Conclusions: In this real-world cohort, switching to a BIC vs. DBR were both associated with lower annualized weight gain post-switch that was not significantly different at Week 48; however, patients switching from EFV gained significantly more weight, while those switching from RPV gained significantly less weight post-switch compared to those switching from INSTIs.

EPB117

Preferences for weight gain compared with other antiretroviral therapy side effects among people living with HIV: a discrete choice experiment

W. Tieosapjaroen[1,2], C. Fairley[2], E. Chow[1,2,3], I. Aguirre[2], J. Hoy[4], J. Ong[1,2]

[1]Monash University, Central Clinical School, Melbourne, Australia, [2]Melbourne Sexual Health Centre, Melbourne, Australia, [3]Melbourne School of Population and Global Health, The University of Melbourne, Centre for Epidemiology and Biostatistics, Melbourne, Australia, [4]Alfred Hospital, Monash University, Department of Infectious Diseases, Melbourne, Australia

Background: Antiretroviral (ARV) side effects are a critical determinant of adherence among people living with HIV (PLWH). Integrase Strand Transfer Inhibitors (INSTIs) are the most commonly used ARV but have recently been reported to cause weight gain. We aimed to determine the relative importance of weight gain compared to other ARV side effects for PLWH.

Methods: We conducted a discrete choice experiment (DCE) survey to explore PLWH's preferences for eight short-term side effects (i.e. weight gain, nausea, headache, dizziness, diarrhoea, depression, trouble sleeping and concentrating) and for four long-term side effects (i.e. long-term weight gain, risks of heart attack, kidney problems and bone fracture).

We sent a link to an anonymous survey through short message service (SMS) and postcards to PLWH attending Melbourne Sexual Health Centre (MSHC) and the Alfred Hospital in Victoria, Australia, between July and August 2021. The choice data were analysed using random parameter logit (RPL) and latent class (LCM) models.

Example question: If you only had the choice between Medication A or Medication B with the following side effects, which would you prefer?

	Medication A	Medication B
Weight gain	You gain an extra ten kg in the next five years	You gain an extra five kg in the next five years
Risk of heart attack	You have a slightly higher risk compared to people your age	Same as people your age
Risk of a broken bone	You have a slightly higher risk compared to people your age	You have a much higher risk compared to people your age
Risk of kidneys not working normally	Same as people your age	You have a much higher risk compared to people your age

Results: A total of 335 respondents were included: most were male (88.1%), and the mean age was 49.7 years. In the RPL analyses, PLWH ranked the relative importance of short-term ARV side effects as follows (from most important to least important): depression, weight gain, headache, diarrhoea, sleep, nausea, fatigue; and for long-term side effects as follows: risk of heart attack, kidney problem, weight gain and risk of bone fracture.

In the LCM analyses, 23.9% were most sensitive to short-term weight gain, while 16.0% were most sensitive to long-term weight gain.

Conclusions: Overall, weight gain was the second most important among eight short-term side effects and the third most important among four long-term side effects in a cohort of Australian PLWH.

However, there was a significant minority who were most sensitive to weight gain as a side effect of ARVs. We recommend that clinicians should actively discuss the possibility of weight gain for all PLWH taking ARVs.

EPB118

Longitudinal analysis of weight change in HIV-1 treatment-naïve and -experienced people living with HIV (PLWH) initiating/switching to an NNRTI- or InSTI-based antiretroviral therapy in four large cohort studies

O. Robineau[1], A. Marongiu[2], H.-J. Stellbrink[3], J.L. Meynard[4], J. Brunetta[5], D. Turner[6], A. D'Arminio Monforte[7], M.Á. Castaño-Carracedo[8], B.J. van Welzen[9], L. Williams[2], R. Haubrich[10], M. Heinzkill[11], S. Sahali[12], S. Schreiber[11], J. Gruber[10], C. Cohen[13], H. Ramroth[2], S. Esser[14]

Background: We analysed weight change from baseline (BL) to 12 months (12M) between PLWH on non-nucleoside reverse transcriptase inhibitors (NNRTIs) or integrase strand transfer inhibitors (InSTIs) and assessed the role of the nucleoside/nucleotide reverse transcriptase inhibitors (NRTIs) backbone (emtricitabine/tenofovir disoproxil-fumarate [FTC/TDF] or FTC/tenofovir alafenamide [FTC/TAF]).

Methods: Linear mixed models were used to estimate early weight change using data from four Gilead-sponsored, post-authorisation, observational HIV cohort studies (2010 to 2020), accounting for selected confounders in treatment-naïve (TN) and -experienced (TE) participants.

Results: 2,666 participants were included in the analysis (Table 1). TN on InSTI-based regimens had higher predicted mean weight gains at 12M than those on NNRTIs, +1.9kg (+FTC/TDF) to +3.1kg (+FTC/TAF) vs +1.2kg (+FTC/TDF) to 1.1kg (+FTC /TAF) respectively. Only the 95%CI for the +FTC/TDF means did not overlap (Figure 1a/b).Among TE, no differences in predicted mean weight change were observed between NNRTI and InSTI by NRTI backbone, and all 95%CI overlapped (mean weight change range at 12M: +1.0 to +1.5kg, Figure 1c/d). Switching from FTC/TDF to FTC/TAF led to greater mean weight increases (+1.8 NNRTI-based and +1.9kg InSTI-based), compared to +1.3kg without switching (NNRTI/InSTI-based); however, the 95% CI between the no-switch and FTC/TDF to FTC/TAF-switch overlapped.

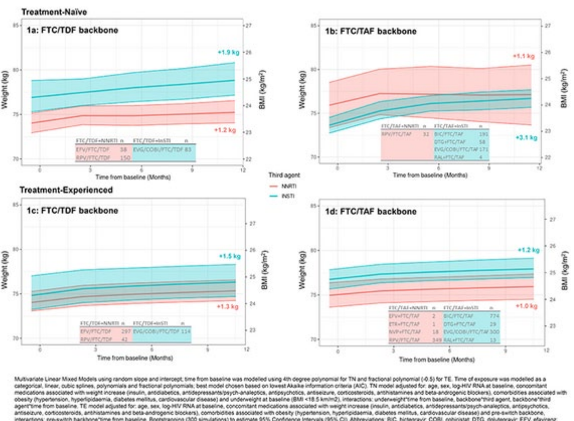

Figure 1. Predicted mean weight (kg) and BMI (kg/m²) change over 12 months follow-up in Treatment-Naive and Treatment-Experienced by third agent (InSTI vs NNRTI) and backbone (FTC/TDF vs FTC/TAF).

	TN - NNRTI (n: 218, 30%)	TN - InSTI (n:509, 70%)	TE - NNRTI (n: 703, 37%)	TE - InSTI (n: 1230, 63%)
Sex: Male, n (%)	195 (89.5)	462 (90.8)	619 (87.3)	1032 (83.9)
Age (years) – median (Q1 - Q3)	39 (31 - 44)	37 (30 - 47)	45 (35 - 53)	48 (39 - 55)
ART backbone: FTC/TDF, n (%)	188 (86.2)	83 (16.1)	339 (47.8)	114 (9.3)
FTC/TDF to FTC/TAF Switch: No, n (%) *			346 (48.8)	568 (46.2)
FTC/TDF to FTC/TAF Switch: Yes, n (%)			343 (48.4)	520 (42.3)
Baseline weight (kg) - median (Q1 - Q3)	75.0 (68.0 - 85.0)	72.0 (65.0 - 81.2)	74.5 (67.0 - 83.0)	76.0 (67.0 - 85.4)
BMI (kg/m2) - median (Q1 - Q3)	23.5 (21.8 - 25.6)	23.1 (21.3 - 25.4)	23.8 (21.6 - 26.0)	24.7 (22.2 - 27.5)

*Switching categories refer to pre-current NRTI; No switch category includes participants whose NRTI remained stable on either FTC/TDF (emtricitabine/tenofovir-disoproxil-fumarate) or FTC/TAF (emtricitabine/tenofovir-disoproxil-fumarate); ABC (abacavir) to FTC/TAF was included NNRTI (n: 20, 2.8%) and InSTI (n: 142, 11.5%). Abbreviations: InSTI, integrase inhibitors; NNRTI, non-nucleoside reverse transcriptase inhibitors. Body mass index (BMI) categories were defined as underweight, <18.5 kg/ m²; normal, ≥18.5 to <25 kg/ m²; overweight, ≥25 to <30 kg/m²; and obese, ≥30 kg/ m².

Table 1: Baseline demographic and clinical characteristics of Treatment-Naïve (TN, n: 727) and -Experienced (TE, n: 1939) participants by NNRTI- and InSTI-based antiretroviral therapy.

Conclusions: 12M mean weight change varied by treatment status, third agent, backbone, and pre-switch backbone. Compared to NNRTI, InSTI-based regimens had greater weight change in TN; however, no differences by third agent were observed in TE. The smaller increases on F/TDF vs F/TAF are consistent with the existing literature documenting a weight suppressive effect of FTC/TDF.

EPB119

Weight changes and pregnancy outcomes among pregnant people living with HIV in use of integrase inhibitors initiated before or after conception: a cohort study

T. Fuller[1,2], M.I. Fragoso da Silveira Gouvêa[1,3], M.L. Benamor Teixeira[1,3], A. Ferreira Medeiros[1], P. Amorim da Silva[4], C. Medeiros Braga[1], M. Constan Werneck de Sant'anna[4], M. De Mattos Salgueiro[1], C. da Silveira Bressan[1,3], W. Mendes-Silva[4], E. Joao[1]

[1]Hospital Federal dos Servidores do Estado, Infectious Diseases Department, Rio de Janeiro, Brazil, [2]University of California Los Angeles, Institute of the Environment and Sustainability, Los Angeles, United States, [3]Instituto Nacional de Infectologia Evandro Chagas - Fiocruz, Rio de Janeiro, Brazil, [4]Hospital Federal dos Servidores do Estado, Maternal Fetal Unit, Rio de Janeiro, Brazil

Background: There is scant data on weight changes (WC) and their association with unfavorable pregnancy outcomes among pregnant people living with HIV (PPLHIV) using integrase inhibitors (II). The P1081 and 2010 studies were RCTs on this subject. However, it is important to assess these issues in real world studies.

The objective of this cohort study is to compare weight gain (WG) and its association with unfavorable pregnancy outcomes in PPLHIV who initiated II before or after conception.

Methods: Retrospective cohort study of WC and obstetric/neonatal outcomes among PPLHIV attending a Prevention of Mother-to-Child Transmission reference center in Brazil from 2018-21, comparing participants who conceived in use of II to those initiating use during pregnancy.

We classified WG based on Institute of Medicine guidelines as low (<0.18 kg/week), normal (≥0.18 to ≤ 0.59 kg/week), or high (> 0.59 kg/week). II regimens consisted of a raltegravir or dolutegravir backbone with two NRTIs. Continuous variables were analyzed with a Kruskal-Wallis test and count data with Chi-squared tests in SPSS 19.

Results: 186 PPLHIV met the eligibility criteria and were included: 48% used dolutegravir, 52% raltegravir. Participants who conceived on II used it for 61 weeks through delivery, versus 22 weeks for those who initiated II after conception (p<0.001) (Table 1).

Near delivery HIV VL was undetectable for all groups. In the baseline BMI ≤ 25 subgroup, the proportion of treatment-naïve participants experiencing high WG (33.3%)

was greater than in the treatment experienced group (13.6%) (p=0.032). No significant differences were observed in obstetric/neonatal outcomes among groups.

	Conceived in use of II, baseline BMI ≤25 (N=22)	Initiated II in pregnancy, baseline BMI ≤ 25 (N=45)	p	Conceived in use of II, baseline BMI > 25 (N=36)	Initiated II in pregnancy, baseline BMI > 25 (N=83)	p
Median baseline log$_{10}$HIV RNA copies/mL (IQR)	0 (0-1.74)	3.78 (3.04-4.53)	<0.001	0 (0-1.15)	3.84 (3.26-4.42)	<0.001
Median gestational age at baseline (IQR)	13 (9-17)	20 (14-25)	0.006	18 (6-24)	18 (9-27)	0.66
Median near delivery log$_{10}$HIV RNA (IQR)	0 (0-0)	0 (0-1.61)	0.15	0 (0-0)	0 (0-0.81)	0.35
Duration of II use up to delivery (weeks)	61 (24-97)	22 (17-26)	<0.001	61 (30-93)	22 (17-28)	<0.001
Low WG during pregnancy, N(%)	5 (22.7%)	2(4.4%)	0.032	13 (36.1%)	25 (30.1%)	0.81
Normal WG, N (%)	14 (63.6%)	28 (62.2%)		17 (47.2%)	43 (51.8%)	
High WG, N (%)	3 (13.6%)	15 (33.3%)		6 (16.7%)	15 (18.1%)	
Composite adverse obstetric/ neonatal outcome*, N (%)	4 (18.2%)	13 (28.9%)	0.344	9 (25%)	8 (9.6%)	0.28

Table 1. Weight gain and pregnancy outcomes.
**Prematurity < 37 weeks, birth weight < 2500 g, or small for gestational age.*

Conclusions: In this cohort, PPLHIV who entered treatment during pregnancy with BMI ≤ 25 experienced significant WG using II. Such gain was not observed in participants who conceived using II or treatment-naïve PPLHIV with baseline BMI > 25.

EPB120
Association between Dolutegravir use and weight gain among adults in Tanzania

W. Maokola[1], R. Kisendi[2], V. Sambu[1], M. Kagashe[1], P. Faustine[1], B. Mutayoba[3], A. Makubi[4], A. Rwebembera[1]
[1]Ministry of Health Tanzania, National AIDS Control Program, Dodoma, Tanzania, The United Republic of, [2]Ministry of Health Tanzania, Directorate of Policy and Planning, Dodoma, Tanzania, The United Republic of, [3]Ministry of Health Tanzania, Directorate of Prevention, Dodoma, Tanzania, The United Republic of, [4]Ministry of Health Tanzania, Dodoma, Tanzania, The United Republic of

Background: Dolutegravir (DTG)-based regimen is recommended by World Health Organization as first line antiretroviral Therapy (ART) for people living with HIV (PLHIV). One of the adverse event associated with DTG is weight gain. We analyzed routine HIV data in Tanzania to determine the factors associated with weight gain for adults on ART in Tanzania between 2018 and 2020.

Methods: Retrospective cohort study for adults (above 20 years of age) enrolled in HIV care and treatment clinics with electronic database from 1st January 2018 until 30 September 2020. The follow up was for maximum of 33 months from ART start. The intervention group were those who started DTG containing regimen as their first ART regimen and continued using DTG regimen throughout the study period whereas the control group were individuals who started with a regimen without DTG as their first ART regimen. Weight gain at six (6) months of follow-up, we defined weight gainers (WGs) as those clients whose weight increased by at least 10% from baseline.

Results: A total of 316, 534 clients were included in the analysis of these 157,563 (49.78%) started DTG as their first ART regimen, whereas 158,971 (50.22%) were in group of ART regimen without DTG. On multivariable analysis PL-HIV in DTG contain regimen groups had higher odds of becoming weight gainers as compared to clients in Non DTG regiment. Group (AOR=1.18, 95% :1.15, 1.21).

This association was also highly significant (p-value <0.001) at 5% level. Female reported to have significantly greater odds of gaining more weight as compared to males when corrected for other factors (AOR=1.15, p<0.001).

Moreover, clients with CD4 cell counts of all groups less than less 500 were significant more likely to become weight gainers in six months of follow-up as compared to those with CD4 counts of at least 500.

Conclusions: DTG use was associated with weight gain in the study population and was more among those with lower immunity. Close monitoring is necessary to identify those who may need to be switched to other regimens due to excessive weight gain. It is also importance to adopt mechanisms for early HIV diagnosis before advanced immunocompromise.

EPB121
Bictegravir-containing ART regimens and weight gain in children with perinatal HIV

G. Fernandez[1], B. Stevens[1], J. Jang[1], A. Khaitan[1]
[1]Indiana University, Indianapolis, United States

Background: Integrase strand transfer inhibitors (INSTI) have been associated with weight gain in adults living with HIV, but there is limited data in children with perinatal HIV (CPHIV). Currently, an increasing number of children are being initiated on Biktarvy (bictegravir/emtricitabine/tenofovir alafenamide), a fixed-combination tablet approved for use in children weighing over 25kg.

With the widening availability of BIC-containing regimens for children and an increasing incidence of pediatric obesity, there is an urgent need to understand the impact of INSTI-containing regimens on weight gain in CPHIV.

Methods: We performed a retrospective analysis of weight gain in CPHIV on INSTI-containing regimens, 24 on BIC and 17 on other INSTIs. Change in weight (kg) and body mass index (BMI,kg/m2) at 52 and 78 weeks after initiation were analyzed with a repeated measures one-way ANOVA test. To compare the weight gain among those on BIC and other INSTIs, we performed a mixed model regression adjusted for baseline BMI% and age.

Oral abstracts
Poster exhibition
E-posters
Late-breaker abstracts
Author Index

Results: CPHIV on BIC were a median age of 12.5 (IQR,10-15) and had median weight increases of 6kg at 52 weeks (p=0.0004) and 6.5kg at 78 weeks (p=0.0004). BMI increased by 2.5 at 52 weeks (p=0.002) and 2.3 at 78 weeks (p=0.004). BMI% increased by 12% and 7% at 52 (p=0.002) and 78 weeks (p=0.03). Z-score increased by 0.5 at 52 weeks (p=0.002) and 0.3 at 78 weeks (p=0.02).

The mean BMI% for the BIC group was 12.03 units greater than that of Other INSTIs at 52 weeks (p=0.06) while adjusting for baseline BMI percentile and age, but there was no significant difference at 78 weeks.

Conclusions: CPHIV on Bictegravir-containing ART regimens exhibit significant increases in weight, BMI, BMI-percentile, and Z-score at 52 and 78 weeks. The increases in BMI-percentile and z-score suggest that the weight gain is more than expected with normal growth.

Our study is limited by a small cohort. It should also be considered that studies in adults have shown that TAF contributes to weight gain in PLWH and this may be contributing to weight gain in CPHIV on BIC/FTC/TAF. Further investigation is needed to evaluate the effects of BIC on weight gain in CPHIV.

Hepatic complications (e.g., NASH)

EPB122

Non-invasive identification of severe NAFLD and risk stratification of clinical outcomes using Fibroscan-AST (FAST) score in 1683 people with HIV

G. Sebastiani[1], J. Milic[2], D. Kablawi[1], C. Gioe[3], A.S. Al Hinai[1], B. Lebouche[1], A. Benmassaoud[1], M. Deschenes[1], A. Cascio[3], G. Mazzola[3], G. Guaraldi[2]

[1]McGill University, Montreal, Canada, [2]University of Modena and Reggio Emilia, Modena, Italy, [3]University of Palermo, Palermo, Italy

Background: Non-alcoholic fatty liver disease (NAFLD) is very frequent in people with HIV (PWH). Guidelines recommend identification of PWH at high risk for NAFLD-related fibrosis and clinical outcomes. The FibroScan-AST (FAST) score was developed to identify patients with nonalcoholic steatohepatitis (NASH) and significant fibrosis, associated with higher risk of end-stage liver disease. We employed the FAST score to identify PWH with severe NAFLD and for risk stratification of clinical outcomes.

Methods: FibroScan was performed in PWH without viral hepatitis coinfection or alcohol abuse from three large prospective cohorts.

We compared prevalence of FAST>0.35 (90% sensitivity and 50% specificity for NASH with significant fibrosis) and FAST≥0.67 (50% sensitivity, 90% specificity). Incidence of liver-related outcomes (ascites, encephalopathy, variceal bleeding, hepatocellular carcinoma) and extra-hepatic outcomes (cancer, cardiovascular disease) was evaluated by survival analysis. The performance of FAST score in predicting clinical outcomes was compared with simple fibrosis biomarkers.

Results: We included 1683 PWH (mean age 50.1 years, 74.5% male). Prevalence of FAST>0.35 and FAST≥0.67 was 8.1% and 1.5%, respectively. At baseline, on multivariable logistic regression higher BMI (aOR 1.15, 95% CI 1.10-1.20), longer duration of HIV infection (aOR 1.05, 95% CI 1.02-1.07), lower CD4 (aOR 0.99, 95% CI 0.99-0.99) and male sex (2.11, 95% CI 1.22-3.65) were associated with FAST >0.35. During a median follow-up of 3.5 years, incidence of liver-related and extra-hepatic outcomes was 7% and 11.5%, respectively. Incidence of liver-related outcomes increased according to FAST score category (see Figure).

On multivariable Cox regression analysis, FAST score >0.35 was an independent predictor of liver-related outcomes (aHR 4.44, 95% CI 1.66-11.9). The area under the curve to predict liver-related outcomes was as follows: FAST score 0.83; FIB-4 0.76; NAFLD fibrosis score 0.77; FibroScan 0.78.

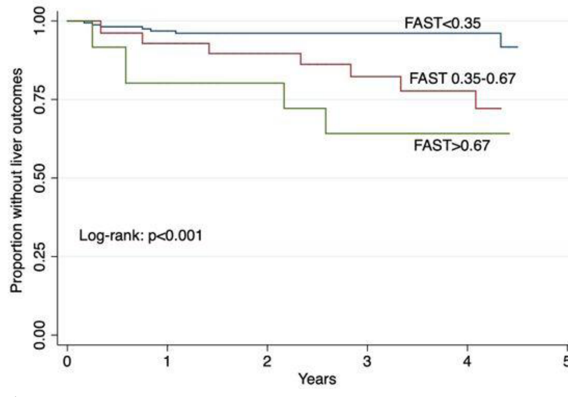

Figure.

Conclusions: A significant proportion of PWH are at risk for severe NAFLD. FAST score predicts liver-related events and can help risk stratification.

Incidence and disease severity of non-alcoholic fatty liver disease among people living with HIV in Thailand

T. Apornpong[1], W.M. Han[1], H.M. Su Lwin[1], K. Woratanarat[1], T. Ueaphongsukkit[1,2], S. Gatechompol[1,3], T. Wichiansan[1], S. Ubolyam[1,3], S. Phonphithak[1], P. Tangkijvanich[4], O. Putcharoen[5], S.J. Kerr[1,6,7], A. Avihingsanon[1,3]
[1]HIV-NAT, Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [2]Chulalongkorn University, Department of Medicine, Bangkok, Thailand, [3]Chulalongkorn University, Center of Excellence in Tuberculosis Faculty of Medicine, Bangkok, Thailand, [4]Chulalongkorn University, Center of Excellence in Hepatitis and Liver Cancer, Department of Biochemistry, Faculty of Medicine, Bangkok, Thailand, [5]Chulalongkorn Hospital, Emerging Infectious Disease Clinical Center, Bangkok, Thailand, [6]Chulalongkorn University, Biostatistics Excellence Centre, Faculty of Medicine, Bangkok, Thailand, [7]University of New South Wales, The Kirby Institute, Sydney, Australia

Background: Non-alcoholic fatty liver disease (NAFLD) has significant clinical implications since it can increase the risk of cardiovascular disease and hepatocellular carcinoma without progression to liver cirrhosis.

We estimated the incidence and outcome of NAFLD among people living with HIV (PLWH) in Thailand to better understanding NAFLD disease burden, so, appropriate monitoring and prevention can be addressed.

Methods: PLWH who were not pregnant and who did not drink alcohol were enrolled.Fibroscan with controlled attenuation parameter (CAP) were performed at HIV-NAT, Thailand during 2013-2021. Participants with at least 2 fibroscan results were analysed. NAFLD was defined as CAP>248 dB/m. Outcome of interests were significant liver fibrosis (fibrosis ≥7.2KPa), chronic kidney disease (CKD-EPI< 60 ml/min/1.73m^2), and atherosclerotic cardiovascular disease (ASCVD) risk score >7.5% using pooled equation.

Results: Of 816 PLWH (67% males, 25% HBV, 16% HCV), 236 (29%) had NAFLD at first CAP measurement. Median follow-up time of 2.2 (IQR, 1.5-3.3) years, 127 PLWH (22%, 127/580) developed NAFLD at second CAP measurement. The incidence of NAFLD was 9.1 (95%CI 7.7-10.8), 8.5 (6.8-10.7), 8.4 (5.2-11.3) and 12.4 (8.5-18.3) per 100 person-years (PYS) for overall, HIV mono-, HBV- and HCV-co-infected participants, respectively.

In multivariate analysis, male [hazard ratio, HR: 1.71 (95%CI 1.12-2.60), p 0.013]; age >50 years [HR: 1.57 (95%CI 1.02-2.41), p 0.038]; and BMI >23 kg/m^2 [HR: 1.24 (95%CI 1.17-1.32), p <0.001] were significantly associated with NAFLD. Median liver stiffness (IQR) at the second fibroscan was 5.0 (IQR 4.2-6.1), 5.1 (4.2-6.5) and 5.6 (4.8-7.8) kPa for HIV mono-, HBV- and HCV-co-infected participants, respectively.

The incidence of significant liver fibrosis was 4.1 ,6.6, and 9.4 per 100 PYFU for HIV mono-, HBV- and HCV-co-infected participants, respectively. ASCVD risk score >7.5% and chronic kidney disease at the last visit was higher among NAFLD (8.8 % vs 5.7%; p=0.011) and (16.7% vs 8.6 %; p=0.005), respectively.

Conclusions: In this Asian PLWH cohort, almost one third had fatty liver disease at first fibroscan and one fifth developed NAFLD in a median of 2.2 years. The routine evaluation of fatty liver disease and the monitoring of its impact on cardiovascular diseases risks and other comorbidities should be integrated in HIV care.

