2%vs.11.2%, X^2=4.41, p=0.04). Factors associated with common mental disorder were any abuse exposure (OR=2.90 [95%CI:1.42-5.90], p=0.003), perceived social support (OR=0.24 [95%CI:0.15-0.38], p=<0.0001) and, exposure to community violence (OR=2.10 [95% CI:1.37-3.22], p=0.001). There was limited evidence of interaction effects between risk and protective factors and, maternal HIV status.

Conclusions: Over one in ten adolescent mothers score above the cut off for mental health problems. This is significantly higher for adolescent mothers who are living with HIV. Identified risk and protective factors span individual, interpersonal and community levels.

While adolescent mothers living with HIV were more likely to report probable common mental disorder, factors associated seemingly did not differ according to maternal HIV status. Provisions for adolescent mothers need to incorporate HIV and mental health care.

EPB074

Bio-Psychosocial predictors of suicidal ideation among recently diagnosed people living with HIV in Ibadan, Nigeria

O. Olukolade[1], Y.O. Olaotan[2], R. Paul[3]

[1]*University College Hospital (UCH), Clinical Psychology, Ibadan, Nigeria,* [2]*University of Ibadan, Psychology, Ibadan, Nigeria,* [3]*University of Missouri, Missouri Institute of Mental Health, St. Louis, United States*

Background: Suicidal ideation (SI) is more prevalent among recently diagnosed people with HIV (PWH) than in the general population. Studies have not examined predictors of SI in recently diagnosed PWH as this is associated with future attempt and poorer outcomes.

Methods: Participants included 200 adults who had been diagnosed with HIV within 6 months of study enrollment. All participants were receiving suppressive treatment.

Marital status, income, adherence to antiretroviral therapy (ART), body mass index (BMI), self-reported sleep quality, self-reported social support, belief in self to achieve personal expectations, psychological distress and report of SI were measured using standardized scales validated for use in Nigeria. Analyses involved multiple regression, ANOVA and t-tests were used in the analysis.

Results: Participants included 61 males (30.5%) and 139 (69.5%). 87 (43.5%) people reported suicidal ideation. Lower adherence to ART, lower BMI, poor sleep quality, gender, lower level of income, higher psychological distress, lower self-efficacy and lower social support jointly predicted SI. [F (9,188) = 19.57, R2 = .484; p < .05] accounting for 48.4% variance.

Individuals who scored higher on psychological distress reported significantly higher SI than those with low level psychological distress. Those who reported lower self-efficacy reported higher SI to those with higher self-efficacy.

Individuals who reported good quality of sleep, lower total psychological distress, higher ratings of self-efficacy and higher ratings of social support reported significantly lower suicidal ideation. (p<.05) while BMI, income and gender did not predict SI in recently diagnosed individuals.

Conclusions: Recently diagnosed PWH experience suicidal ideation following diagnosis. The study suggests that the frequency of SI is high among recently diagnosed PWH population. Therefore, symptoms combinations of sleep problems, self-efficacy and problems of social support are important indices clinicians can look out for in newly diagnosed PWH. Longitudinal data driven studies with more biological indices will provide further understanding of suicidality in the early stage of HIV diagnosis and on the long-term of living with HIV.

Bacterial translocation of LPS is associated with lower cognitive abilities in men living with HIV receiving antiretroviral therapy

S. Isnard[1,2,3], L. Royston[1,2,3], S. Scott[4], T. Mabanga[2,3], J. Lin[3], B. Fombuena[3], C. Berini[2,3,5], M. Finkelman[6], N. Mayo[4,7,8], M.-J. Brouillette[3,2,9], J.-P. Routy[2,3,10]

[1]*Canadian Institutes for Health Research, Canadian HIV Trials Network, Vancouver, Canada,* [2]*McGill University Health Centre, Chronic Viral Illness Service, Montréal, Canada,* [3]*McGill University Health Centre - Research Institute, Infectious Diseases and Global Health, Montréal, Canada,* [4]*McGill University Health Centre, Division of Clinical Epidemiology, Centre for Outcomes Research and Evaluation, Montréal, Canada,* [5]*CONICET - Universidad de Buenos Aires, Instituto de Investigaciones Biomédicas en Retrovirus y SIDA (INBIRS), Buenos Aires, Argentina,* [6]*Associates of Cape Cod Inc, Falmouth, United States,* [7]*McGill University, Department of Medicine, School of Physical and Occupational Therapy, Montréal, Canada,* [8]*McGill University Health Centre, Division of Geriatrics, Montréal, Canada,* [9]*McGill University, Division of Psychiatry, Montréal, Canada,* [10]*McGill University Health Centre, Division of Hematology, Montréal, Canada*

Background: Gut protective CD4 T-helper producing interleukin 17 (Th17), are preferential target of HIV and are rapidly depleted upon infection. Such depletion persists under antiretroviral therapy (ART) in people living with HIV (PLWH). This gut damage allows bacterial lipopolysaccharide (LPS) and fungal β-D-glucan (BDG) microbial translocation contributing to systemic inflammation and risk of non-AIDS comorbidities, including neurocognitive diseases.

Herein, we assessed whether:

1). Markers of gut damage like intestinal fatty acid-binding protein (I-FABP) and regenerating islet-derived protein 3α (REG3α) and

2. Microbial translocation markers, LPS and BDG were associated with cognitive function in ART-treated PLWH.

Methods: A total of 80 ART-treated men living with HIV from the *Brain Health Now* Canadian cohort was included. Detailed socio-demographic and clinical characteristics were collected for all participants. Brief cognitive ability measure (B-CAM) and 20-item patient deficit questionnaire (PDQ) were administered to all participants. Three groups of 26-27 participants were selected based on their B-CAM levels: low (<19), intermediate (19-26) or high (>26).
We excluded participants who received antibiotics or proton pump inhibitors or antiacids which modify microbial translocation, in the past 3 months. Cannabis users were also excluded. Plasma levels of I-FABP, REG3α, and LPS were quantified by ELISA, while BDG levels were assessed using the Fungitell assay.

Results: Plasma levels of I-FABP, REG3α, LPS and BDG were not different between groups of low, intermediate and high B-CAM levels. However, LPS and REG3α levels were higher in participants with PDQ higher than the median of 26.5, indicating that those with lowest self-reported cognitive function had higher levels of those markers (p=0.01 and 0.004 respectively).
Multivariable analyses showed that LPS association with PDQ was independent of age and level of education. However, similar analyses showed no significant association between LPS levels and B-CAM levels. I-FABP, REG3α and BDG levels were not associated with B-CAM nor PDQ levels in multivariable analyses.

Conclusions: In this well characterized prospective cohort of ART-treated men living with HIV, bacterial but not fungal translocation was associated with lowest self-reported cognitive function. The mechanism behind such association should be explored in interventional studies.

EPB076

Association between mental health symptoms and adherence to ART among people living with HIV in Kazakhstan

G. Mergenova[1], J. DeHovitz[2], L. Gilbert[3], A. Davis[3], A. Terlikbayeva[1], S. Primbetova[1], Z. Nugmanova[4], A. Norcini Pala[3], N. El-Bassel[3]
[1]*Global Health Research Center of Central Asia, Almaty, Kazakhstan,* [2]*State University of New York Downstate Health Sciences University, Downstate Health Sciences University, New York, United States,* [3]*Columbia University, Columbia University School of Social Work, New York, United States,* [4]*Asfendiyarov Kazakh National Medical University, Almaty, Kazakhstan*

Background: HIV incidence has continued to rise in Eastern Europe and Central Asia including Kazakhstan. One of the main priorities for HIV transmission prevention in the region is antiretroviral therapy (ART) adherence improvement. Multiple studies have shown that a range of mental health symptoms is associated with poor HIV adherence, but little is known about the role of mental health in achieving optimal ART adherence among people living with HIV (PLWH) in Kazakhstan. The goal of this cross-sectional study is to examine the associations between mental health symptoms of depression, anxiety and post-traumatic stress disorder (PTSD) with ART adherence among 230 PLWH in Almaty, Kazakhstan.

Methods: 230 PLWH who were at least 6 months on ART were randomly selected from the Almaty AIDS center registry in 2019. We used logistic regression to examine the association between symptoms of depression PHQ−9, anxiety GAD−7, PTSD (PTSD Checklist – Civilian Version), and self-reported adherence (number of pills missed for last 3 days, 1 week, 2 weeks, 1 month), adjusting for age, education, marital status, injection drug use, and hazardous drinking.

Results: PLWH had a high prevalence of depressive symptoms 66 (28.7%), anxiety symptoms 74 (32.2%), and PTSD symptoms 17 (7.4%), using widely accepted cut-offs of clinical symptoms. Twenty-two (9.6%) participants missed at least one dose of medication for the last 2 weeks and 42 (18.3%) for last month.
Those who missed any dose of ART for the last 2 weeks had a higher probability of symptoms:of depression (OR: 3.50, 95%CI: 1.16- 10.54), anxiety (OR: 3.28, 95% CI: 1.18- 9.08), PTSD (OR: 4.00, 95%CI: 1.13- 14.13). Similarly, those who reported any missed dose of ART for last month had a higher probability of symptoms: of depression (OR: 3.45, 95%CI: 1.49 -7.98), anxiety (OR: 2.556, 95%CI: 1.21 -5.40).

Conclusions: The high rates of depression, anxiety, and PTSD and significant associations between these mental health symptoms and poorer ART adherence after controlling for drug and alcohol use highlight the critical need to improve the mental health and well-being of PLWH in Kazakhstan and further suggest the need for integrated mental health and ART adherence interventions for this population.

EPB077

Reversibility of neuropsychiatric adverse events after switching to darunavir/cobicistat or doravirine in men on INSTI based regimen

M.S. Rodríguez Evaristo[1], J.A. Mata Marin[2], A. Chaparro Sanchez[2], O.C. Martinez Carrizales[3], J.L. Parra Hernandez[2], E. Perez Barragan[2], J.E. Gaytan Martinez[2]
[1]*Hospital General La Raza National Medical Center, Internal Medicine, Mexico City, Mexico,* [2]*Hospital de Infectologia La Raza National Medical Center, Infectious Diseases, Mexico City, Mexico,* [3]*Hospital de Infectologia La Raza National Medical Center, Psychiatry, Mexico City, Mexico*

Background: Integrase strand transfer inhibitors (INSTI) are associated with sleep disturbances, anxiety and depression. Switching patients with neuropsychiatric adverse events (NPAEs) to other regimen could improve symptoms.

The aim of this study was to evaluate improvements in NPAEs after switching INSTI based regimen to Darunavir/cobicistat (DRV/c) or Doravirine (DOR) based regimen.

Methods: We designed a single arm trial, at the Hospital de Infectologia, "La Raza" National Medical Center since March to December 2021 in order to evaluate the reversibility of NPAEs detected with Patient Health Questionnaire (PHQ-9) and sleep disturbances with Insomnia Severity Index (ISI) in patients who started INSTI based regimen with Dolutegravir (DTG) or Bictegravir (BIC). NPAEs leading to INSTI discontinuation were consider when PHQ-9 ≥15 points or ISI ≥15 points. These patients were switched to DRV/c or DOR based regimen. Then we compared scales at the moment of switch and 4 weeks later using Wilcoxon test.

Results: We included 339 treatment-naïve male patients with HIV infection who started antiretroviral therapy with INSTI based regimen, 238 (70%) with BIC and 101 (20%) with DTG. In 5 (1.4%) patients we lost follow up; of the 334 patients analyzed, baseline characteristics were median age of 27 years old (IQR 24-31), CD4+ cells count 258 (IQR163-362) and HIV-1 RNA viral load 4.4 $\log_{10}$ (IQR 3.9-4.9).

A total of 15 (4.5%) experience NPAEs that lead to discontinuation, of these 9 (60%) were moderate-severe or severe depression, PHQ-9 median points 20 (IQR 15-24).

Moderate-severe or severe insomnia by ISI was found in 9 (60%) of the patients with a median of 22 points (IQR 16.5-25.5). Some patients had more than one NPAE that leaded to discontinuation; 4 (27%) and 11 (73%) were switched to DRV/c and DOR respectively. After 4 weeks we observed significant improvements in PHQ-9, with median of 9 points (IQR 5-14), p= 0.003 and ISI 9 points (IQR 4-14), p= 0.008.

Conclusions: NPAEs seem to be associated in patients on INSTI based regimen; these NPAEs improve after switching to DRV/c or DOR based regimen since the first 4 weeks. ISI and PHQ-9 are quick, easy, and self-reported questionnaires to test on each visit.

Sleep disorders and depression in people living with HIV during SARS-CoV-2 pandemic

M. Ceccarelli[1,2], V. Moscatt[1,3], S. Lanzafame[4], G. Bruno[5], L. Todaro[1,3], F. Tosto[1,3], A. Marino[6,4], F. Cosentino[1,3], B. Bellocchi[1,3], A.E. Campanella[1,3], E. Pistarà[1,3], R. Bruno[1,4], V. Coco[6,4], B.S. Cacopardo[1,4], B.M. Celesia[4]

[1]University of Catania, Department of Clinical and Experimental Medicine, Catania, Italy, [2]University of Messina, Department of Biomedical, Dental, Morphological and Functional Imaging Sciences, Messina, Italy, [3]University of Messina, Department of Clinical and Experimental Medicine, Catania, Italy, [4]ARNAS Garibaldi - PO Nesima, Unit of Infectious Diseases, Catania, Italy, [5]University of Catanzaro ,Magna Graecia', Department of Medical and Surgical Sciences, Catanzaro, Italy, [6]University of Catania, Department of Biomedical and Biotechnological Sciences, Catania, Italy

Background: Depression and insomnia have been frequently associated with HIV infection and treatment, even more so during COVID-19 pandemic. The aim of this study is to evaluate the prevalence of sleep disorders and depression in HIV patients on ART for at least 6 months and the potential role of the therapeutic regimen.

Methods: A single center study was performed from July to October 2021. The Pittsburgh Sleep Quality Index (PSQI) and the Beck Depression Inventory (BDI) were administered through Google form to detect sleep abnormalities and depression related symptoms.

Results: 196 subjects (81.6% males), with a median age of 48.3 years (IQR 37.7-55.2) were enrolled. Median time on ART was 104 months (IQR 49-226), median time on the current regimen was 22 months (IQR 10-40). Table 1 shows patients' treatments.

177 subjects (90.3%) had a plasma viral load < 50 cps/mL at the moment of the interview. Median CD4+ T-cells were 721/µL (IQR 532-917).

72 subjects (36.7%) had a BDI score higher than 5.

99 subjects (50.5%) declared they did not have any trouble sleeping. However, the results of PSQI showed that 146 subjects (74.5%) had troubles sleeping.

ANCHOR DRUG	NUMBER	%
Dolutegravir (DTG)	73	37.2
Bictegravir (BIC)	41	20.9
Darunavir (DRV)	25	12.8
Raltegravir (RAL)	25	12.8
Rilpivirine (RPV)	22	11.2
Doravirine (DOR)	7	3.6
Atazanavir (ATV)	1	0.5
Nevirapine (NVP)	1	0.5
Elvitegravir/cobicistat (EVG/c)	1	0.5

There wasn't any significant association between depression or troubles sleeping difficulties and third drug (p=0.57 and p=0.26), ART regimen (p=0.11 and p=0.8), anchor drug (p=0.46 and p=0.50). We studied in particular DTG vs DRV (p=0.83 and p=0.23) and INSTI vs non-INSTI (p=0.30 and

p=0.21). We found a significant association between showing depression symptoms and sleeping difficulties (p<0.001).

Conclusions: Sleep disorders and depression have a high prevalence in HIV population. Depression could be the primary cause leading to sleep disorders, even if it isn't easily demonstrated. The therapeutic regimen was not found to influence their onset.

However, our results might be influenced by the ongoing SARS-CoV2 pandemic. More studies are needed to ascertain this influence.

EPB080

Associations between HIV status and sexual orientation, disability status and gender identity and the experience of intimate partner violence in Nigeria

I.O. Oloniniyi[1], M.O. Folayan[2], I. Nwakamma[3], E.-J. Stevens-Murphy[4], G. Undelikwo[4]

[1]Obafemi Awolowo University, Department of Mental Health, Ile-Ife, Nigeria, [2]Obafemi Awolowo University, Department of Child Dental Health, Ile-Ife, Nigeria, [3]Coalition of Civil Society Networks on HIV and AIDS in Nigeria, Abuja, Nigeria, [4]UNAIDS, Abuja, Nigeria

Background: A large number of vulnerable populations exists among People Living With HIV/AIDS (PLWHA), such as sexual minorities and people living with disability. Currently, in addition to treating the disease and managing the associated transdisciplinary problems such as depression, stigma, adverse effects of medications and discrimination. Living with HIV requires identifying vulnerable sub-populations for targeted interventions.

The aim of this study was to determine associations between intimate partner violence, sexual orientation, gender identity and HIV status in Nigeria.

Methods: The study comprised a secondary analysis of an online survey data collected to seek the perspectives of respondents on the ease of access and quality of HIV prevention, treatment and ancillary care services, respect for rights, payment for services, and stigma in January to February 2021. The dependent variable was the HIV status.