Other ART complications and adverse reactions

EPB124
Low incidence of adverse drug reactions associated with generic-equivalent antiretroviral product substitutions in a publicly-funded HIV treatment program

O.L. Hunt[1], K.J. Lepik[1,2], N. Bacani[1], L. Wang[1], J. Toy[1,2], P. Sereda[1], T. McLinden[1], L. Akagi[1,2], M. Harris[1,3], E. Ready[2], J. Trigg[1], J.S.G. Montaner[1,3], R. Barrios[1,3]
[1]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]St Paul's Hospital, Pharmacy, Vancouver, Canada, [3]University of British Columbia, Faculty of Medicine, Vancouver, Canada

Background: Generic antiretrovirals (ARVs) provide low-cost alternatives to brand-name products. In British Columbia Canada, persons living with HIV (PLWH) receive ARVs free-of-charge through a publicly-funded HIV Drug Treatment Program (DTP). Brand-name products are automatically switched to available generic equivalents in accordance with Health Ministry policies.

We describe the incidence and type of adverse reactions attributed to generic ARVs (generic product substitution issues, "PSIs") reported to DTP Pharmacovigilance.

Methods: We included PLWH age ≥19 years who received ≥1 commonly used generic ARV between 01-Jun-2017 and 30-Jun-2021: abacavir-lamivudine (ABC-3TC), emtricitabine-tenofovir disoproxil fumarate (FTC-TDF), efavirenz-FTC-TDF (EFV-FTC-TDF), atazanavir or darunavir. Manufacturer-specific generics were categorized as "generic-1" (brand-to-generic transition) and "generic-2" (generic-1-to-2 transition).

All data were extracted from DTP databases. Antiretroviral use and PSIs were summarized monthly. PSI incidence proportion (95% confidence interval, [95%CI]) and symptoms were described during the first year following each generic transition (product rollout) date.

After pooling across products, a logistic regression model (using generalized estimating equations) compared PSI incidence for generic-2 versus generic-1.

Results: Between 01-Jun-2017 and 30-Jun-2021, 5560/8842 (63%) of ARV-treated PLWH received generic ARVs, of whom 5421/5560 (98%) received ≥1 of the generics studied.

Of N=5421, 83% were male, median age 52 (Q1-Q3=43-58) years. Overall, 27% received one, 40% two, and 33% three or more different generics.

Figure 1a-1e shows longitudinal ARV usage, PSI frequency, and first-year PSI incidence, which was <1% for most generics. Of 93 PSIs, 71/93 (76%) were reported ≤1 year post-generic transition date. Common symptoms included mild-moderate gastrointestinal, central nervous system (predominantly efavirenz-related), dermatologic, and general (unwellness/ malaise) effects.

Pooled analysis of ABC-3TC, FTC-TDF and EFV-FTC-TDF showed significantly lower first-year PSI incidence for generic-2 (0.55%, 95%CI=0.31-0.78%) versus generic-1 (0.98%, 95%CI=0.69-1.27%), p=0.029, suggesting fewer PSIs with generic-to-generic versus initial brand-to-generic transitions.

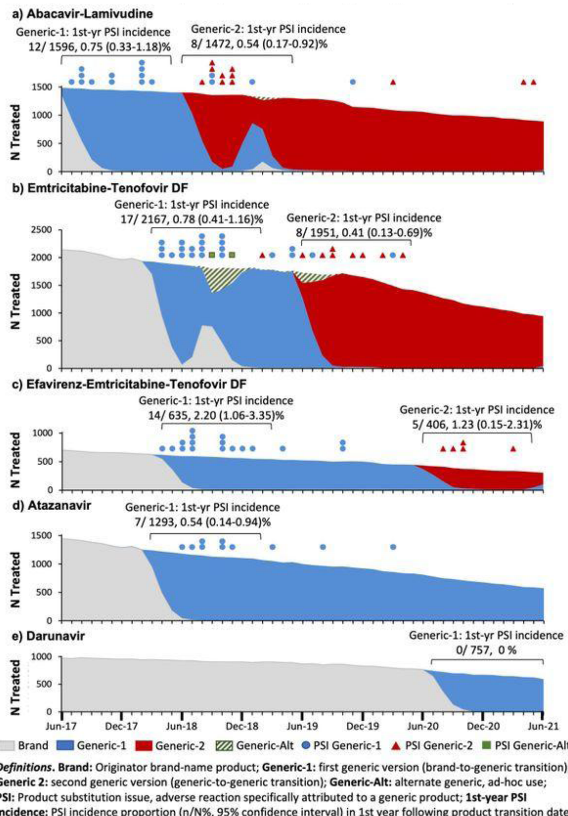

Figure 1. Longitudinal antiretroviral product usage, generic product substitution issue (PSI) frequency, and PSI incidence (in 1st-year following each generic product transition)

Conclusions: We report a low incidence of adverse drug reactions attributed to ARV generic product substitution.

EPB125

Switching to dual drug HIV regimen is associated with macrophage activation on a 2-years follow-up

M. Vassallo[1], J. Durant[2], R. Fabre[2], L. Lotte[1], A. Sindt[1], A. Puchois[1], A. De Monte[2], R. Cezar[3], P. Corbeau[3], C. Pradier[2]

[1]Cannes General Hospital, Cannes, France, [2]Nice University Hospital, Nice, France, [3]Nîmes University Hospital, Nimes, France

Background: Immunadapt is a study evaluating the impact of combination antiretroviral treatment (cART) simplification on immune activation. We previously showed that switching to dual therapies could be associated 6 months later with macrophage activation. Follow-up continued up to 24 months after treatment simplification.

Methods: Immunadapt is a prospective, single arm study, performed in Nice and Cannes, France, of stable and successfully treated subjects simplifying cART from triple to dual regimens.

The following immune activation markers were measured before cART change, 6 months and between 18 and 24 months after the switch: IP-10, MCP-1, soluble CD14 (sCD14), soluble CD163 (sCD163) and lipopolysaccharide binding protein.

Patients were stratified according to low or high risk factors of immune activation (CD4 nadir < 200, previous AIDS or very-low-level viremia during the follow-up). Variables were compared using matched Wilcoxon test. Statistical analysis were performed using R 4.0.3 software.

Results: From April 2019 to September 2021, 14 subjects completed follow-up (mean age 60 years, 12 men, 26 years since HIV infection, CD4 668 cells/mm3, CD4 nadir 302 cells/mm3, CD4/CD8 ratio 0.9, 18 years on cART, 6 cART regimens received, 53 months on last cART regimen before switch). Twenty-one months following the switch, all but one subjects maintained their viral load < 50 cp/ml. One subject had two viral blips during the follow-up (66 cp/ml and 52 cp/ml) and changed therapy to a triple-drug combination.

For the entire population, the trajectory of sCD163 increased significantly from baseline (+36%, p =0.003) and from the sample collected 6 months after the switch. The other markers did not change. As after 6 months, such sCD163 increase was more pronounced in subjects with high risk of immune activation (+53% vs +19%, p= 0.026).

Conclusions: cART simplification to dual therapy is associated with macrophage activation despite successful virological control after almost two years' follow-up. Further studies are needed in order to understand the long-term clinical impact of such macrophage activation.

EPB126

Incidental anaemia in patients started on antiretroviral therapy in Harare, Zimbabwe: a retrospective cohort study

L. Mandikiyana Chirimuta[1], C. Chimbetete[1,2], T. Shamu[1,3,4], C. Part[5]

[1]Newlands Clinic, Harare, Zimbabwe, [2]University of Geneva, Geneva, Switzerland, [3]University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland, [4]University of Bern, Graduate School of Health Sciences, Bern, Switzerland, [5]LSHTM, Faculty of Epidemiology and Population Health, London, United Kingdom

Background: Although antiretroviral treatment (ART) reduces the prevalence of anaemia, some patients remain at risk of developing anaemia after commencing ART. Anaemia is associated with disease progression, reduced quality of life and mortality in people living with HIV (PLWHIV). The burden of anemia in PLWHIV on ART in Zimbabwe is unknown. We estimated the incidence of anaemia after ART commencement and identified associated risk factors for anaemia in a cohort of PLWHIV.

Methods: Using routine clinic patient records, we conducted a retrospective cohort study of patients at Newlands Clinic, Harare, Zimbabwe who started ART between January 2016 and December 2020. Patients were followed up for 104 weeks after ART commencement. Anaemia was defined according to the World Health Organisation age and sex specific reference ranges of haemoglobin. Cox regression was used to assess for independent risk factors for anaemia.

Results: A total number of 1,110 patients ≥ 5 years old, were commenced on ART during the study period. The prevalence of anaemia at ART commencement was 40.0%. After excluding patients with prevalent anaemia at ART commencement, incomplete blood results, and pregnant women, 529 patients were included in the analysis with a total follow up time of 823.6 person-years.

The median age was 36.1 years (IQR 27.0 - 44.6) and 290 (58.4%) were female. The incidence rate of anaemia after ART commencement was 176.1 per 1,000 person-years (95% CI 149.6-207.2) with 146 (27.6%) of the participants developing anaemia during follow up.

The median time to developing anemia after ART commencement was 48.1 weeks (IQR 24.1-91.5). Of those with incidental anemia, 79.6% had normocytic,13.6% had macrocytic and 6.8% had microcytic anemia. Female patients (aHR 2.06 95% CI 1.45-2.94, p=0.001), zidovudine use (aHR 4.10 96%CI 2.65-6.33, p=0.001) and age < 18 years (aHR 1.47 95% CI 1.17-1.86, p=0.001) had higher risks of developing incidental anaemia.

Conclusions: Almost one in every five participants a year developed anaemia. Female sex, zidovudine use, and young age were independent risk factors for developing anaemia. Further research is needed to assess the impacts of a high incidence of anaemia on HIV progression, quality of life and comorbidities in this cohort of PLWHIV.

EPB127

Platelet reactivity and activation in people living with HIV

M. Kolosaka[1], S. Antonopoulou[2], A.-L. Delastic[2], G. Schinas[1], A. Mouzaki[2], C. Gogos[3], K. Akinosoglou[3]

[1]General University Hospital of Patras, Internal Medicine, Patras, Greece, [2]University of Patras, Laboratory Hematology, Patras, Greece, [3]General University Hospital of Patras, Internal Medicine/Infectious Disease, Patras, Greece

Background: The increased risk of cardiac events in people living with HIV (PLWHIV) treated with Abacavir or Tenofovir has come under scrutiny in the past years. Increased platelet reactivity and activation have been described as potential biological mechanisms. We aim to evaluate P2Y12 receptor-mediated platelet reactivity among PLWHIV and determine whether the underlying inflammatory status contributes to it. Platelet activation intensity will be assessed in vitro.

Methods: This study was carried out among PLWHIV on treatment combinations that include Abacavir (ABC) or Tenofovir (TAF or TDF). Platelet reactivity was measured in P2Y12 reaction units (PRU). Platelet activation intensity was assessed as per P-selectin and GPIIb/IIIa expression increase following activation with ADP. Major pro and anti-inflammatory cytokines, CD4 counts, and viral loads were measured in patients' serum.

Results: In total, 73 PLWHIV on different treatment combinations and 22 healthy controls were included in this study (Table). Inferential analysis revealed that PRU values were significantly elevated in PLWHIV compared to control [Mean; 257.85 vs. 196.67, p<0.000], but no significant difference was noted between treatment subgroups. PRU values did not correlate strongly with CD4 counts, detectable viral load values, or cytokine values. P-selectin and GPIIb/IIIa expression increase following ADP-activation was significantly more prominent in PLWHIV (p<0.005) (Image). However, no difference was detected in-between antiretroviral treatment regimens.

	Healthy Controls (n=22)	Naïve to treatment (n=12)	Abacavir (n=21)	Tenofovir [TDA+TDF] (n=38)
Male n (%)	63.6 (14)	10 (83.3)	15 (71.4)	28 (73.7)
Age, median (IQR)	48.5 (29.75-58.25)	36.5 (23.5-45.25)	42 (30.5-53.5)	43 (34.75-57)
CD4 (cells/mm^3) ,median (IQR)	----	324 (53.5-797.75)	702 (503-1064.5)	575 (413.75-726.25)
Viral load (copies/ml), median (IQR)	----	26.14 (0-64.5)	0	0 (0- 10750)
PRU, median (IQR)	190 (160.5-240)	296.5 (217-326)	245 (200-298)	243.5 (200-296)
IFN (pg/ml)		14.610 (0-17.1525)	14.080 (0-18.700)	8.908 (0-17.7)
IL-2 (pg/ml)		4.2640 (0- 7.277)	7.9520 (0-9.3940)	3.218 (0-7.494)
IL-6 (pg/ml)	6.86 (1.56-16.2)	23.265 (10.87-28.9)	24.520 (13.66-34.73)	19.040 (12.67-25.88)
IL10 (pg/ml)	3.18 (2.3-13.23)	10.16750 (0-15.425)	12.190 (4.5-15.63)	8.9125 (4.5-16.565)
TNF-a (pg/ml)	26.37 (4-155.9)	39.950 (6.21-42.86)	39.090 (0-46.230)	27.475 (0-44.045)

Table.

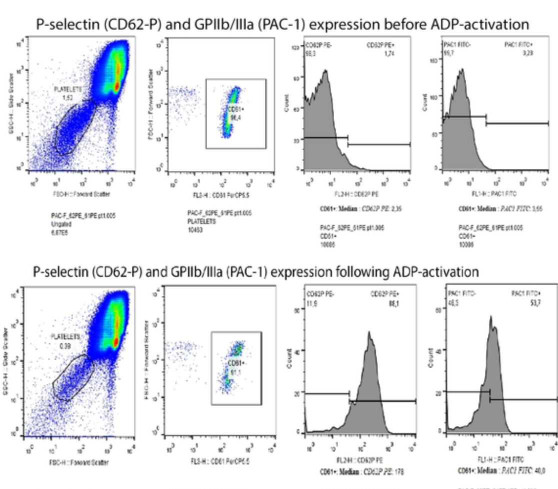

Figure.

Conclusions: PLWHIV exhibit increased platelet reactivity in-vivo and attenuated activation in-vitro. Treatment combinations of ABC or TDF/TAF do not display significantly different platelet reactivity. Platelet activation intensity does not seem to differ significantly across treatment combinations.

EPB128

Impact of differentiated service delivery models on retention and viral load suppression among ART clients in Katakwi Destrict

B. Jemba[1], S. Waiswa[1], J. Balinaine[1], R. Lomuria[1], G.G. Nabutanyi[1], E. Ongala[2], B. Opus[2], M. Abwola[3], J.S. Iramiot[1], R. Nekaka[1]
[1]*Busitema University, Mbale, Uganda,* [2]*Katakwi District, Katakwi, Uganda,* [3]*Soroti University, Soroti, Uganda*

Background: Although Uganda rolled out Differentiated Service Delivery (DSD) models in 2017 to improve retention and achieve viral load suppression, these have remained low relative to UNAIDs targets of 95-95-95. We determined the impact of facility and community DSD Models on viral load suppression and retention among ART clients in Katakwi district in North Eastern Uganda.

Methods: A retrospective cohort study of all ART clients in the different approaches of DSD models who were active by 2017, were followed up to 2020.

The primary outcomes were retention and viral load suppression of ART clients in different approaches. Eight health facilities providing ART services were purposively sampled and 771 ART clients were sampled by simple random sampling out of 4742 total population of clients on ART in Katakwi district.

We analyzed the retention, viral load suppression, and their determinants by logistic regression method using STATA.

Results: A total of 771 participants were sampled of whom 42.7% were males and 57.3% were females, with a mean age of 40 years. While the retention rates at 95% CI were 99% at 12 months, 94% at 24 months, 90% at 36 months, and 85% at 48 months. The viral load suppression rates were 57% at 12 months, 70%at 24 months, 70.3% at 36 months, and 69% at 48 months. Retention was highest among ART clients in the community-based DSD model with 100% retention in CDDP and95% in CCLAD as compared to facility-based models in which FBIM had the lowest achievement of (61.6%) followed by FBG (90.7%) and FTDR (93.9%). Viral load suppression was highest amongst the community-based DSD models in which CDDP had the highest achievement (92%) followed by CCLAD (79%) compared to the facility-based DSD models in which FBIM performance (34%)was far below the set standard of 955 followed by FBG (65%) with FTDR having a relatively better performance (81%).

Conclusions: Both facility and community-based DSD models have led to improved retention and viral load suppression however, community-based DSD model have shown to be more effective than facility-based DSD through mitigation of barriers to effective HIV/AIDS care of patients on ART.

Polypharmacy

EPB129

Pharmacotherapeutic profile, polypharmacy and its associated factors in a cohort of people living with HIV in Rio de Janeiro, Brazil

R.P.N. Silva[1], L.M.S. Marins[1], L. Guaraldo[1], S.W. Cardoso[1], R.I. Moreira[1], V.G. Veloso[1], B. Grinsztejn[1], R. Estrela[1], T.S. Torres[1]
[1]*Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz, Rio de Janeiro, Brazil*

Background: Inadequate polypharmacy may reduce expected clinical benefit, and increase the risk of drug interactions, toxicity, adherence problems, and hospitalization. Among people living with HIV (PWH) important interactions between antiretroviral therapy (ART) and concomitant medications are common.

We described the pharmacotherapeutic profile, polypharmacy and its associated factors among PWH in the largest HIV service in Rio de Janeiro, Brazil.

Methods: Cross-sectional study including PWH on ART who received at least one medical prescription (outpatient and hospitalized) in 2019. We described the proportion of prescribed medications according to Anatomical Therapeutic Chemical (ATC) index stratified by age (<50 vs. ≥50 years). Polypharmacy was defined as ≥5 medications prescribed except ARV. Logistic regression models assessed demographic and clinical factors associated with polypharmacy.

Results: A total of 143,306 prescriptions of 4547 participants were analyzed. Median age was 44.4 years (IQR:35.4-54.1) and 1615 (35.6%) were ≥50 years-old. The

majority were cisgender men (2958;65.1%), and 224(4.9%) were transgender women. Over half self-declared as Black/*Pardo* (2582;56.8%) and 671(14.9%) completed higher education. Median time since HIV diagnosis was 10.9 years (IQR:6.2-17.7). Most frequently prescribed concomitant medications were nervous system drugs (64.8%; e.g. diazepam) and antiinfectives for systemic use (60.0%; e.g. azithromycin) (Figure).

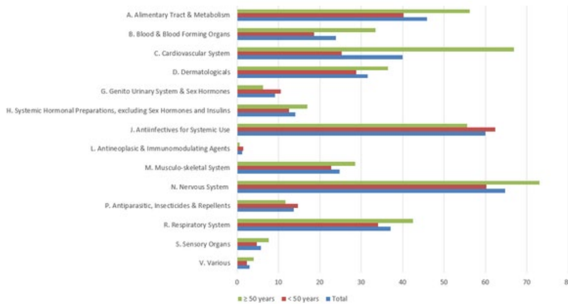

Figure. Frequency (percentage) of concomitant medications (ATC index) prescribed to people living with HIV stratified by age strata (<50 vs. ≥50 years), Rio de Janeiro, 2019.

Prevalence of polypharmacy was 50.6% (95%CI:49.2-52.1). On multivariate logistic model, being older, cisgender woman, having less education and longer time since HIV diagnosis increase the odds of polypharmacy (Table).

	Polypharmacy (≥5 concomitant drugs)		Bivariate models		Multivariate model

>10	990 (40.0)	1482 (60.0)	3.00 (2.36-3.83)	<.001	1.79 (1.36-2.37)	<.001

Table.

Conclusions: We found high rates of polypharmacy and concomitant medication use in a cohort of PWH in Brazil. Targeted interventions to prevent drug interactions and improve treatment adherence are warranted. Standardized protocols for continuous review of the patient's therapeutic regimens should be implemented.

Frailty

EPB130

Associations of frailty with cardiovascular disease risks in older people living with HIV

W.M. Han[1,2], T. Apornpong[3], S. Gatechompol[2], S. Ubolyam[2], S. Kerr[1,2,4], A. Avihingsanon[2]
[1]The Kirby Institute, UNSW Sydney, Faculty of Medicine and Health, Sydney, Australia, [2]HIV-NAT/ Thai Red Cross AIDS Research Centre and Centre of Excellence in Tuberculosis, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand, [3]HIV-NAT/ Thai Red Cross AIDS Research Centre, Bangkok, Thailand, [4]Biostatistics Excellence Centre, Faculty of Medicine, Chulalongkorn University, Bangkok, Thailand

Background: We assessed associations between frailty and clinical and subclinical CVD risks using atherosclerotic cardiovascular disease (ASCVD) score, coronary artery calcium (CAC) score, epicardial fat volume (EFV) and carotid intima-media thickness (cIMT).

Methods: A cross-sectional study was done in older people living with HIV (PWH) aged >50 years and age- and sex-matched HIV-negative people in Bangkok, Thailand. ASCVD risk was calculated using pooled cohort equations. Coronary calcium and EFV were measured using non-contrast cardiac CT scans. Frailty was defined using Fried criteria. Separate multivariable logistic regression used CVD risks (ASCVD ≥7.5%, CAC score ≥100, EFV ≥100 cm³ and cIMT) as outcomes and frailty as the predictor. Multinomial logistic regression was employed using frailty as the outcome and CVD risks as predictors and adjusted relative risk ratios (RRRs) were reported.

Results: A total of 439 participants (308 PWH and 131 HIV-negative) with median age of 55 years (IQR 52-60) were recruited between 2017 and 2018; 157 (36%) were female. Overall, 53% (232) were pre-frail and 7% (33) were frail. Higher prevalence of frailty was seen in PWH (9% vs. 3%, p=0.001). The median ASCVD risk score and EFV was 6.8% (IQR 3.5-12.6) and 93 cm³ (IQR 73-119), respectively, and 65 (15%) had CAC score ≥100. The median cIMT was 0.6 (0.5-0.7) mm and 46 (11%) had cIMT ≥0.9mm. In multivariable models using CVD risks as outcomes, frailty was associated with ASCVD risk ≥7.5% (odds ratio 2.38, [95%CI 1.06-5.33]), CAC score ≥100 (3.05 [1.18-7.92]) and EFV ≥100 cm³(2.54 [1.05-6.15]), compared to non-frail participants.

ASCVD risk ≥7.5%, CAC score ≥100 and EFV ≥100 cm³were also more likely seen among frail individuals (adjusted RRRs, 2.05 [1.01-4.61], 2.93 [1.10-7.80] and 3.10 [1.27-7.55], respectively) than non-frail participants. Higher cIMT was also more likely seen among frail participants than those without frailty (RRR for 0.1mm increase in cIMT, 1.60 [1.20-2.13].

Conclusions: Frailty was associated with multiple atherosclerotic risk scores independent of HIV infection. Our results highlight the importance of frailty screening in HIV care, especially among settings with high prevalence of aging population.

EPB131

Risk factors for frailty in a geriatric cohort on long term antiretroviral treatment in Uganda

P. Mbabazi[1,2], S. Naikoba[1], G. Banturaki[1], A. Kiragga[1], K.F. Reid[3], M. Cesari[4], E.L. Siegler[5], G. Guaraldi[6], B. Castelnuovo[1]

[1]Infectious Disease Institute, Research, Kampala, Uganda, [2]Mulago National Referral Hospital, Medicine, Kampala, Uganda, [3]Brigham and Women's Hospital, Havard Medical School, Exercise Physiology and Physical Performance, Boston, United States, [4]Universita' degli Study di Milano, Geriatrics, Milan, Italy, [5]Weill Cornell Medical College, Geriatrics, New York, United States, [6]University of Modena e Reggio Emilia, Infectious Disease, Modena, Italy

Background: Antiretroviral treatment (ART) scale-up has led to a generation aging with HIV in sub-Saharan Africa (SSA). Frailty, an age-related syndrome heightened by HIV infection, is marked by diminished physiologic reserve and vulnerability to stress, and is predictive of adverse clinical outcomes. We determined the prevalence and risk factors of frailty in a geriatric cohort in Kampala, Uganda.

Methods: We determined frailty prevalence and predictors in an aging cohort (≥60 years) enrolled between December 2020 and December 2021.

Frailty was defined by criteria proposed by Fried and colleagues:

1. Unintentional weight loss,
2. Exhaustion,
3. Weakness
4. Slow walking, and;
5. Low physical activity.

We performed logistic regression controlling for: gender, age, BMI, pre-ART and current CD4 count, WHO stage, years on ART, co-morbidities (NCDs), household income, depression, and cognitive status.

Results: Of 500 participants, 51.2 % were male, median age was 64 (IQR:62-68) years, and median time on ART was 15 (IQR:10-17) years. Twenty-eight (5.6%) were underweight, and 154 (31.2%) had an income lower than 1 USD/day. CD4 count at the ART start and at the time of enrolment were 159 cells (IQR:74-235) µL and 645 (IQR:450-805) µL, respectively. Two had a viral load >1,000 copies/ml, 127(25.4%) >1 NCD, 72.8% some degree of cognitive impairment, and 10.2% depression. Forty-five (9%) were frail, 229(45.8%) pre-frail, and 226(45.2%) robust. CD4 count and WHO stage were similar across the three groups.

Men (AOR 0.30, CI: 0.11-0.77, p-value: 0.012), those with normal BMI (AOR 0.06, CI:0.01-0.3, p-value: 0.03), and those overweight (AOR 0.08, CI 0.01-0.48, p-value: 0.005) were less likely to be frail. Participants who were below the poverty line (AOR 2.60, CI: 1.13-6.01, p-value: 0.025), cognitively impaired (AOR 5.70, CI:1.49-21.71, p-value 0.011) and depressed (AOR 20.68, CI:6.46-66.37 p-value: 0.000) were more likely to be frail.

Conclusions: Despite the exceptional rates of viral suppression and robust CD4 count recovery, more than half of the patients with HIV infection were frail or pre-frail in our cohort, highlighting the clinical relevance of this condition.

The assessment of frailty may pave the way for interventions for preventive/multidisciplinary interventions in nutrition, mental health, and lifestyle.

EPB132

Albuminuria is not associated with pre-frailty/frailty among PLWH in Botswana

P.L. Ponatshego[1], K. Molebatsi[2], S. Lockman[1,3], N. Youssouf[1,4], M. Montano[5], M. Mosepele[1,2]

[1]Botswana Harvard AIDS Institute Partnership, Clinical Trials Unit, Gaborone, Botswana, [2]University of Botswana, Statistics, Gaborone, Botswana, [3]TH Chan School of Public Health, Boston, United States, [4]London School of Hygiene & Tropical Medicine, London, United Kingdom, [5]Harvard Medical School, Boston, United States

Background: Easy to measure biomarkers of inflammation associated with pre-frailty/frailty are urgently required as many people living with HIV (PLWH) age. Albuminuria, an easy to assess biomarker of inflammation, has been linked to pre-frailty/frailty in some non-sub-Saharan cohorts but not extensively studied among clinical cohorts in sub-Saharan Africa.

We investigated the association between albuminuria and composite outcome of pre-frailty/frailty in a clinical cohort of PLWH in Botswana, sub-Sahara Africa.

Methods: In a cross-sectional study of 1017 PLWH, ≥40 years, pre-frailty/frailty was assessed using the Fried's frailty criteria. 0, 1-2 and ≥3 of any of unintentional weight loss, low physical activity, exhaustion, weak grip strength or slow walk determined pre-frail/frail participants.

Using sex-based Albumin-Creatinine Ratio (ACR), albuminuria was defined as 25-355m/g for females and 17-250mg/g for males.

Multivariate logistic regression analysis evaluated the association between albuminuria and composite outcome of pre-frailty/frailty.

Results: Of the 1017 participants assessed for pre-frailty/frailty, 484 (47.6%) were female. The median age was 51 [IQR= (57-45)] years. Albuminuria prevalence by ACR was 20.7% versus pre-frailty/frailty prevalence of 64% [591 (58.1%) pre-frail and 59 (5.8%) frail].

After adjusting for age, gender, education, income, alcohol use, diagnosis of hypertension, chronic kidney disease, multimorbidity (defined as having more than one major chronic conditions such as diabetes mellitus, hypertension and other), HIV duration, current CD4 count and ART regimen, there was no association between albuminuria and pre-frailty/frailty [aOR=1.07 (0.92, 1.24), p=0.377].

Author Index

Conclusions: Albuminuria was not independently associated with pre-frailty/frailty in this cohort of PLWH. Future studies should assess whether different albuminuria measures and cut-off points could be used to predict pre-frailty/frailty among PLWH in this setting.

EPB133

Approaches to optimally target frailty screening among people with HIV in clinical care: findings from the Centers for AIDS Research Network of Integrated Clinical Systems (CNICS)

Saag[9], A. Willig[9], C. Pandya[10], F. Cartujano Barrera[11], C. Kamen[11], A. Hahn[2], M. Kitahata[2], W. Lober[2], H. Crane[2]

[1]University of Washington, Epidemiology, Seattle, United States, [2]University of Washington, Medicine, Seattle, United States, [3]University of Manitoba, Pharmacy, Manitoba, Canada, [4]Fenway Health Institute, Medicine, Boston, United States, [5]University of North Carolina, Chapel Hill, United States, [6]University of California San Francisco, San Francisco, United States, [7]University of California San Diego, San Diego, United States, [8]University of Washington, Nursing, Seattle, United States, [9]University of Alabama Birmingham, Medicine, Birmingham, United States, [10]Johns Hopkins University, Baltimore, United States, [11]University of Rochester, Rochester, United States

Background: There is broad consensus that frailty screening in the primary care setting is useful and this may be particularly important for people with HIV (PWH) due to their high prevalence of frailty. We compared criteria to optimally target clinic-based frailty screening among PWH to reduce screening burden.

Methods: PWH in care at 6 CNICS sites across the United States completed patient reported outcome (PRO) assessments at their routine clinic visits.

Frailty was assessed based on self-report of 4 of the 5 components of the Fried phenotype: fatigue, unintentional weight loss, low mobility, and poor physical activity. PWH with ≥3 components were considered frail. Using logistic regression to predict frailty, we evaluated different combinations of demographic, clinical, and laboratory variables selected via 3 variable selection approaches (clinical, stepwise, and Bayesian Model Averaging).

We compared receiver operator characteristic (ROC) curves (which measure sensitivity and specificity) and used the regression coefficients from each model to develop screening criteria tools.

Results: Among 6,260 PWH in clinical care, 769 (12%) were frail. ROC curve values ranged from 0.57 for simple clinical approaches, such as age alone, to 0.85 for complex approaches. For example, a complex tool which included depressive symptom score (using PHQ-7 from PHQ-9 excluding sleep items to limit collinearity with frailty phenotype), age, sex, cigarette smoking, hepatitis C virus, alcohol use disorder, and current CD4 count ≤350 cells/mm^3 had ROC curve values of 0.85 for frailty. A targeted screening criteria tool based solely on age, sex, and depressive symptoms (ROC=0.84) had a sensitivity of 90% and specificity of 58% for frailty and identified 47% of PWH in CNICS as meeting criteria for frailty screening.

Conclusions: Similar variables for frailty screening (e.g., depression symptoms and age) were selected across multiple variable selection approaches. More complex tools had better testing characteristics, however would also be more difficult to implement in clinical settings.

A simple, targeted screening approach based on 3 readily available characteristics (age, sex, and depressive symptoms) identified 90% of PWH with frailty and reduced the number of PWH who needed to be screened by 53%.

Drug-drug interaction (DDI)

EPB134

Multi-medicine use and potential drug-drug interactions among people living with HIV on antiretroviral therapy in Australia

J. de Oliveira Costa[1], S. Lau[2], N. Medland[3], S. Gibbons[4], S.-A. Pearson[1], A. L Schaffer[1]

[1]UNSW Sydney/Centre for Big Data Research in Health, Medicines Policy Research Unit, Sydney, Australia, [2]UNSW Sydney/Centre for Big Data Research in Health, Sydney, Australia, [3]The Kirby Institute, Sydney, Australia, [4]University of Liverpool, Department of Pharmacology, Liverpool, United Kingdom

Background: The lifelong use of combination antiretroviral therapy (cART) and the earlier ageing process in people living with HIV (PLWH) increase susceptibility to comorbidities, multi-medicine use and drug-to-drug interactions (DDIs), possibly increasing treatment toxicity and reducing treatment effectiveness. Currently, there are no Australian population-based studies comprehensively evaluating patterns of comedication use and the occurrence of potential DDIs in PLWH.

Methods: In this cohort study, we identified 2,230 people dispensed cART from 2018 to 2019 (mean age 49.0 SD 12.0 years old, 88% male, 11% new users) using a nationwide 10% random sample of dispensing claims. We identified systemic comedications dispensed within 90-days of antiretroviral medicines for a period of 12-months. For every antiretroviral and non-antiretroviral pair, we classified possible DDIs using the University of Liverpool HIV drug interactions database. We report the proportion of people receiving multiple medicines by medicine class, type of interaction and antiretrovirals used.

Results: A total of 1,728 (78%) patients were dispensed at least one and 633 (28%) five or more comedications over one year; median = 3 (IQR 2, 6), increasing to 4 (IQR 2, 7)

among people aged 50+ years old. Among people who received multiple medicines, systemic anti-infectives and nervous system medicines were the most common (68% and 56%, respectively).

Most people on comedications had at least one interaction unlikely to require dosage alteration (n = 1,637, 95%), 558 people (32%) had interactions requiring close monitoring/ dose adjustment and 94 (5%) received medicines that should not be used concomitantly, of which the top 5 were: budesonide, clopidogrel, fluticasone, esomeprazole and pantoprazole.

Contraindications or interactions requiring close monitoring/dose adjustment were more common among people taking protease inhibitors (50%-73% across different antiretrovirals), non-nucleoside reverse transcriptase inhibitors (35%-64%), people using single-tablet combinations containing elvitegravir (30%-46%) and those using tenofovir disoproxil (26%-30%).

Conclusions: Multi-medicine use is widespread amongst PLWH in Australia and a high proportion of people receive medicines that require close monitoring or dose adjustment. Patterns of interactions vary by cART regimen and occur even among people on novel single-tablet regimens. Selecting regimens based on patient's comorbidities and comedications is key to optimising treatment.

Other issues related to aging with HIV

EPB135

Antiretroviral therapy gaps and discontinuation among people living with HIV in Medicare program

P. Li[1], G. Prajapati[2], Z. Geng[1], V.P. Ladage[1], J.M. Arduino[2], D.L. Watson[1], R. Gross[1], J.A. Doshi[1]

[1]University of Pennsylvania, Philadelphia, United States, [2]Merck & Co., Inc., Kenilworth, United States

Background: Antiretroviral therapy (ART) adherence is critical to achieve durable virologic suppression and minimize resistance in people living with HIV (PLWH). This study aimed to assess treatment gaps and discontinuation in PLWH in Medicare.

Methods: A retrospective analysis of 2013-2018 100% Medicare fee-for-service claims examined continuous treatment gaps over 12-months of follow-up among PLWH initiating a new (index) anchor ART agent (INSTI, NNRTI, or PI class). Treatment gap in any anchor ART use was defined as a fixed continuous period with no supply of an anchor medication after the entire days' supply of the most recent anchor ART prescription was exhausted.

Multivariable logistic and Cox regressions were used to examine factors associated with discontinuation (≥90-day continuous gap in any anchor ART agent) and time to discontinuation, respectively.

Results: The final study sample included 48,627 PLWH (mean age 54.5 years, 74.4% male, 47.5% White, 87.4% disabled). At least one ≥7-day treatment gap was common (55.2%) with lower gap rates in INSTI vs. PI group, and 10.1% PLWH discontinued treatment (Table).

	Overall sample (N=48,627)	INSTI† (N= 32,751)	NNRTI† (N=7,842)	PI† (N=8,034)
Length of continuous gaps in any anchor ART use				
0 (no gap)	19.3%	20.4%	18.5%	15.2%
≥1 day	80.7%	79.6%	81.5%	84.8%
≥7 days	55.2%	53.5%	55.5%	61.9%
≥14 days	41.0%	39.0%	41.7%	48.8%
≥90 days (discontinuation)	10.1%	8.6%	11.0%	15.3%
Time to discontinuation‡ in days (median)	106	115	93	95

†Index anchor ART agent: ‡≥90 days continuous gap in any anchor ART agent; ART, antiretroviral therapy; INSTI, Integrase Strand Transfer Inhibitor; NNRTI, Non-Nucleoside Reverse Transcriptase Inhibitor; PI, Protease Inhibitor; PLWH, people living with HIV

Table. Continuous gaps in any anchor ART and discontinuation over 12 months of follow-up from initiation of new anchor ART agent among PLWH enrolled in Medicare

Younger age (age ≤34 years: Odds Ratio [OR] 1.54; age 35-44: OR 1.54 vs. age 65-74), female sex (OR 1.20), Black race (OR 1.17 vs. White race), higher comorbidity score (OR 1.08), and comorbidities such as mental illnesses (OR 1.16) and substance use (OR 1.32) were associated with higher odds of discontinuation (all p-values <.001). PI-based index ART was associated with higher odds of discontinuation vs. both INSTI- and NNRTI-based index ART. Multivariable Cox regressions showed qualitatively similar results.

Conclusions: Among Medicare beneficiaries living with HIV who initiated a new anchor ART agent, gaps in any anchor ART use were commonly observed with 1 in 10 discontinuing anchor ART over 12-months of follow-up.

The study results highlight characteristics of PLWH at higher risk of discontinuing (and earlier discontinuation of) their ART in Medicare program.

EPB136

Use of the Patient Generated Index to identify physical health challenges among people living with HIV

A. Quigley[1], L. Fellows[2], M.-J. Brouillette[2], N. Mayo[2,1]

[1]McGill University Health Centre, Montreal, Canada, [2]McGill University, Montreal, Canada

Background: People living with HIV have more physical health challenges such as problems with fatigue, mobility, and gait relative to their HIV-negative counterparts. Physical health challenges have received little attention in the literature despite being associated with an increased fall risk, greater mortality, and reduced health-related

Oral abstracts

Poster exhibition

Author Index

quality of life. Other work has shown that individualized measures provide unique information that is not captured by standardized health-related quality of life measures.

The purpose of this study is to estimate the prevalence of physical health challenges from areas that patients spontaneously report as substantially affecting their quality of life.

Methods: The patient generated index (PGI), an individualized measure of health-related quality of life, was administered to 866 people living with HIV drawn from the Brain Health Now cohort across five sites in Canada.

In the PGI, participants are asked to indicate, in their own words, the five most important areas of their lives affected by HIV. PGI text threads from their first visit were coded according to the World Health Organization's International Classification of Functioning, Disability, and Health (ICF). The rate and content of nominated physical health problems were tabulated.

Results: The sample comprised 866 participants (mean age: 53; years with HIV: 16.8; women: 15.7%). The mean age of the participants was 53 years and the mean number of years living with HIV was 16.8 years. PGI text threads were coded to 18 domains of the ICF. 248 [28.6%; 95% CI (25.6, 31.6%)] respondents nominated at least one physical health problem and 46 (5%) participants indicated two or more physical health problems.

The most commonly nominated area was physical health unspecified (25% of total codes), followed by energy (22%), fatigue (11%), managing fitness (11%), endurance (7%), pain (5%), mobility (3.5%), sports participation (3%), effects of aging (3%), and walking (2%).

Conclusions: Physical health challenges are common among people living with HIV. By capturing what matters to the person, personalized health-related quality of life measures such as the PGI are well-suited to identify the unique physical challenges of people living with HIV and those potentially in need of a patient-centred rehabilitative approach.

EPB137
Evaluating healthy aging among Canadian HIV-positive older adults in the CHANGE HIV cohort

A. Zhabokritsky[1,2], R. Clarke[3], R. Rosenes[4], S. Walmsley[1,3], CHANGE HIV study team

[1]University of Toronto, Toronto, Canada, [2]University Health Network, Toronto, Canada, [3]Toronto General Hospital Research Institute, Toronto, Canada, [4]University Health Network, Community Health Advocate and Researcher, Toronto, Canada

Background: Life expectancy among people living with HIV (PLWH) is approaching that of the general population, however, PLWH continue to experience greater burden and earlier onset of medical comorbidities. Important differences in clinical outcomes and quality of life persist. Examining healthy aging as a multidimensional state can guide development of preventative and management strategies that are appropriate for the complex social and healthcare needs of people aging with HIV.

Methods: The CHANGE HIV (Correlates of Healthy Aging iN GEriatric HIV) study is a Canadian cohort of PLWH age 65 or older. In this cohort, healthy aging is assessed using the Rotterdam Healthy Aging Score (HAS), calculated across 7 domains of health (chronic disease, mental health, pain, social support, quality of life, cognitive and physical function).

We report on the HAS for the first 227 participants in the cohort and determine the proportion of those with healthy (scores 13-14), intermediate (scores 11-12), and poor aging (scores 0-10) scores. Scores were compared based on sociodemographic and HIV-related factors using Kruskal-Wallis and Fisher's exact tests.

Results: Median [IQR] age was 70 [68,74], majority of participants were men (89%), white (77%), born in Canada (66%) and retired (77%). Median [IQR] HAS was 12 [10,13] with 34% of participants achieving healthy, 39% intermediate and 27% poor aging scores.

Women and transgender participants had lower median [IQR] HAS (10.5 [9,13] compared to 12 [11,13] among men) and higher proportion of poor aging scores (50% compared to 24% among men, p=0.015). Women had fewer comorbidities compared to men (p=0.024), but worse cognitive function scores (p=0.002) and more pain (p<0.001).

HAS scores were lower among retired individuals compared to those employed or engaged in volunteer activities (p=0.013) but did not differ by age (p=0.641), race (p=0.698), country of birth (p=0.887), CD4 count nadir (p=0.510), or duration of HIV infection (p=0.066).

Conclusions: Gender seems to have an important impact on the aging experience of PLWH, especially across comorbidity, cognitive function and pain domains of health. Using a multidimensional score like the HAS can identify individuals at risk of poor clinical outcomes and direct interventions that support their healthy aging.

EPB138
Poor HIV outcomes among older adults newly diagnosed with HIV in Malaysia: a four-year retrospective analysis

H.Y. Wong[1], P.L. Wong[1], Y.K. Lee[2], M.L. Chong[1], M. Kahar Bador[1], S. Shenoi[3], J. Rozanova[3], S. Faridah[1], R. Rajasuriar[1]

[1]University of Malaya, Department of Medicine, Kuala Lumpur, Malaysia, [2]University of Malaya, Department of Primary Care Medicine, Kuala Lumpur, Malaysia, [3]Yale University, Department of Internal Medicine, New Haven, United States

Background: There is a high burden of HIV among the older population globally, but little is known about their clinical characteristics and health outcomes, especially

in the Asia-Pacific region. Our study aimed to assess the prevalence and outcomes of new HIV infection among adults aged ≥50, compared to those diagnosed at age <50years.

Methods: This is a retrospective study involving individuals newly diagnosed with HIV from 2016-2019 at the University of Malaya Medical Center, Malaysia. Follow up data was censored on 31.12.2020. Late diagnosis was defined as having a baseline CD4 counts <200cells/µL or WHO stage-3 or 4 HIV/AIDS at diagnosis. Clinical characteristics of older people with HIV >50years (OPWH) compared to <50years were compared using x^2 test. A Kaplan-Meier curve and log-rank test were used to compare the survival probability between the two age groups.

Results: Of 594 new cases, 68 (11.5%) were diagnosed in individuals ≥50 years. Males predominated in both groups with an overrepresentation of ethnic Indians among OPWH (p<0.001). The main transmission route in those ≥50 and <50 years old was heterosexual and homosexual contact, respectively (p=0.001). Late diagnosis was more common among OPWH (69.1% vs 49.8%, p=0.003).

A lower proportion in the OPWH achieved CD4 counts ≥500cells/µL by end of 2020, 26.9% vs 42.4%, respectively (p=0.020). OPWH had a significantly higher prevalence of hypertension (42.7% vs 5.9%), dyslipidemia (25.0% vs 5.3%), diabetes mellitus (27.9% vs 3.6%) and multimorbidity (26.5% vs 2.9%) at presentation (P<0.001 for all) than the younger group. Older patients had a significantly higher mortality risk (Figure 1).

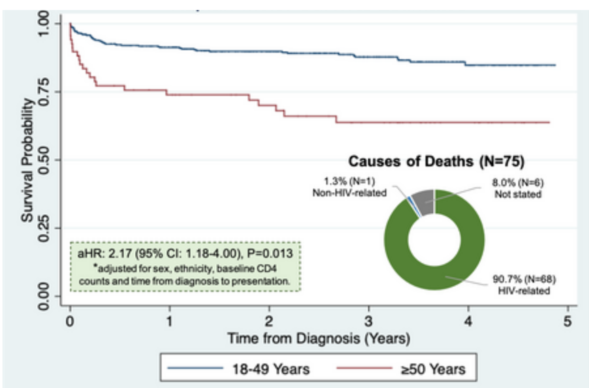

Figure 1. Kaplan-Meier survival estimates of new HIV/AIDS cases stratified by age of diagnosis.

Conclusions: Older people with HIV present late, experience greater mortality and less robust immunological responses as compared to their younger counterparts. Prompt action is needed to enhance early testing and linkage to care among older individuals. Further studies are needed to better understand the unique needs of this population.

EPB139
Physical activity can reduce adiposity in older adults with HIV in the modern HIV era

A. Webel[1], C. Horvat Davey[2], V. Oliveira[1], J. Cleveland[3], H. Crane[4], B. Gripsholver[2], D. Long[3], G. Burkholder[3], J. Fleming[5], T.W. Buford[3], A. Willig[3]
[1]University of Washington, School of Nurisng/Department of Child, Family and Population Health Nursing, Seattle, United States, [2]Case Western Reserve University, Cleveland, United States, [3]University of Alabama, Birmingham, Birmingham, United States, [4]University of Washington, Seattle, United States, [5]Fenway Institute, Boston, United States

Background: People with HIV (PWH) are living longer and developing chronic comorbidities at higher rates than those without HIV. Aging and HIV are associated with increased abdominal adiposity, which is a modifiable risk factor for cardiovascular disease, diabetes mellitus, chronic kidney disease, and frailty. In the general aging population, physical activity is one of the few non-pharmacological interventions that improves adiposity. The relationship between physical activity and adiposity in people with well-controlled HIV is unclear.

Our aim was to describe the association between objectively-measured physical activity and abdominal adiposity (i.e., waist circumference) in PWH.

Methods: As part of the multisite, observational PROSPER-HIV study, adults with HIV, who are virally suppressed wore an Actigraph accelerometer for 7-10 days and completed duplicate measures of waist and hip circumference. Valid accelerometer data included those who wore the device for ≥ 10 hours a day for a minimum of 4 days (i.e., at least one weekend day). Demographic and medical characteristics were abstracted from the CFAR Network of Integrated Clinical Systems (CNICS) dataset. Descriptive statistics and multiple linear regressions were used to analyze the data.

Results: A total of 374 PWH enrolled in the PROSPER-HIV study met our accelerometer wear time criteria. On average, they were 58 years of age (IQR: 50, 64), male (75%), Black (60%), and currently taking an integrase inhibitor (93%). Median engagement in moderate-to-vigorous physical (MVPA) activity per week was 0 (0, 15) minutes and 4,899 (3133, 7118) steps per day. Median waist circumference was 100 cm (91, 110) and the median waist-to-hip ratio was 0.90.

Controlling for age, sex, employment and integrase inhibitor use, the number of steps taken per day was associated with reduced abdominal adiposity (b= -68.9; p=0.027) and the hours of daily sedentary time was associated with increased abdominal adiposity (b= 0.06; p=0.017) Relationships between MVPA and abdominal adiposity were not observed (p>0.05).

Conclusions: Physical activity reduces abdominal adiposity in aging PWH. Specifically, increasing the number of steps per day is an acceptable physical activity interven-

tion in a mostly sedentary population. Future work should investigate how to tailor the amount, type and intensity of physical activity needed to reduce adiposity in PWH.

EPB140

Improvements in patient-reported outcomes in older adults aged ≥50 years with HIV-1 after switching to a 2-drug regimen of fixed-dose combination DTG/3TC: 48-Week results From the SALSA study

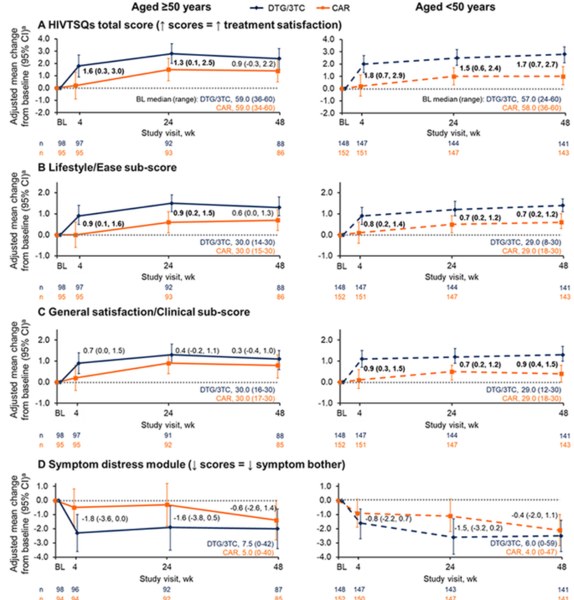
P. Kumar[1], L. Hocqueloux[2], C. Jonsson-Oldenbüttel[3], M.G. Deltoro[4], A.E. Clarke[5], S. Di Giambenedetto[6], P.-L. Lu[7], C. Brites[8], J. Oyee[9], L.A. Evitt[10], L.A. Gordon[11], E. Blair[11], B. Wynne[11], C. Okoli[10], J. van Wyk[10], J. Priest[11]

[1]Georgetown University Medical Center, Washington, DC, United States, [2]Centre Hospitalier Régional d'Orléans, Orléans, France, [3]MVZ München am Goetheplatz, Munich, Germany, [4]Consortium General University Hospital of Valencia, Valencia, Spain, [5]Royal Sussex County Hospital and Brighton & Sussex Medical School, Brighton, United Kingdom, [6]Fondazione Policlinico Universitario Agostino Gemelli IRCCS and Università del Sacro Cuore, Rome, Italy, [7]Kaohsiung Medical University, Kaohsiung, Taiwan, Province of China, [8]Universidade Federal da Bahia, Salvador, Brazil, [9]GlaxoSmithKline, Brentford, United Kingdom, [10]ViiV Healthcare, Brentford, United Kingdom, [11]ViiV Healthcare, Research Triangle Park, United States

Background: Older adults living with HIV (OALWH) have unmet needs beyond viral suppression, and patient-reported health outcomes provide insight into these needs in this important population. In the SALSA study (NCT04021290), switching to the 2-drug regimen DTG/3TC was non-inferior in maintaining virologic suppression at Week 48 compared with continuing 3-/4-drug (3/4DR) current antiretroviral regimen (CAR) in virologically suppressed adults, including OALWH. We present patient-reported health outcomes from SALSA analyzed by age at baseline.

Methods: SALSA is a randomized, open-label study of virologically suppressed (HIV-1 RNA <50 c/mL) adults on stable 3/4DR who switched to DTG/3TC or continued CAR for 52 weeks. A post hoc analysis of treatment satisfaction and symptom bother by age (≥50 and <50 years) at Weeks 4, 24, and 48 using the HIV Treatment Satisfaction Questionnaire, status version (HIVTSQs) and symptom distress module (SDM), respectively, was performed.