The explanatory variables were sexual orientation (sexual minority, heterosexuals), living with disability, gender identity (cis- and transgender), history of bullying victimisation and experience of intimate partner violence. Binary logistic regression model was constructed to determine the risk indicators for the HIV status after adjusting for age, sex at birth, marital status, and educational level.

Results: There were 2194 respondents. Individuals who identified as transgender had significantly higher odds of having an HIV positive status than those who identified as cisgender males or female (AOR: 3.21; 95%CI: 1.75-5.88). People living with disability had significantly higher odds of living with HIV than people without disability (AOR: 3.40; 95%CI: 1.74-6.67). Respondents who had experienced sexual abuse had significantly higher odds of living with HIV than those who had not experienced sexual abuse (AOR: 1.64; 95%CI: 1.10-2.43). However, individuals who identified as sexual minorities were not significantly more likely to report HIV positive status (AOR:1.24; 95%CI: 0.98-1.57). Those who experienced bullying victimization had significantly lower odds of living with HIV than those who had not experienced bullying victimization (AOR: 0.57; 95%CI:0.45-0.72).

Conclusions: Individuals who identified as transgender, living with disability and had experienced sexual abuse were more likely to be HIV positive in Nigeria. Targeted intervention for vulnerable populations may help identify at risk persons and support prevention or management programs for them.

EPB081

Associations between depression, anxiety and clinical outcomes during HIV care and treatment

C.A. Moe Bowers[1,2], A. Bardon[1,2], M. Shivakumar[2], M. Krows[2], S. Govere[3], M.Y.S. Moosa[4], C. Celum[2,5], P.K. Drain[2,5,1]

[1]University of Washington, Department of Epidemiology, Seattle, United States, [2]University of Washington, Department of Global Health, Seattle, United States, [3]AIDS Healthcare Foundation, Durban, South Africa, [4]University of KwaZulu-Natal, Department of Infectious Diseases, Durban, South Africa, [5]University of Washington, Department of Medicine, Seattle, United States

Background: Depression and anxiety may influence clinical outcomes among people living with HIV (PLHIV). We evaluated these associations among newly-diagnosed PLHIV and after 12 months in care.

Methods: We conducted a prospective study in Umlazi township, South Africa. Depression and anxiety (mild or worse) were assessed at baseline (pre-HIV diagnosis) and 12 months using the 9-item Patient Health Questionnaire and 7-item Generalized Anxiety Disorder screening tool. Retention and clinical outcomes (hospitalization in prior 12 months, HIV viral load, TB, death) were measured. We estimated adjusted odds ratios (aORs) and prevalence ratios (aPRs) for each outcome to compare those with likely depression or anxiety (baseline and 12 months) to those with no evidence of depression or anxiety.

Results: Among 3,105 participants, 57% were male with median age 31 years. Pre-HIV diagnosis, 19% (n=583) reported mild or worse depression, and 16% (n=495) had mild or worse anxiety *(Figure 1)*. Baseline depression was significantly associated with worse clinical outcomes at 12 months including hospitalization (aOR=1.54), TB diagnosis (aOR=1.88), default from care (aOR=1.41), and death (aOR=1.69) *(Table 1)*. Baseline anxiety was associated with TB diagnosis (aOR=1.49,) and default from care (aOR=1.24). Hospitalization, elevated viral load, and default from care were also more prevalent among those with depression or anxiety at 12 months.

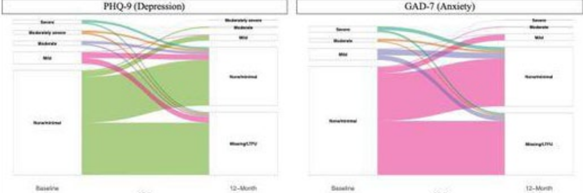

Figure 1. Alluvial plots of depression and anxiety scores, baseline to 12 months.

	Baseline (Pre-HIV Diagnosis)				12-Month Visit			
	Depression		Anxiety		Depression		Anxiety	
Clinical Outcomes	aOR (95%CI)	P-value	aOR (95%CI)	P-value	aPR (95%CI)	P-value	aPR (95%CI)	P-value
Hospitalized	1.54 (1.07, 2.22)	0.020	1.08 (0.72, 1.62)	0.715	3.77 (2.42, 5.88)	<0.001	3.35 (2.14, 5.24)	<0.001
Elevated viral load (200 copies/mL)	1.25 (0.85, 1.84)	0.253	1.03 (0.68, 1.57)	0.876	1.59 (0.96, 2.63)	0.074	1.74 (1.06, 2.85)	0.029
TB diagnosis	1.88 (1.39, 2.53)	<0.001	1.49 (1.07, 2.07)	0.019	1.39 (0.85, 2.28)	0.191	1.57 (0.98, 2.52)	0.061
Not retained in care after 12 months	1.41 (1.16, 1.72)	<0.001	1.24 (1.00, 1.53)	0.045	1.37 (1.04, 1.81)	0.027	1.31 (0.99, 1.73)	0.059
Died	1.69 (1.07, 2.67)	0.024	1.20 (0.72, 2.00)	0.488	—	—	—	—

All models adjusted for age, sex, education level, employment status, and food insecurity. aOR: adjusted odds ratio; aPR: adjusted prevalence ratio. Depression defined as scoring≥5 on PHQ-9, anxiety defined as scoring≥5 on GAD-7.

Table 1. Adjusted odds ratios and prevalence ratios comparing clinical outcomes by depression and anxiety screening scores.*

Conclusions: Newly-diagnosed PLHIV with mild or worse depression may be more likely to experience poor clinical outcomes than those without depression, and less likely to be retained in care.

These findings indicate a need for interventions for PLHIV with depression to prevent poor outcomes, including hospitalization and death.

EPB082

Syndemic trajectories of heavy drinking, cigarette smoking, and depressive symptoms are associated with all-cause, non-AIDS, and non-overdose mortality in women living with HIV

N. Chichetto[1], N. Gebru[1], M. Plankey[2], H.A. Tindle[3], J.R. Koethe[3], D.B. Hanna[4], S. Shoptaw[5], D.L. Jones[6], J.M. Lazar[7], J.R. Kizer[8], M.H. Cohen[9], S. Haberlen[10], A.A. Adimora[11], C.D. Lahiri[12], J.M. Wise[13], M.S. Freiberg[3]

[1]University of Florida, Gainesville, United States, [2]Georgetown University Medical Center, Washington, DC, United States, [3]Vanderbilt University Medical Center, Nashville, United States, [4]Albert Einstein College of Medicine, Bronx, United States, [5]David Geffen School of Medicine at UCLA, Los Angeles, United States, [6]University of Miami Miller School of Medicine, Miami, United States, [7]SUNY-Downstate Medical Center, Brooklyn, United States, [8]University of California, San Francisco, United States, [9]Stroger Hospital/Cook County Health and Hospitals System, Chicago, United States, [10]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [11]UNC-Chapel Hill, Chapel Hill, United States, [12]Emory University School of Medicine, Atlanta, United States, [13]University of Alabama at Birmingham, Birmingham, United States

Background: We investigated the sustained syndemic patterns of heavy drinking, smoking, and depressive symptoms among women living with HIV (WLWH) and whether syndemic phenotypes were associated with mortality.

Methods: Data from Oct. 1, 1994 to Dec. 31, 2017 of WLWH in the Woman's Interagency HIV Study, a prospective, observational cohort were included (N=3,693). Biannual measures of self-reporteddrinking, cigarette smoking, and depressive symptoms (Centers for Epidemiologic Studies Depression Scale) were used to model group-based trajectories (GBT).

A variable of syndemic phenotypes was based on membership in the high-risk trajectories of each condition. National Death Index (NDI) review identified death and cause of death (n=824, mean follow-up 7.8 years).

Cox proportional hazards models estimated associations of syndemic phenotypes with all-cause, non-AIDS, and non-overdose mortality, adjusting for confounding factors (age, race/ethnicity, enrollment wave, illicit drug use, HIV viral load and CD4+ T-cell count).

Results: WLWH were 62% Black, 22% Hispanic, with mean age of 37.3 years at baseline.The GBT analyses identified sustained high-risk trajectories for each factor (heavy drinking, 7%; current smoking, 43%; severe depressive symptoms, 24%).

Syndemic phenotypes included zero high-risk trajectories (43%, n=1,603), heavy drinking only (1%, n=36), smoking only (29%, n=1,071), severe depressive symptoms only (9%, n=323), any two (16%, n=584), and all three (2%, n=76) trajectories.

Compared to zero syndemic trajectories, having any two or all three syndemic were associated with greater all-cause mortality risk after controlling for confounders and each high-risk trajectory alone (Table). These findings remained when considering non-AIDS and non-overdose mortality.

Death by Type		All-Cause Mortality N=824	Non-AIDS Mortality N=522	Non-AIDS or Overdose Mortality N=461
Syndemic Trajectories (N)	Within Group Deaths (row %)	Mean FU 7.8 years	Mean FU 8.0 years	Mean FU 8.1 years
Zero Trajectories (1,603, REF)	192 (12)	HR (95% Confidence Intervals)		
Heavy Drinking Only (36)	8 (22)	1.54 (0.72, 3.29)	1.45 (0.53, 3.97)	1.51 (0.55, 4.13)
Depressive Symptoms Only (323)	74 (23)	1.58 (1.20, 2.09)***	1.34 (0.91, 1.98)	1.20 (0.79, 1.82)
Current Smoking Only (1,701)	285 (27)	2.10 (1.73, 2.56)***	2.50 (1.95, 3.20)***	2.30 (1.78, 2.99)***
Any Two Trajectories (584)	230 (39)	3.02 (2.46, 3.71)***	3.97 (3.07, 5.13)***	3.80 (2.91, 4.95)***
All Three Trajectories	35 (46)	3.44 (2.32, 5.09)***	3.13 (1.84, 5.31)***	2.73 (1.50, 4.95)***

*Table. Association between syndemic trajectory phenotypes and all-cause, non-AIDS and non-overdose mortality. ***p<.001; FU, follow-up; REF, reference group; heavy drinking trajectory consitently >7 drinks/week; depressive symptoms trajectory consistently with CESD ≥16.*

Conclusions: Sustained syndemics of heavy drinking, smoking, and depressive symptoms affected nearly 1 out of 5 WLWH and were associated with higher mortality than having none or one condition, even when removing AIDS and overdose-related mortality.

Our findings underscore the need for coordinated strategies to screen and treat these co-occurring conditions.

EPB083

High rates of suicide attempts among adolescents with perinatally acquired HIV in Uganda

A. Nanteza[1,2], J.L. Gumikiriza[3], A. Santoro[4], S. Dirajlal-Fargo[5], C. Ferraris[4], R.N. Robbins[4]

[1]*Butabika National Referral Mental Hospital, Kampala, Uganda,* [2]*University of Cape Town, Cape Town, South Africa,* [3]*Makerere University, Department of Psychiatry, Kampala, Uganda,* [4]*New York State Psychiatric Institute and Columbia University, HIV Center for Clinical and Behavioral Studies, New York, United States,* [5]*Case Western Reserve University, School of Medicine, Cleveland, Ohio, United States*

Background: Mental illness and suicidality often emerge during adolescence – an optimal time for intervention – and youth with HIV have higher rates of both than the general global population. Furthermore, suicide is a leading cause of death among adolescents and history of attempted suicide is a strong predictor of completed suicide. Adolescents with HIV and a mental health problem are particularly vulnerable to adversity, including discrimination, stigma, educational difficulties, risk-taking behaviors, and medical complications. In Uganda, adolescents with perinatally acquired HIV (PHIV) experience a high burden of mental health problems, but there is scant information regarding their suicidality.

This study examined current depressive symptoms, adverse experiences, and past suicide attempts among adolescents with PHIV and demographically matched HIV-negative adolescents.

Methods: Fifty-seven adolescents (35 PHIV – all VL ≤50 copies/mL; 22 HIV-negative; M_{age}= 15.77; 52.6% female) completed the Adverse Childhood Experiences (ACE) scale, Patient Health Questionnaire-9 (PHQ-9), Children's Depression Inventory (CDI), and questions about lifetime suicide attempts. Independent samples T-tests and Chi-square analyses were used to compare HIV status groups.

Results: There were no differences in age and sex across the two HIV status groups. Mean scores were: ACEs *M*=3.37 (SD=2.67), PHQ-9 *M*=2.36 (*SD*=3.96), and CDI *M*=5.16 (*SD*=5.34).

Although the PHIV group had higher scores on all measures and were slightly older than the HIV-negative group, these differences were not statistically significant. Among adolescents with PHIV, 20% (*n*=7) reported having at least one lifetime suicide attempt; none of the HIV-negative adolescents reported any previous suicide attempt (c^2= 5.02, *p* =.03).

Conclusions: In this small sample, adolescents with PHIV were significantly more likely to have made a suicide attempt in their lifetime than demographically similar HIV-negative peers. Despite this, mean scores on the ACEs, PHQ-9 and CDI did not significantly differ, though the PHIV had higher scores overall. Despite a higher risk for past suicide attempt, PHIV adolescents who survive an attempt may recover and experience periods of low depressive symptoms.

Future research is warranted to further explore why so many adolescents with PHIV are attempting suicide, what factors contribute to their attempts, and what factors aid in their recovery

Symptoms of depression and anxiety in adolescents and young adults living with HIV in Botswana

B. Burmen[1], M. Brooks[2], A. Gezmu[3], A. Olashore[4], K. Morales[5], K. Molebatsi[4], M. Monyane-Pheko[6], O. Phoi[7], O. Tshume[7], M. Matshaba[8], E. Lowenthal[9]
[1]Botswana UPENN Partnership, Brooks Lab, Gaborone, Botswana, [2]Botswana UPENN Partnership/Children's Hospital of Philadelphia, Department of Pediatrics Division of Adolescent Medicine, Gaborone, Botswana, [3]University of Botswana, Department of Pediatrics and Adolescent Health, Gaborone, Botswana, [4]University of Botswana, Department of Psychiatry, Gaborone, Botswana, [5]University of Pennsylvania Perelman School of Medicine, Department of Biostatistics, Epidemiology and Informatics, Philadelphia, United States, [6]Botswana UPENN Partnership, Gaborone, Botswana, [7]Botswana Baylor Children's Clinic, Gaborone, Botswana, [8]Botswana-Baylor Children's Clinical Centre of Excellence, Gaborone, Botswana, [9]University of Pennsylvania, Perelman School of Medicine and Children's Hospital of Philadelphia Global Health Center, Philadelphia, United States

Background: Anxiety and depression are prevalent among adolescents and youths and young adults living with HIV (AYAHIV). Few studies have focused on the mental health needs of youth in LMIC or African nations where the majority of AYAHIV live. Untreated mental illness among AYAHIV can lead to poor adherence to medication, poor self-care, and increased likelihood of severe sequelae. We screened AYAHIV in Botswana for anxiety and depressive symptoms as part of their routine HIV clinic visits.

Methods: We implemented a universal mental health screening program for AYAHIV aged 12 to 25 years in a paediatric national referral outpatient HIV clinic, in Gaborone, Botswana in 2019.

A self-administered Patient Health Questionnaire-9 (PHQ-9) and Generalized Anxiety Scale-7 (GAD-7) were used to screen for anxiety and depression, respectively. PHQ-9 scores of <5, 5-9, 10-14 and ≥ 15 indicated no symptoms of depression, mild, moderate, moderately severe and severe symptoms of depression. GAD-7 scores of <2, 2-6 and ≥ 7 indicated no symptoms of generalize anxiety, mild/moderate anxiety symptoms and severe anxiety symptoms.

Two-way ANOVA was used to describe the effects of gender and age group (12-15, 16-19, and 20-25 years) on PHQ9and GAD7 scores with post-hoc pairwise comparisons for variables attaining statistically significant omnibus test.

Results: A total of 1591 AYAHIV aged 12-15 (19%), 16-19 (52%) and 20-25 years (29%) were screened; 800 (50.3%) were males. Among them, 33% and 44.5% screened positive for symptoms of anxiety and depression; 22%, 8% and 3% screened positive for mild, moderate and severe anxiety symptoms and 29%, 11%, 3.6% and 0.9% had mild, moderate, moderately severe and severe symptoms of depression. Female AYAHIV aged 20-25 had significantly higher rates of symptoms of anxiety and depression when compared to 12-15-year-olds (*p<0.001 and p=0.001, respectively).* Female AYAHIV aged 16-19 had significantly higher rates of symptoms of anxiety when compared to 12-15-year-olds (*p=0.012).*

Conclusions: Routine mental health screening in an HIV care setting in Botswana revealed a high proportion of AYAHIV with concerning mental health symptoms.

Further studies will evaluate the clinical significance of these results. HIV service clinics should consider enhanced investments in mental health services, particularly for older adolescents and young adults.