Results: Participants aged ≥50 years who switched to DTG/3TC vs continued CAR had greater improvements (higher increases from baseline) in mean HIVTSQs total score and lifestyle/ease sub-score at Weeks 4 and 24, which were stable through Week 48 (Figure); general satisfaction/clinical sub-scores were comparable between treatment groups. Participants aged <50 years in the DTG/3TC group had improved HIVTSQs total score and sub-scores vs CAR at all time points assessed. Participants aged ≥50 years in the DTG/3TC group had numerical improvements in SDM score vs CAR at Weeks 4 and 24 (greater decreases from baseline), which remained stable through Week 48. Participants aged <50 years in the DTG/3TC group had SDM scores comparable to CAR.



For HIVTSQs and related sub-scores, higher scores indicate improvement; for SDM, lower scores indicate improvement. Dotted lines indicate no change from baseline. Median baseline scores and adjusted difference between DTG/3TC and CAR are presented within each graph; bolded values indicate significance. The n for each study week is presented below each graph. [a]Estimated mean change from baseline at each visit in each group calculated using mixed-model repeated measures adjusting for treatment, visit, baseline third agent class, race, sex, baseline value, age, treatment-by-visit interaction, baseline value-by-visit interaction, visit-by-age interaction, treatment-by-age interaction, and treatment-by-visit-by-age interaction, with visit as the repeated factor. The correlation matrix for within-participant errors was unstructured. BL, baseline.

Figure. Adjusted mean change from baseline (95% CI) at Weeks 4, 24 and 48 analyzed by age ≥50 years (solid lines) and <50 years (dashed lines) in (A) HIVTSQs total score, (B) HIVTSQs lifestyle/ease sub-score, (C) HIVTSQs general satisfaction/clinical sub-score, and (D) SDM.

Conclusions: Rapid and stable improved treatment satisfaction through 48 weeks was reported by OALWH who switched to DTG/3TC. Comparable results were observed among participants aged <50 years. These findings support improved patient outcomes among OALWH after switch to DTG/3TC vs continuing CAR.

EPB141

Assessing sexual satisfaction amongst midlife women living with HIV in Canada

E. King[1,2], A. Kaida[3,2], M. Loutfy[4,5], M. Murray[1,2,6], P. Frank[3], A. de Pokomandy[7], A. Carter[8,9]

[1]*University of British Columbia, Medicine, Vancouver, Canada,* [2]*Women's Health Research Institute, Women's Hospital, Vancouver, Canada,* [3]*Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada,* [4]*Women's College Research Institute, Women's College Hospital, Toronto, Canada,* [5]*University of Toronto, Medicine, Toronto, Canada,* [6]*Oak Tree Clinic, BC Women's Hospital, Vancouver, Canada,* [7]*McGill University Health Centre, Medicine, Montreal, Canada,* [8]*Kirby Institute, Faculty of Medicine and Health, Sydney, Australia,* [9]*Australian Human Rights Institute, Faculty of Medicine and Health, Sydney, Australia*

Background: Although sexual activity and function both decline in older women living with HIV, positive dimensions of their sexual health, such as sexual satisfaction, are relatively unexplored. To address this gap, we evaluated the prevalence of sexual satisfaction and its correlates in midlife women living with HIV (aged≥45).

Methods: We used cross-sectional questionnaire data from cis and trans-gendered women living with HIV participating in the Canadian HIV Women's Sexual and Reproductive Health Cohort Study (CHIWOS; 2013-2015). We excluded women who were <45 years (n=783), only reported non-consensual sex (n=11) or had missing sexual health/satisfaction data (n=92).

Sexual satisfaction was evaluated using one item from the Sexual Satisfaction Scale for Women (SSS-W): "Overall, how satisfactory or unsatisfactory is your present sex life?" Responses were dichotomized into "satisfied" ("completely/very/reasonably satisfactory") or "not satisfied" ("not very/not at all satisfactory"). Multivariable logistic regression determined correlates of sexual satisfaction.

Results: Among 524 women of median age 51.8 (IQR 48.2-56.9), 40.1% were sexually active. A total of 50.0% met criteria for probable depression (CES-D score≥10) and 89.6% reported an undetectable viral load.

Overall, 60.9% reported being satisfied with their sexual lives with higher prevalence among sexually active vs inactive women (74.1% vs 51.6%; p<0.001).

Women with probable depression had 56.3% lower odds of sexual satisfaction than women without (aOR:0.44;95% CI:0.28-0.69). Women who were sexually active (aOR 2.42;1.46-4.01) or were in a relationship (aOR 2.50;1.07-5.83) had higher odds of sexual satisfaction than those not.

Those with a detectable viral load also had higher odds of sexual satisfaction (aOR 2.50;1.07-5.83), however, this effect was no longer seen when differences in substance use and education were accounted for. Sexual orientation, menopause status, physical health, HIV stigma and sexual violence were not significantly associated with sexual satisfaction.

Conclusions: Most midlife women living with HIV were satisfied with their sexual lives, even those who were not sexually active. Associations with sexual activity, relationship status, and depression suggest that these aspects should be evaluated during sexual health screening. The close connection between mental and sexual health highlights the need to address both of these aspects of health in conjunction.

EPB142

Randomness of motor activity and cognitive performance in people living with HIV infection

P. Li[1,2], C. Gao[1,2], L. Gao[3,1,2], R.A. Parker[4,2], I.T. Katz[5,2], M.A. Montano[5,2], K. Hu[1,2]

[1]*Brigham and Women's Hospital, Division of Sleep and Circadian Disorders, Boston, United States,* [2]*Harvard Medical School, Boston, United States,* [3]*Massachusetts General Hospital, Department of Anesthesia, Critical Care and Pain Medicine, Boston, United States,* [4]*Massachusetts General Hospital, Biostatistics Center, Boston, United States,* [5]*Brigham and Women's Hospital, Department of Medicine, Boston, United States*

Background: Motor activity in healthy young adults exhibits self-similar fluctuations (i.e., fractal) with temporal correlations across multiple timescales. Circadian intactness is causally related to the fractal dynamics. The temporal correlations decrease (i.e., increased randomness) with aging and in neurodegeneration, which is also associated with faster cognitive decline and risk of dementia. Older PLWH experience neurocognitive complications that impinge on quality of life and impede effective clinical management.

This study aimed to examine randomness of motor activity and association with neurocognitive performance in PLWH.

Methods: Among ~100,000 UK Biobank participants with 7-day actigraphy, 102 PLWH were identified based on HIV-1 seropositivity, hospital records, or self-report. Five people without identified infection were extracted to match each PLWH on age, sex, ethnicity, social-economic status, and comorbidities. Randomness of motor activity at timescales from 2-10h was quantified by a scaling exponent α (α=0.5 indicates complete randomness, greater α indicates stronger temporal correlations). Reaction time (RT) during a card identifying task was used to quantify information processing speed, a measure of executive function.

Results: 102 PLWH [age: 56.9±7.2 (mean±SD); female/male: 21/81] and 510 matched uninfected controls (age: 56.8±8.2; female/male: 107/403) were examined. There was no significant difference in α between PLWH [0.90±0.01 (estimate ±SE)] and uninfected controls (0.91±0.01, *p*=0.4). PLWH displayed longer RTs [6.30±0.02 (unit: log ms)] than uninfected controls (6.25±0.01, *p*=0.03). Group (i.e., PLWH/control) significantly moderated the association between α and

RT (p=0.02), adjusting for age and sex. For a 1-SD decrease in α, RT changed by -0.01±0.01 (p=0.2) in uninfected controls whereas it changed by 0.05±0.02 (p=0.05) in PLWH.

Conclusions: PLWH displayed longer RTs than uninfected controls, suggesting compromised executive function. Increased randomness in motor activity was associated with longer RT in PLWH but not in uninfected controls, implying a potential relation of circadian dysfunction with executive function.

Further studies are warranted to examine whether drivers of aging (e.g., inflammation, immune activation) and consequent multimorbidity frequently seen in PLWH maybe related to the observed association. Further understanding of circadian dysfunction that leads to the increased randomness of motor activity may help better phenotype cognitive aging process of PLWH.

EPB143

Comparative prevalence of mild cognitive impairment and Alzheimer's dementia in adult Ugandans living with HIV and demographically matched HIV-negative controls

A. Ezeamama[1], A. Sikorskii[1], M. Boivin[1], S. Zalwango[2], N. Nakasujja[3], L. Rubin[4], B. Giordani[5]

[1]Michigan State University, Psychiatry, East Lansing, United States, [2]Kampala Capital City Authority, Kampala, Uganda, [3]Makerere University School of Medicine, Psychiatry, Kampala, Uganda, [4]Johns Hopkins University, Baltimore, United States, [5]University of Michigan, Psychiatry, Ann Arbor, United States

Background: The comparative prevalence rate of mild cognitive impairment (MCI) and Alzheimer's dementia (AD) in cART treated people living with HIV (PWH) and age-matched peers without HIV is unknown.

Methods: 471 adults between 20 and 87 years (277 PWH and 189 HIV-negative controls) matched by age, sex, and village of residence were evaluated with a comprehensive neuropsychological test battery in Kampala, Uganda. Impairment in seven cognitive domains including immediate recall, memory and learning (delayed recall, recognition), language (verbal fluency), processing speed, executive function, attention/working memory and motor function were defined.

Cognitive status – i.e., not cognitively impaired, asymptomatic cognitive impairment (ANI), minor neurocognitive disorder (MND) or HIV-associated dementia (i.e., HAD, if HIV+) , was defined according to Frascatti criteria and age-related cognitive dysfunction of the AD subtype was defined per Bondi et al. (2014). MCI- i.e., presence of cognitive impairments of moderate (i.e. ≥ 1 SD worse in ≥2 tests) or pronounced (i.e. >2.0 SD worse in≥1 tests) severity without functional limitation.

Amnestic MCI (aMCI) type is defined if memory - i.e., impaired recognition or delayed recall, was present. AD was defined if ≥1 pronounced memory impairment accompanied with functional limitation. Differences in MCI and AD rate according to HIV status were quantified and odds ratio (OR) with 95% confidence intervals (CI) overall and stratified by age (<60vs. ≥60 years) calculated.

Results: Among unimpaired/ANI adults, amnestic MCI rate was respectively 28.9% (60/204) and 14.7% (21/133) among PWH and HIV- controls (OR=2.18, 95% CI:1.25, 3.84). Among cognitively unimpaired/ANI affected individuals <60 years old, amnestic MCI prevalence was 16.2% for controls and 30.3% for PWH (OR=1.9, 95%CI:1.02, 3.60).

Among MND/HAD individuals ,AD rate was 16.3% and 38.6% for controls and PWH (OR=3.23, 95% CI: 1.23, 8.52), respectively. Among adults ≥60 years with ANI/no impairment (n=65), prevalent amnestic MCI was 14.7% for controls and 41.9% for PWH (OR = 4.04, 95% CI:1.23, 13.40). The prevalence of AD was identical at 38.9% each for HIV+ (n=18) and for HIV- controls (n=18) ≥60 years with MND/HAD.

Conclusions: Ugandan PWH have higher MCI/AD rates that may may occur at younger age than HIV-negative Ugandans.

EPB144

Association of age at ART initiation with CD4:CD8 ratio recovery among virally suppressed people living with HIV, 2001-2019

C. Holden[1], F. Lampe[1], S. Kinloch de Loes[2,3], F. Burns[1,3], M. Johnson[3], C. Chaloner[1], C. Smith[1]

[1]University College London, Institute for Global Health, London, United Kingdom, [2]University College Medical School, London, United Kingdom, [3]Royal Free Hospital NHS Foundation Trust, London, United Kingdom

Background: We aimed to characterize the potential for CD4:CD8 recovery by age in a virally supressed HIV-positive population on long-term antiretroviral therapy (ART). Understanding this is important in the context of an aging HIV-positive population, in which age-related diseases are an increasing health burden.

Methods: In a longitudinal study, CD4:CD8 ratio trajectory was assessed among 1859 people with HIV attending the Royal Free Hospital London, who initiated ART between 2001 and 2015, achieved viral suppression (VL<1000 c/mL) within 6 months, and maintained this subsequently.

The association of age at ART initiation with the CD4:CD8 ratio after 5 and 10 years on virally suppressive ART was examined using multivariable linear regression to adjust for: baseline CD4 count, gender, ethnicity, and probable HIV transmission route.

Results: Increases in CD4:CD8 ratio occurred over 10 years on ART for all ages, from median ratio value 0.24 at baseline to 0.88 at year 10. However, the increase was progressively less with older age (from 0.28 to 0.95 for age 20-29; from 0.24 to 0.92 for age 30-39; from 0.24 to 0.84 for age 40-49; from 0.22 to 0.80 for age 50-59; from 0.20 to 0.57 for ages 60-79). Compared to the reference group starting ART aged 30-39, after 5 and 10 years on ART CD4:CD8 ratio was substantially lower for those starting ART after age 60, even more so after age 70 (Table).

	Year after ART initiation					
	Year 5			Year 10		
	Fold difference[1,2]	95% CI	p	Fold difference[1,2]	95% CI	p
Age at ART initiation						
20-29	0.96	0.89, 1.05	0.395	0.97	0.87, 1.09	0.653
30-39 (reference)	1.00			1.00		
40-49	0.93	0.88, 0.99	0.017	0.95	0.87, 1.02	0.161
50-59	0.91	0.84, 0.99	0.024	0.95	0.85, 1.06	0.401
60-69	0.83	0.71, 0.97	0.018	0.82	0.63, 1.05	0.121
70+	0.73	0.52, 1.04	0.079	0.62	0.42, 0.93	0.021

Table: Association between age at ART initiation and CD4:CD8 ratio after 5 and 10 years of virally suppressive ART, adjusted for baseline CD4 count and demographic variables.

[1]Compared to age 30-39 (reference category)

[2]CD4:CD8 ratios were logged before analysis and subsequently exponentiated

Conclusions: Age had a substantial impact on CD4:CD8 ratio recovery for people starting ART after age 60. Results may indicate the level of CD4:CD8 recovery possible in a virally suppressed, aging HIV positive population.

EPB145

Prevalence and Associated Factors of Healthy Aging with HIV in Latin America

B. Crabtree-Ramirez[1], Y. Caro Vega[1], L. Guerrero Torres[1], V. Hernández Ruiz[2], P.F. Belaunzarán Zamudio[1], B.E. Shepherd[3], J.L. Castilho[4], P.F. Rebeiro[5], C. César[6], S.W. Cardoso[7], C. Cortes[8], M.T. Luque[9], G. Carriquiry[10], C.C. McGowan[4], J.G. Sierra Madero[1]

[1]Instituto Nacional de Ciencias Médicas y Nutrición, Salvador Zubirán, Infectología, Mexico City, Mexico, [2]Instituto Nacional de Ciencias Médicas y Nutrición, Salvador Zubirán, Geriatría, Mexico City, Mexico, [3]Vanderbilt University, Department of Biostatistics, Nashville, United States, [4]Vanderbilt University School of Medicine, Division of Infectious Diseases, Department of Medicine, Nashville, United States, [5]Vanderbilt University School of Medicine, Division of Epidemiology, Nashville, United States, [6]Fundación Huésped, Buenos Aires, Argentina, [7]Instituto Nacional de Infectologia Evandro Chagas-Fiocruz, Rio de Janeiro, Brazil, [8]Universidad de Chile- Fundación Arriarán, Santiago, Chile, [9]Instituto Hondureño de Seguro Social and Hospital Escuela Universitario, Tegucigalpa, Honduras, [10]Instituto de Medicina Tropical Alexander von Humboldt, Lima, Peru

Background: Older adults living with HIV in Latin America represent a growing and heterogeneous population, though few studies have addressed correlates of healthy aging (HA) among them

Methods: We included patients aged <50 years at enrollment (on/after January 1, 2002) who aged to ≥50 years while in care at Caribbean, Central and South America network for HIV epidemiology (CCASAnet) sites. We followed individuals from enrollment until death, first gap in care of 12 months, or study end (November 4, 2021). Patients were classified as HA annually after age 50 if they had suppressed HIV-1 viral loads (<200 copies/mL), last CD4+ count ≥350cells/µL, no prior AIDS-defining event, and <2 non-communicable diseases.

We estimated odds ratios (OR) for associations between characteristics and annual HA using a multivariable mixed logistic model, including birth sex, HIV acquisition risk, follow-up time before age 50, CD4+ count at enrollment, educational attainment, and site. We multiply imputed missing baseline data and used time-to-event analysis to estimate median times from first year of HA to loss of HA.

Results: We followed 3,782 individuals for a median of 7.2 years (interquartile range [IQR]: 3.5, 11.7) before age 50 and 8 years (IQR:5-12) after age 50; 47% were HA during their first year, 2,503 (66%) were HA at least once (median 2, IQR: 0, 4 years), and 1,120 (45%) were HA for ≥80% of follow-up. Of those with HA at least once: 72% were male, median baseline age was 43 years (IQR: 39, 47), 47% acquired HIV through heterosexual sex, and most had high educational attainment (41% Secondary, 23% University, 11% <Primary). Adjusted median time from first HA to loss of HA was 3 years (IQR: 2, 4).

Those with HA at least once were more likely to be female (OR=1.28), have higher baseline CD4+ count (OR=1.12 per 100 cells/µL), higher education (OR=1.43 for Secondary and OR=1.63 for University compared to <Primary) and shorter time in care before age 50 (OR=0.96 per year).

Conclusions: HA was prevalent in this large Latin American cohort reaching 50 years of age while in HIV care. Associated characteristics highlight groups who require tailored strategies to promote HA.

ART in acute, first- and second-line therapies

EPB146

Cost-effective continuous flow synthesis of HIV second and third generation integrase inhibitor drugs: a step towards local API manufacturing in Africa

S. Nqeketo[1]

[1]Nelson Mandela University, Chemistry, Port Elizabeth, South Africa

Background: The sub-Saharan African region, which has the highest Human Immunodeficiency Virus (HIV) prevalence in the world and has invested heavily in running its HIV programme is currently facing a catastrophic prob-

lem of production, distribution, cost and availability of antiretroviral (ARV) drugs. Exploring the recently emerged "enabling technique", namely flow chemistry in the production of APIs has gained a lot of attention.

This study evaluated the application of flow chemistry on the production of dolutegravir; a recently approved highly important and effective antiretroviral drug that has become the backbone of South Africa's HIV programme together with many other countries and cabotegravir.

Methods: Synthesis of dolutegravir and cabotegravir was achieved in a traditional batch synthetic route starting from a commercially available benzylated pyran *viaa* seven steps chemical transformation process. The same steps were followed to achieve continuous flow chemistry and the results were paralleled. Different continuous flow procedures including little things factory (LTF) microrector, packed bed reactor, Labtrix Start and uniqsis systems were explored to achieve excellent yields in short time.

Obtained products were characterized using techniques such as Nuclear Magnetic Resonance (NMR) and High-performance liquid chromatography (HPLC) for purity and yield.

Results: The study demonstrated batch synthesis of dolutegravir and cabotegravir in overall time of 70.5hours with an overall yield of 67%. The flow process took approximately 10% of the time of the traditional batch process affording desired products in improved excellent yields. The key features are a significant reduction in the time for the pyran amination step from 18 hours at room temperature in 86% isolated yield to 100% in 20minutes and1 minute at 100°C using LTF and Uniqsis flow systems respectively.

Moreover, amidation reaction resulted in 100% yield over 30seconds residence time from 33% over 4.5hours in batch method for both drugs. The uniform heat transfer, efficient and intensive mixing in flow technology systems contributed to the high yields.

Conclusions: To a great extent, efficient and cost-effective continuous flow procedure towards dolutegravir and cabotegravir was developed. The local API manufacture could be facilitated using this very efficient approach to the synthesis to effort an end of HIV epidemic.

Treatment experience of single-tablet dolutegravir/lamivudine in the United States: results from the 'real-world outcomes with dolutegravir-based two-drug-regimens for the treatment of HIV-1' (TANDEM study)

S. Schneider[1], C.M. Burke[2], D. Ward[3], P. Benson[4], C.C. Donovan[5], G. Harper[6], D. Merrill[5], A.A. Metzner[5], K. Mycock[6], J. Patarroyo[5], A. Oglesby[5]

[1]ProHealth Partners, Long Beach, United States, [2]CAN Community Health, St. Petersburg, United States, [3]Dupont Circle Physicians Group, Washington, United States, [4]Be Well Medical Center, Berkeley, United States, [5]ViiV Healthcare, Durham, United States, [6]Adelphi Real World, Bollington, United Kingdom

Background: Treatment for people living with HIV-1 (PLWH) continues to advance with a two-drug regimen (2DR) approach. Dolutegravir/lamivudine (DTG/3TC) is indicated as a 2DR for both treatment-naïve and virally suppressed PLWH. Despite sustained virologic efficacy for DTG-based 2DRs observed in clinical trials, there is limited evidence in US real-world clinical settings. The TANDEM study characterizes real- world prescribing behaviors and treatment outcomes for DTG-based 2DR.

Methods: TANDEM was a retrospective medical chart review conducted across 24 US sites. Eligible PLWH were adults initiated on DTG/3TC or DTG/rilpivirine (DTG/RPV) prior to Sept/30/2020 with a minimum clinical follow-up of six months. Treatment-naïve PLWH had no prior history of HIV therapy while stable switch (SS) PLWH were defined as having HIV-1 RNA <50 copies/mL, on a stable anti-retroviral treatment regimen for ≥3 months upon DTG-based 2DR initiation. Clinical characteristics, treatment history and outcomes were abstracted. Analyses were descriptive. Results are reported for the DTG/3TC cohort. DTG/RPV results are reported separately.

Results: From an overall sample of 469 PLWH on DTG-based 2DR, 318 received DTG/3TC. Of the DTG/3TC cohort, 126 were treatment-naïve and 192 were SS. 48.4% naïve PLWH received DTG/3TC as part of a test-and-treat paradigm. For DTG/3TC naïve and SS PLWH respectively, mean age was 37.4 and 49.1 years, 88.1% and 82.3% were male, 61.1% and 64.6% were Caucasian. By data cut-off, mean time on DTG/3TC was 1.3 and 1.5 years naïve and SS respectively. SS PLWH received an average 10.4 years prior ART, 66.1% received ≥2 prior regimens. Most common reasons for initiating DTG/3TC were avoidance of long-term toxicities in both naïve (32.5%) and SS (27.1%) cohorts.

Simplification / streamlining in SS (25.0%) and convenience in naïve PLWH (15.9%) were also common. 93.7% naïve PLWH achieved virological suppression and 83.3% remained suppressed; 95.8% SS maintained suppression receiving DTG/3TC. N=1 naïve and N=3 SS PLWH discontinued DTG/3TC by the data cut-off.

Conclusions: Results reflect data from clinical trials, demonstrating DTG/3TC is effective and well tolerated in the real-world. DTG/3TC was primarily initiated to avoid po-

tential long-term toxicities. Nearly all DTG/3TC users, whether treatment-naïve or SS, experienced sustained virologic suppression with few treatment discontinuations.

EPB148

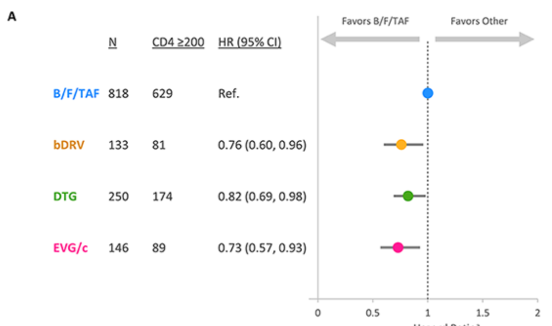
Advanced HIV infection in the US: immune response to ART initiation

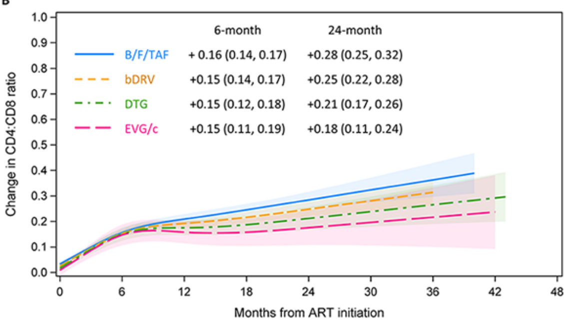
K. Mounzer[1], L. Brunet[2], J. Fusco[2], I. McNicholl[3], M. Dunbar[3], M. Sension[4], L. McCurdy[5], G. Fusco[2]

[1]University of Pennsylvania, School of Medicine, Philadelphia, United States, [2]Epividian, Durham, United States, [3]Gilead Sciences, Inc, Foster City, United States, [4]CAN Community Health, Sarasota, United States, [5]Atrium Health, Charlotte, United States

Background: Up to 20% of individuals newly diagnosed with HIV in the US have advanced HIV infection (CD4<200 cells/µL). We compared the absolute CD4 cell count and CD4:CD8 ratio recovery among people with advanced HIV after common antiretroviral therapy (ART) regimens initiation in 2018-2020.

Methods: In the OPERA cohort, all ART-naïve, adults with advanced HIV (CD4<200 cells/µL) initiating bictegravir/emtricitabine/tenofovir alafenamide (B/F/TAF) or a boosted darunavir (bDRV)-, dolutegravir (DTG)- or elvitegravir/cobicistat (EVG/c)-based three-drug regimen were selected. A Cox proportional hazard model was used to assess time to CD4 cell count ≥200 cells/µL. A linear mixed model was used to assess changes in CD4:CD8 ratio from baseline. Inverse probability weighting was employed to control for confounding (Figure).





[a] Cox proportional hazards model, inverse probability of treatment weights (baseline age, CD4 cell count, log10 viral load, eGFR, sex, Black race, ADAP/Ryan White, AIDS history, any comorbidities)
[b] Predicted values from linear mixed model, restricted cubic splines on time (knots: 2, 6, 12, 24), inverse probability of treatment weights; reference: male, 40 years old, non-Black, no comorbidity, no AIDs history, no ADAP/Ryan White coverage, baseline CD4 cell count: 86 cells/µL, log10 viral load: 5, baseline CD4:CD8 ratio measured on index day

Figure. Association between regimen and (A) reaching a CD4 cell count ≥200 cells/µ³, or (B) changes in CD4:CD8 ratio from index[b]

Results: Of 1349 individuals included, those initiating B/F/TAF were least likely to have a history of AIDS-defining illness, any comorbidity or ADAP/Ryan White coverage (Table). Compared to those initiating B/F/TAF, a statistically lower likelihood of achieving a CD4 cell count ≥200 cells/µL was observed (HR; 95% CI) with bDRV (0.76; 0.60-0.96), DTG (0.82; 0.69-0.98) and EVG/c (0.73; 0.57-0.93; Figure A).

All groups presented a similar pattern of CD4:CD8 ratio changes: a rapid increase in the first 6 months, followed by a slower increase thereafter (Figure B). Overall, only 40 individuals (4%) achieved CD4:CD8 ratio normalization (≥1).

	B/F/TAF N=816	bDRV N=134	DTG N=253	EVG/c N=146
Age, median years (IQR)	36 (29, 46)	34 (27, 46)	37 (28, 47)	36 (28, 44)
Female, n (%)	156 (19)	29 (22)	43 (17)	29 (20)
Black Race, n (%)	505 (62)	84 (63)	167 (66)	98 (67)

Background: CD4/CD8 ratio is a surrogate marker of immune dysfunction. Low ratios in people living with HIV (PWH) on antiretroviral therapy (ART) are associated with non-AIDS defining illness and mortality.

We evaluated trends in CD4/CD8 ratio among PWH starting ART with first line integrase strand transfer inhibitors (INSTI) compared to non-INSTI-based ART, and the incidence of CD4/CD8 ratio normalization.

Methods: All participants enrolled in adult HIV cohorts of IeDEA Asia-Pacific who started with triple-ART with at least one CD4/CD8 ratio and one HIV-1 RNA measurement post-ART were included. Baseline was defined as 6 months pre-ART. CD4/CD8 ratio normalization was defined as the ratio ≥1. Longitudinal changes in CD4/CD8 ratio were analyzed by linear mixed model, and the incidence of the normalization was analyzed using Cox regression.

Results: Of a total of 38,785 PWH, 36,353 (94%) started with ≥3 antiretroviral drugs. Among these, 5529 (15%) had CD4 and CD8 measurements at baseline and at least one time after ART initiation and were included in the analysis. Their median age was 35 years (interquartile range [IQR], 29-43) and 80% were male; 65%, 19% and 16% started with non-nucleoside reverse transcriptase inhibitor (NNRTI), protease inhibitor (PI) and INSTI, respectively.

The overall baseline CD4/CD8 ratio was 0.19 (IQR, 0.09-0.33). In an adjusted linear mixed model, PWH starting with NNRTI- (p=0.005) or PI-based ART (p=0.030) had reduced CD4/CD8 recovery over 5 years of ART, compared to INSTI-based ART. During 24,304 person-years of follow-up (PYS), 32% PWH had CD4/CD8 ratio normalization.

After 5 years of ART, the probability of normalization for NNRTI, PI and INSTI was 23% (95%CI 21-24), 30% (95%CI 26-33) and 40% (95%CI 35-46), respectively. Using Cox regression, PWH who started with NNRTI- (adjusted hazard ratio, 0.63 95%CI 0.52-0.79, p<0.001) or PI-based ART (0.76 95%CI 0.61-0.95, p=0.015), compared to INSTI-based ART, had significantly lower risk of achieving CD4/CD8 ratio normalization.

Conclusions: Our study confirms that INSTI use is associated with higher rates of CD4/CD8 ratio recovery and normalization. These data support the importance and benefits of more rapidly scaling up INSTI-based ART in the Asia-Pacific region.

[1]Brigham and Women's Hospital, Boston, United States, [2]Hospital Universitario La Paz, Madrid, Spain, [3]Queen Mary University of London, London, United Kingdom, [4]San Raffaele Hospital Milan, Milan, Italy, [5]Chelsea and Westminster Hospital, London, United Kingdom, [6]Orlando Immunology Center, Orlandon, United States, [7]Azienda Ospedaliera Papa Giovanni XXIII, Bergamo, Italy, [8]ICH Study Center, Hamburg, Germany, [9]Hôpital Bichat Claude Bernard, Paris, France, [10]Gilead Sciences, Foster City, United States, [11]UNC School of Medicine, Chapel Hill, United States

Background: Bictegravir/emtricitabine/tenofovir alafenamide (B/F/TAF) is a guideline-recommended single-tablet regimen for people with HIV-1 (PWH). Week (W) 48 primary and W96 and W144 secondary endpoint results of the blinded phase from two studies established non-inferiority of B/F/TAF to dolutegravir/abacavir/lamivudine (DTG/ABC/3TC) and DTG+F/TAF in treatment-naïve PWH. We present pooled outcomes from a 96W open-label extension (OLE) in participants initially randomized to B/F/TAF for a total follow up of W240.

Methods: We conducted two randomized, double-blind, phase 3 studies in treatment-naïve adult PWH: Study-1489 (B/F/TAF vs DTG/ABC/3TC) and Study-1490 (B/F/

TAF vs DTG+F/TAF). Unblinding occurred after all participants completed W144, after which all were offered B/F/TAF in OLE. Participants originally randomized to B/F/TAF who entered OLE were pooled into B/F/TAF group. An analysis at W240 assessed efficacy as proportion with HIV-1 RNA <50 c/mL using missing=excluded (M=E) and missing=failure analyses; safety assessed adverse events (AEs) and laboratory results.

Results: 634 participants originally randomized/treated with B/F/TAF (506 [80%] treated in OLE), 89% men, 33% Black, median age 32 years (range 18-71). W240 98.6% (426/432) of B/F/TAF participants maintained HIV-1 RNA <50 c/mL (M=E) with a mean CD4 increase of +338 cells/ml from baseline. No B/F/TAF participant in the final resistance analysis developed virologic resistance.

Among B/F/TAF group through W240, 28% (178/634) experienced a study drug-related AE, 1% (9/634) were Grade 3 or 4. AEs led to drug discontinuation in <1.6% (n=10/634) of participants. There were no discontinuations due to renal AEs. Lipid changes were similar at W240 to W192, with minimal change in TC:HDL. Median weight change (IQR) from baseline to W240 was +6.1kg (2.0, 11.7), +3kg (0.3, 5.8) occurring during year one.

	Pooled B/F/TAF (N= 634 originally randomized to B/F/TAF, N=506 entered the OLE)*				
	Week 48	Week 96	Week 144	Week 192	Week 240
HIV-1 RNA <50 c/mL Missing = Excluded – Pooled Data, n/N (%)	585/589 (99.3)	554/557 (99.5)	528/531 (99.4)	476/480 (99.2)	426/432 (98.6)
HIV-1 RNA <50 c/mL Missing = Failure[ǂ] – Pooled Data, n/N (%)	585/634 (92.3)	554/634 (87.4)	528/634 (83.3)	476/634 (75.1)	426/634 (67.2)
Change from baseline in CD4 cell count cells/mm³, mean (SD)	208 (178), n=584	263 (207), n=546	288 (231), n=517	317 (246), n=475	338 (236.2) n=415
eGFR [Cockcroft-Gault], change, mL/min, median (Q1, Q3)	-8.8 (-18.4, 0.3)	-7.5 (-16.6, 2.9)	-5.8 (-16, 3.4)	-8 (-19.3, 2.8)	-8.4 (-19.4, 2.6)
Fasting lipids change, mg/dL, median (Q1, Q3)					
Total cholesterol	12 (-3, 30)	16 (0, 35)	13 (-8, 32)	19 (3, 38)	21 (1, 42)
LDL cholesterol	8 (-5, 22)	18 (3, 35)	20 (2, 40)	22 (6, 39)	19 (2, 40)
HDL cholesterol	5 (-1, 11)	4 (-1, 10)	4 (-2, 10)	6 (0, 12)	4 (-2, 11)
Total:HDL cholesterol ratio	-0.1 (0.5, 0.3)	0 (-0.5, 0.5)	0 (-0.6, 0.4)	0 (-0.6, 0.4)	0.1 (-0.5, 0.6)
Triglycerides	6 (-21, 32)	7 (-17, 39)	5 (-23, 37)	8 (-21, 37)	10 (-16, 46)
Body weight change from baseline, kg, median (Q1, Q3)	(n=588)	(n=557)	(n= 533)	(n= 485)	(n=431)
	3 (0.3, 5.8)	3.5 (0, 8.2)	4.2 (0.5, 8.9)	4.9 (1.3, 9.9)	6.1 (2.0, 11.7)

*Includes only participants that were initially randomized and treated with B/F/TAF

ǂof 634, 115 prematurely discontinued study-drug during randomized phase, 13 did not enter OLE, 62 prematurely discontinued study drug during OLE (LTFU 28, participant decision 22, AE 4, investigator's discretion 3, non-compliance w/study-drug 2, death 1, lack of efficacy 1, protocol violation 1)

Table. Changes from baseline to Week 240

Conclusions: Through 5-years of follow-up, B/F/TAF maintained high rates of virologic suppression with no treatment-emergent resistance and rare drug discontinuations due to AEs. These results demonstrate the durability and safety of B/F/TAF in PWH.

EPB151

A pilot study of the impact of a rapid ART initiation in advanced HIV disease

M. Camici[1], R. Gagliardini[1], S. Lanini[1], S. Ottou[1], A. Mondi[1], M.M. Plazzi[1], C. Pinnetti[1], A. Vergori[1], E. Grilli[1], F. De Zottis[1], I. Mastrorosa[1], V. Mazzotta[1], J. Paulicelli[1], R. Bellagamba[1], S. Cicalini[1], A. Antinori[1]

[1]*INMI L. Spallanzani IRCCS, Viral Immudodeficiency, Rome, Italy*

Background: Rapid ART initiation is important in patients with advanced HIV disease because of their high morbidity and mortality.

Methods: Pilot, single-center, single-arm, prospective, phase IV, clinical trial conducted in a tertiary care Italian hospital from 1.05.2020 to 31.12.2021. 30 ART-naïve participants, presenting at HIV-1 diagnosis with advanced disease described as the presence of an AIDS-defining condition and/or CD4 cell count <200 cells/µL, were enrolled.

Exclusion criteria were: CrCl <30 mL/min, severe hepatic impairment, active tuberculosis (TB), cryptococcosis, pregnancy or breastfeeding and systemic cancer chemotherapy. Bictegravir/emtricitabine/tenofovir alafenamide (B/F/TAF) 50/200/25 mg was started within 7 days of HIV diagnosis.

The primary endpoint was time-to-clinical or virologic failure (VF) (ITT analysis). Safety and feasibility were also assessed.

Results: 30 patients were enrolled: 16% female, 90% white, median age 45yrs (38-58), 43% presented with CDC stage C disease, CD4 cell count was 90 cells/µL (39-147), HIV RNA log10 cp /ml 6.0 (5.4-6.4), 40% of patients had ≥ 1 comorbidity. Proportion with HIV RNA <50 cp/mL increased from 9/30 (30%) at w4 to 27/30 (90%) at w48. No viral rebound was observed. Proportion with CD4 >200 cells/µL increased form 2/30 (7%) at BL to 24/30 (80%) al w 48. CD4/CD8 improved, while the eGFR decreased slightly (Figure 1).

There were no ART discontinuations due to toxicity or VF. 3 participants had 6 SAEs (4 unrelated; 2 potentially related to B/F/TAF): 1 seizure (w4 and w12) + PML with IRIS (w5) + 2 *Pneumocystis*pneumonia with IRIS (w4) + pneumomediastinum (w5); 3 clinical worsening (w1) + acute appendicitis and disseminated TB with IRIS (w2) that required ART switch. There were no ART modifications based on review of baseline genotype (no NRTI mutations, 3 accessory INSTI mutations [E157Q, G163K, L74I]).

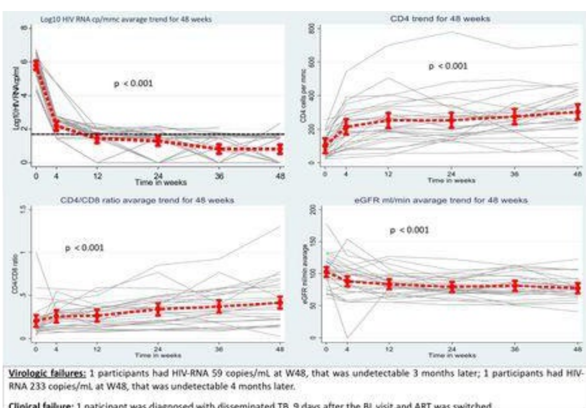

Figure 1. Viral decay, immunological results and eGFR average trend for 48 weeks.

Conclusions: Our results support the efficacy, safety and feasibility of a rapid start strategy with B/F/TAF in patients with advanced HIV.

EPB152

Country of birth influences INSTI prescription in treatment-naive patients living with HIV in France

R. Palich[1], M. Hentzien[2], L. Hocqueloux[3], C. Duvivier[4], C. Allavena[5], T. Huleux[6], P. Delobel[7], A. Makinson[8], D. Rey[9], L. Cuzin[10], Dat'AIDS Study Group

[1]Pitié Salpètrière Hospital, Paris, France, [2]University Hospital, Reims, France, [3]University Hospital, Orléans, France, [4]Pasteur Institut, Paris, France, [5]University Hospital, Nantes, France, [6]Regional Hospital, Tourcoing, France, [7]University Hospital, Toulouse, France, [8]University Hospital, Montpellier, France, [9]University Hospital, Strasbourg, France, [10]Martinique University Hospital, Infectious Diseases, Fort de France, Martinique

Background: INSTI-based regimens are recommended in France for treatment-naive patients living with HIV. However, NNRTIs and boosted PIs remain alternative choices. We aimed to describe factors associated with the use of these possible regimens in ART-naive patients in France.

Methods: From the Dat'AIDS prospectively collected database, we selected all adults having an HIV-RNA ≥400 copies/mL who started their first ART between 01/01/2014 (INSTI availability) and 12/31/2020. Uni- and multivariable logistic regressions were used to analyze patients' characteristics driving to an INSTI-based first prescribed regimen.

Results: We analyzed data from 9094 patients, 44.7% MSM, 27% women and 26.8% heterosexual men ; 48% born abroad ; 4.7% and 2.8% with concomitant hepatitis B and tuberculosis, respectively. INSTIs were prescribed as first line in 49.9%, increasingly over the years – from 21.6% in 2014 to 74.7% in 2020. Characteristics related with the choice of an alternative regimen appear in the Table.

Patients born in France were more likely to receive an INSTI-based regimen than patients born abroad (OR 1.85, 95%CI 1.68-2.04)

Logistic regression		Univariate		Multivariate	
		OR	95%CI	OR	95%CI
Age at HIV diagnosis		1.01	1.00-1.01	1.01	1.00-1.02
Gender and sex	Women	Ref		*	
	Men having sex with men	1.98	1.78-2.20		
	Men having sex with women	1.48	1.32-1.66		
Born in France		1.64	1.50-1.78	1.85	1.68-2.04
Year of prescription	2014	Ref		Ref	
	2015	2.34	1.98-2.77	2.49	2.10-2.96
	2016	2.93	2.48-3.47	3.06	2.58-3.63
	2017	4.84	4.09-5.73	4.98	4.19-5.92
	2018	4.80	4.04-5.71	5.17	4.33-6.17
	2019	8.59	7.18-10.3	9.30	7.75-11.20
	2020	15.1	12.1-18.9	12.2	9.87-15.10
HIV-RNA (for 1 Log)		1.20	1.15-1.26	1.14	1.09-1.21
Concomitant hepatitis B		0.72	0.59-0.88	0.78	0.63-0.98
Concomitant tuberculosis		3.11	2.26-4.28	3.47	2.58-4.67
CD4 cell count at initiation	<200	Ref		Ref	
	200-350	1.07	0.95-1.21	1.25	0.14-1.50
	350-500	1.11	0.98-1.21	1.29	1.13-1.48
	>500	1.12	0.99-1.25	1.31	1.14-1.50
CDC stage C		1.08	0.95-1.22	-	-

*: Because of collinearity, place of birth and gender could not be analyzed in the same multivariate model, thus we chose to keep place of birth.

Table.

Conclusions: Despite unrestricted access to INSTIs in France, independently from HIV disease parameters, patients born abroad less frequently received INSTIs as a first regimen. Qualitative data are needed to better understand physicians' prescribing practices.

EPB153

Starting antiretroviral therapy (ART) at the first HIV-specialist appointment with or without baseline laboratory data with BIC/FTC/TAF (The BIFAST study)

A.W.M. Al-Hayani[1], I. Carrillo[1], A. Cabello[1], C. Algar[1], L. Prieto-Pérez[1], B. Álvarez[1], R. Téllez[2], Á.L. Castaño[2], J. Sanchez[3], G. Fuensalida[1], M. Bonilla[4], I. Burillo[1], M. Muñoz[1], M. Verano[3], M. Górgolas[1]

Background: Starting ART as soon as possible, even without baseline laboratory data, is highly recommended in undeveloped settings, however its implementation in developed countries is controversial.We sought to evaluate the safety of this strategy in a referral HIV clinic in downtown Madrid.

Methods: Phase IV, open-label, non-randomized, single-centre clinical trial. Patients referred to the HIV-clinic were offered same day ART with BIC/FTC/TAF whether or not having baseline laboratory data (Group 1, without lab data (WOLD); group 2 with lab data (WLD). Results of VL, CD4 and PRO at week 24 are shown here.

(bDRT). Efficacy at week-24 in the ITT-E and PP analysis were 80% (16/20) (CI95%: 62.5-97.5%) in WOLD vs 87.2% (34/39) (CI95%: 76.7-97.7%)in WLD, and 88.9% (16/18) (CI95%: 74.4-100%) vs 94.4% (34/36) (CI95%: 87-100%) respectively.
Four patients (6.8%) were lost to follow-up (2 in each arm); one patient discontinued treatment because a suspected TB infection and four patients presented > 50 cop/mL at week 24 (90, 68, 53, 53 cop/mL, respectively).
The mean time to achieve VL <50 cop/ml was 14.5 weeks (±11.4 weeks) in WOLD vs 61.3 weeks (±169 weeks) in WLD from HIV diagnosis. An improvement in subjects' self-perception (decrease of anxiety/depression symptoms and increase in happiness and optimistic perception about the future) was observed in PRO in both groups.
Conclusions: Starting ART at the first HIV-specialist appointment with BIC/FTC/TAF, with or without laboratory data, is a safe strategy and diminishes patient anxiety within the first weeks of treatment.

ART in highly treatment-experienced persons

Doravirine associated resistance mutations in antiretroviral therapy naïve and experienced HIV-1C infected people in Botswana

O. Bareng[1,2], S. Seselamarumo[1,3], K.K. Seatla[4,2], W.T. Choga[1,5], B. Bakae[1], D. Maruapula[1,3], N. Kelentse[2], N.O. Moraka[1,6], B. Mokaleng[1,2], R. Shapiro[1,7], T. Gaolathe[1], J. Makhema[1,7], S. Lockman[1,7,8], M. Essex[1,7], V. Novitsky[1,7], S. Mpoloka[3], S. Moyo[1,7], S. Gaseitsiwe[1,7]
[1]Botswana Harvard AIDS Institute Partnership, Research Lab, Gaborone, Botswana, [2]University of Botswana, Medical Sciences, Gaborone, Botswana, [3]University of Botswaana, Biological Science, Gaborone, Botswana, [4]Botswana Harvard Aids Institute Partnership, Research Lab, Gaborone, Botswana, [5]University of Cape Town, Department of Pathology, Cape Town, South Africa, [6]Stellenbosch University, Division of Medical Virology, Cape Town, South Africa, [7]Harvard T. H Chan School of Public Health, Immunology and Infectious Diseases, Boston, Massachusetts, United States, [8]Brigham and Women's Hospital, Boston, Massachusetts, United States

Objectives: Doravirine (DOR), a non-nucleoside reverse transcriptase inhibitor (NNRTI), has an opportunity for use as part of first-line antiretroviral therapy (ART) regimen or salvage ART regimen for individuals with HIV multidrug resistance mutations.
However, there is limited data on the prevalence of DOR-associated resistance mutations in people with HIV (PWH) in Botswana. We determined the prevalence of DOR-associated resistance mutations among ART-naïve and ART-experienced PWH with virologic failure on efavirenz- or nevirapine-based ART in Botswana.
Methods: HIV-1C Pol sequences from 6078 PWH in Botswana were analyzed for DOR-associated resistance mutations. Virologic failure was defined, as HIV-1 RNA load (VL) >400 copies/mL. DOR-associated resistance mutations were identified and their levels were predicted according to the Stanford HIV database "DRM penalty scores and resistance interpretation". Proportions were estimated with 95% confidence intervals (CI) and compared among groups.
Results: Among 6078 available HIV-1C sequences, 99% (5999) had known ART status and 79% (4738/5999) were on ART while 21.0% (1261/5999) were ART naive at study entry. The suppression rate among ART-experienced was 95% (4517/4738).
The overall prevalence of any DOR-associated resistance mutations was 4.3% (64/1473); by ART status: 11.3% (24/212) among ART failing and 3.2% (40/1261) among ART-naïve individuals. The prevalence of intermediate DOR-associated resistance mutations was 0.6% (95% CI: 0.2-11.4) in ART-naïve individuals and 4.7% (95% CI: 2.3-8.5) among ART failing individuals. The prevalence of high level DOR-associated resistance mutations was 2.6% (95% CI: 1.8-3.7) among ART-naïve and 6.6% (95% CI: 3.7-10.8) among ART-failing PWH (Figure 1). PWH failing ART with efavirenz or nevirapine-associated resistance mutations had higher prevalence (28.9%:22/76) of DOR-associated resistance mutations.

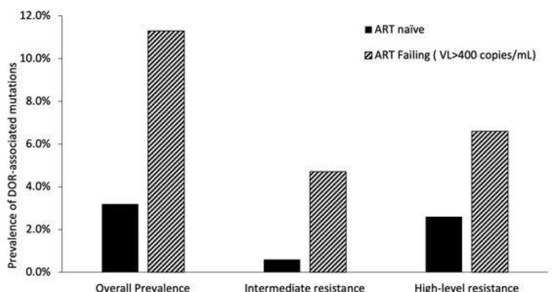

Figure 1. The overall prevalence, intermediate and high-level resistance of DOR-associated mutations by ART groups.
***Statistically higher among ART failing individuals (all p-value >0.01)*

Conclusions: Prevalence of DOR-associated resistance mutations was low among ART-naïve individuals, but DOR-associated mutations were found in >20% of individuals failing NNRTI-based ART with at-least one efavirenz or nevirapine-associated resistance mutations in Botswana. The use of DOR among first-generation NNRTI-experienced PWH should be based on HIV drug resistance testing.

EPB155

The presence of minority HIV Drug resistance variants in the protease and Gag regions confers poor response to therapy among subtype A and D patients

I. Nankya[1], E. Nabulime[1], F. Kyeyune[1], C. Kityo[2], M. Quinones[3,4]
[1]*Joint Clinical Research Centre, Molecular Biology, Kampala, Uganda,* [2]*Joint Clinical Research Centre, Kampala, Uganda,* [3]*University of Otago, Dunedin, New Zealand,* [4]*Case Western Reserve University, Molecular Biology, Cleveland, United States*

Background: The extensive use of antiretroviral therapy has favored the emergence of novel patterns of mutations conferring drug resistance. Most of these mutations are found in genes targeted by the drugs and are detectable using the conventional Sanger sequencing technology which has a 20% limit of detection. The more sensitive sequencing approaches currently being employed are not readily available in the developing countries.
Methods: Samples were obtained from patients failing on a protease inhibitor (PI) based regimen (n = 500). Sanger based sequencing was performed as part of the standard of care.
Mutation analysis was performed using the Stanford HIV drug Resistance (HIV DR) database. A subset of these samples was grouped into two: those failing a PI based with mutations in the protease region (n = 100) and those failing without mutations in the protease region (n = 128).
These samples were analyzed in the protease and Gag regions using Next Generation Sequencing (NGS) technology and analysis of the drug resistance mutations was performed at the 20% and 1% cutoffs.
Results: An initial analysis revealed that most patients harbored mutations that confer resistance to Lopinavir and Atazanavir, but these mutations had little effect on Darunavir. NGS revealed that in patients failing with or without drug resistance mutations, minority drug resistance mutations were present at each of the codons even those that confer multi-drug resistance to PIs.
Further analysis of the Gag gene revealed more genetic diversity among patients failing with no mutations in the protease.
Conclusions: Patients who fail a PI regimen with a susceptible genotype based on Sanger sequencing harbor minority variants in the protease region and numerous polymorphisms in the Gag region which when combined could explain their poor response to therapy. Therefore, in order to improve patient care in low resource settings, there is need to adapt NGS as the standard genotyping technique.
In addition, since mutations in the Gag also play a role in response to PIs, this region should be included in the routine monitoring for response to therapy in patients on a PI based regimen.