Malignancies (AIDS and non-AIDS)

EPB085
HIV status is associated with reduced risk for precancerous lesions

V. Hayumbu[1], J. Hangoma[1], M. Malumani[1], B.M. Hamooya[1], S.K. Masenga[1]
[1]Mulungushi University, School of Medicine and Health Sciences, Livingstone, Zambia

Background: Cervical cancer is one of the leading causes of death in women and the commonest cancer in sub-Sahara Africa in the reproductive age group. Screening for precancerous lesions using visual inspection with acetic acid (VIA) is an early diagnosis method used to detect cervical lesions that can be treated successfully with cryotherapy or Loop electrosurgical excision procedure to prevent cervical cancer.

The aim of this study was to determine the risk of precancerous lesions among women of child bearing age living with or without HIV.

Methods: We conducted a cross-sectional study at Livingstone Teaching Hospital among 329 adult women between January 2019 and December 2020. Precancerous lesions were defined by a positive VIA indicated by presence of a dense ulcerative acetowhite area in the transformation zone of the cervix.

We collected demographic, laboratory and clinical information using medical records and a questionnaire. Data were analyzed using SPSS version 22.0. Chi-square test, Mann-Whitney and logistic regression were the statistical methods used.

Results: The median (interquartile range) age of participants was 37 (29, 44) years. Among 329 participants, 208 were living with treated HIV and were virally suppressed. The prevalence of precancerous lesions was 19% (95%CI 15, 24). Among the HIV-positive participants, only 12.9% compared to 29.1% HIV negative had precancerous lesions. After controlling for age, marital status, full term pregnan-

cies, alcohol consumption, history of tuberculosis and use of family planning, HIV-positive participants had a significantly 63% reduced odds of having precancerous lesions as compared to the HIV-negative participants [odds ratio (OR) 0.37; 95% confidence interval (CI) 0.19, 0.70)].

Conclusions: Precancerous cervical lesions are common among our study participants; however, they are less common in the HIV positive population compared with the HIV negative.

This unique finding may have been influenced by other factors beyond the scope of our study such as differential infection with human papilloma virus (HPV) and use of antiretroviral therapy in HIV that reduces the risk of precancerous lesions. Screening for precancerous lesions and HPV must be intensified to mitigate the burden of cervical cancer.

EPB086

Retention in care in pregnant HIV positive Kaposi Sarcoma (KS) patients seen at a tertiary hospital in Harare, Zimbabwe: a case control study

P. Gorejena-Chidawanyika[1], M.Z. Borok[1], T. Campbell[2]

[1]University of Zimbabwe, Faculty of Medicine and Health Sciences, Internal Medicine, Harare, Zimbabwe, [2]University of Colorado, Medicine-Infectious Disease, Denver, United States

Background: Evidence is required to guide chemotherapy treatment of HIV positive pregnant patients on antiretroviral therapy with concurrent KS. We sought to document completion outcomes in pregnant HIV positive patients with KS compared to age and stage-matched non-pregnant HIV positive female counterparts at a university-affiliated hospital in Harare, Zimbabwe.

Methods: From January 1994 to January 2020, records of all female participants who received care in the KS clinic whilst pregnant were analysed retrospectively. Age and stage-matched non-pregnant controls were identified and matched in a ratio of 1:3. The primary outcome was loss-to-care after initiation of therapy. Multivariate analysis was performed to identify significant predictors of loss-to-care. The short-term foetal consequences were a secondary outcome.

Results: A total of 23 cases and 76 controls were enrolled for this study. 81% of the total participants were on antiretroviral therapy (ART), with 76% of the controls and 91% of the cases on ART. There was no difference in chemotherapy administered between the two groups. A total of 67(67.7%) patients were lost to follow-up with no statistical difference between the cases and controls [69.6% of cases and 67.1 controls (p=0.825)]. There was no statistical difference in the outcome between cases and controls based on baseline CD4+, current CD4+ count and viral load [OR-1.00(0.998-1.00) p=0.342; OR-1.00(0.996-1.00) p=0.276; OR- 1.00(0.999-1.00) p=0.367]. Pregnant women in WHO HIV Clinical stage 3 and 4 were not at a higher risk of loss to follow up than their non-pregnant counterparts [OR-1.87(0.24-14.65) p=0.553; OR-1.70(0.24-11.95) p=0.592]. Concurrent hypertension or tuberculosis had no statistical difference in outcome between the cases and controls [OR-0.49(0.03-8.13) p=0.620; OR-0.91(0.32-2.57) p=0.859]. There was one documented foetal stillbirth.

Conclusions: There is no difference in loss to follow up in HIV positive pregnant KS patients receiving chemotherapy treatment in comparison to non-pregnant age and stage-matched female patients with KS. Baseline CD4+, current CD4+ count, viral load or HIV clinical stage had no bearing on retention to care between pregnant and non-pregnant HIV positive KS patients.

EPB087

Where do we stand in the path towards cervical cancer elimination in Mozambique?

M. Urso[1], D. Correia[1], J. Greenberg Cowan[1], C. Amado[2], M. Massangaie[2], C. Jonas Mate[2], E. Bila[3], A. Wate[4], E. David[5], C. Lorenzoni[2]

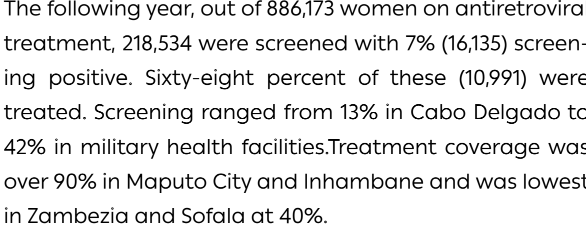
[1]Centers for Disease Control and Prevention, Maternal and Child Branch, Maputo, Mozambique, [2]Mozambican Ministry of Health, Maputo, Mozambique, [3]DOD (US Department of Defense), Maputo, Mozambique, [4]USAID, Maputo, Mozambique, [5]JHPIEGO Mozambique, Maputo, Mozambique

Background: Cervical cancer is the leading cancer among women in Mozambique with an incidence of 42.8 cases per 100,000 women. Cervical cancer is six times more frequent in women living with HIV (WLHIV) than non-infected women. The prevalence of HIV among women of reproductive age is 15.1% in Mozambique. The World Health Organization90-70-90 targets call for 90% of women to be immunized against HPV, 70% to be screened for cervical dysplasia, and 90% to be treated by 2030 to ensure countries are on the path toward cervical cancer elimination.

The Ministry of Health began its partnership with PEPFAR, implementing partners and the MD Anderson Cancer Center in 2011 with the aim of improving access to high quality screening and treatment for precancerous cervical lesions among WLHIV. These efforts were scaled up in 2018 with a yearly investment of more than 5 million US dollars. Optimized dolutegravir based ART regimens were introduced in 2018.

Description: We reviewed screening and treatment data from PEPFAR implementing partner supported health facilities in Mozambique's 11 provinces.

Lessons learned: From October 2018 to September 2019, 77,815 of the 727,700 women on antiretroviral treatment in Mozambique were screened for cervical dysplasia, with 10% (7,407) screening positive. Of these, 61% (4,533) were treated for precancerous lesions. During this period, screening varied by province from 4% in Manica to 17% in military health facilities (DOD) while treatment coverage was higher and ranged from 3% in Tete to 87% in Maputo city.



The following year, out of 886,173 women on antiretroviral treatment, 218,534 were screened with 7% (16,135) screening positive. Sixty-eight percent of these (10,991) were treated. Screening ranged from 13% in Cabo Delgado to 42% in military health facilities.Treatment coverage was over 90% in Maputo City and Inhambane and was lowest in Zambezia and Sofala at 40%.

Conclusions/Next steps: This review demonstrates a 2.8-fold increase in the number of WLHIV who have been screened for cervical cancer over the past 2 years. Mozambique has the opportunity to eliminate cervical cancer.

Increases in screening and treatment coverage rates are a result of successful coordination between government and stakeholders, but further improvement is needed.

EPB088

The role of expanded human papillomavirus genotyping in detecting high-grade cervical dysplasia by HIV status in Botswana

R. Luckett[1,2,3,4], A. Gompers[1], N. Moraka[2], S. Moyo[2,5], L. Tawe[3], T. Kashamba[3], K. Gaborone[2], A. Mathoma[3], F. Noubary[6], K. Rammipi[7], P. Tlhomamo[7], G. Dreyer[8], J. Makhema[2,5], M. Hacker[1,4,5], R. Shapiro[1,2,4,5], D. Ramogola-Masire[3,8]

[1]Beth Israel Deaconess Medical Center, Obstetrics and Gynecology, Boston, United States, [2]Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana, [3]University of Botswana, Gaborone, Botswana, [4]Harvard Medical School, Boston, United States, [5]Harvard T.H. Chan School of Public Health, Boston, United States, [6]Northeastern University, Department of Health Sciences, Boston, United States, [7]Ministry of Health and Wellness, Gaborone, Botswana, [8]University of Pretoria, Pretoria, South Africa

Background: The World Health Organization's cervical cancer elimination strategy calls for high-performance screening with human papillomavirus (HPV) testing, but HPV primary screening and triage strategies in low- and middle-income countries (LMICs) with high HIV prevalence are not clear. Triage by HPV genotypes most associated with cervical cancer (HPV 16/18/31/33/35/45/52/58) may provide more sensitive detection of high-grade cervical dysplasia in both women with and without HIV in LMICs.

Methods: We analyzed data from an ongoing cross-sectional study in Botswana that performs HPV primary screening at 6 government health facilities using Atila AmpFire©HPV (Atila Biosystems, USA), which detects 15 individual HPV genotypes. Women who tested positive for any HPV genotype had visual triage evaluation and biopsy. High-grade cervical dysplasia was defined as histopathology of cervical intraepithelial neoplasia grade 2 or worse (CIN2+).

Results: In a preliminary analysis of 1905 women, 897 (47%) were HPV positive; of these, 366 (41%) had complete histopathology data at the time of analysis. Women living with HIV (WLHIV) represented 41% of all women, and 48% of women who tested positive for HPV; 99.9% were on antiretroviral therapy, 98.7% were virologically suppressed, median CD4 cell count was 686 (IQR 528-874) cells per µL.

The prevalence of CIN2+ was 18% among women who tested positive for HPV. HPV18 had the highest positive predictive value (PPV) for detecting CIN2+ in women with and without HIV (47% and 38%, respectively). Other individual HPV genotypes had variable PPV by HIV status, but differences did not reach statistical significance (Table 1).

Among HPV positive women, the sensitivity of triage with pooled HPV genotypes 16/18/31/33/35/45/52/58 to detect CIN2+ was 85% in WLHIV and 84% in women without HIV (p=1.00).

Conclusions: Nearly half of women in Botswana screened HPV positive, and prevalence of associated CIN2+ was similar in women with and without HIV. Triage of HPV positive results with pooled HPV genotypes 16/18/31/33/35/45/52/58 maintained high sensitivity in detecting CIN2+ in all women. In the modern antiretroviral era, streamlining of high-performance cervical cancer screening with HPV primary testing and genotype triage in both women with and without HIV is a promising strategy.

EPB089

Persistent low-level viremia may increase the risk of cancer in people living with HIV

V. Lara-Aguilar[1], C. Crespo-Bermejo[1], D. Valle-Millares[1], M. Llamas-Adán[1], S. Grande-García[1], I. de los Santos[2], R. Madrid[3], L. Martín-Carbonero[4], A. Fernández-Rodríguez[1], V. Briz[1]

[1]Institute of Health Carlos III, Madrid, Spain, [2]Hospital La Princesa, Madrid, Spain, [3]Complutense University, Madrid, Spain, [4]Hospital La Paz, Madrid, Spain

Background: Inflammation plays a critical role in tumor initiation, growth, and metastasis. Despite of antiretroviral therapy (ART) some patients maintain persistent low-level viremia (pLLV) (50-200 copies/mL), which could promote a state of chronic residual inflammation that contribute to an increased risk of developing carcinogenesis.

The aim is to assess the impact of pLLV on immune checkpoint inhibitors related to cancer and inflammatory markers in people living with HIV.

Methods: Transversal study in 54 individuals: 27 HIV+ virologically suppressed (uVL) and 27 with pLLV (≥2 years). Patients were matched for clinical and epidemiological characteristics. Plasma levels of 28 immune checkpoint inhibitors associated with cancer and 14 inflammatory markers were quantified by Multiplex Immunoassays (xMAP-Luminex technology). Adjusted Arithmetic Mean Ratio was calculated by Generalized Linear Model.

Results: Patients had a median age of 54 years and 77.8% were men. No differences were observed between groups in clinical and epidemiological characteristics (Table1).

Overall, 74.1% (n=40) of patients received triple therapy, being INIs (61.1%, n=33) the most frequent followed by NNRTI (22.2%, n=12). 74.1% (n=20) of pLLV patients were on INIs (median 17 months) compared to 48.1% (n=13) of uVL

(median 16 months). PLLV patients showed significantly higher levels of IDO (p=0.013) and CD96 (p=0.029), and a tendency in ULBP3 (p=0.060). At inflammation level only IL-12 showed lower values (p<0.001) in viremic patients (Table1).

Conclusions: Significantly higher levels of poor prognostic biomarkers for different cancer types are shown in patients with pLLV: IDO, associated with reservoir size, regulatory T-cell activation and T-cell exhaustion in patients on ART, as well as CD96 and ULBP3, which regulate decreased NK cell activity. The higher levels of these biomarkers and lower values of IL-12, a potent cytokine mediating anti-tumour activity, in individuals with pLLV suggest that pLLV may contribute to an increased risk of cancer development compared to virally suppressed individuals.

Values are expressed as absolute number (percentage) and median (interquartile range). Values of immune checkpoint inhibitors and inflammatory markers are expressed as Adjusted Arithmetic Mean Ratio (aAMR) and 95% confidence interval calculated by Generalized Linear Model with gamma distribution, adjusted by integrase inhibitors, non-nucleoside reverse transcriptase inhibitors and resistance mutations. Comparison between categorical variables: Pearson's Chi-Square, comparison between continuous variables: Kruskal-Wallis and Mann-Whitney U test. uVL, patients HIV+ with undetectable viral load; pLLV, patients HIV+ with persistent low level viremia; ART, antiretroviral therapy; NRTI, nucleoside analogue HIV reverse transcriptase inhibitor; NNRTI, non-nucleoside analogue HIV reverse transcriptase inhibitor; PI, protease inhibitor; INI, integrase inhibitor.

Table 1. Differences among patients living with HIV with undetectable viral load and persistent low-level viremia.

EPB090

Kaposi sarcoma in ART-treated PLWH and HIV-uninfected people: differences in viral and immune characteristics

L. Royston[1,2,3], S. Isnard[4,1], A. Jary[5], C. Berini[1,6], J. Lin[2], J. Girouard[1,2], V. Leducq[5], V. Calvez[5], A.-G. Marcelin[5], J.-P. Routy[1,2,7]

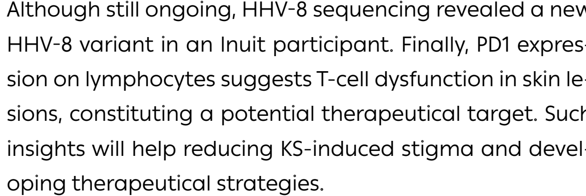
[1]Chronic Viral Illness Service, McGill University Health Centre, Montreal, Canada, [2]Research Institute of the McGill University Health Centre, Montreal, Canada, [3]Division of Infectious Diseases, Geneva University Hospitals, Geneva, Switzerland, [4]McGill University Health Centre, Montreal, Canada, [5]Sorbonne Université, INSERM, Institut Pierre Louis d'Epidémiologie et de Santé Publique, Assistance Publique - Hôpitaux de Paris (AP-HP), Hôpitaux Universitaires Pitié-Salpêtrière, Paris, France, [6]CONICET - Universidad de Buenos Aires, Instituto de Investigaciones Biomédicas en Retrovirus y SIDA (INBIRS), Buenos Aires, Argentina, [7]Division of Hematology, McGill University Health Centre, Montreal, Canada

Background: The incidence of HHV-8-induced Kaposi sarcoma (KS) in people living with HIV (PLWH) has dramatically decreased with antiretroviral therapy (ART). However, emergence of KS in ART-treated PLWH with restored CD4 and sustained HIV control is reported, raising concerns on HHV-8 pathogenesis and optimal management.

Methods: We compared ART-treated PLWH with KS (KS ART+) and HIV-uninfected patients with classic KS (KS HIV-). We assessed CD4 and CD8 counts, anti-HHV-8 IgGs, gut permeability (LPS/I-FABP/Reg3) and senescence plasmatic markers (GDF15/suPAR). In PBMCs and skin biopsies, HHV-8 viral loads were quantified by digital-droplet PCR and positive samples are currently sequenced by next-generation sequencing. In skin biopsies, cells were isolated and analyzed by flow cytometry.