EPB156

How clinical trials of combination antiretroviral therapy for adults with HIV capture health-related quality of life with patient-reported measures: a systematic review

A. Normandin[1], D. Ortiz-Paredes[2], K. Engler[2], E. Houlding[2], K. Mate[2,3,4,5], D. Lessard[2], N. Kronfli[4], J. Cox[4,6], B. Lebouché[2,3,4,7]
[1]*University of Toronto, Department of Family and Community Medicine, Toronto, Canada,* [2]*Research Institute of the McGill University Health Centre, Centre for Outcomes Research & Evaluation, Montreal, Canada,* [3]*McGill University, Department of Family Medicine, Montreal, Canada,* [4]*McGill University Health Centre, Division of Infectious Diseases/Chronic Viral Illness Service, Montreal, Canada,* [5]*Cleveland Clinic, Health Outcomes and Research, Centre for Neurological Restoration, Cleveland, United States,* [6]*McGill University, Department of Epidemiology, Biostatistics and Occupational Health, Montreal, Canada,* [7]*Canadian Institutes of Health Research Strategy for Patient-Oriented Research (CIHR/SPOR) Mentorship Chair in Innovative Clinical Trials in HIV, Montreal, Canada*

Background: Beyond biochemical treatment goals (e.g., HIV viral load, CD4 cell count), health-related quality of life (HRQoL) is used as an indicator of combination antiretroviral therapy (cART) performance. In cART trials, HRQoL is assessed using patient-reported outcome measures (PROMs). The purpose of this review was to describe the scope of HRQoL assessment among cART clinical trials.
Methods: PubMed, Embase, PsycInfo, and CINAHL were searched for cART clinical trials published between 2015 and 2020 that reported PROM data on HRQoL. To understand the scope of HRQoL representation, PROMs were mapped to the Wilson and Cleary domains of symptom status, functional status, general health perceptions, and overall quality of life (QOL). Qualitative content analysis of PROM items was conducted to identify subdomains.
Results: Of 3602 identified records, 35 trials were included. All 35 assessed two or more domains and most (n=26; 74%) assessed at least 3. All studies measured functional status, while 32 (91%) assessed general health perceptions, 26 (74%) overall QOL, and 17 (49%) symptom status. A total of 26 PROMs were used in the included studies. Trials reported on average 2.2 PROMs (range 1–5), with most (n=22; 63%) combining two or more PROMs.
The HIV Treatment Satisfaction Questionnaire (n=17) and the Short-Form Health Survey (n=11) were the most frequently used HIV-specific and generic PROMs, respectively; both of which assess various domains. Half of PROMs assessed the domain of symptom status, with physical symptoms (n=18) being the most frequent subdomain.
Functional status was assessed by 16 PROMs, and work productivity (n=9) was the most common measured subdomain. General health perceptions were assessed by 9 PROMs, with perceived health status (n=6) being the most frequent subdomain.

Nine PROMs assessed overall QOL, and the perceived value of life (n=5) and enjoyment of life (n=5) were the most frequent measured subdomains (n=5).

Conclusions: HRQoL assessment in cART clinical trials particularly focus on functional status and general health perceptions. HRQoL was measured broadly, which was accomplished by combining PROMs and prioritizing comprehensive PROMs. Our findings not only detail a portrait of HRQoL assessment in HIV trials but help inform PROM selection in future research.

EPB157

Comparison of virologic suppression rates among first- and second-line antiretroviral therapy patients at an urban clinic in Zimbabwe: a cohort study

T. Shamu[1,2,3], C. Chimbetete[1], T. Mudzviti[1,4], J. Manasa[5], M. Egger[2,6,7], N. Anderegg[2]

[1]Newlands Clinic, Harare, Zimbabwe, [2]University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland, [3]University of Bern, Graduate School of Health Sciences, Bern, Switzerland, [4]University of Zimbabwe, Department of Pharmacy and Pharmaceutical Sciences, Harare, Zimbabwe, [5]University of Zimbabwe, Innovation Hub, Harare, Zimbabwe, [6]University of Cape Town, Centre for Infectious Disease Epidemiology and Research, School of Public Health and Family Medicine, Cape Town, South Africa, [7]University of Bristol, Population Health Sciences, Bristol Medical School, Bristol, United Kingdom

Background: The most common reason for virologic failure (VF) on antiretroviral therapy (ART) is suboptimal adherence. We compared virologic suppression (VS) rates among people living with HIV (PLWH) receiving efavirenz (EFV) based first-line ART and those with VF history receiving atazanavir (ATV/r) or dolutegravir (DTG) based second-line ART.

Methods: We abstracted routinely collected patient records from the electronic medical records of Newlands Clinic in Harare, Zimbabwe. We defined baseline as time of commencing ART for first-line and switch for second-line patients.

We included patients aged ≥12 years at baseline with at ≥24 weeks duration on the respective ART regimen. We computed VS rates (viral load <50 copies/mL) at weeks 12, 24, and 48 post-baseline.

Restricted to second-line patients, we estimated the odds and probability of VS at week 48 by ART regimen, sex, age, and CD4 count using logistic regression models.

Results: Among 1445 (60% female) patients initiating first-line ART and 1050 (58% female) patients switching to second-line ART, median (interquartile range [IQR]) age was 37 years (29–44) and 29.5 years (19–42), respectively.

Among the second-line patients, 835 (79.5%) received ATV/r-based ART while 215 (20.5%) received DTG-containing ART. Except at week 12, VS rates were lower in second-line compared to first-line patients.

Among second-line patients, switching to DTG-containing ART was associated with a 1.6-fold increase in the odds of VS at week 48 compared to ATV/r. The odds of VS also increased with female sex, baseline CD4 counts >500 cells/mm^2, and older ages; with age being the most important predictor of VS (Figure).

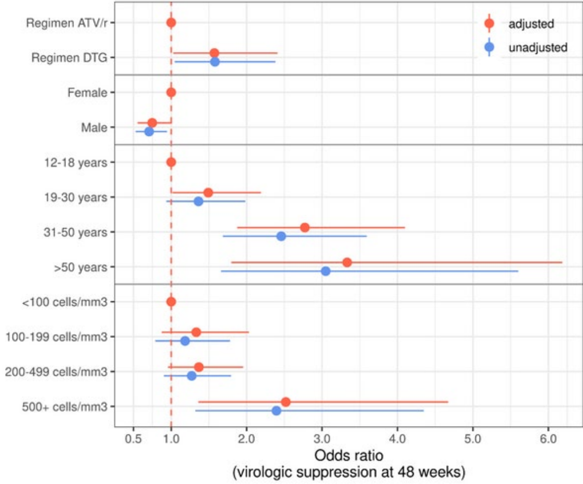

Figure.

Conclusions: PLWH with history of VF are still less likely to achieve virologic suppression after switching to second-line ART. We recommend close monitoring and adherence support among this population after switching, particularly among young PLWH with history of VF, even in the DTG era.

EPB158

Low level of virologic failure and resistance in ART-experienced, integrase inhibitor-naïve participants receiving dolutegravir (DTG) and Nucleoside Reverse Transcriptase Inhibitors (NRTIs) combined regimens: 10-year follow-up in the SAILING Study

R. Wang[1], J. Horton[2], N. Gebremedhin[2], A. Joshi[3], B. Wynne[1], S. Griffith[1], M. Underwood[1]

[1]ViiV Healthcare, Research Triangle Park, United States, [2]PAREXEL International, Durham, United States, [3]GlaxoSmithKline, Bangalore, India

Background: DTG demonstrated superiority to RAL in the SAILING study at Week 48 (WK48) in treatment-experienced, integrase inhibitor-naïve patients with HIV-1 who harbored resistance to ≥2 antiretroviral drug classes. A previous ad hoc analysis of SAILING reported no protocol-defined virologic failure (PDVF) through WK48 in participants receiving DTG with only NRTIs as background regimen (BR) that was suboptimal due to baseline NRTI resistance. This 10-year follow-up assesses virologic outcomes and viral resistance in this subpopulation receiving DTG plus dual NRTIs through the end of study (EOS).

Methods: 29 DTG participants receiving only NRTIs as BR throughout the study were analyzed. Virologic outcomes were determined by last available on-treatment HIV-1

RNA (VL) through the EOS (up to WK480). Genotyping and phenotyping were performed on baseline and PDVF timepoint samples by Monogram Biosciences.

Results: The virologic response rate for DTG participants receiving only NRTIs through EOS was 79% (23/29). With 28 of them entering continuation phase, the viral suppression rate (VL<50 c/mL) remained high (82%, 23/28).

PDVF occurred in 3 participants with BR consisting of 2 fully active NRTIs, and treatment-emergent IN substitutions were detected in 2: one had R263K and S230R at WK120; the 2nd had N155H and S230S/R at WK208. Both demonstrated low fold change (FC<4) to DTG.

None of them developed treatment-emergent NRTI resistance to BR. High virologic response rate (80%, 8/10) and low PDVF (1) was also observed in 10 DTG participants with baseline M184V who received NRTI-only BR containing either 3TC or FTC along with a 2nd NRTI.

Participant characteristics	VL <50 c/mL	VL ≥50 c/mL	PDVF[a] occurrence	Resistance incidence
Received only NRTIs as BR (n=29[b])	23/29 (79%)	6/29 (21%)	3/29 (10%)	2/29 (7%)
2 fully active[c] (by PSSf)	14/23 (61%)	4/6 (67%)	3/3 (100%)	2/2 (100%)
1 fully active	8/23 (35%)	1/6 (17%)	0	0
Missing phenotypes	1/23 (4%)	1/6 (17%)	0	0
Baseline M184V/I receiving 3TC or FTC plus a 2nd NRTI (n=10)	8/10 (80%)	2/10 (20%)	1/10 (10%)	1/10 (10%)
M184V/I alone	4/8 (50%)	2/2 (100%)	1/1(100%)	1/1 (100%)
M184V/I + >1 NRTI RAMs[d]	4/8 (50%)	0	0	0

[a]Protocol-defined virologic failure (PDVF): non-response was VL decrease <1 log_{10} c/mL, unless <400 c/mL by Week 16 or VL ≥400 c/mL on or after Week 24; virologic rebound was VL ≥400 c/mL after confirmed VL <400 c/mL or >1 log_{10} c/mL increase above any nadir of ≥400 c/mL. [b]Total of 32 participants were identified in this subpopulation, but 3 didn't have on-treatment VL for virologic outcome assessment so they were excluded from this analysis. [c]Fully active based on phenotype as per Monogram Bioscience's PhenoSense assay (using lower cutoff if upper and lower exist). [d]RAM = resistance-associated mutation.

Table 1. Cumulative Virologic Response and PDVF Through 10-Year Follow-up in DTG Participants Receiving a Background Regimen of NRTIs Only.

Conclusions: Although this analysis was on a selected small subgroup, the low rate of virologic failure, PDVF, and viral resistance observed through extended 10-year follow-up continuously support the higher resistance barrier of DTG, and that DTG+NRTIs regimen is durable and effective treatment for treatment-experienced patients harboring ART-resistant HIV-1.

EPB159

Safety and efficacy of switching to BIC/FTC/TAF plus DOR in HIV-infected patients with multiclass-resistant virus

F.L. Sterman[1,2], J. Lalezari[1], U. Kowalczyk[1], D. Main[3], E. Grant[3], L. Caro[4]

[1]*Quest Clinical Research, San Francisco, United States,* [2]*Gilead Sciences, Inc, Foster City, United States,* [3]*DP Clinical, Inc, Rockville, United States,* [4]*Merck & Co, Inc, Kenilworth, United States*

Background: Patients with a history of antiretroviral resistance often require a multi-tablet regimen to achieve virologic control, increasing the risk for adverse events (AEs) and drug-drug interactions (DDIs). With approval of the single-tablet regimen bictegravir/emtricitabine/tenofovir alafenamide (BIC/FTC/TAF) and the nonnucleoside reverse transcriptase inhibitor (NNRTI) doravirine (DOR), switching patients with multiclass-resistant virus to BIC/FTC/TAF plus DOR may be beneficial as both BIC/FTC/TAF and DOR have a high barrier to resistance, no food restrictions, and low potential for DDIs and AEs.

This study evaluated the safety and efficacy of switching from rilpivirine/emtricitabine/tenofovir alafenamide (RPV/FTC/TAF) plus dolutegravir (DTG), to BIC/FTC/TAF plus DOR in multiclass-resistant patients. A pharmacokinetic (PK) analysis was conducted in a subset of patients to assess the potential interaction between BIC and DOR.

Methods: This was an open-label switch trial in HIV-infected males recruited from a US private practice, aged ≥45 years and with documented viral resistance on historical genotyping to protease inhibitors, nucleoside reverse transcriptase inhibitors, and/or NNRTIs but no resistance to RPV or DOR and no K65R mutation. Virologic suppression (≤50 copies/mL) while on RPV/FTC/TAF plus DTG for ≥6 months was required prior to study enrollment.

The primary endpoint of the study was viral suppression (<50 copies/mL) at 48 weeks. Secondary endpoints included safety, tolerability, weight changes, and PK assessments.

Results: The study enrolled 20 males with a median age of 65 years (range, 46-74), median CD4 count of 624 cells/µL (range, 193-1273), and median time since HIV diagnosis of 37 years (range, 12-42). BIC/FTC/TAF plus DOR was well tolerated with no serious or treatment-related AEs reported and no appreciable changes in body mass index from baseline to Week 48. At Week 48, 100% of participants had <50 viral copies/mL and the median CD4 count was 589 cells/µL (range, 257-934). The PK parameters for BIC and DOR in a subset of 10 patients were consistent with historical data and no clinically significant interactions occurred between BIC and DOR.

Conclusions: Switching from RPV/FTC/TAF plus DTG to BIC/FTC/TAF plus DOR in HIV-infected males with multiclass-resistant virus was well tolerated and efficacious with an advantageous AE profile and no food restrictions.

EPB160

Efficacy and safety of fostemsavir plus optimized background therapy in heavily treatment-experienced adults with HIV-1: week 240 results of the Phase 3 BRIGHTE study

J. Aberg[1], B. Shepherd[2], M. Wang[3], F.M. Urbina[4], C. Katlama[5], S. Schrader[6], J.J. Eron[7], S. Chabria[8], A. Clark[9], A. Pierce[10], M. Lataillade[8], P. Ackerman[8]
[1]Icahn School of Medicine at Mount Sinai, New York, United States, [2]GlaxoSmithKline, Brentford, United Kingdom, [3]GlaxoSmithKline, Collegeville, United States, [4]Hospital Nacional Edgardo Rebagliati Martins, Lima, Peru, [5]AP-HP, Hôpital Pitié-Salpêtrière, Service de Maladies Infectieuses et Tropicales, INSERM-Sorbonne Universités, Paris, France, [6]Schrader Clinic, Houston, United States, [7]University of North Carolina at Chapel Hill School of Medicine, Chapel Hill, United States, [8]ViiV Healthcare, Branford, United States, [9]ViiV Healthcare, Brentford, United Kingdom, [10]ViiV Healthcare, Research Triangle Park, United States

Background: In the ongoing phase 3 BRIGHTE study, fostemsavir plus optimized background therapy (OBT) demonstrated durable virologic suppression through 96 weeks in heavily treatment-experienced (HTE) adults with HIV-1.

Methods: In the Randomized Cohort (RC), participants with fully active agents in 1 or 2 remaining antiretroviral classes received fostemsavir 600 mg twice daily or placebo for 8 days followed by open-label fostemsavir plus OBT.

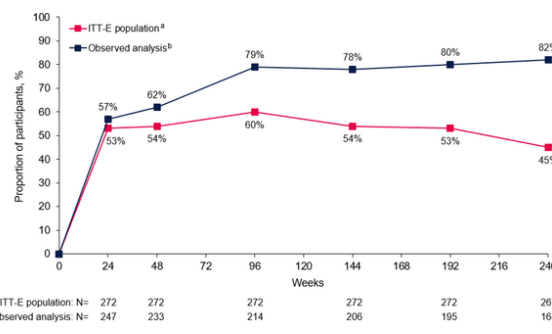
In the Non-randomized Cohort (NRC), participants with no approved fully active agents received fostemsavir 600 mg twice daily plus OBT. Week (W) 240 assessments included virologic outcomes (Snapshot [intention-to-treat exposed] and observed analyses), CD4+ cell count, and safety.

Results: Of 371 participants enrolled, 71% (193/272) in the RC and 55% (54/99) in the NRC were ongoing at W240. In the RC, virologic response rates generally remained consistent over time through W240 (Figure).

Lower virologic suppression by Snapshot analysis beyond W192 was partially confounded by missing data due to COVID-19.

By observed analysis, mean (SD) CD4+ cell counts steadily increased from baseline (n=272) over time and increased by 296 (228) cells/mm^3 by W240 (n=139); mean CD4+/CD8+ ratio increased from 0.20 to 0.60. In the RC, 78% (73/94) of participants with baseline CD4+ count <200 cells/mm^3 had CD4+ counts increase to ≥200 cells/mm^3. Consistent with earlier findings across the RC and NRC, the most common drug-related adverse events (AEs) were nausea (35/371, 9%) and diarrhea (18/371, 5%).

Grade 2 to 4 drug-related AEs were reported in 24% (88/371) of participants; 8% (30/371) reported AEs leading to discontinuation. No reported deaths (RC: 15/272, 6%; NRC: 20/99, 20%) were due to COVID-19.



ITT-E, intention-to-treat exposed. [a]Change in optimized background therapy due to lack of efficacy = failure. [b]Includes only participants with an observed HIV-1 RNA measurement at that visit. [c]N=267 in the ITT-E population at Week 240 due to 5 participants who completed the study before Week 240 and therefore did not have available HIV-1 RNA values at Week 240.

Figure. Virologic response (HIV-1 RNA <40 copies/mL) through Week 240 by Snapshot analysis in the ITT-E population and by observed analysis for the Randomized Cohort.

Conclusions: HTE participants treated through ~5 years with optimized fostemsavir-based regimens demonstrated durable virologic responses, continued clinically meaningful improvements in CD4+ cell count, and favorable safety. Although COVID-19 impacted Snapshot virologic response rates, overall observed rates remained high (≥80%).

Switching EFV/FTC/TDF to B/F/TAF or generic EFV/FTC/TDS in virologically suppressed adults with human immunodeficiency virus: a 96-week retrospective cohort

L.Y. Zuluaga Jaramillo[1], L.G. Castillo Reyna[2], A. Camacho Ortiz[3], L.M. Nuzzolo Shihadeh[4], A. Balderas Sarmiento[5], E. Perez Alba[6]

[1]Universidad Autónoma de Nuevo León, Infectology Service of the University Hospital „Dr. José Eleuterio González", Monterrey, Mexico, [2]Universidad Autónoma de Nuevo León, Undergraduate and Postgraduate Professor at „Dr. Jose Eleuterio González" Hospital and Coordinator of the Center for the Prevention and Care of HIV/AIDS, Monterrey, Mexico, [3]Universidad Autónoma de Nuevo León, Head of the Infectology Service of the University Hospital „Dr. José Eleuterio González", Monterrey, Mexico, [4]Universidad Autónoma de Nuevo León, Coordinator of the Infectology Undergraduate Program at the „Dr. José Eleuterio González" University Hospital, Monterrey, Mexico, [5]Universidad Autónoma de Nuevo León, General Medicine, Monterrey, Mexico, [6]Universidad Autónoma de Nuevo León, Fellow Coordinator for Infectious Diseases, Monterrey, Mexico

Background: Drastic cuts to the Mexican health budget led to a governmental decision to switch patients from EFV/FTC/TDF to either B/F/TAF or generic EFV/FTC/TDS. While tenofovir disoproxil succinate is approved in some countries, no information is available regarding its efficacy in maintaining virologic control. We aimed to describe the rates of virologic suppression after 96 weeks of said switch.

Methods: A retrospective cohort with data gathered from files at CAPASITS Nuevo León. Participants were ≥18 years and had plasma HIV-1 RNA <50 copies/mL while taking EFV/FTC/TDF for at least 6 consecutive months. This study was approved by UANL and Secretaría de Salud Nuevo León ethics committees.

The primary objective was determining the proportion of participants who maintained HIV- 1 <50 copies/mL at Week 96 after switch. We included subjects who reached 96 weeks with their new therapy between May 1st and October 30th, 2021. Demographics were analyzed using descriptive statistics and a Fisher's exact test with an α of 0.05 for the primary objective.

Results: Out of 421 files reviewed from patients receiving either B/F/TAF or EFV/FTC/TDS, 358 met inclusion criteria. Authors aimed to gather information from 129 patients per group, but maintaining recruitment for six more months would render less than ten additional cases. Completion of 96- week period was achieved by 266 and 92 patients receiving B/F/TAF and EFV/FTC/TDS respectively.

Baseline demographics for both groups are described in Table 1. HIV-1 RNA < 50 copies/mL was maintained in 93.9% (250/266) of B/F/TAF and 85.8% (79/92) of the EFV/FTC/TDS arm (8.1% difference; P =.01). Median CD4 cell difference was -33 cells/mL in the B/F/TAF group and 15 for the patients receiving EFV/FTC/TDS.

	B/F/TAF	EFV/FTC/TDS	Pvalue
Age in years [Median (IQR)]	51.5 (39.2-57)	37 (30-42)	<.001
Gender (Cisgender Women % / Transgender Women % / Cisgender Men%)	24.8/10.5/64.6%	31.5/0/68.4%	<.001 for Transgender Women
Years taking ARV [Median (IQR)]	6.9 (5.2-10.8)	5.9 (4.5-7.7)	<.001
Patients with additional previous ARV before EFV/ FTC/TDF [n (%)]	66/266 (24.8)	13/92 (14.1)	.02
At least one blip during the 96- week period [n (%)]	51/266 (19.1)	33/92 (35.8)	.002

Table 1.

Conclusions: While generic EFV/FTC/TDS might represent more than 50% savings, B/F/TAF maintained more patients undetectable than EFV/FTC/TDS. A nearly universal integrase inhibitor approach for switching patients with previous virologic control while taking EFV/FTC/TDF might be pricier but allows for fewer patients to develop virologic failure and blips.

EPB162

Integrase resistance emergence with dolutegravir/lamivudinewith prior HIV-1 suppression

B. Revollo[1], F. García[2], L. de la Mora[3], L. Viñuela[4], M. Noguera-Julián[5], M. Parera[5], R. Paredes[5], J.M. Llibre[6]

[1]Hospital Universitario Germans Trias I Pujol, Infectious Diseases, Badalona, Spain, [2]University Hospital Clinico San Cecilio, Clinical Microbiology, Granda, Spain, [3]Hospital Clinic and IDIBAPS, Department of Infectious Diseases, Barcelona, Spain, [4]University Hospital Clinico San Cecilio, Clinical Microbiology, Granada, Spain, [5]IrsiCaixa AIDS Research Institute, Badalona, Spain, [6]University Hospital Germans Trias i Pujol, Infectious Diseases, Badalona, Spain

Background: There are no reports of virological failure (VF) with emergence of integrase or reverse transcriptase (RT) resistance mutations in treatment-experienced individuals starting co-formulated DTG/3TC with a suppressed HIV viremia. This switch strategy has been studied in two large phase III randomized trials including 615 participants, no resistance selection reported to date.

Methods: We report the first case of integrase resistance emergence in an individual who switched to co-formulated DTG/3TC started after a history of prolonged viral suppression.

Results: A 57-year-old man was diagnosed with HIV-1 infection on 2013 with 77 CD4+ cells/mm3 and HIV-1-RNA viral load (VL) 80,700 copies/ml. A basal HIV-1 genotype was not performed. Antiretroviral treatment (ART) with

Author Index

3TC/AZT and Efavirenz 600 mg was started. Seven months after ART initiation his CD4+ count increased to 371 cells/mm3 and HIV-1 VL was <20 copies/ml. His ART was subsequently switched to LPV/r + FTC/TDF. On 2015 he interrupted his ART for three months and was then restarted on DRV/r 800/100mg + FTC/TDF, re-suppressing again. In 2017 his ART was simplified to DRV/c OD + 3TC.

In 2019 he was switched to co-formulated DTG/3TC to avoid a pharmacokinetic interaction with clobazam, a known weak inducer of CYP3A4/UGT-1A1 with no expected DTG dose-adjustment needed. In October 2020 he had two consecutive detectable HIV-1 VLs (149 and 272 copies/mL) despite receiving a directly observed treatment in a residential home.

Plasma HIV-1 population sequencing (Vela genomics) detected emergence of R263K and S230N in the IN region, conferring intermediate DTG resistance. The RT and protease regions could not be amplified.

Proviral DNA sequencing revealed mutations in both the RT and IN regions: M184I (14.29%) and M230I (6.25%), conferring high level resistance to 3TC and low-level or intermediate resistance to all non-nucleoside reverse transcriptase inhibitors, and mutations G163R (9.77%) and S230N (98.8%),conferring low-level resistance to elvitegravir and raltegravir. ART with DRV/c/FTC/TAF + DTG 50 mg BID was started in October 2020. After three months, the HIV-1 VL was undetectable.

Conclusions: This is the first reported case of integrase resistance selection in an INI-naive individual treated with co-formulated DTG/3TC started as a switch strategy following a prior long-term virological suppression.

EPB163

Real-world HIV renal outcomes with TDF-to-TAF switch

R. Rathbun[1], L. Skol[1], R. Kandilian[1], I.-L.A. Liu[2], Z. Zhuang[2], S. Caparosa[2], R. Madievsky[3], W. Towner[2], J. Shi[2], V. Guzman[1], L. Gordon[3], M. Nashed[3], D. Gharibian[3], J. Stern[2]

[1]*Kaiser Permanente Southern California, San Diego, United States,* [2]*Kaiser Permanente Southern California, Department of Research & Evaluation, Pasadena, United States,* [3]*Kaiser Permanente Southern California, Los Angeles, United States*

Background: With the advent of tenofovir alafenamide (TAF), many people living with HIV (PLWH) at Kaiser Permanente Southern California switched their antiretroviral therapy (ART) from tenofovir disoproxil fumarate (TDF) based to TAF-based regimens. Renal outcomes associated with TDF-to-TAF switch were evaluated.

Methods: This retrospective study included PLWH who switched TDF-to-TAF with no other ART changes, with ≥6 months of therapy, and ≥2 estimated glomerular filtration rates (eGFR) on both TDF and TAF. eGFR was calculated using the CKD-EPI equation (mL/min/1.73m^2). Mean eGFR was calculated in 6-month intervals (up to 18 months). Outcomes included mean eGFR comparison (TAF – TDF), and eGFR slope calculations (annual eGFR change), comparing eGFR_TDF_Baseline to first available eGFR_TAF and last available eGFR_TAF.

Multivariable regression or mixed model analysis was used to adjust for individual and clinical characteristics, comorbidities, concomitant medications and was stratified by baseline eGFR (≥90 and <90).

Results: The mean age of the 1,037 participants was 47 years; most were male (90%), 15% were African American and 59% had eGFR_TDF_Baseline <90. Comorbidities included CVD (12%), HTN (27%), DM (10%), and obesity (23%). Concurrent medications included cotrimoxazole (10%) and NSAIDs (32%).

Known overall previous TDF exposure was 3.6 years. Adjusted mean eGFR increased after TAF switch for all PLWH (+2.81 mL/min/1.73m^2; p<0.001) and for participants with eGFR_TDF_Baseline <90 (+5.5; p<0.001), but not eGFR_TDF Baseline ≥ 90 (-0.58; p=0.202).

Adjusted differences observed in eGFR_TAF slopes (Table 1) were more pronounced in those participants with eGFR_TDF_Baseline <90, using: first available eGFR_TAF (+6.51 mL/min/1.73m^2; p<0.001) and last available eGFR_TAF (+3.23; p<0.001).

eGFR_TDF_ Baseline[1]	N	eGFR_TAF Slope[2] (TAF First Available)	p-Value	95% CI	Mean (SD) Days[3]
≥ 90	426	+0.54	0.820	(-4.16, 5.24)	270.2 (79.3)
< 90	611	**+6.51**	<0.001	(3.09, 10.96)	268.6 (75.3)

≥ 90	426	-0.77	0.520	(-3.11, 1.57)	517.9 (77.0)
< 90	611	**+3.23**	<0.001	(1.59, 4.86)	524.4 (72.8)
Total eGFR	1037	**+1.51**	0.025	(0.19, 2.83)	521.7 (74.6)

[1]eGFR (mL/min/1.73m2); [2]Annualized eGFR slope calculation between eGFR_TDF_Baseline and eGFR_TAF (mL/min/1.73m2); [3]Mean days between eGFR_TDF_Baseline and eGFR_TAF

Table 1. Adjusted eGFR TAF Slope Calculations

Conclusions: In this real-world review of PLWH who switched their ART from TDF-to-TAF, we observed an improvement in mean eGFR upon switch to TAF.

Overall eGFR improvement was driven by a significant positive change in participants with TDF baseline eGFR <90, as no significant difference was observed in the ≥ 90 group.

EPB164

Switching to dolutegravir/lamivudine two-drug regimen: durability and virologic outcomes in routine U.S. clinical care

G. Pierone[1], L. Brunet[2], J. Fusco[2], C. Henegar[3], S. Sarkar[3], J. van Wyk[4], V. Vannappagari[3], G. Fusco[2]

[1]Whole Family Health, Vero Beach, United States, [2]Epividian, Durham, United States, [3]ViiV Healthcare, Research Triangle Park, United States, [4]ViiV Healthcare, London, United Kingdom

Background: The FDA expanded the indication for the two-drug regimen dolutegravir/lamivudine (DTG/3TC) on 08Apr19 to include ART-experienced, suppressed individuals.

This study aimed to describe the real-world experience of virologically suppressed, ART experienced adults switching to DTG/3TC from one of three commonly prescribed traditional three-drug regimens in the U.S.: bictegravir/tenofovir alafenamide/emtricitabine (BIC/TAF/FTC), dolutegravir/abacavir/lamivudine (DTG/ABC/3TC) or DTG+TAF/FTC.

Methods: Using data from the OPERA cohort, all adults who switched from a three-drug regimen of interest to DTG/3TC with a viral load (VL) <50 copies/mL between 08Apr19 and 30Apr21 were followed until 31Oct21.

Incidence rates of discontinuation, loss of suppression (first VL ≥50 or ≥200 copies/mL) and confirmed virologic failure (2 VL ≥ 200 copies/mL or discontinuation after 1 VL ≥ 200 copies/mL) were assessed with univariate Poisson regression, stratified by age, sex and race.

		N	n (%)	IR per 100 py (95% CI)

* Among individuals with ≥1 viral load(s) over follow-up

Figure. Incidence rates of DTG/3TC discontinuation and loss of suppression, stratified by age, sex and race.

Results: Of 787 PLWH switching to DTG/3TC, 54% switched from DTG/ABC/3TC, 31% from BIC/TAF/FTC and 16% from DTG+TAF/FTC. Median follow-up was 13.6 months (IQR: 8.2-22.3). Loss of suppression defined as 1 VL ≥50 copies/mL occurred at a rate of 14.02 per 100 person-years, or 3.29 per 100 person-years when defined as 1 VL ≥200 copies/mL (Figure). There were ≤5 confirmed virologic failures (incidence rate: 0.43 per 100 person-years; 95% CI: 0.16-1.00). The incidence rate of DTG/3TC discontinuation was 17.47 per 100 person-years (Figure).

Of 170 total discontinuations, only 6 (4%) were attributed to treatment-related undesirable events (loss of suppression, lab abnormality, adverse diagnosis/side effect). Rates of loss of suppression and discontinuation were consistent across age, sex, and race strata (Figure).

Conclusions: This descriptive study of virally suppressed adults switching to DTG/3TC demonstrated that this two-drug regimen is an effective treatment option, with low rates of loss of viral suppression (≥200 copies/mL) and rare virologic failure events. DTG/3TC seemed to be well tolerated with few discontinuations linked to treatment-related events.

EPB165

Changes in inflammatory biomarkers and baseline variables after switching to dolutegravir/lamivudine (DTG/3TC) in 2 randomized clinical trials of virologically suppressed adults: 48-week pooled analysis

J.M. Llibre[1], S. Scholten[2], O. Osiyemi[3], R. Grove[4], J. Oyee[4], R. Wang[5], B. Wynne[5], C. Donovan[5], B. Jones[6], C. Okoli[6], M. Kisare[7], M. Ait-Khaled[6]

[1]Hospital Universitari Germans Trias i Pujol, Barcelona, Spain, [2]Praxis Hohenstaufenring, Cologne, Germany, [3]Triple O Research Institute PA, West Palm Beach, United States, [4]GlaxoSmithKline, Brentford, United Kingdom, [5]ViiV Healthcare, Research Triangle Park, United States, [6]ViiV Healthcare, Brentford, United Kingdom, [7]GlaxoSmithKline, Nairobi, Kenya

Background: Persistent inflammation has been linked to increased risk of non–AIDS-related comorbidities in people with HIV-1. International guidelines recommend the 2-drug regimen DTG/3TC as a switch option, supported by randomized clinical trials demonstrating its durable efficacy and high barrier to resistance. We present inflammatory biomarker results in virologically suppressed adults switching to DTG/3TC.

Methods: This analysis included 48-week pooled data from the phase 3 TANGO and SALSA trials of adults with HIV-1 RNA <50 c/mL randomized to switch to once-daily DTG/3TC fixed-dose combination or continue current antiretroviral regimen (CAR). Using a multivariate ANCOVA model adjusting for relevant baseline variables, log-transformed Week 48 serum inflammatory biomarker levels and CD4+/CD8+ ratio were compared between groups and associations with baseline variables evaluated as fixed effects.

Results: Week 48 levels of soluble CD14 (sCD14) and C-reactive protein (CRP) appeared lower in the DTG/3TC vs CAR groups, and for sCD163, IL-6, and CD4+/CD8+ ratio, Week

48 values were similar between groups (Table). Across biomarkers, higher baseline values were strongly associated with higher Week 48 levels. Female participants had higher Week 48 levels of all inflammatory biomarkers compared with male participants. Asian participants appeared to have lower Week 48 levels compared with other races across all inflammatory biomarkers, although sample sizes were small.

Increasing age appeared to be associated with higher sCD14, sCD163, and IL-6 levels but not with CRP and CD4+/CD8+ ratio. Higher IL-6 and CRP levels at Week 48 were observed in participants with obese BMI at baseline.

	Variable: Reference	n: n	Ratio (95% CI)

	Obese: Underweight/Normal	213:475	0.99 (0.96-1.02)
Age	Per 10 years	1091	1.00 (0.99-1.01)
Baseline CD4+/CD8+ ratio		1091	2.48 (2.43-2.54)

n = number of participants with non-missing data at Week 48. Ratio calculated using an ANCOVA model on $\log_e$-transformed data adjusting for treatment, sex, race, baseline BMI, baseline CDC category, baseline smoking status, HCV co-infection, age, baseline CD4+/CD8+ ratio, $\log_e$-transformed baseline biomarker value, study, and baseline third agent class. Analyses for IL-6 and CD4+/CD8+ ratio also adjusted for baseline CRP. Analysis for CRP also adjusted for baseline triglycerides, baseline lipid-modifying agent, baseline total cholesterol, baseline LDL-C, and baseline HDL-C. Results are only displayed for covariates found to be associated with ≥1 of the inflammatory biomarkers analyzed.

Table. Ratios of inflammatory biomarker levels with DTG/3TC vs CAR at week 48

Conclusions: At Week 48 in this pooled analysis of 2 randomized trials, inflammatory biomarker levels were similar between the 2-drug regimen DTG/3TC and a broad range of 3-/4-drug antiretroviral regimens. Multiple baseline variables besides ART were associated with each inflammatory biomarker. These data highlight the multifactorial aspect of the inflammatory response.

Rapid tenofovir-lamivudine-dolutegravir transition in Papua New Guinea: a virtual approach to antiretroviral prescriber refresher trainings during a global pandemic

P. Temu[1], J. Nankinga[1], R. Nopa[1], G. Manuk[1], W. Yeka[1], I. Moide[1], I. Mogaba[1]

[1]FHI 360, Port Moresby, Papua New Guinea

Background: The rates of pre-treatment HIV drug resistance among first-line antiretroviral therapy (ART) initiators in Papua New Guinea (PNG) have been alarmingly high. In response, the National Department of Health (NDoH) planned a rapid transition of first-line ART to dolutegravir-based regimens in 2019–2020 in all high-burden provinces. When the COVID-19 pandemic reached PNG in March 2020, refresher training for ART prescribers on the revised treatment guidelines could not be conducted as planned. To ensure that patients could safely transition to new regimens, the NDoH, supported by PEPFAR and partners, facilitated the development of a virtual training platform for country-wide prescriber trainings.

Description: The USAID HIV Support in PNG project implemented by FHI 360 played a critical role in the development, facilitation, and implementation of the first virtual training for ART prescribers in PNG. This involved establishing a virtual training platform using Google Classroom and creating 21 video lectures with more than six hours of content covering all aspects of HIV care and treatment, including revised care-and-treatment guidelines and tenofovir-lamivudine-dolutegravir (TLD).

The virtual training, launched in May 2020, reached 108 prescribers (33.3% nursing officers, 30% health extension officers, 23.3% community health workers, 13.3% doctors) from all 22 provinces.

Among the training participants, 76.7% had not attended an HIV refresher training in the previous three years; 83.4% rated the training as four (out of five) or higher, and training evaluation scores averaged more than 80%.

This resulted in safe, rapid rollout of TLD, with more than 64% of ART clients transitioned to dolutegravir-based regimens within three months of the training and more than 93% transitioned by September 2021.

Lessons learned: Despite initial concerns that virtual training would not be feasible in PNG due to limited connectivity and low computer literacy, free platforms such as Google Classroom and the widespread availability of smartphones allowed successful training of health care workers in PNG.

Conclusions/Next steps: Virtual training of health care practitioners was viable for highly-effective, low-cost capacity building in resource-constrained environments during the COVID-19 pandemic. Similar approaches may be considered for other capacity-building initiatives instead of regular in-person trainings.

Intermittent doravirine/lamivudine/tenofovir disoproxil fumarate (DOR/3TC/TDF) maintains viral suppression in real life in controlled HIV-infected patients

R. Palich[1], S. Saliba[1], S. Landowski[2], B. Abdi[3], M.-A. Valantin[1], R. Mahrez[2], C. Katlama[1], P. de Truchis[2]

[1]Sorbonne University, Pitié-Salpêtrière Hospital, Infectious Diseases, Paris, France, [2]Paris-Saclay University, Raymond Pointcaré Hospital, Infectious Diseases, Garches, France, [3]Sorbonne University, Pitié-Salpêtrière Hospital, Virology, Paris, France

Background: The ANRS QUATUOR trial has demonstrated the non-inferiority of triple regimens given 4 days a week, compared with 7 days a week. We aimed to report here our experience with intermittent doravirine/lamivudine/tenofovir disoproxil fumarate (DOR/3TC/TDF), not licensed at time of QUATUOR, for maintaining the viral suppression.

Methods: This observational study enrolled all adults who initiated DOR/3TC/TDF given 5 or 4 days a week between 10/01/2019 and 01/31/2021, in two French hospitals.

The primary outcome was the rate of virological success (no virological failure [VF]: confirmed HIV-RNA ≥50 copies/mL, or single HIV-RNA ≥200 copies/mL, or ≥50 copies/mL with ART change) at W48.

Secondary outcomes included: strategy success rate (HIV-RNA <50 copies/mL with no ART change), evolution of CD4 count, CD4/CD8 ratio and rate of residual viremia over follow-up.

Age, years, median (IQR)	52 (48-58)

NOTES. 2-DR: two-drug regimen. 3-DR: three-drug regimen. a. Calculated from cumulative historical HIV-RNA and HIV-DNA genotypes with reverse transcriptase available sequences (N=28). b. These four patients had a past M184V/I mutation. c. Including 5 patients under daily DOR/3TC/TDF. d. Other than DOR/3TC/TDF.

Table. Patient characteristics at baseline (N=42).

Results: Forty-two patients were included, with median age: 52 years (IQR 48-58), ART duration: 15 years (IQR 8-23), duration of virological suppression: 6 years (IQR 2-10) [Table]. All had HIV-RNA <50 copies/mL at study entry. Four had a past M184V/I mutation. Median follow-up was 65 weeks (IQR 50-80). The virological success rate was 97.6% (95%CI 87.4-99.9) and the strategy success rate was 90.5% (95%CI 77.4-97.3) at W48.

One VF occurred at W38 (HIV-RNA=61 and 76 copies/mL), in a patient reporting a good compliance, without resistance at baseline, with no emergence of resistance, and with HIV-RNA <50 copies/mL after resumption of daily tenofovir alafenamide/emtricitabine/bictegravir.

There were four strategy discontinuations over the entire study period for adverse event (hepatic cytolysis: n=2, neuropsychic disorder: n=2), two deaths and one lost of follow-up. There was no significant change in CD4 count, CD4/CD8 ratio and residual viremia rate over follow-up.

Conclusions: This observational study shows the potential for the NNRTI next-generation DOR/3TC/TDF regimen given intermittently to maintain a high virological success rate, while reducing cumulative exposition and cost of ART.

EPB168

Switching to Dolutegravir/lamivudine or Bictegravir/Emtricitabine/Tenofovir alafenamide. A comparative real-world study

H. Knobel[1], E. Cañas[1], A. Guelar[1], J. Villar[1], A. González[1], C. Canepa[1], I. Arrieta[1], A. Marcos[1], R. Güerri[1]

[1]Hospital del Mar, Infectious Diseases, Barcelona, Spain

Background: Few studies compared Dolutegravir/Lamivudine (D/L) and Bictegravir/Emtricitabine/Tenofovir alafenamide (B/F/T) in switch therapy. Our objective was to evaluate the performance of these two treatments in the real-world setting.

Methods: A retrospective single-center study was conducted between April 2019 and November 2021 in Barcelona, Spain. All patients who started D/L or B/F/T on switching therapy (baseline HIV-RNA: <50 copies/mm^3) were included. Safety and virologic outcomes at the end of follow-up were evaluated. Descriptive statistics and multivariate Cox logistic analysis were performed to identify differences in the rate of discontinuation between both regimens.

Results: We analyzed data from 358 patients on D/L (mean age: 47.3 years) and 332 on B/F/T (mean age: 45.5) with a median follow-up of 293 and 440 days respectively. Eighty-six percent of patients were men, without differences between groups. Patients in D/L group previously received 13 different regimens (dolutegravir 42%, abacavir 60%, tenofovir alafenamide 24%), while 22 on B/F/T (tenofovir alafenamide 40%, tenofovir disoproxil fumarate 40%, elvitegravir/cobicistat 36%, non-nucleoside reverse transciptase inhibitors, 35% Darunavir/cobicistat 35%).

Fourty-two percent of patients treated with D/L were not exposed to new drugs. Oppositely, all participants in the B/F/T group were exposed to at least one new drug.

No differences were observed in the virologic outcome between both groups. Viral Load (VL) < 50 copies/mm^3 was 98.3% in D/L vs. 97.3% in B/F/T, VL 51-500 copies/mm^3 was 1.4% vs 2.5% and VL > 500 copies/mm^3 was 0.3% in both groups.

Discontinuation rate was 8.7% for D/L, side effects, 4 (1.1%) (3 anxiety and/or insomnia, 1 abdominal pain), 5.9% loss of follow-up, 1.4% deaths, 0.3% interactions. B/F/T discontinuation rate was 15%: side effects, 1 (0.3%) (1 arthralgia), 10.5% loss of follow-up, 1.5% deaths, 2.4% physician decision (3 weight gain, 2 dyslipidemia), 0.3% interaction.

When considering only patients not exposed to the same drugs, adverse events with D/L were more frequent than with B/T/F 1.97% and 0.3%, respectively (P:0.1). The adjusted risk of discontinuation of B/T/F was: 1.37 (95% CI: 0.85-2.20; P:0.19)

Conclusions: Both treatments were effective and well-tolerated in the real-world setting. The few discontinuations in the B/T/F group seem related to the switch from TDF.

EPB169

Efficacy and safety of switching to Dolutegravir/ Lamivudine by baseline regimen in virologically suppressed adults: 48-week pooled analysis

S. Scholten[1], P. Cahn[2], P. Ruane[3], R. Kaplan[4], J. Portilla[5], S. Hodder[6], F. Bisshop[7], B.R. Wynne[8], R. Grove[9], G. Bontempo[8], R. Moodley[10], B. Jones[10], M. Ait-Khaled[10], C. Okoli[10]

[1]Praxis Hohenstaufenring, Cologne, Germany, [2]Fundación Huésped, Buenos Aires, Argentina, [3]Ruane Medical & Liver Health Institute, Los Angeles, United States, [4]Desmond Tutu Health Foundation, Cape Town, South Africa, [5]Hospital General Universitario de Alicante, Alicante, Spain, [6]School of Medicine, West Virginia University, Morgantown, United States, [7]Holdsworth House Medical, Brisbane, Australia, [8]ViiV Healthcare, Research Triangle Park, United States, [9]GlaxoSmithKline, Brentford, United Kingdom, [10]ViiV Healthcare, Brentford, United Kingdom

Background: Dolutegravir/Lamivudine (DTG/3TC) has durable efficacy and a high barrier to resistance, supporting its inclusion in international guidelines as a recommended INSTI-based regimen.

We present pooled efficacy and safety outcomes among virologically suppressed adults switching to DTG/3TC by baseline regimen.

Methods: This analysis includes 48-week data from the phase 3 TANGO and SALSA trials of adults with HIV-1 RNA <50 c/mL randomized to switch to once-daily DTG/3TC fixed-dose combination or continue current antiretroviral regimen (CAR). Primary and key secondary endpoints were proportions with HIV-1 RNA ≥50 and <50 c/mL at Week 48, respectively (Snapshot, intention-to-treat exposed).

Results: Among 1234 participants, the most commonly used baseline third agent class and NRTI backbone were INSTIs (63%) and TAF/FTC (74%), respectively. Overall, at Week 48, few participants had HIV-1 RNA ≥50 c/mL (adjusted difference, −0.5; 95% CI, −1.3, 0.4); results were consistent across baseline regimen subgroups.

High proportions of participants maintained HIV-1 RNA <50 c/mL in the DTG/3TC and CAR groups across baseline regimen use (Table). No DTG/3TC participants had confirmed virologic withdrawal (CVW); 1 CAR participant had CVW (no resistance detected).

In the overall analysis, proportions of any AEs and Grade 2-5 AEs were similar between treatment groups, with few AEs leading to withdrawal or serious AEs; drug-related AEs were more frequent in the DTG/3TC group, as expected in stable switch studies. Similar results were observed by baseline regimen use.

Virologic outcomes: proportion of participants with HIV-1 RNA <50 c/mL (Snapshot)

Baseline regimen	Subgroup	DTG/3TC N	DTG/3TC n (%)	CAR N	CAR n (%)	Adjusted difference (95% CI)[b]

	No	510	510	392 (77)	381 (75)	235 (46)	251 (49)	17 (3)	5 (<1)	83 (16)	18 (4)	23 (5)	28 (5)

[a]In TANGO, 1 participant was found to be taking a TDF-based regimen and was excluded from the safety population. [b]Estimates and CIs were based on a stratified analysis using Cochran-Mantel-Haenszel weights adjusting for baseline third agent class and study. [c]Other NRTI backbone regimens were included in SALSA (zidovudine, tenofovir disoproxil succinate, biovir [NOS]).

Table. Efficacy and safety outcomes at week 48: ITT-E and safety populations[a]

Conclusions: DTG/3TC maintained high proportions of virologic suppression, had a high barrier to resistance, and demonstrated a good safety and tolerability profile 1 year after switch regardless of prior 3-/4-drug regimen use, supporting this 2-drug regimen as a robust, well-tolerated switch option with fewer antiretrovirals.

EPB170

Changes in non alcoholic fatty liver disease spectrum and metabolic markers in people with HIV after switching to a raltegravir-based regimen

M. Shengir[1], W. Elgretli[2], B. Lebouche[3], S. Saeed[4], A.V. Ramanakumar[5], A. Giannakis[3], A. De Pokomandy[3], J. Cox[3], C. Costiniuk[3], J.-P. Routy[3], M. Klein[3], G. Sebastiani[3]

[1]McGill University, Experimental Medicine, Montreal, Canada, [2]University of Tripoli, Tripoli, Libya, [3]McGill University Health Centre, Montreal, Canada, [4]Washington University, St. louis, United States, [5]Research Institute, McGill University Health Centre, Montreal, Canada

Background: Nonalcoholicfatty liver disease (NAFLD) is a major comorbidity among people with HIV (PLWH). Its aggressive nature in such population, mandates exploring less steatogenic antiretroviral therapies (ART). We aimed to evaluate the effect of switching to raltegravir (RAL) based regimen on NAFLD, body mass index (BMI), and lipids among PLWH with NAFLD.

Methods: In this phase IV, open-label randomized control trial (ClinicalTrials.gov: NCT02210715), PLWH without viral hepatitis co-infection were randomized 1:1 either to switch arm (RAL 400mg BID) and control arm (continuing any other ART not containing integrase inhibitors). Patients with suppressed HIV viral load and NAFLD (defined as controlled attenuation parameter (CAP) ≥238 dB/m) at baseline were included.

Outcomes were evaluated as changes between baseline and 24 months of follow-up. Liver fibrosis was measured as liver stiffness by Fibroscan. Nonalcoholic steatohepatitis (NASH) was determined using cytokeratin-18 (CK-18), a hepatocyte apoptosis marker.

Changes in outcomes were represented as standardized mean differences (SMD) and a fixed-effect linear regression model was applied to compare outcomes between both study arms.

Results: 31 PLWH were included (mean age 53.9yrs). Compared to baseline, SMD of aspartate aminotransferase decreased in switch arm in comparison to control arm (switch -9.54, control 5.57, p=0.036) (see Figure).

In the adjusted multivariate model, NASH measured by CK-18 and liver fibrosis represented as liver stiffness measurement improved in switch group compared to control group. However, these observations were not significant when comparing both arms (see Table). No changes in BMI and lipids were observed.

Variables	Multivariate model*		
ΔCAP (24 months – baseline)	coefficient	p-value	Difference in slope
Control	-0.641	0.4013	0.8853
Switch	-0.450	0.5547	0.8853
ΔLSM			
Control	0.063	0.0306	0.8853
Switch	-0.050	0.1376	0.8853
ΔCK–18			
Control	-1.242	0.1254	0.4500
Switch	-2.407	0.0649	0.4500

Conclusions: This study indicated that switching to RAL improves AST and may potentially alleviate the progression of NASH and fibrosis. However, larger interventional studies are needed to conclude the same.