Results: 11 KS ART+ and 11 KS HIV- have been recruited. KS ART+ were younger than KS HIV- (53 vs 77 years, p<0.001). Despite similar CD4 counts, KS ART+ had higher CD8 counts (p=0.007) and lower CD4/CD8 ratios (p=0.03). Gut permeability markers were similar while GDF15 and suPAR plasmatic levels were higher in KS HIV- (p=0.01). In PBMCs, HHV-8 DNA was detected in 6/11 KS ART+ while only in 3/11 KS HIV-. Anti-HHV-8 IgG titers tended to be higher in KS ART+ than KS HIV- (p=0.07). In skin biopsies, HHV-8 DNA was detected in all participant and isolated CD4 and CD8 T-cells highly expressed PD1 (>50%) in both groups. Among KS ART+, 3 HHV-8 strains were classified as subtype C and one as subtype A. In KS HIV-, 2 HHV-8 strains were classified as subtype A, 2 as subtype C and one strain, found in an Inuit patient from Northern Canada, constitutes a newly identified variant.

Conclusions: ART-treated PLWH with KS exhibited younger age and higher CD8 counts compared to HIV-uninfected KS patients. HHV-8 control seems altered in KS ART+, with HHV-8 DNA more frequently detected in PBMCs despite higher anti-HHV-8 IgG titers.



Although still ongoing, HHV-8 sequencing revealed a new HHV-8 variant in an Inuit participant. Finally, PD1 expression on lymphocytes suggests T-cell dysfunction in skin lesions, constituting a potential therapeutical target. Such insights will help reducing KS-induced stigma and developing therapeutical strategies.

Evaluation of screening algorithms based on HPV testing with partial genotyping for the prevention of cervical cancer among HIV-infected women in resource-limited countries: results of the ANRS 12375 study

P. Debeaudrap[1], F. Kabore[2], L. Setha[3], J. Tegbe[4], B. Doukoure[5], O. Segeral[6], A. Jaquet[7], P. Petignat[8], G. Clifford[9], A. Horo[4]

[1]Institut de Recherche pour le Développement, CEPED, Paris, France, [2]Centre Muraz, Bobo Dioulasso, Burkina Faso, [3]Calmette Hospital, Phnom Penh, Cambodia, [4]Programme PACCI, Abidjan, Cote D'Ivoire, [5]Université Felix Houphouet Boigny, Abidjan, Cote D'Ivoire, [6]ANRS site in Cambodia, Phnom Penh, Cambodia, [7]ISPED, Bordeaux, France, [8]Hôpitaux Universitaire de Genève, Geneva, Switzerland, [9]International Agency of Research on Cancer, Lyon, France

Background: In resource-limited countries, cervical cancer (CC) is the leading cause of cancer death among women living with HIV (WLHIV). The WHO recommended the use of HPV testing for primary CC screening because of its high sensitivity as compared to other screening methods. However, triage is desirable to identify HPV+ women having cervical intraepithelial neoplasia grade 2 or worse (CIN2+) and requiring treatment. In resource-limited contexts, Visual inspection with acetic acid and/or lugol (VIA/VILI) and partial genotyping are both feasible in a single-visit approach (screen-and-treat).

The ANRS-12375 study aimed to assess the performance (sensitivity, specificity), feasibility and benefit of different triaging options to detect CIN2+ lesions: partial genotyping (16/18/45), VIA/VILI alone and VIA/VILI combined with partial genotyping.

Methods: From Nov 2019 to Dec 2021, 2,255 WLHIV aged between 30 and 49 recruited in Abidjan (Côte d'Ivoire [CI], n = 1500), Bobo-Dioulasso (Burkina Faso [BF], n = 422) and Phnom Penh (Cambodia [KH], n = 333) were primarily screened with an Xpert HPV test, followed by VIA/VILI when positive and treatment if required. Relaxed criteria (or ABCD-criteria for **A**cetowhiteness, **B**leeding, **C**oloring, and **D**iameter) were used to identify CIN2+ lesion suring the VIA/VILI. The performance of the triage strategies to identify CIN2+ lesions were evaluated considering histology as standard reference.

Results: High risk-HPV infection was reported in 881 (41%) participants (median age: XX) with significant differences between sites (CI: 47%, BF: 33%, KH: 21%; P<xxx). HPV 16 accounted for 18% of infections and HPV 16/18/45 for 31%.

Among the 533 (60%) HPV+ participants with available histology (all data will be available by July), 15% had CIN2+ lesions, 71% were VIA+ and 31% HPV16/18/45+.

VIA sensitivity , partial HPV 16/18/45 genotyping and their combination as triage were 88% [79-94], 53% [42-63] and 91% [83-96], respectively, while the specificities were 33% [37-28], 73% [77-69], and 25% [36-27] (inter-sites heterogeneity: p=0.04).

Conclusions: Visual inspection after a positive HPV result is a good triage option with high sensitivity to identify women needing treatment even if inter-sites heterogeneity suggests differences in practice. While partial genotyping showed insufficient sensitivity, an algorithm combining partial genotyping and VIA/VILI appears to be the most efficient.

Chan School of Public Health, Department of Epidemiology, Boston, United States, [12]Emory University School of Medicine, Atlanta, United States, [13]Bloomberg School of Public Health, Department of International, Baltimore, United States, [14]Gillings School of Public Health, Department of Health Behavior, Chapel Hill, United States, [15]Georgetown University School Medicine, Department of Medicine, Washington, United States, [16]John H. Stroger, Jr. Hospital of Cook County, Chicago, United States, [17]SUNY Downstate Health Sciences University, Brooklyn, United States

Background: Cardiovascular disease (CVD) is a leading cause of morbidity and mortality among women living with HIV and may be influenced by gender identity and

hormone use. Few studies of CVD risk have included both transgender and cisgender women (TW; CW).

Methods: Harmonized data collected in 2019-2020 from two cohorts, LITE Plus (Black and Latina TW living with HIV) and the Women's Interagency HIV Study (WIHS; CW of mixed HIV serostatus), were used to estimate CVD risk.

The sample was restricted to those ≥ 40 years old, consistent with validity parameters of the American College of Cardiology pooled cohort estimator for Atherosclerotic CVD (ASCVD) risk. The estimator incorporates sex, age, race, cholesterol, blood pressure, diabetes, and smoking status. Female sex was used for all ASCVD estimates in this study. Logistic regression models estimated odds of an ASCVD score > 7.5% (i.e., intermediate or greater 10-year risk) by gender identity, including age, race, ethnicity, HIV status, hormone use, and depression. Multiple imputation accounted for missing data.

Results: The sample included 25 TW living with HIV (TWLH), 1329 CW living with HIV (CWLH) and 521 HIV seronegative CW. Mean age, BMI, cholesterol, and blood pressure did not differ across groups. Among women living with HIV, viral suppression (<200 copies/mL) and mean CD4 count did not differ by gender identity. TWLH had lowest prevalence of anti-hypertensive medication use, diabetes, and depression but highest prevalence of smoking. 64% of TWLH and 5% of both CW and CWLH reported hormone use (contraceptive or hormone replacement). 24% of TWLH had an ASCVD risk score >7.5% (v. 16% each for CW and CWLH). See table for results of bivariate and multivariable regression analyses.

	Bivariate analyses	Multivariable Model
Age (in years)	**1.15 (1.13-1.18)**	**1.16 (1.14-1.18)**
Transgender (ref: cisgender)	0.92 (0.36-2.31)	0.99 (0.33-2.93)
HIV+ (ref: HIV-negative)	0.80 (0.63-1.02)	**0.74 (0.56-0.97)**
White race (ref: Black)	0.81 (0.55-1.19)	**0.59 (0.39-0.91)**
Other race (ref: Black)	0.62 (0.39-1.98)	**0.46 (0.22-0.97)**
Multiracial (re: Black)	1.01 (0.74-1.38)	0.80 (0.55-1.15)
Hispanic (ref: non-Hispanic)	0.78 (0.56-1.08)	1.01 (0.60-1.68)
Hormone use (of any type)	0.72 (0.44-1.17)	1.12 (0.58-2.18)
Depression	**1.32 (1.02-1.72)**	**1.43 (1.07-1.93)**

Conclusions: Gender identity did not predict CVD risk scores. However, CVD risk was higher among TWLH than cisgender women. Studies with larger samples of TWLH are needed.

EPB093

IL-32 isoforms differentially impact coronary artery endothelium functions and potential to recruit inflammatory cells

R. Bunet[1,2], H. Ramani[1,2], M. Durand[3,2], C. Chartrand-Lefebvre[4,2], J.-P. Routy[5], T. Rejean[6], B. Trottier[7], P. Ancuta[1,2], A. Landay[8], M. El Far[2], C. Tremblay[1,2]

[1]Université de Montréal, Département de Microbiologie, Infectiologie et Immunologie, Montréal, Canada, [2]Centre de Recherche du Centre Hospitalier de l'Université de Montréal (CRCHUM), Montréal, Canada, [3]Université de Montréal, Département de Médecine, Montréal, Canada, [4]Université de Montréal, Département de Radiologie, Radio-Oncologie et Médecine Nucléaire, Montréal, Canada, [5]Research Institute of McGill University Health Centre, Montréal, Canada, [6]Clinique Médicale l'Actuel, Montréal, Canada, [7]Centre de Médecine Urbaine du Quartier Latin, Montréal, Canada, [8]Rush University Medical Center, Department of Internal Medicine, Chicago, United States

Background: HIV-induced inflammation leads to the premature development of cardiovascular diseases (CVD). We have previously shown that interleukin-32 (IL-32), a proinflammatory cytokine that is expressed in multiple isoforms (α, β, γ, D, ε, θ, ζ, η, and small/sm) with different inflammatory potential, is chronically upregulated in HIV-1 infection, even under ART and is associated with CVD. However, the mechanistic role of these different IL-32 isoforms in CVD is yet to be identified.

In this study, we aimed to investigate the potential impact of the different IL-32 isoforms on coronary artery endothelial cells (CAEC), the dysfunction of which is a major driver for atherosclerotic plaque formation.

Methods: Recombinant IL-32 isoforms (α, β and γ; the only commercially available isoforms) were used at 500ng/ml to stimulate primary CAEC (pCAEC/Creative Bioarray). pCAEC dysfunction in response to IL-32 stimulation was measured by studying the upregulation of VCAM-1 and ICAM-1 using flow cytometry, expression of the chemokines CCL2, CXCL1 and CXCL8 using both qRT-PCR (for gene expression) and ELISA for protein expression in supernatant as well as chemoattraction abilities by transwell assays.

Results: IL-32 isoforms showed differential effects on pCAEC. While IL-32β and to a lesser extent IL-32γ, upregulated the expression of ICAM-1 and VCAM-1 ($p=0.0347$ and $p=0.0019$, respectively) in pCEAC, the impact of IL-32α was not significant.

Furthermore, both IL-32β and IL-32γ significantly upregulated the expression of the chemoattractants CCL2, CXCL1 and CXCL8 at the protein level (CCL2: $p=0.002$ and $p=0.002$, CXCL1: $p=0.002$ and $p=0.002$, and CXCL8: $p=0.002$ and $p=0.0039$, respectively).

In contrast, IL-32α significantly downregulated CCL2 ($p=0.0068$) and CXCL1 ($p=0.0020$). In line with these results, classical monocytes isolated with negative selec-

tion (StemCell) from Peripheral blood mononuclear cells (PBMCs) showed significantly higher migration towards pCEAC cells stimulated with IL-32β and IL-32γ, but not IL-32α in transwell assays (p=0.0004, p=0.0008 and p=0.356, respectively).

Conclusions: Our results suggest that IL-32β and IL-32γ isoforms induce coronary artery endothelial cell dysfunction and enhance their potential to recruit inflammatory cells such as monocytes. These IL-32 isoforms are upregulated in HIV infection and likely contributing to endothelial cell inflammation and CVD and may represent a therapeutic target.

EPB094
Lp(a) in people living with HIV

S. Noe[1], S. Heldwein[1], F. Schabaz[1], A. von Krosigk[1], C. Wiese[1], E. Julia[1], A. Balogh[2], E. Wolf[2], C. Jonsson-Oldenbuettel[1], ArcHIV Study Group
[1]*MVZ München am Goetheplatz, Munich, Germany,* [2]*MUC Research, Munich, Germany*

Background:
Cardiovascular morbidity and mortality have become major concerns in the medical care of people living with HIV. While a lot of traditional and even HIV-specific risk factors are implemented in frequently used scores for cardiovascular risk assessment, the contribution of Lp(a) in people living with HIV is often under-recognized.
This study aimed to describe findings on Lp(a) in a sample of people living with HIV.

Methods: Retrospective analysis from electronic patient files from the ongoing Munich ArcHIV cohort. Cardiovascular risk was assessed using the Framingham score (high risk: > 20%; low- or intermediate risk ≤ 20%). Lp(a) concentrations > 30 md/dL were considered to be elevated. Medians with interquartile ranges and absolute numbers and percentages were used for continuous and categorical variables, respectively.

Results: Overall, 451 people living with HIV were included into this analysis. 376 (83.4%) were male, median age was 50 (IQR: 42; 56) years. Median Lp(a)-concentration was 12.8 (IQR: 5.1, 36) mg/dL. In 134 (29.7%) subjects, Lp(a) concentrations were elevated. Of 223 subjects with low- or intermediate cardiovascular risk, elevated Lp(a) concentration was found in 145 (45.7%). Of these, 55 (37.9%) did not receive lipid-lowering medication, 5 (3.4%) had submaximal doses of a statin, and 12 (8.3%) were on high-dose statins but did not receive ezetimibe.

Conclusions: We found a high prevalence of elevated Lp(a) concentrations in people living with HIV, demonstrating the importance of its consideration in cardiovascular risk assessment. The number needed to test to identify a person with elevated Lp(a) concentrations was 4, while on average 7 people had to be tested to identify one person that might possibly benefit from treatment intensification or intensivation.

EPB095
Silent coronary heart disease in patients on ART: prevalence and risk factors

M. Cresta[1], A. Brun[1], P. Merlet[1], G. Hamet[1], G. Sideris[2], N. De Castro[1], W. Rozenbaum[1], C. Lascoux-Combe[1], J.-M. Molina[1]
[1]*Saint-Louis Hospital, Paris, France,* [2]*Lariboisiere Hospital, Paris, France*

Background: Aging among HIV-infected patients is associated with an increase in co-morbidities, including cardiovascular disease. We wished to assess the prevalence and risk factors associated with silent coronary heart disease (SCHD) in well suppressed patients on antiretroviral therapy (ART).

Methods: A retrospective analysis of all consecutive patients who underwent screening for SCHD between November 1, 2015 and March 1, 2021 at the Saint-Louis Hospital in Paris. Patients without a history of coronary heart disease underwent myocardial scintigraphy coupled with exercise testing. Those with a positive scintigraphy had coronarography. SCHD was defined as either significant stenosis on coronarography or a myocardial infarction during follow-up. Baseline risk factors for SCHD were then assessed using univariate analysis.

Results: A total of 475 patients were studied. Most patients were male (87.8%), with a median age of 56 years, and 58.1% were smokers. 71.3% were on ART, with a median CD4 cell count of 500 and 91.6% had a viral load ≤ 50 cp/ml. 19 patients were diagnosed with SCHD, 10 had coronarography stenosis which led to stents and medical treatment and 9 additional patients had a myocardial infarction during follow-up. Myocardial scintigraphy performed better than exercise testing to detect SCHD with sensitivity of 47%, a negative predictive value of 98% and a positive predictive value of 31%.
Smokers (current or former) (RR 3.84 IC95% [1.1 - 13.0], p= 0.02) and patients receiving antiplatelet therapy (RR 3.13 IC95% [1.2 - 7.9], p=0.02) had a increased risk for SCHD.

Conclusions: The prevalence of SCHD among HIV-infected patients with controlled HIV-infection is low and similar to the general population. Smokers and patients receiving antiplatelet therapy for arteriopathy should be screened for SCHD.

EPB096

Arterial remodeling is associated with CD4 T cell count and plasma IL-10 in persons with HIV

A. Werede[1], C. Wanjalla[2], S. Nair[3], J. Terry[4], T. Temu[5], B. Shepherd[6], S. Bailin[2], M. Mashayekhi[7], C.L. Gabriel[8], B. Woodward[9], S.A. Mallal[10], J.A. Beckman[11], J. Li[12], J.J. Carr[13], D. Harrison[14], J. Koethe[2]

Background: Persons with HIV (PWH) have a higher prevalence of non-calcified coronary plaque compared to their HIV-negative counterparts. Although traditional risk factors are important, they do not fully explain the increased risk and presenting phenotype. We assessed coronary cross-sectional area (corCSA) from non-contrast computed tomography (CT) imaging, a measure of arterial remodeling that may have clinical significance among PWH on long-term antiretroviral therapy (ART).

Methods: We assessed 105 PWH with sustained virologic suppression and a spectrum of cardiometabolic health (37 non-diabetics, 36 pre-diabetics, and 32 diabetics). Participants underwent electrocardiogram gated non-contrast CT scans of the chest to measure the mean corCSA of the proximal left anterior descending artery. Partial Spearman rank correlation adjusted for CVD risk factors (age, sex, smoker status, hypertension, hemoglobin A1C, body mass index, and statin use) was used to assess relationships of corCSA with anthropometric measurements, HIV-related factors, and plasma cytokines (IL-10, IL-6 and IL-1β).

Results: Mean corCSA was similar between the three metabolic groups but higher in individuals with detectable coronary calcium on CT imaging ($p=0.08$). In adjusted models we observed an inverse correlation between corCSA and CD4 T-cell count ($\rho=-0.22$, $p<0.05$) and plasma IL-10 ($\rho=-0.25$, $p=0.03$) but not IL-6 ($\rho=0.13$, $p=0.26$) or IL-1β ($\rho=0.07$, $p=0.58$). We also observed a positive correlation between corCSA with duration of ART ($\rho=0.33$, $p<0.001$), but this was only significant if not adjusted for age.

Conclusions: A larger external coronary artery diameter on non-contrast CT imaging, a combined measure of coronary lumen diameter and wall thickness, was observed in PWH with lower circulating CD4 T cell counts and anti-inflammatory IL-10. Future studies will determine the contribution of atherosclerosis and arterial remodeling to corCSA in PWH.

EPB097

The effect of an HIV pharmacist on cardiovascular risk assessment in a regional HIV clinic: a cohort study

O. Kebire[1], K. Mackie[1,2], A. Wade[3,4]

[1]Barwon Health, Pharmacy Department, Geelong, Australia, [2]Alfred Health, Pharmacy Department, Melbourne, Australia, [3]Barwon Health, Infectious Diseases and Infection Prevention, Geelong, Australia, [4]Burnet Institute, Disease Elimination Program, Melbourne, Australia

Background: The adherence to cardiovascular disease (CVD) screening/monitoring guidelines for people living with HIV (PLHIV) by a regional outpatient clinic was assessed before and after the introduction of the HIV pharmacist to the multidisciplinary team.

Methods: This retrospective study included PLHIV actively attending the clinic for their HIV care (defined as 2 or more visits over 2-year study period) and were 40 years or older as at April 1st 2018. For PLHIV without established CVD, compliance to annual CVD risk screening (using Australian CVD risk calculator, based on Framingham) were assessed, including the parameters: documented CVD risk calculation, blood pressure, lipids (total cholesterol AND high-density lipids), diabetes status and smoking status. Adherence was assessed during study period 1 (April 1st 2018 – March 31st 2019; no HIV pharmacist in clinic) and study period 2 (April 1st 2019 – March 31st 2020; HIV pharmacist in clinic).

Results: Of the 73 clinic PLHIV (mean age 47.7 years), 37 were 40 years or older (89.2% male) and 28 did not have established CVD.

Of the patients with no CVD risk score documented, 7 patients in each study period had adequate information available to complete the CVD risk screen but the risk calculation was not documented.

Conclusions: While there was a trend towards improvement of documentation of CVD risk screening in PLHIV by the clinic, lack of annual BP and full lipid panel are common downfalls (lack of onsite pathology, patient and clinician factors all at play). The pharmacist role in meeting comorbidity screening and monitoring guidelines is just one component of overall medication management of our aging PLHIV cohort in ambulatory care.

Impact of HCV treatment on markers of kidney disease among persons with monoinfection and HCV/HIV co-infection

J. Cepeda[1], K. Zook[2], M. Atta[2], M. Sulkowski[2], A. Cox[2], G. Schwartz[3], G. Lucas[2]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [2]Johns Hopkins School of Medicine, Baltimore, United States, [3]University of Rochester, Rochester, United States

Background: Chronic hepatitis C virus (HCV) infection causes systemic inflammation and is associated with higher risk of chronic kidney disease (CKD). Uptake of highly curative direct acting antiviral treatment has increased within the past 5 years, reducing HCV-related liver mortality.

However, the impact of sustained virological response (SVR) of HCV on kidney disease has not been rigorously assessed.

Methods: From 2010 – 2020, we enrolled 373 participants (21%,n=77) with neither HIV nor HCV infection, 19% (n=69) with HCV infection only, 27% (n=100) with HIV infection only, and 34% (n=127) with both HCV and HIV infection in Baltimore, Maryland. Participants were non-diabetic and had an estimated glomerular filtrate rate > 45 mL/min/1.73m^2 at baseline.

We collected specimens at annual visits and measured GFR by iohexol disappearance from plasma (iGFR). SVR was defined by HCV RNA below the limits of detection ≥12 weeks from the end of HCV treatment. Outcomes included annualized changes in iGFR and incident stage 3b CKD (iGFR <45). We used generalized estimating equations to model the association between SVR and changes in iGFR (continuous). Incident stage 3b CKD was modeled using Cox proportional hazards, adjusted for sociodemographic and behavioral confounders.

Results: At baseline, the median age was 49.5, 71% male, 90% Black, and 61% were living with HIV. Out of 1,342 study visits with non-missing iGFR, 954 annualized visit changes in iGFR were calculated. Among the 196 individuals with chronic HCV, 116 (60%) initiated treatment during follow-up and achieved SVR. The mean annualized iGFR slopes (standard deviation) among those with SVR and untreated infection were 0.20 (14.5) and -2.83 (15.1) mL/min/1.73m^2 per year, respectively (adjusted slope difference 2.98; 95% CI: 1.03, 4.3, p<0.01).

Among those with HIV, detectable HIV RNA was associated with 1.67 lower annualized iGFR slope difference (95% CI: -3.37, 0.03, p=0.05) compared to undetectable viral load visits. SVR was associated with 64% lower risk of chronic kidney disease progression (adjusted hazard ratio: 0.36 95% CI: 0.09 – 1.44, p=0.15).

Conclusions: SVR in HCV-infected persons and HIV RNA suppression in HIV-infected persons were associated with favorable changes in iGFR slope. SVR was associated with a non-significantly lower risk of progression to stage 3b CKD.

Epigenome-wide association study of liver function biomarkers identifies albumin-associated DNA methylation sites among male veterans with HIV

B. Titanji[1], M. Lee[2], Z. Wang[2], Q. Hui[3], V. Lo Re III[4], K. So-Armah[5], A. Justice[6], X. Ke[6], M. Freiberg[7], M. Gwinn[8], V. Marconi[3], Y. Sun[2]

[1]Emory University, Infectious Disease, Atlanta, United States, [2]Emory University, Epidemiology, Atlanta, United States, [3]Emory University, Atlanta, United States, [4]University of Pennsylvania, Atlanta, United States, [5]Boston University, Boston, United States, [6]Yale University, New Haven, United States, [7]Vanderbilt University, Nashville, United States, [8]Centers for Disease Control, Atlanta, United States

Background: Liver disease (LD) is an important cause of morbidity for people with HIV (PWH) accounting for 13-18% all-cause mortality in this population. Progress in elucidating the biological mechanisms underlying LD has been slow due to the complexity of the many roles the liver plays in homeostasis and metabolism.

Epigenetic factors driving LD in PWH are not fully characterized. We performed an epigenome-wide association study (EWAS) to identify associations between DNA meth-

ylation (DNAm) and biomarkers of liver function—aspartate transaminase, alanine transaminase, albumin, total bilirubin, platelet count, FIB-4 score, and APRI score—in male US veterans with HIV.

Methods: Blood samples and clinical data were obtained for 960 male veterans with HIV from the Veterans Aging Cohort Study (VACS). DNAm associations with each liver biomarker were investigated using the Illumina 450K or EPIC850K array, adjusted for age, race, current smoking, BMI, diabetes, hazardous alcohol use, ever HBV infection, ever HCV infection, ever ART use, CD4+ T cell count, HIV RNA suppression (<200copies/mL), and leukocyte cell-type proportions.

We performed a meta-analysis for DNAm sites identified by both platforms. Associations between four DNAm age acceleration (AA) measures and liver biomarkers were assessed by linear regression after correcting for multiple testing.

Results: Nine DNAm sites mapped to the*TMEM49*, *SOCS3*, *FKBP5*, *ZEB2*, *SAMD14*genes were significantly associated with lower serum albumin levels in the EWAS meta-analysis. No significant associations were detected for the other six liver biomarkers. Higher PhenoAA was significantly associated with lower level of serum albumin (mg/dL) (b= -0.007,*p*-value = 8.6´10^{-4}).

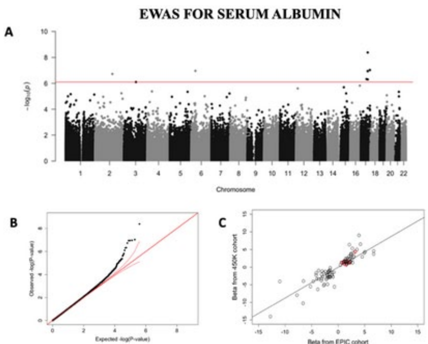

Figure. A Manhattan plot (A) and a Q-Q plot (B) of the distribution of p-values obtained from the meta-analysis of the results of serum albumin across the human genome relative to the expected distribution assuming a null hypothesis. (C) Beta coefficients for top associated CpG sites for serum albumin were consistent between the EPIC and 450K cohorts. Circles representing p-value pairs that were significant after meta-analysis and FDR correction to Q < 0.05 are highlighted in red.

Conclusions: We identified epigenetic associations of both individual DNAm sites and DNAmAA with liver function through serum albumin in men with HIV. EWAS may provide information on LD pathogenesis and generate new hypotheses for predicting LD progression among PWH. Further replication analyses are warranted to confirm the epigenetic mechanisms underlying liver function and LD in PWH.

EPB100

Women with HIV are at higher risk for obstructive lung disease in Kampala, Uganda after pulmonary tuberculosis

R. Abelman[1], J. Fitzpatrick[1], J. Zawedde[2], I. Sanyu[2], P. Byanyima[2], S. Kaswabuli[2], J. Hsieh[1], K. Gardner[1], M. Zhang[1], K. Byanova[1], A. Sessolo[2], J.L. Davis[3], P. Hunt[1], K. Crothers[4], W. Worodria[2,5], L. Huang[1]

[1]University of California, San Francisco, San Francisco, United States, [2]Makerere University-University of California San Francisco (MU-UCSF) Research Collaboration/ Infectious Diseases Research Collaboration, Kampala, Uganda, [3]Yale University, New Haven, United States, [4]University of Washington, Seattle, United States, [5]Makerere University, Kampala, Uganda

Background: Tuberculosis (TB) and obstructive lung disease (OLD) are major contributors to global years of life lost and are common conditions in people with HIV. HIV and TB are risk factors for OLD. As women without HIV have a predilection for developing OLD as compared to men, we hypothesized that women with HIV (WHIV) are at a higher risk for OLD.

Methods: The Inflammation, Aging, Microbes, and Obstructive Lung Disease (I AM OLD) cohort is a prospective longitudinal cohort study of adults initially presenting with pulmonary TB in Kampala, Uganda. Both HIV-positive and HIV-negative non-pregnant adults are eligible. In this cross-sectional analysis, pre- and post-bronchodilator spirometry (ndd Easy on-PC) with demographic and clinical data were obtained within three months of completion of TB therapy.

The associations between sex and lung function were evaluated using multivariable linear and logistic regressions adjusting for age, BMI, smoking status, HIV status, and biomass fuel exposure. These models were then stratified by HIV status to examine whether these associations differed among men and women with and without HIV.

Results: Of 330 participants, 138 (42%) were women; 121 (38%) were HIV positive and 201 were HIV seronegative. Women represented 50% of the participants with HIV.

Multivariable analysis revealed women with HIV had greater than 4-fold odds of having OLD compared to men with HIV (OR 4.57, 95% CI 1.23, 20.93; p=0.03), with BMI as the most significant covariate.

In contrast, there was no significant difference in OLD between women and men without HIV.

Female versus Male	Obstructed (Post-BD FEV1/FVC < 0.70) vs normal	Restricted (Post-BD FEV1/FVC ≥ 0.70 and FVC < 80 % pred) vs normal
	OR (95% CI; P-value)	
Among HIV+ (N=121)		
Unadjusted	2.77 (0.92, 9.47; 0.08)	1.63 (0.64, 4.26; 0.3)
Adjusted	**4.57 (1.23, 20.93; 0.03)**	2.62 (0.85, 8.83; 0.1)
Among HIV- (N=201)		
Unadjusted	0.4 (0.09, 1.33; 0.17)	1.15 (0.61, 2.16; 0.65)
Adjusted	1.19 (0.21, 6.31; 0.83)	1.89 (0.86, 4.26; 0.12)

Conclusions: Our study shows that WHIV in Kampala, Uganda post-TB infection are at a significantly higher risk for OLD as compared to men with HIV. Women without HIV did not demonstrate the same significant increase in risk for pulmonary dysfunction when compared to their male counterparts, suggesting that both sex and HIV-associated risks factor in OLD development.

EPB101

Increasing non-AIDS comorbidity burden among hospitalized persons with HIV (PWH) in the US and Canada

Nijhawan[8], J.A. Colasanti[9], M.Y. Karris[10], J.E. Thorne[2], C.S. Rabkin[11], K.A. McGinnis[12], J.M. Jacobson[13], M. Loutfy[14], R.D. Moore[2], S.A. Berry[2]

[1]UNC Chapel Hill, Chapel Hill, United States, [2]Johns Hopkins University, Baltimore, United States, [3]Kaiser Permanente Northern California, Oakland, United States, [4]Kaiser Permanente Mid-Atlantic States, Rockville, United States, [5]University of California, San Francisco, United States, [6]Yale University, New Haven, United States, [7]Southern Alberta HIV Clinic, Calgary, Canada, [8]University of Texas Southwestern Medical Center, Dallas, United States, [9]Emory University, Atlanta, United States, [10]University of California, San Diego, United States, [11]National Cancer Institute, Bethesda, United States, [12]Veterans Affairs Connecticut Healthcare System, West Haven, United States, [13]Case Western Reserve University, Cleveland, United States, [14]University of Toronto, Toronto, Canada

Background: Recent studies found the primary reason for most hospitalizations among PWH is non-AIDS-related. We investigated the burden among hospitalized PWH of chronic clinical conditions that may be underlying contributors to hospitalization and could affect outcomes like readmission.

Methods: For each calendar year 2008-2018, among hospitalized PWH in care in five cohorts in the NA-ACCORD, we estimated the prevalence at the time of hospitalization of HBV and HCV infection (any history), hypertension (defined as hypertension diagnosis with antihypertensive use), hyperlipidemia (defined as lipid-lowering agent use), diabetes mellitus (DM), stage ≥3 chronic kidney disease (CKD), and multimorbidity (≥2 and ≥3 conditions), using previously validated definitions. Unadjusted and age-adjusted calendar time trends in prevalence were estimated using linear-risk models with GEE.

Results: We examined ≈1000-1100 hospitalized PWH each year, totaling 6785 unique PWH (75% cisgender men, 40% White, 38% Black, 18% with IDU risk). Median ages of hospitalized PWH increased from 47 years (IQR 40-54) in 2008 to 54 (45-61) years in 2018. In 2018, prevalence estimates were 53% (95% CI 49%-56%) for hypertension, 42% (39%-45%) for hyperlipidemia, 25% (22%-27%) for DM, 22% (20%-25%) for CKD, 22% (20%-25%) for HCV, and 7% (5%-8%) for HBV; in addition, 50% (47%-53%) had ≥2 conditions and 31% (28%-34%) had ≥3 conditions.

In unadjusted analyses (Fig. 1A-F), HCV prevalence decreased, HBV prevalence remained stable, and the prevalence of other conditions and multimorbidity increased over the study period. After adjusting for age (not shown), there was no significant change in the prevalence of hypertension or having ≥2 conditions, while other trends were attenuated but similar to unadjusted results.

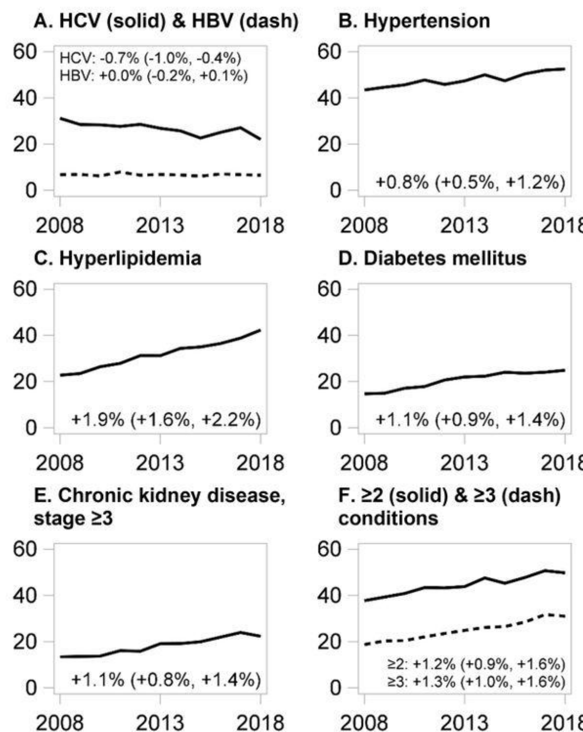

Fig. 1. Prevalence (%) of non-AIDS comorbidities among hospitalized PWH with unadjusted absolute change per year.

Conclusions: Among hospitalized PWH in care, non-AIDS morbidity and multimorbidity (≥3 conditions) increased from 2008 to 2018 even when accounting for age. These trends may reflect both changes in the population of PWH and increased hospitalization risk with greater clinical complexity.

EPB102
Factors associated with lower physical function among adults with HIV in the United States

A.L. Willig[1], L. Yang[1], J.D. Cleveland[1], D.M. Long[1], M. Katundu[1], V. Oliveira[2], C. Horvat Davey[3], H.M. Crane[2], T.W. Buford[1], J. Fleming[4], K.H. Mayer[4], G. Burkholder[1], M.S. Saag[1], A.R. Webel[2]
[1]University of Alabama at Birmingham, Birmingham, United States, [2]University of Washington, Seattle, United States, [3]Case Western Reserve University, Cleveland, United States, [4]Fenway Institute, Boston, United States

Background: People living with HIV (PWH) experience higher risk for frailty and lower physical function compared to adults without HIV. Our objective was to determine which factors may influence measures of physical function among PWH in the United States (U.S.).
Methods: We recruited PWH aged ≥ 18 years to participate in the multisite, observational PROSPER-HIV study. Frailty risk and physical function was assessed with: handgrip strength; 5-time repeated sit/stand chair test; and the Short Physical Performance Battery (SPPB). SPPB summary scores ranged 0 (frail) to 12 (not frail).
Triple-pass24-hour diet recalls were analyzed using NDSR Nutrition Analysis Software to determine total nutrient intake and compute the Healthy Eating Index-2015 (HEI-2015) score.
Physical activity was measured using at least 4 days (≥10 hours per day, including at least one weekend day) of accelerometry. Demographics, medical history, and patient reported outcomes (pain, fatigue, depression) were abstracted from the CFAR Network of Integrated Clinical Systems (CNICS) dataset.
Univariate analyses were performed using Chi-square or Kruskal-Wallis tests to evaluate associations between baseline factors and frailty risk. Multivariable models were created to evaluate the independent association between significant parameters from univariate analyses and frailty risk.
Results: The median age of our 413 participants was 54.0 years (±11.2); 54.5% self-reported Black race; 23.5% were female. 23% of participants were frail or at-risk for frailty. Overall diet quality and physical activity levels were sub-optimal: median HEI-2015 score was 51.4 (average U.S. score 59.0), dietary protein intake was 0.9 gm/kg/body weight (recommended intake 1.2 gm/kg/body weight for PWH), and only 31% spent at least 150 minutes/week in moderate-to-vigorous physical activity.
Participants assessed as frail/at-risk were more likely to be older (p<0.001), consume less dietary protein (p<0.01), and report experiencing at least some pain (p<0.01). Relationships of frailty with HEI-2015 and physical activity were not observed (p>0.05).
Conclusions: Dietary protein intake and pain were associated with frailty risk among PWH. Regardless of frailty status, diet quality and physical activity levels were sub-optimal compared to values typically reported for U.S. adults. Future investigations should study the impact of pain management and dietary protein intake on frailty prevention for PWH.

EPB103
Should HIV control programmes in Africa screen patients with HIV for multi-morbidity: findings from non-communicable diseases screening in the META trial in Dar es Salaam, Tanzania

S. Kivuyo[1], A. Garrib[2], F. Moyo[2], K. Bates[2], J. Okebe[2], J. Birungi[3,4], F. Kasujja[3], S. Mfinanga[1,2], S. Jaffar[2]
[1]National Institute for Medical Research, Dar es Salaam, Tanzania, The United Republic of, [2]Liverpool School of Tropical Medicine, Department of International Health, Liverpool, United Kingdom, [3]Medical Research Council/ Uganda Virus Research Institute & London School of Hygiene and Tropical Medicine (MRC/UVRI & LSHTM), Uganda Research Unit, Entebbe, Uganda, [4]The AIDS Support Organisation, Mulago Hospital Complex, Kampala, Uganda

Background: About 80% of people living with HIV in sub Saharan are now accessing antiretroviral therapy programmes but screening for non-communicable diseases is not done routinely, despite the sharp rises of these conditions. We screened patients attending HIV clinics in Dar es Salaam Tanzania for raised glycaemia, blood pressure, and other indicators.
Methods: Patients with HIV were screened for a placebo-controlled trial of metformin at 4 tertiary hospitals in Dar es Salaam. Screening was biased towards those of higher body mass index (BMI) to identify patients with pre-diabetes. Patients screened were aged ≥18 years and on antiretroviral therapy for ≥6 months. Two blood pressure measurements were taken, 5 minutes apart and the mean reading was used. Patients returned after overnight fasting for point-of-care fasting blood glucose and 2-hour oral glucose tolerance test.
Results: 1220 participants were invited to fast for 8 hours and have their BP tested and 245 (20.1%) did not return, leaving 975 (79.9%) who were screened. Their median age (interquartile range) of screened participants was 47 (42-54) years and 731/975 (75.0%) were women. Women were younger and had a higher BMI than men (p<0.001). The proportion of overweight or obese participants was, respectively, 38/56 (67.9%), 388/511 (75.9%) and 293/408 (71.8%) in the ≤34, 35-49 and ≥50 years age groups (p= 0.218).
None of the participants reported having pre-diabetes or diabetes. Fasting blood glucose was ≥7mmol/L in 142/975 (14.6%) participants and 129/972 (13.3%) had HbA1c ≥6.5%. OGTT was between 7.8 to 11.0 mmol/L among 313/974 (32.1%, 95% CI 29.2%-35.2%) of participants and ≥11.1 mmol/L among 65/974 (6.7%, 95% CI 5.2%-8.5%).
Among 921 participants who were not known to be hypertensive, 347/921 (37.7%, 95% CI 34.5%-40.9%) had blood pressure of ³140/90 mmHg and 31/921 (3.4%, 95% CI 2.3%-

4.7%) had blood pressure of ≥180/120 mmHg. Among 18/975 (1.8%) participants with BMI <25 kg/m²and age ≤34 years, 1/18 (5.6%, 95% CI 0.1%-27.3%) had an oral glucose tolerance test ≥11.1 mmol/L and 3/18 (16.7%, 95% CI 3.6%-41.4%) had BP of ≥140/90 mmHg

Conclusions: There is a substantial burden of raised BP and impaired glycaemia among people with HIV, including among younger people, with normal BMI.

EPB104

Prevalence and severity of nonalcoholic fatty liver disease in obese and non-obese patients with and without HIV infection in Asia

T. Wichiansan[1], H.M.S. Lwin[1], K. Woratanarat[1], W.M. Han[1], T. Ueaphongsukkit[1,2], T. Apornpong[1], S. Gatechompol[1,3], S. Ubolyam[1,3], S. Phonphithak[1], P. Tangkijvanich[4], O. Putcharoen[5], S.J. Kerr[1,6,7], A. Avihingsanon[1,3]

[1]The HIV Netherlands Australia Thailand Research Collaboration (HIV-NAT), Medical Team, Bangkok, Thailand, [2]Chulalongkorn University, Medicine, Bangkok, Thailand, [3]Chulalongkorn University, Center of Excellence in Tuberculosis, Bangkok, Thailand, [4]Chulalongkorn University, Center of Excellence in Hepatitis and Liver Cancer, Bangkok, Thailand, [5]Chulalongkorn University, Emerging Infectious Disease Clinical Center, Bangkok, Thailand, [6]Chulalongkorn University, Biostatistics Excellence Centre, Bangkok, Thailand, [7]University of New South Wales, The Kirby Institute, Sydney, Australia

Background: Nonalcoholic fatty liver disease (NAFLD) is usually associated with obesity. However, non-obese NAFLD is prevalent in Asia. Obese and non-obese NAFLD is associated with cardiovascular disease and liver cancer. The burden and factors associated with NAFLD are largely unknown among Asians with HIV.

We investigated the burden and severity of non-obese NAFLD among people living with HIV (PLWH) compared to HIV-negative populations.

Methods: A cross-sectional study of 1,111 PLWH and 609 HIV-negative hospital staff were randomly recruited in Bangkok, Thailand from 2017-2020 for transient elastography with controlled attenuation parameter (CAP). Pregnancy, regular alcoholic drinking (>1 day/week), hepatitis B and C were excluded. NAFLD was defined as CAP >248 dB/m. The Asian body mass index (BMI) cut-off <25 kg/m²was used to define non-obese NAFLD. The outcomes of this study were significant liver fibrosis (fibrosis >7.1kPa) and ASCVD risk ≥7.5%.

Results: HIV-negative were older, had higher BMI and majority were females. For PLWH, median ART was 12 years, CD4 count was 669 cells/mm³, and 95% had HIV RNA <50 copies/ml. NAFLD was significantly higher among HIV-negative participants compared to PLWH (49.6% vs 29.2%), obese group (75.9% vs 55.3%) and non-obese group (29.2% vs 20.0%) among HIV-negative participants and PLWH respectively.

However, liver fibrosis was significantly higher among PLWH compared to HIV-negative participants (13.1% vs 2.9%), obese group (22.5 % vs 4.9%) and non-obese group (8.7% vs 1.2%) among PLWH and HIV-negative participants respectively. ASCVD risk was also significantly higher in PLWH, proportion of ASCVD risk (≥7.5%) were 24.6%, 10.2%, 20.1% and 6.5% among Obese HIV, Obese non-HIV, non-obese HIV and non-obese non-HIV respectively.

In a multivariate model, after age, BMI, diabetes, hypertension, dyslipidemia, CD4 and ARV exposure were adjusted among PLWH, only BMI (≥25 kg/m², adjusted OR=4.3; 95%CI, 3.2-5.9; p<0.001) was significantly associated with NAFLD.

Conclusions: One-third of PLWH had NAFLD, 20% non-obese participants had NAFLD and 55.3% obese participants had NAFLD. HIV-negative participants had higher NAFLD prevalence, partly due to higher BMI.

Nevertheless, significant liver fibrosis and ASCVD risk was prevalent among PLWH, in both obese and non-obese participants. Weight management should be encouraged for both HIV-negative and PLWH populations.

EPB105

Associations between quality of oral health, HIV status, oral health practices and mental health status among adolescents in Nigeria: a cross-sectional study

O.I. Ibigbami[1], M. Folayan[2], O. Oginni[1], U. Philip[3], N. Ntonoba Mfam[3], C. Mbam[3], A. Ganyam[3], A. Salem[3], C. Osuji[3]

[1]Obafemi Awolowo University, Department of Mental Health, Ile-Ife, Nigeria, [2]Obafemi Awolowo University, Department of Child Dental Health, Ile-Ife, Nigeria, [3]Total Health Empowerment and Development Initiative, Makurdi, Nigeria

Background: Poor oral health is associated with poor general health. Adolescents living with HIV and with poor mental health might be at risk of poorer quality of oral health than their peers.

This study aimed to determine the associations between self-reported HIV status, oral health quality, oral health practices, and mental health among adolescents in Nigeria.

Methods: The was a cross-sectional study that collected data through an online survey administered to 13-19-year-olds in Nigeria. Data was collected on self-reported HIV status (negative, positive, unknown), oral health quality, oral health practices (frequency of toothbrushing, dental service utilization, refined carbohydrates consumption in-between-meals), mental health (depression, anxiety, and self-esteem) between September and October 2020.

Binary logistic regression was conducted to determine associations between the dependent (good quality of oral health) variables and the independent (HIV status, anxiety, depression, self-esteem, age, gender and oral health practices). The level of significance was p>0.05.

Results: There were 1419 complete responses. The mean (SD) age of study participants was 17.10 (1.61) years. A total of 47 (3.3%) respondents were HIV positive, 974 (68.6%) reported quality of oral health, 381 (26.8%) had high levels of anxiety, 119 (8.4%) had high levels of depression and 883 (62.2%) had good self-esteem.
Adolescents who reported "higher frequencies of toothbrushing" (β=2.15: 95% CI; 1.50-3.07, p<0.001) and "higher dental service utilization" (β=2.13: 95% CI; 1.55-2.94, p<0.001), had significantly higher odds of reporting good oral health quality.
Respondents with "unknown HIV status" (β=0.70: 95% CI; 0.52-0.93, p=0.014), "higher levels of refined carbohydrate consumption in-between-meals" (β=0.64: 95% CI; 0.47-0.86, p=0.003), "higher levels of depression" (β=0.96: 95% CI; 0.92-0.99, p=0.030), "higher levels of anxiety" (β=0.91: 95% CI; 0.86-0.95, p<0.001) and "higher self-esteem" (β=0.92: 95% CI; 0.86-0.95, p=0.020) had significantly lower odds of reporting good oral health quality.
Conclusions: Poor mental health and having an unknown HIV status increases the risk for reporting poor quality of oral health. Efforts geared at improving uptake of HIV testing by adolescents and those improving their mental health can positively influence the perception of oral health quality as this may also positively impact their general health in the future.

EPB106

Non-alcoholic to metabolic associated fatty liver disease: cardiovascular implications of a change in terminology in patients living with HIV

G. Guaraldi[1], J. Milic[1], S. Renzetti[2], F. Motta[1], L. Gozzi[3], A. Cervo[3], G. Burastero[3], V. Iadisernia[3], G. Franceschi[3], M. Faltoni[3], G. Sebastiani[4], S. Calza[2], P. Raggi[5], C. Mussini[3]
[1]University of Modena and Reggio Emilia, Modena, Italy, [2]University of Brescia, Brescia, Italy, [3]Azienda Ospedaliero-Universitaria Policlinico of Modena, Department of Infectious Diseases, Modena, Italy, [4]McGill University Health Centre, Montreal, Canada, [5]University of Alberta, Edmonton, Canada

Background: It has recently been suggested that the definition of non-alcoholic fatty liver disease (NAFLD) be changed to Metabolic Associated FLD (MAFLD) to better reflect the complex metabolic aspects of this syndrome.
We compared the ability of MAFLD and NAFLD to correctly identify high CV risk patients, sub-clinical atherosclerosis or a history of major cardiovascular event (MACE) in people living with HIV (PWH).
Methods: Single center, cross-sectional study of PWH on stable anti-retrovirals. NAFLD was diagnosed by transient liver elastography; published criteria were used to diagnose MAFLD (JHepatol.2020;73(1):202-209). Four mutually exclusive groups were considered: low (<7.5%) vs high (>7.5%) ASCVD risk, subclinical CVD (carotid IMT ≥1 mm and/or coronary calcium score >100), and MACE. The association of NAFLD and MAFLD with the CVD risk groups was explored via a multinominal model adjusted for age, sex, liver fibrosis, HIV duration, nadir CD4 and current CD4 cell count.
Results: We included 1249 PWH (mean age 55 years, 74% men, median HIV duration 24 years). Prevalence of overweight/obesity and diabetes was 40% and 18%. Prevalence of NAFLD and MAFLD and overlapping groups are shown in Fig 1A. Fig 1B shows distribution of NAFLD/MAFLD in the 4 patient categories (p-for-trend <0.001).

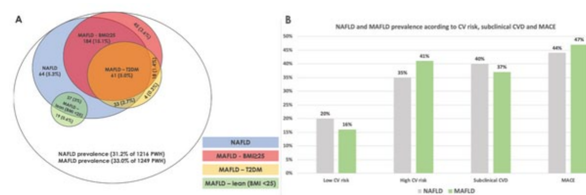

Fig 1.

Both MAFLD and NAFLD were significantly associated with an increased risk of CVD compared to the reference level (ASCVD<7.5%) (all p-values ≤0.004; Fig 2).

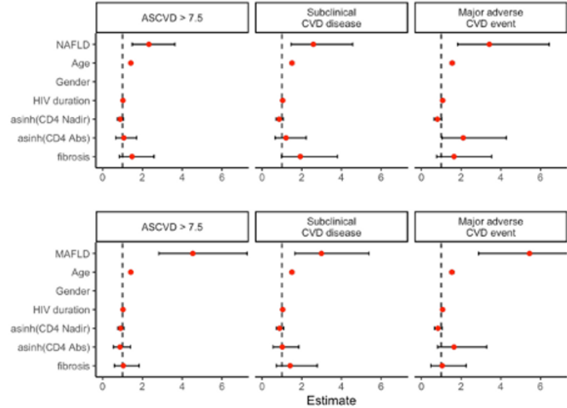

Fig 2.

Conclusions: NAFLD and MAFLD perform equally in detecting CVD or its risk. The proposed change in terminology may not help to identify PWH requiring enhanced surveillance and preventative interventions for cardiovascular disease.

Metabolic, lipid and endocrine complications (including lipodystrophy)

EPB107

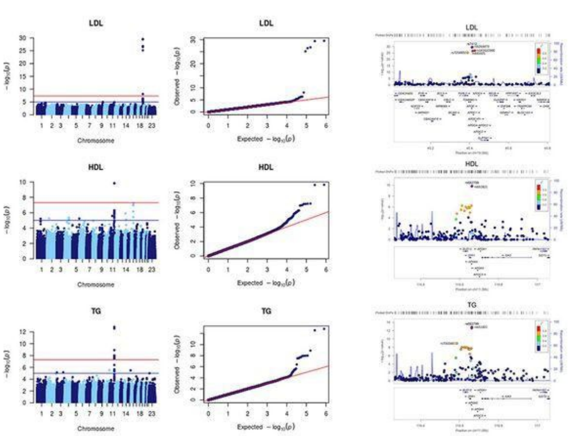
Genome-wide association study of plasma cholesterol and triglycerides among people living with HIV

J. He[1,2], H. Lin[3], X. Chen[3], X. Liu[1,2], Y. Ding[1,2], N. He[1,2]
[1]Fudan University, Epidemiology, Shanghai, China, [2]Fudan University, Yi-Wu Research Institute, Shanghai, China, [3]Taizhou City Center for Disease Control and Prevention, AIDS/STD, Taizhou, China

Background: HIV infection and antiretroviral therapy (ART) are closely linked to abnormalities in lipid metabolism. Several candidate gene studies have implicated genetic susceptibility to dyslipidemia among people living with HIV (PLWH); however, these have not been reliably investigated at the genome wide.

Methods: Genome-wide association study (GWAS) was conducted on 2745 PLWH enrolled in the Comparative HIV and Aging Research in Taizhou (CHART) cohort, an ongoing prospective cohort study in Zhejiang province, Eastern China. Low-density lipoprotein cholesterol (LDL-C), high density lipoprotein cholesterol (HDL-C), triglycerides (TG) and total cholesterol (TC) were measured at baseline. Single nucleotide polymorphisms (SNPs) were assayed using the Infinium[TM] Chinese Genotyping Array (CGA-24 v1.0. Illumina[R], 727,000 SNPs). Linear mixed regression analyses were constructed adjusting for age, gender, smoking, alcohol use, waist-hip-ratio and use of ART. Multiple testing was corrected.

Results: Overall, 1627 of 2745 (59.3%) PLWH had dyslipidemia including abnormal LDL-C (72; 2.6%), HDL-C (1297; 47.2%), TG (785; 28.6%) and TC (214; 7.8%). After standardized quality control and adjustment for non-genetic covariate, one novel SNP in APOE (rs72654473, P=2.90e-30) and four known SNPs in NECTIN2 (rs7254892, P=6.97e-26), APOE (rs7412, P=3.89e-30; rs445925, P=3.48e-27) and APOC1 (rs141622900, P=1.55e-27) were associated with a decreased LDL-C level. Two SNPs at minor allele carriers in APOA5 were related to an increased HDL-C level (rs662799, P=1.46e-10; rs651821, P=1.55e-10).



However, one novel SNP in BUD13 (rs3825041, P = 1.08e-8) and eleven known SNPs in APOA5 (rs662799, P = 1.45e-13; rs651821, P = 2.70e-13; rs2266788, P = 1.86e-8), BUD13 (rs10790162, P = 1.16e-8; rs180326, P = 1.05e-8; rs9326246, P = 9.91e-9), ZPR1 (rs2160669, P = 1.97e-8; rs6589566, P = 2.76e-8; rs964184, P = 2.95e-8) and LINC02702 (rs7350481, P = 1.22e-9; rs1558861, P = 3.14e-8) were associated with an increased TG level. These associations remained significant after multiple testing corrections.

Conclusions: Two new SNPs on loci commonly associated with dyslipidemia were identified in this genome-wide association study among PLWH, which may help individualize ART or define new prognostic tests to improve HIV patient care.

EPB108

Incidence of cardiometabolic outcomes among people living with HIV initiated on INSTI versus non-INSTI antiretroviral therapies

P.F. Rebeiro[1], B. Emond[2], C. Rossi[2], B.K. Bookhart[3], R. Rogers[4], A. Shah[2], G. Caron-Lapointe[2], M.-H. Lafeuille[2], P. Donga[3]
*[1]Vanderbilt University, Division of Infectious Disease & Epidemiology, Nashville, United States, [2]Analysis Group, Inc., Montreal, Canada, [3]Janssen Scientific Affairs, LLC, Titusville, United States, [4]Janssen Scientific Affairs, LLC (*at the Time of the Study), Titusville, United States*

Background: Antiretroviral therapy (ART) containing integrase strand transfer inhibitors (INSTIs) has been associated with weight gain, though there is limited information on associations between ART-related weight gain and cardiometabolic outcomes among people with HIV-1 (PWH).

We therefore evaluated risks of incident cardiometabolic outcomes following INSTI vs. non-INSTI-based ART initiation in the United States (US).

Methods: We conducted a retrospective study using IBM MarketScan Commercial Claims and Encounters, Medicare Supplemental, and Multi-State Medicaid databases (8/12/2012-1/31/2021). Treatment-naïve PWH initiating ART (index date) on/after 8/12/2013 (approval date of first second-generation INSTI, dolutegravir) were included and were censored at regimen switch/discontinuation, end of insurance eligibility, or end of data availability.

We used inverse probability of treatment weights constructed with baseline (12 months pre-index) characteristics to account for differences between INSTI- and non-INSTI-initiating cohorts. Doubly-robust hazard ratios (HRs) obtained from weighted multivariable Cox regression were used to compare time to incident cardiometabolic outcomes by INSTI-initiation status.

Cardiometabolic outcomes included congestive heart failure, coronary artery disease, myocardial infarction, stroke/transient ischemic attack, hypertension, type II diabetes, lipid disorders, lipodystrophy, and metabolic syndrome.

Results: Weighted INSTI and non-INSTI cohorts included 7,059 and 7,017 PWH, respectively (overall mean age=39 years, ~23% female, ~69% with commercial insurance, ~29% with Medicaid insurance). The most common INSTI-containing regimens were elvitegravir-based (43.4%), dolutegravir-based (33.3%), and bictegravir-based (18.4%); the most common non-INSTI-containing regimens were darunavir-based (31.5%), rilpivirine-based (30.4%), and efavirenz-based (28.3%).

Mean ± standard deviation follow-up were 1.5±1.5 and 1.1±0.7 years in INSTI- and non-INSTI-initiating cohorts, respectively. INSTI initiators were somewhat more likely to experience ≥1 incident cardiometabolic outcome (HR=1.13, p=0.076) than non-INSTI initiators; they were substantially and significantly more likely to experience incident congestive heart failure (HR=2.12, p=0.036), myocardial infarction (HR=1.79, p=0.036), and lipid disorders (HR=1.26, p=0.020) than non-INSTI initiators. Other risks were not significantly different (HR range=0.78-1.52).

Conclusions: Among treatment-naïve PWH in the US, INSTI initiation was associated with greater risk of developing congestive heart failure, myocardial infarction, and lipid disorders during a short follow-up period.

With increasing life expectancy among PWH, further research including additional clinical variables and using longer follow-up is warranted to examine the impact of INSTI-containing ART on long-term clinical outcomes.

EPB109

Lipid parameters and lipid modifying agent use in participants initiating F/TAF or F/TDF for PrEP in the DISCOVER trial

K. Mounzer[1], C. Tremblay[2], A. Clarke[3], S. Doblecki-Lewis[4], G. Crofoot[5], A. Avery[6], J. Szabo[7], C. Carter[8], Y. Shao[8], R. Ebrahimi[8], M. Das[8], A. Kintu[8], J. Yager[8], C. Hojilla[8], J. Baeten[8], D. Wohl[9], DISCOVER Study Group

[1]*Philadelphia FIGHT, Philadelphia, United States,* [2]*Université de Montréal, Montreal, Canada,* [3]*Brighton and Sussex University Hospitals NHS Trust, Brighton, United Kingdom,* [4]*University of Miami Miller School of Medicine, Miami, United States,* [5]*Crofoot Research Center, Houston, United States,* [6]*MetroHealth Medical Center, Cleveland, United States,* [7]*McGill University Health, Montreal, Canada,* [8]*Gilead Sciences, Foster City, United States,* [9]*University of North Carolina at Chapel Hill, Chapel Hill, United States*

Background: The tenofovir prodrugs TDF and TAF have differing effects on lipid levels, with F/TDF causing reductions in both HDL and LDL cholesterol. DISCOVER, a large Phase 3 randomized controlled trial of F/TAF versus F/TDF for PrEP, provides a unique opportunity to examine the effects of TAF and TDF on lipid parameters in people without HIV.

Methods: We assessed fasting concentrations of total cholesterol (TC), LDL, HDL, and triglycerides in participants who were not on PrEP at randomization. We identified lipid modifying agent (LMA) initiations in the blinded phase from concomitant medication records. We used multivariable logistic regression in a predictive analysis including study arm, age, BMI, race, and baseline history of diabetes, hypertension, cardiovascular disease, or hyperlipidemia as potential predictors of LMA initiation.

Results: Median TC, LDL, and HDL decreased in both arms through week (W) 96, but by a greater degree in the F/TDF arm; TC:HDL ratios were similar (Figure).

Median triglyceride levels increased slightly in the F/TAF arm and decreased slightly in the F/TDF arm. In the F/TAF and F/TDF arms, 113(4.2%) and 121(4.5%) participants were taking an LMA at randomization (P=0.59), and 33(1.5%) versus 26(1.2%) initiated an LMA post-randomization (p=0.36). In the multivariable model, older age (OR=1.31 per 5 years [95%CI 1.17,1.47]), diabetes (OR=4.03 [95%CI 2.02,8.05]), and hyperlipidemia (OR=3.05 [95%CI 1.66,5.62]) were associated with LMA initiation while study arm assignment was not (OR=1.31 [95%CI 0.77,2.23]).

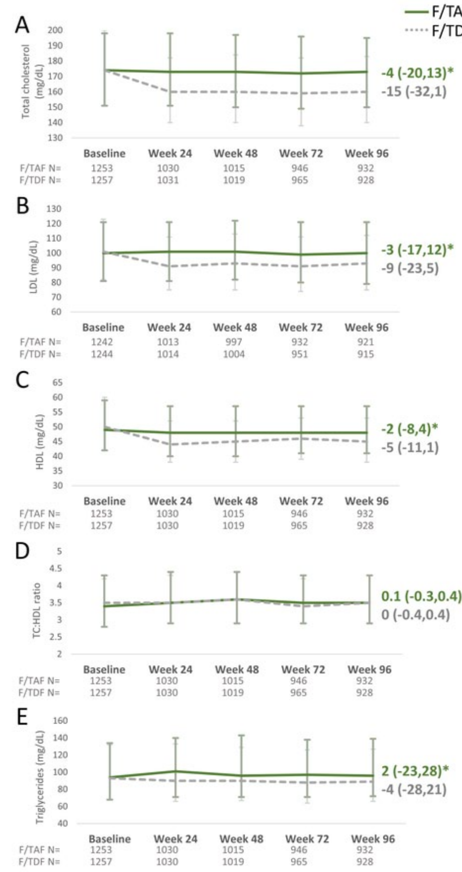


Figure. Median total cholesterol (A), LDL (B), HDL (C), total cholesterol to HDL ratio (D) and triglycerides (E) in participants initiating F/TAF (green solid lines) or F/TDF (grey dashed lines). Error bars represent the interquartile range (IQR). Data labels indicate median (IQR) change at week 96, with asterisks representing p value <0.05 by 2-sided Wilcoxon rank sum test.

Conclusions: Among participants who initiated PrEP in DISCOVER, F/TAF was associated with mostly stable lipids while F/TDF was associated with reductions especially in TC, LDL and HDL. TC:HDL ratio was similar between arms, and clinically significant triglyceride changes were not observed in either arm.

Late-breaker abstracts

Author Index

Study arm assignment was not associated with LMA initiation, while traditional factors including age, diabetes and hyperlipidemia were. These results suggest that daily oral PrEP has only small effects on lipids.

Weight gain

EPB110
Weight gain after antiretroviral therapy initiation in people living with HIV

X. Zhao[1], G. Prajapati[2], J. Tse[1], A. Near[1], P. Kumar[3]
[1]*IQVIA, Durham, United States,* [2]*Merck & Co., Inc., Kenilworth, United States,* [3]*Georgetown University School of Medicine, Washington, DC, United States*

Background: Treatment guidelines recommend integrase strand transfer inhibitor (INSTI)-based antiretroviral therapy (ART) for treatment naïve people living with HIV (PLWH).
The study aimed to compare weight changes in treatment naïve PLWH in the United States after initiating INSTI-, non-nucleoside reverse transcriptase inhibitor (NNRTI)-, or protease inhibitor (PI)-based ART.
Methods: Adult (≥18 years) PLWH initiating INSTI, NNRTI, or PI plus ≥2 nucleoside reverse transcriptase inhibitors (NRTI) between 01JAN2014-31AUG2019 were identified in electronic medical records (EMR) linked to prescription drug claims (Rx) data.
Included PLWH had ≥12 months (M) of EMR and Rx data before ART initiation (baseline), ≥6M of continuous ART after initiation (follow-up), ≥1 weight record at ART initiation, and ≥2 weight records during follow-up. PLWH were censored at earliest of: virologic failure (HIV RNA ≥200 copies/ml) after 6M of treatment, switch to different anchor agent class, loss to follow-up, or study period end (29FEB2020).
Weight changes up to 36M follow-up were compared among PLWH on INSTI- vs. NNRTI- and PI-based ART separately using multivariate non-linear mixed effect models.
Results: In the INSTI (N=931), NNRTI (N=245), and PI (N=124) groups, the majority were male (78.2%-81.2%) and overweight/obese (53.6%-61.6%) at baseline; 40.8%-45.2% were African American.
The INSTI vs. NNRTI/PI groups were younger (mean age [years]: 40 vs. 44/45) and had higher baseline prevalence of anxiety (9.1% vs. 6.1%/2.4%) or depression (10.2% vs. 8.2%/3.2%), lower weight at ART initiation (mean: 80.9kg vs. 85.7kg/85.0kg), and higher follow-up TAF usage (55.6% vs. 24.1%/25.8%; all p<0.05).
Multivariate models showed higher follow-up weight gain among PLWH in INSTI vs. NNRTI and PI groups (estimated 36M weight gain: 7.1kg vs. 3.8kg and 3.8kg, both p<0.05; Figure).

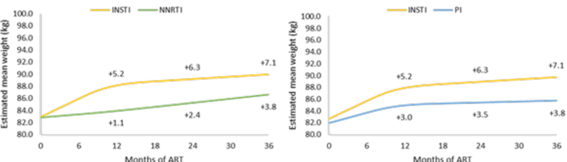

Figure. Weight changes over time among treatment naive PLWH iniated on INSTI-, NNRTI- and PI- based ART‡
ART, antiretroviral therapy; INSTI, integrase strand transfer inhibitor; NNRTI, non-nucleoside reverse transcriptase inhibitor; PI, protease inhibitor.
‡Mean weight changes were estimated from non-linear mixed effects models with restricted cubic splines.

Conclusions: Findings of higher weight gain in treatment-naïve PLWH initiated on INSTI-based regimen compared to non-INSTI-based regimens highlight the need to monitor weight and potential metabolic complications among PLWH starting INSTI-based ART.

EPB111
Can ART switch mitigate or reverse INSTI-related weight or BMI gain in at-risk people living with HIV-1?

P. Donga[1], B. Emond[2], A. Shah[2], B.K. Bookhart[1], D. Anderson[1], M. Vermette-Laforme[2], C. Rossi[2], M.-H. Lafeuille[2]
[1]*Janssen Scientific Affairs, LLC, Titusville, United States,* [2]*Analysis Group, Inc., Montreal, Canada*

Background: Compared to protease inhibitors (PIs), integrase strand transfer inhibitor (INSTI)-based antiretroviral therapies have been associated with weight/body mass index (BMI) gain, particularly in females, African American (AAs), and Hispanics with HIV-1.
However, there is limited data on weight/BMI changes after switching off INSTIs. This study compared weight/BMI outcomes among at-risk patients switching from an INSTI to either a PI- or another INSTI-based regimen.
Methods: Adult females, AAs, or Hispanics with HIV-1 treated with an INSTI-based regimen who switched to a PI- or another INSTI-based regimen (index: switch date), had ≥6 months of observation pre-index (baseline) and ≥1 weight/BMI measurement in both pre- and post-index periods in the Symphony Health, IDV database (10/1/2014-3/31/2021) were included. Inverse probability of treatment weighting method was used to balance baseline differences between cohorts. Mean weight/BMI change and the proportion of patients with weight/BMI increase from pre-index to 12 months post-index were compared between cohorts using weighted mean differences and odds ratios, respectively.
Results: After weighting, 153 patients in PI (mean age=42.5 years, 60.3% female, mean baseline BMI=29.5 kg/m^2; 74.1% of post-switch regimens contained darunavir, 50.0% contained tenofovir alafenamide [TAF]) and 203 patients in INSTI (mean age=45.5 years, 52.4% female, mean baseline BMI=29.8 kg/m^2, 52.3% of post-switch regimens contained bictegravir, 65.5% contained TAF) cohorts were included.

Among patients with weight/BMI measurements at 9 (PI: N=64; INSTI: N=90) and 12 months (PI: N=46; INSTI: N=84) post-index, weight/BMI increases were observed in the INSTI cohort while decreases were observed in the PI cohort; differences between cohorts widened over time *(Table)*.

		INSTI Cohort		PI Cohort		Adjusted Weighted Mean Difference or Odds Ratio (INSTI vs PI)	p-value
		Pre-index measurement	Post-index measurement	Pre-index measurement	Post-index measurement		
9 months (PI: N=64; INSTI: N=90)	Mean weight, kg	86.77	88.32	95.01	94.79	1.66	0.212
	Any weight gain, n (%)	51 (56.8%)		21 (32.1%)		2.85	0.160
	Mean BMI, kg/m²	30.19	30.79	33.29	33.28	0.57	0.236
	Any BMI increase, n (%)	51 (56.8%)		21 (32.1%)		1.99	0.373
12 months (PI: N=46; INSTI: N=84)	Mean weight, kg	86.55	88.15	91.01	89.42	3.23	0.132
	Any weight gain, n (%)	58 (68.4%)		25 (55.9%)		2.97	0.393
	Mean BMI, kg/m²	30.20	30.84	31.64	31.17	1.12	0.144
	Any BMI increase, n (%)	56 (67.3%)		25 (55.9%)		2.34	0.517

Table.

Conclusions: This is the first study evaluating weight/BMI changes post-INSTI switch among females, AAs, and Hispanics. Among these patients, there was a numerically higher increase in weight/BMI among those switching to another INSTI versus a PI.

Future studies with larger sample sizes and additional follow-up are needed to confirm these findings.

Switching ART Regimens is associated with greater weight gain in people living with HIV

L. Mavarani[1], S. Albayrak-Rena[2], F. Kaiser[2], N.H. Brockmeyer[3], A. Potthoff[3], M. Hower[4], D. Schadendorf[2], R. Erbel[1], K.-H. Jöckel[1], B. Schmidt[1], N. Reinsch[5,6], S. Esser[2,7]

[1]*Institute for Medical Informatics, Biometry and Epidemiology (IMIBE), University Hospital Essen, Essen, Germany,* [2]*University Hospital Essen, Department of Dermatology and Venereology, Essen, Germany,* [3]*Interdisciplinary Immunological Outpatient Clinic, Center for Sexual Health and Medicine, Ruhr Universität Bochum, Department of Dermatology, Venereology and Allergology, Bochum, Germany,* [4]*Klinikum Dortmund, Department of Pneumology, Infectious Diseases and Internal Medicine, Dortmund, Germany,* [5]*Alfried-Krupp Hospital, Department of Cardiology, Essen, Germany,* [6]*University Witten/ Herdecke, Department of Cardiology, Witten, Germany,* [7]*Institute for Translational HIV Research, University Hospital Essen, Essen, Germany*

Background: The prevalence of overweight and obesity has increased world-widely within the last decade, and thus in people living with HIV (PLWH). Weight gain in PLWH is complex and influenced by many parameters including antiretroviral therapy (ART) and ART-regime changes over the time.

Description: The ongoing HIV-HEART Aging study (HIVH) is a prospective cohort to assess cardiovascular risk in PLWH in Germany since 2004. Here, weight change was analysed retrospectively over the last 2.5 years. The participants were grouped based on ART-regimen change vs. no regimen changes. Relative (%) and absolute (kg) weight change were assessed and analysed in linear regression models adjusted for age and sex.

Lessons learned: 916 mainly Caucasian participants from HIVH aged 51±10 years were included in the analysis (ART-regimen change within 2.5 years: n=468 [male=375 female=73]; continuous ART-regimen within 2.5 years: n=448 [male=398 female=70]).General and HIV-specific characteristics, including weight change within 2.5 years are shown in Table 1.

Despite comparable mean weight (~80 kg) and body mass index (BMI) (~26) at the start of the observation, the regression models showed an absolute weight change that was 1.35 kg (95% CL 0.17-2.53) higher in individuals with changing ART-regimen compared to participants who did not change their regimen.

Most switches in the ART-regimen were observed towards an integrase strand transfer inhibitor (INSTI)-containing regimen (63%) and involved simplification to a single-tablet-regimen (STR) (59%).

After 2.5 years, the proportion of protease inhibitor (PI)-containing regimens was similar in both groups, while non-nucleoside reverse transcriptase inhibitor (NNRTI)-containing regimens were more frequent in the continuous ART-regimen group.

Conclusions/Next steps: We showed that recent changes to contemporary ART-regimens in HIVH during the last 2.5 years were associated with greater weight gain compared to continuous ART-regimen during the observation period. This difference may be explained by the more frequent use of INSTIs in the switch group.

EPB113

Perceptions of health, body size and nutritional risk factors for obesity among people with and without HIV in South Africa

J. Manne-Goehler[1], E. Van Empel[2], R. De Vlieg[2], N. Rahim[3], G. Chamberlain[3], A. Castle[3], S. Mabweazara[4], M. Siedner[5]

[1]*Brigham and Women's Hospital, Division of Infectious Diseases, Boston, United States,* [2]*Maastricht University, Maastricht, Netherlands, the,* [3]*Medical Practice Evaluation Center, Boston, United States,* [4]*Africa Health Research Institute, Mtubatuba, South Africa,* [5]*Massachusetts General Hospital, Boston, United States*

Background: As of 2018, South Africa was home to >5 million people with HIV (PWH) on antiretroviral therapy (ART). Recently, the South African HIV treatment program has begun to transition all patients to dolutegravir-based ART, despite evidence that this medication may promote weight gain.

In this study, we sought to first evaluate self-perceptions of health and body size among people with and without HIV and then explore the relationship between nutritional behavior and obesity in PWH in South Africa.

Methods: We used nationally representative, population-based survey data from the South Africa Demographic and Health Survey 2016. This survey included people aged 15-49 years and collected demographics, body mass index

(BMI), HIV serostatus and information about chronic disease risk and behavior. We defined the following groups based on HIV serostatus and BMI: No HIV-Normal Weight, No HIV-Overweight/Obese, PWH-Normal Weight, PWH-Overweight/Obese. People with BMI <18.5 kg/m² were excluded. The primary outcomes were self-assessed health and body size and fried food and sugar-sweetened beverage (SSB) intake.

We first compared outcomes across groups. Finally, we used multivariable logistic regression to evaluate factors associated with accurate assessment of body weight in all participants and to assess the relationship between nutritional behavior and overweight or obesity in PWH.

Results: Half of all participants had a BMI ≥25 kg/m²and there were no significant differences in mean BMI by HIV serostatus. Among those with a BMI <25 kg/m², a greater percentage of PWH rated themselves as being in poor or average health compared to those without HIV (54.7% v. 35.4%, p<0.001). Among those with BMI ≥25 kg/m², a greater percentage of PWH perceived themselves to be „underweight or normal weight" compared to those without HIV (83.7% v. 78.6%, p=0.05).

In adjusted models, PWH had a lower odds of accurately self-assessing their BMI (OR: 0.69, 95% CI: 0.57-0.83). There were no significant differences in fried food or SSB intake by HIV serostatus, but in adjusted models among PWH, SSB was associated with having a BMI ≥25 kg/m² (OR: 1.40, 95% CI: 1.00 – 1.97).

Conclusions: Both self-perception and SSB intake may offer entry points for future interventions to reduce obesity among PWH.

EPB114

Weight change when discontinuing integrase strand transfer inhibitors in people living with HIV

W. Tieosapjaroen[1,2], E. Chow[1,3,2], C. Fairley[2], J. Hoy[4], I. Aguirre[2], J. Ong[1,2]

[1]Monash University, Central Clinical School, Melbourne, Australia, [2]Melbourne Sexual Health Centre, Melbourne, Australia, [3]Melbourne School of Population and Global Health, The University of Melbourne, Centre for Epidemiology and Biostatistics, Melbourne, Australia, [4]Alfred Hospital, Monash University, Department of Infectious Diseases, Melbourne, Australia

Background: Integrase Strand Transfer Inhibitors (INSTIs) can cause weight gain, but little is known about whether ceasing INSTI treatment results in weight loss. This study evaluated weight changes associated with different antiretroviral (ARV) regimens, including weight change when discontinuing INSTIs.

Methods: A retrospective longitudinal cohort was conducted using data extracted from the electronic database at Melbourne Sexual Health Centre (MSHC), Australia, from 2011-2021. We calculated the weight change per time unit by ARV regimen using generalized estimated equations (GEE). We adjusted for age, gender, time on ARV and concomitant use of Tenofovir Alafenamide (TAF). GEE was used to analyse risk factors for weight gain when using INSTIs.

Results: There were 1,540 people living with HIV(PLWH) (4,548 person-years) included: 1,292 using INSTIs (mean age 34, 90% males), 147 using protease inhibitors (PIs, mean age 39, 85% males), and 369 using non-nucleoside reverse transcriptase inhibitors (NNRTIs, mean age 37, 82% males). PLWH using INSTIs, PIs, and NNRTIs gained 0.65 kg per year (P<0.001), 0.20 kg per year (P=0.166) and 0.35 kg per year (P=0.008), respectively. When switching off INSTI, there was no significant weight change at 0.82 kg per year (P=0.055), regardless of INSTI types.

Only PLWH who were on raltegravir continued to gain weight after discontinuing raltergravir at 1.30 kg per year (P=0.025). Risk factors for weight gain in INSTI users were age under 60 years, male and concomitant use of tenofovir alafenamide (TAF).

		Sample size	Adjusted Weight change (kg/year)	95%CI	P-value
Overall weight change	INSTIs	1,054	0.65	0.54 to 0.77	<0.001*
	PIs	122	0.20	-0.08 to 0.47	0.166
	NNRTIs	298	0.35	0.09 to0.62	0.008*
Weight change when discontinuing INSTIs	INSTIs	53	0.82	-0.02 to 1.65	0.055
	Dolutegravir	31	1.04	-0.19 to 2.25	0.097
	Bictegravir	5	0.47	-4.87 to 5.82	0.861
	Elvitegravir	10	1.59	-0.85 to 4.02	0.201
	Raltegravir	7	1.30	0.16 to 2.43	0.025*

Data is represented as kilogram weight change per year. Age, gender, time on ARV and concomitant use of TAF were adjusted. Kg/year; Kilogram change in weight per year, CI; Confidence intervals, INSTIs; Integrase strand transfer inhibitors, PIs; Protease inhibitor, NNRTIs; Non-nucleoside reverse transcriptase inhibitors *P<0.05

Table.

Conclusions: The weight gain after INSTI use in PLWH does not appear reversible to the pre-INSTI level. Careful observation of weight after INSTI use and early initiation of strategies to avoid weight gain are important to prevent permanent weight gain and associated morbidity.

EPB115

Weight gain after non-nucleoside reverse transcriptase-to-integrase inhibitor switch in the United States

G. Prajapati[1], J. Tse[2], X. Zhao[2], A. Near[2], P. Kumar[3]

[1]Merck & Co., Inc., Kenilworth, United States, [2]IQVIA, Durham, United States, [3]Georgetown University School of Medicine, Washington DC, United States

Background: This retrospective study assessed the impact of switching to integrase strand transfer inhibitor (INSTI)- from non-nucleoside reverse transcriptase inhibitor (NNRTI)-based antiretroviral therapy (ART) on weight in treatment-experienced people living with HIV (PLWH).

Methods: Adult (≥18 years) PLWH treated with NNRTI+≥2 nucleoside reverse transcriptase inhibitors (NRTI) and those who switched from NNRTI- to INSTI+≥2 NRTIs (IN-

STI group) were identified between 01JAN2013-29FEB2020 in electronic medical records (EMR) linked to prescription drug claims (Rx). Included PLWH had ≥6 months (M) of NNRTI treatment before switch (index date) in INSTI group and before the sham index date assigned to PLWH without switch (NNRTI group). PLWH were excluded if viral load (VL) ≥200 copies/mL during 6M pre-index (baseline) or post-index (follow-up) period.
All PLWH had ≥12M of baseline EMR and Rx data, ≥6M of continuous follow-up ART, and ≥1 weight record at baseline and 12(±6)M follow-up. PLWH were censored at the earliest of: VL ≥200 copies/mL after 6M follow-up, index anchor class discontinuation, TAF to non-TAF NRTI switch, loss to follow-up, or 29FEB2020.
The association between NNRTI to INSTI switch and ≥5% weight gain at 12M follow-up was assessed using multivariable logistic regression.
Results: The INSTI (N=501) and NNRTI (N=614) groups (mean age: 48.8-49.7 years; 78.0-78.3% male; 36.1-37.8% African American) had mean baseline weight of 84.8-86.2kg. The INSTI vs. NNRTI group had higher baseline prevalence of diabetes (13.6% vs. 8.6%) and dyslipidemia (39.9% vs. 27.9%) and follow-up TAF usage (49.9% vs. 1.8%; all p<0.05). The INSTI vs. NNRTI group had higher frequency (33.5% vs. 20.7%; Figure) and odds of ≥5% 12M weight gain (odds ratio [95% confidence interval]: 1.73[1.24, 2.43]).

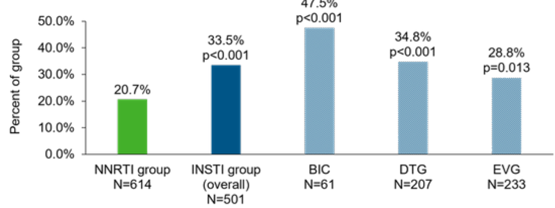

Figure. Frequency of ≥5% weight gain at 12 months among PLWH switching from NNRTI- to INSTI-based ART and those continuing NNRTI-based ART.
ART, antiretroviral therapy; BIC, bictegravir; DTG, dolutegravir; EVG, elvitegravir; INSTI, integrase strand transfer inhibitor; NNRTI, non-nucleoside reverse transcriptase inhibitor; PLWH, people living with HIV.
Note: P-values are from bivariate comparisons of the frequency of ≥5% weight gain in the overall INSTI group and specific INSTI drug groups vs. NNRTI group; RAL data not presented due to small sample size (N=7)/

Conclusions: The observed weight gain following switch from NNRTI- to INSTI-based ART highlights the need for alternative ART regimens for PLWH requiring switch from NNRTI-based ART to reduce the risk of potential metabolic complications.

EPB116
Change in weight and BMI associated with switching to bictegravir/emtricitabine/tenofovir alafenamide vs. a dolutegravir-based regimen among a prospective longitudinal cohort of virologically suppressed adults living with HIV

C.-P. Rolle[1,2], J. Garrett[1], D. Sterling[3], B. Cohen[3], P. Chandan[3], D. Castro[3], V. Nguyen[1], K. Patel[4], E. DeJesus[1,5]
[1]Orlando Immunology Center, Research Department, Orlando, United States, [2]Emory University Rollins School of Public Health, Global Health, Atlanta, United States, [3]University of Central Florida, Orlando, United States, [4]Gilead Sciences, Foster City, United States, [5]University of Central Florida College of Medicine, Orlando, United States

Background: Increased weight and BMI have been observed among treatment-naïve-and-experienced patients initiating bictegravir (BIC) and dolutegravir (DTG). Here, we report change in weight and BMI among patients switched to a BIC vs. DTG-based regimen (DBR) through the first 48 weeks compared to 2 years prior to switch.
Methods: Data on demographics, clinical characteristics, weight, and BMI are collected from virologically suppressed adults switched to BIC/emtricitabine(F)/tenofovir alafenamide (TAF), F/TAF plus DTG, DTG/abacavir (ABC)/lamivudine (3TC), DTG/rilpivirine (RPV) and DTG/3TC 2 years prior to switch through 144 weeks post switch. Linear spline models were fit to estimate and compare the trajectories of weight and BMI changes observed pre-and-post-switch.
Adjusted piecewise linear mixed-effects models were fit to examine factors associated with weight and BMI change pre-and-post-switch.
Results: Of 956 enrolled, 673 switched to BIC/F/TAF, 148 switched to F/TAF plus DTG, 51 switched to DTG/ABC/3TC, 48 switched to DTG/RPV and 36 switched to DTG/3TC. At baseline median age was 53 years, 15% were female, 45% were non-white, median weight was 85 kg, and median BMI was 27.9 kg/m^2.
At Week 48, switching to BIC/F/TAF vs. a DBR were both associated with lower annualized weight gain post-switch (-0.59 kg/year vs. -0.13 kg/year respectively, p=0.45), with similar trends observed for changes in BMI.
Compared to switching from integrase strand transfer inhibitors (INSTIs), switching from efavirenz (EFV) was associated with significantly higher annualized weight gain post-switch (+3.11 kg/year, p<0.001), whereas switching from RPV was associated with significantly lower annualized weight gain post-switch (-2.17 kg/year, p=0.022).
There was no significant difference in annualized weight gain post-switch among those switching from other non-nucleoside reverse transcriptase inhibitors and protease inhibitors compared to those switching from INSTIs.
Male sex, baseline CD4 ≥200 cells/mm^3, and duration of HIV infection >5 years were the only evaluated factors associated with significantly higher annualized weight gain post-switch.