EPB171

Efficacy of Tenofovir alafenamide versus tenofovir disoproxil fumarate among HIV positive Zambian adults switched from NNRTI to dolutegravir-containing ART: results from the VISEND clinical trial

L. Mulenga[1,2,3,4,5], D. Engamba[1,2], A. Kumar[1], N. Mbewe[1,6], S. Fwoloshi[2,3,2], A. Mweemba[6], M. Mwitumwa[1,2], S. Sivile[1,2,3], M. Siwingwa[1,2], D. Kampamba[1,3], A. Shibemba[1,2], H. Phiri[3], M. Mutinta-Mbewe[1], B. Simons[7], A. Hill[8], L. Chirwa[1], C.W. Wester[5,4]

[1]University Teaching Hospital, Adult Infectious Diseases Center, Lusaka, Zambia, [2]University of Zambia, Department of Medicine, Division of Infectious Diseases, Lusaka, Zambia, [3]Ministry of Health, Lusaka, Zambia, [4]Vanderbilt Institute for Global Health (VIGH), Nashville, United States, [5]Vanderbilt University Medical Center (VUMC), Division of Infectious Diseases, Nashville, United States, [6]Levy Mwanawasa Medical University, Infectious Diseases, Lusaka, Zambia, [7]London School of Economics & Political Science, London, United Kingdom, [8]Liverpool University, Translational Medicine, Liverpool, United Kingdom

Background: Tenofovir alafenamide (TAF) is recommended by the WHO as a favorable option for special circumstances when osteoporosis and/or renal impairment are of particular concern. Compared to tenofovir disoproxil fumarate (TDF), there is paucity of data on TAF use in resource-constrained settings. Additionally, there is limited information on its efficacy in important subpopulations like pregnant women.

In the VISEND trial, we compared virologic outcomes among HIV-positive Zambian adults (including pregnant women), receiving TDF/lamivudine (3TC)/dolutegravir (DTG) or TAF/emtricitabine (FTC)/DTG after switching from TDF/3TC/Efavirenz (EFV) or Nevirapine (NVP).

Methods: We conducted a 144 week, randomized, open label, phase 3 non-inferiority trial. In both Arm A (participants having baseline HIV RNA <1,000 copies/mL) and Arm B (participants having baseline HIV RNA ≥ 1,000 copies/mL), individuals were randomized to either TDF/3TC/DTG or TAF/FTC/DTG.The primary end point was VLS at 48 weeks, assessed using the FDA snapshot algorithm (Intent-to-treat (ITT) population). HIVDR was assessed for reverse transcriptase, protease and integrase Sanger sequences using the Stanford University HIVdb algorithm for individuals with HIV-1 RNA ≥ 1,000 copies/mL.

Results: At Week 48 for Arm A, 88% of TDF/3TC/DTG-treated participants were virally suppressed vs. 87% of TAF/FTC/DTG-treated participants [difference, -0.5%, 95%CI -6.9 to 5.9]. For Arm B, 82% of TDF/3TC/DTG-treated participants were virally suppressed vs. 87% of TAF/FTC/DTG-treated participants [difference, +5%, 95%CI 2.2 to 8.9].

A total of 16 women (8 on TDF/3TC/DTG; 8 on TAF/FTC/DTG) became pregnant during the study and only 1 had HIV RNA >1,000 copies/mL. Among individuals with HIV RNA >1,000 copies/mL, HIVDR was detected in 12 (38%) individu-

als receiving TDF/3TC/DTG versus 9 (33%) for those receiving TAF/FTC/DTG in Arm B and no participant was resistant to DTG.

Conclusions: In the VISEND trial, there was no difference in virologic outcomes between participants receiving either TDF or TAF based ART after switching from NNRTI-based ART though there was a trend towards better VLS for individuals receiving TAF based ART with baseline HIV RNA ≥ 1,000 copies/mL.

In addition, virologic outcomes for pregnant women receiving TAF based ART were comparable to those receiving TDF based therapy. There is therefore need to expand the use of TAF in HIV-1 infected individuals.

Pharmacokinetics/pharmacodynamics/pharmacogenomics and therapeutic drug monitoring

EPB172

Targeted delivery of dolutegravir to HIV reservoirs in the mesenteric lymphatic system by lipophilic ester prodrug approach

Y. Chu[1,2], A. Wong[1], M. Stocks[1], P. Gershkovich[1]

[1]*University of Nottingham, school of pharmacy, Nottingham, United Kingdom,* [2]*Tri-Service General Hospital, Medical Supplies and Maintenance Office, Taipei, Taiwan, Province of China*

Background: Dolutegravir (DTG) is a first-line HIV integrase inhibitor. Mesenteric lymph nodes (MLNs) are one of the most important HIV reservoirs. Delivering antiretroviral agents to MLNs *via* intestinal lymphatic transport can lead to high levels of drugs in these reservoirs.

However, DTG does not have the required physicochemical properties for intestinal lymphatic transport. Therefore, highly lipophilic prodrugs of DTG have been designed, synthesized, and assessed in this work for efficient delivery of DTG to viral reservoir in MLNs.

Methods: The intestinal lymphatic transport potential of DTG and its prodrugs was assessed by previously reported *in silico*, *in vitro* and *ex vivo* methods. Male Sprague Dawley rats were used in subsequent pharmacokinetic and biodistribution studies. Blood samples were collected at predetermined time points following intravenous and oral administration of DTG. Mesenteric lymph fluid, MLNs and additional tissues were collected at 2, 4 and 8 hours following oral administration in the lipid-based formulation. All biological samples were analyzed for DTG concentration by means of a validated HPLC method.

Results: DTG had negligible association with chylomicrons in *in silico*, *in vitro* and *ex vivo* assessments. The ester prodrugs of DTG had moderate to high affinity to chylomicrons *in silico* (23-98%), *in vitro* (30-70%) and *ex vivo* (55-70%).

The absolute oral bioavailability of DTG following oral administration in the lipid-free vehicle (53%) is similar to the lipid-based formulation (64%). Substantial concentrations of DTG were found in MLNs and mesenteric lymph following oral administration in lipid-based formulation (1432±327 ng/g and 6597±1040 ng/mL, 887±147 ng/g and 6571±1849 ng/mL, 607±94 ng/g and 4158±2064 ng/mL at 2, 4 and 8 hours, all results are shown as mean ± SD, n=4).

Conclusions: Substantial levels of DTG were found in mesenteric lymph and MLNs when co-administered with lipids. However, current cART including DTG does not eradicate HIV from these reservoirs in MLNs. Therefore, it is likely that higher levels of DTG are required for eradicating the virus from MLNs.

This potentially could be achieved by oral administration of highly lipophilic prodrugs of DTG that have high intestinal lymphatic transport and efficient release of the active drug within the MLNs.

EPB173

Characterization of the absorption, metabolism, and excretion of islatravir, an HIV nucleoside reverse transcriptase translocation inhibitor, in humans

R.P. Matthews[1], K. Fillgrove[1], M. Patel[1], W. Liu[1], C. Matthews[1], Y. Liu[1], I. Mirkin[2], S.A. Stoch[1], M. Iwamoto[1]

[1]*Merck & Co., Kenilworth, United States,* [2]*Labcorp Clinical Research Unit, Madison, United States*

Background: Islatravir (ISL) is a nucleoside reverse transcriptase translocation inhibitor under clinical investigation for the treatment and prevention of HIV-1 infection. After cellular uptake, ISL is phosphorylated to its active form (ISL-triphosphate), which has a long intracellular half-life. As a nucleoside analogue, ISL is expected to be well absorbed from the gastrointestinal tract. Preclinical and clinical data demonstrate that 4'-ethynyl-2-fluorodeoxyinosine (M4) is the major metabolite, and previous trials have also demonstrated that both M4 and unchanged parent are excreted in the urine. A definitive human AME (absorption, metabolism, excretion) trial was performed to more fully characterize ISL AME.

Methods: A single-dose, open-label study in 6healthy male participants was conducted. Participants received a single oral dose of 10mg (~62µCi) [^{14}C]ISL. Blood (whole blood and plasma), urine, and fecal samples were collected throughout the study. Total radioactivity recovery was assessed, and metabolic profiling was performed. ISL concentrations were assessed in plasma samples only. Participants were discharged from the study when the radioactivity in the collected samples fell below a prespecified threshold; all participants qualified for discharge at 15 days post dosing.

Results: A single dose of 10 mg [^{14}C]ISL was generally well-tolerated; there were no AEs, SAEs, or discontinuations, and no meaningful trends in vital signs or safety labora-

Author Index

tory studies. Overall, a mean of 97.7% of the radioactive dose was recovered, with 91.4% in urine and 6.3% in feces. In plasma, 29% of the total radioactivity AUC0-24 and 35% of the total radioactivity Cmax was from [^{14}C]ISL. The major metabolite in AUC-proportional pooled plasma was M4, with 31% of the radioactivity attributable to M4 and 58% to ISL. In urine, the majority of the radioactivity was assigned to M4, accounting for 53% of the administered dose, while unchanged ISL accounted for 32% of the dose.

Conclusions: ISL is well absorbed after oral dosing. The majority of the absorbed ISL in plasma is unchanged ISL, but there is a significant amount of the inosine metabolite M4.

In contrast, M4 is the major species in urine, with a significant amount of unchanged parent ISL. These findings are consistent with previous and expected results for this compound.

EPB174

Impact of intrinsic and extrinsic factors on the pharmacokinetics of long-acting lenacapavir for treatment of HIV

N. Shaik[1], F. Bellanti[2], C. Comisar[2], S. Girish[1], M. Rhee[1], R. Singh[1], R. Palaparthy[1]

[1]Gilead Sciences, Clinical Pharmacology, Foster City, United States, [2]Certara, Clinical Pharmacology, Princeton, United States

Background: Lenacapavir (LEN) is a novel, first-in-class selective inhibitor of HIV-1 capsid protein, currently being investigated in heavily treatment experienced (HTE) participants with HIV-1 (PWH). The ongoing Phase 2/3 studies in PWH uses every 6 months subcutaneous (SC) dosing with oral loading/lead-in (oral LEN 600 mg on Days 1 and 2, and oral LEN 300 mg on Day 8 followed by SC LEN 927 mg on Day 15 and every 6 months thereafter).

The objective was to characterize the population pharmacokinetics (PopPK) of LEN and evaluate the effect of intrinsic/extrinsic factors that may affect LEN exposures.

Methods: Pharmacokinetic (PK) data were pooled from 7 studies in participants with and without HIV who received intravenous/oral/SC LEN. A total of 6855 LEN concentrations from 384 participants were analyzed in the PopPK analysis using nonlinear mixed effects modeling. Several intrinsic and extrinsic factors/covariates including pharmacoenhancers (cobicistat or ritonavir), body weight (BW), age, sex, race, ethnicity, dose, disease status, food, formulation and estimated glomerular filtration rate were evaluated. LEN exposures were simulated using the bayesian posthoc PK parameters and presented across applicable covariates.

Results: A 2-compartment model with 1st order process for oral absorption, with a parallel 1st and transit compartment absorption for SC and linear elimination, adequately described LEN concentration data.

The typical total clearance (CL), intercompartmental CL, central volume, and peripheral volume values were 4.05 L/h, 41.2 L/h, 68 L and 908 L, respectively. Dose was found to affect oral bioavailability and CL of LEN. HTE participants had lower CL (23.3% decrease) compared to participants without HIV.

Pharmacoenhancers were found to affect oral LEN bioavailability (58.7% increase). The change in LEN exposures with BW ranged from approximately −32.3% to +23.5% (relative to the median exposures) for participants with 5th to 95th BW percentiles, respectively. No additional covariates were found to significantly affect LEN exposure.

Conclusions: Higher LEN exposures were observed with lower body weightsand for participants on pharmacoenhancers. In addition, higher exposures were observed in HTE participants compared to participants without HIV, potentially due to unaccounted and complex disease-related cofounders. These changes in LEN exposures were not considered clinically meaningful.

EPB175

Pharmacokinetic modeling and simulation of intramuscular and subcutaneous ibalizumab delivery

K.-L. Kuo[1], Y. Lai[1], J. Boulos[2], M. Zogheib[2], M. Markowitz[3], P. Mesquita[2]

[1]TaiMed Biologics, Taipei, Taiwan, Province of China, [2]Theratechnologies, Montreal, Canada, [3]TaiMed Biologics, Irvine, United States

Background: Ibalizumab (IBA) is a long-acting post-attachment inhibitor approved for the treatment of heavily treatment-experienced (HTE) adults with multidrug resistant HIV-1 failing their current antiretroviral (ARV) regimen. In approved dosing, IBA is diluted in 250 mL of saline and administered via intravenous infusion (IVI) as a loading dose of 2000 mg followed by 800 mg maintenance doses, every 2 weeks (q2w). We used population pharmacokinetic (PopPK) modeling to simulate intramuscular (IM) and subcutaneous (SC) dosing.

Methods: A three-compartmental model with parallel Michaelis-Menten and first order elimination was used to describe the PopPK for IM and SC administration. PK data from 7 clinical studies (phase 1, 2 and 3) conducted in HIV infected patients (n=281) were used to build the models, with age, weight, CD4 count and sex added sequentially as covariates. The predictive performance was evaluated by visual predictive check (VPC). IBA concentrations were estimated for dosing simulations of 2000 mg IVI followed by 400 mg weekly (qw) or 800 mg q2w for both IM and SC administration. One hundred subjects were simulated for each dosing regimen with body weight ranging from 50-140 Kg.

Results: The goodness-of-fit plots showed that data were evenly distributed across the line of identity, indicating no major bias and appropriateness of the models for the

population and each individual, with inclusion of body weight as a significant covariate. The VPC results showed that approximately 95% of data points were within the 90% prediction interval for both IM and SC models, indicating good predictability.

All dosing regimens evaluated with IM and SC delivery support maintenance of IBA trough serum concentrations (C_{trough}) above the previously demonstrated effective value (0.3 µg/mL). IM administration supported higher C_{trough} with less variability than SC. In addition, 400 mg qwk dosing led to higher C_{trough} than 800 mg q2wk.

Conclusions: These data support the potential administration of IBA via IM or SC injection weekly or every 2 weeks, and warrant the ongoing investigation to provide additional IBA delivery options convenient for HTE patients.

The safety and PK of IM administration are currently being evaluated in an open-label non-randomized phase 3 study (TMB-302).

EPB176

Pharmacokinetics (PK) and tolerability of cabotegravir (CAB) and rilpivirine (RPV) long-acting (LA) intramuscular (IM) injections to the vastus lateralis (lateral thigh) muscles of healthy adult participants

K. Han[1], J.S. Shaik[1], H. Crauwels[2], C. Leemereise[3], G. Bontempo[4], B. Win[5], C. Seal[1], R. DeMoor[1], O. Upadhyay[1], V. Chounta[6], W. Spreen[4], S.L. Ford[7]

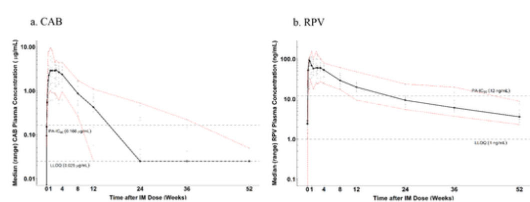
[1]GlaxoSmithKline, Collegeville, United States, [2]Janssen Research and Development, Beerse, Belgium, [3]GlaxoSmithKline, Amersfoort, Netherlands, the, [4]ViiV Healthcare, Research Triangle Park, United States, [5]GlaxoSmithKline, Stevenage, United Kingdom, [6]ViiV Healthcare, Brentford, United Kingdom, [7]GlaxoSmithKline, Research Triangle Park, United States

Background: CAB + RPV LA IM gluteal injections monthly and every 2 months demonstrated efficacy for maintaining HIV viral suppression and were well tolerated. Vastus lateralis thigh muscle could be a potential alternative site of administration due to injection fatigue, intolerability, or inaccessibility of the gluteal muscle or in future applications allowing self-administration. CAB and RPV PK and participant tolerability were evaluated following single IM injections to the lateral thigh; preliminary results are presented.

Methods: Healthy adult participants received 4 weeks of daily oral CAB 30mg and RPV 25mg, followed by 10-14 day washout and single 3-mL IM injections of CAB LA 600mg and RPV LA 900mg to contralateral vastus lateralis muscles. Safety, tolerability, and sparse PK were collected through 52 weeks post-injection. PK parameters were estimated using noncompartmental analysis (NCA).

Results: Fifteen participants (6 females) enrolled with median age 33 years, weight 93.6 kg, and BMI 31.4 kg/m^2. One female participant withdrew during oral dosing due to pregnancy. Injection site reactions (ISRs) occurred in 14/14 participants: 12/14 (86%) Grade 1 (mild) and 2/14 (14%) Grade 2 (moderate), most resolving in 3-7 days. Most common ISRs were pain (14/14 [100%]), erythema (8/14 [57%]), induration (7/14 [50%]), bruising (4/14 [29%]), warmth (3/14 [21%]), and pruritis (2/14 [14%]). Observed CAB and RPV concentration-time profiles are shown in the Figure.

Plasma concentrations at Weeks 4 and 8 were 15- and 5.3-fold above protein-adjusted IC_{90} (PA-IC_{90}) for CAB and 4.7- and 2.4-fold for RPV, respectively.



Plasma concentrations below the lower limit of quantification (LLOQ) were imputed as the value of LLOQ. Black solid line represents the median and dotted red lines represent min and max of the observed data. Grey open circles represent individual observed data. PA-IC_{90}: in vitro protein-adjusted concentration resulting in 90% of the maximum inhibition of viral growth.

Figure. Preliminary median (range) of plasma concentration-time profiles of CAB (a) and RPV (b) after single IM administration of (a) CAB LA 600 mg (3 mL) and (b) RPV LA 900 mg (3 mL) to the lateral thigh muscle in healthy adult participants.

	Cmax	Tmax	AUClast	Concentration At Week 4	Concentration At Week 8
CAB LA (n=14)	3.38 mg/mL (66%)	1 week (1, 8)	3832 h*mg/mL (22.8%)	2.56 mg/mL (38.9%)	0.88 mg/mL (84.2%)
RPV LA (n=14)	93.5 ng/mL (37.7%)	0.8 week (0.42, 4)	145000 h*ng/mL (33.1%)	56.7 ng/mL (28.5%)	30.8 ng/mL (37.7%)
PK parameters were estimated using noncompartmental analysis. Values displayed are geometric mean (CV%) except for Tmax, which is displayed as median (range). Plasma concentrations below LLOQ were omitted. AUClast: area under concentration-time curve from time 0 to the last observation above LLOQ. Cmax: maximum plasma concentration post IM injection. Tmax: time at which Cmax occurs.					

Table. Preliminary plasma PK parameters after single IM administration of CAB LA 600 mg (3 mL) and RPV LA 900 mg (3 mL) to the lateral thigh muscles in healthy adult participants.

Conclusions: CAB and RPV LA IM injections to the vastus lateralis muscle were well tolerated with mild-to-moderate ISRs, and showed favorable plasma PK profiles, supporting further evaluation of thigh IM administration in target population(s).

Emtricitabine triphosphate in dried blood spots predicts current HIV viremia in people living with HIV and ongoing substance use disorders

J. Havens[1], S. Avedissian[2], A. Podany[2]
[1]*University of Nebraska Medical Center, College of Medicine, Department of Internal Medicine, Infectious Diseases, Omaha, United States,* [2]*University of Nebraska Medical Center, College of Pharmacy, Department of Pharmacy Practice, Omaha, United States*

Background: Bictegravir/emtricitabine/tenofovir alafenamide (B/F/TAF) exhibits high efficacy and a favorable safety profile. People with HIV (PWH) and substance use disorders (SUD) are at risk of medication non-adherence. The BASE study (NCT03998176) is an open-label, phase IV, single-arm study evaluating the effectiveness, safety, durability, and adherence of B/F/TAF amongst PWH with SUD. We evaluated antiretroviral concentrations in dried blood spots (DBS) to compare with viral suppression (VS) at 24 weeks (W24) post B/F/TAF initiation.

Methods: BASE enrolled 43 viremic (HIV RNA > 1000 c/mL) treatment naïve or experienced PWH with ongoing SUD to receive B/F/TAF daily for 48 weeks. DBS concentrations, from two 7mm punches, of emtricitabine-triphosphate (FTC-TP) and tenofovir-diphosphate (TVF-DP) were analyzed by LC/MS/MS and results were dichotomized into quantifiable vs. below the limit of quantification (BLQ). Limits of quantification were 1000 and 50 fmol/punches for FTC-TP and TFV-DP respectively. Median FTC-TP and TFV-DP concentrations were compared with Mann-Whitney test. Multivariate logistic regression analysis estimated an odds ratio (OR) for VS (HIV RNA <50 c/mL) based on whether DBS concentrations were detectable for each FTC-TP and TFV-DP.

Results: Thirty-six BASE participants (84%) provided paired DBS and HIV RNA samples at W24. All participants reported current methamphetamine use. Mean (range) age was 41 years (26-62); 22% female, 83% White, 11% Black. At W24, 31/36 (86%) were VS. Median (range) DBS concentrations of FTC-TP and TVF-DP were 3463 (BLQ-11325) and 1724 (BLQ-4100) fmol/punches, respectively. Participants with VS had significantly higher FTC-TP (p=0.0187) but not TFV-DP (p=0.2778) compared with participants with HIV RNA >50cpm. Participants with BLQ FTC-TP concentrations were more likely to have detectable HIV compared to those with detectable FTC-TP (aOR 20.8; 95% CI, 1.9-227.3). Four participants with detectable HIV RNA and BLQ FTC-TP had detectable, but low, TVF-DP concentrations (median, 595.5 fmol/punches).

Conclusions: Undetectable FTC-TP in DBS was a strong predictor of current HIV viremia in PWH with SUD taking B/F/TAF. The highest TFV-DP concentrations in participants with detectable viremia correlated with levels previously shown to be associated with 2 doses per week. PWH exhibiting poor short-term adherence, as indicated by undetectable FTC-TP DBS concentrations, may benefit from adherence interventions and resistance testing.

Drug interactions

EPB178

Drug-drug interactions between antiretrovirals and remdesivir

H. Okochi[1], L. Benet[2], M. Gandhi[1]
[1]*University of California, Medicine, San Francisco, United States,* [2]*University of California, Bioengineering and Therapeutic Sciences, San Francisco, United States*

Background: Although COVID-19 vaccination is expanding worldwide, deaths due to COVID-19 continue to increase due to unequal distribution. HIV infection, specifically with CD4 counts <200cells/mm^3, is one of the risk factors for COVID-19 symptoms becoming severe, with comorbidities also serving as risk factors of severe COVID-19 among people with HIV. Remdesivir and dexamethasone are the mainstays of inpatient COVID-19 treatment, with colchicine and favipiravir being studied for outpatient therapy, so we sought to evaluate drug-drug interaction (DDIs) between antiretrovirals (ARVs) and these drugs *in vitro*.

Methods: DDIs between ARVs and anti-COVID-19 drugs and candidates were evaluated via *in vitro* studies as a function of:

a. Drug metabolism for midazolam (MDZ) in human liver microsomes (effect for cytochrome P450 3A (CYP3A));

b. Drug efflux for loperamide (LPM) in P-glycoprotein (P-gp) stably expressing MDCK, and

c. Uptake transport for rosuvastatin (ROS) in organic anion transporting polypeptide 1B1 (OATP1B1) stably expressing HEK-293.

Initially, the effects of remdesivir (RDV), dexamethasone (DEX), colchicine, and favipiravir were evaluated in each system at each drug's clinical maximum plasma concentration. The *in vitro* inhibitory kinetics of RDV toward CYP3A, P-gp, and OATP1B1 were evaluated over RDV concentration ranges of 0.01-500 µM.

Finally, the effects of ARVs on 10 µM RDV metabolism and transport were evaluated for ARVs that inhibit CYP3A4, P-gp, or OATP1B1.

Results: RDV (10 µM) significantly inhibited CYP3A (47.9%), P-gp (35.8%), and OATP1B1 (33.0%) activities. DEX (1 µM) significantly inhibited CYP3A (15.2%) and OATP1B1 (25.4%) activities. IC_{50} values of RDV toward MDZ metabolism and LPM efflux were 21.7 µM and 59.8 µM, respectively. RDV metabolism was significantly inhibited by zidovudine (53.5%), efavirenz (50.1%), darunavir (50.2%), lopinavir (53.8%), ritonavir (69.8%), and cobicistat (25.4%). RDV uptake was significantly inhibited by darunavir (15.4%), rilpivirine (25.0%), and ritonavir (19.3%). No ARVs inhibited RDV efflux.

Conclusions: Our current study suggests that RDV is a weak inhibitor of CYP3A, P-gp and OATP1B1, leading to DDIs with ARVs that should be monitored. Other treatments for COVID-19 studied here did not demonstrate significant DDIs with ARVs. As new COVID-19 therapeutics emerge, and given the prevalence of HIV worldwide, DDIs with ARVs must continue to be assessed.

Long-acting agents and other drug delivery systems (e.g., injectables, implants, dual therapies, microneedle patches)

Initiating long-acting cabotegravir and rilpivirine in a real-world setting – clinical characteristics and switch reasons from people living with HIV (PLHIV) and health care provider perspective in the German CARLOS cohort

C. Wyen[1], J. Scherzer[2], C. Jonsson-Oldenbuettel[3], C. Lieb[4], K. Ummard-Berger[5], C. Cordes[6], N. Postel[7], S. Dakhia[8], B. Westermayer[9], K. Bernhardt[2]

[1]*Praxis Ebertplatz, Cologne, Germany,* [2]*ViiV Healthcare, Munich, Germany,* [3]*MVZ München am Goetheplatz, Munich, Germany,* [4]*Praxis Goldstein, Berlin, Germany,* [5]*UBN Praxis, Berlin, Germany,* [6]*Praxis Dr. Cordes, Berlin, Germany,* [7]*prinzmed, Munich, Germany,* [8]*ViiV Healthcare, Brentford, London, United Kingdom,* [9]*GlaxoSmithKline, Munich, Germany*

Background: 2-monthly cabotegravir (CAB) + rilpivirine (RPV) long acting (LA) for HIV treatment offers a less frequent dosing alternative to daily oral antiretroviral therapy (ART). The CARLOS cohort is a non-interventional, multicenter, prospective study in PLHIV receiving CAB+RPV LA in routine care in Germany. Here we describe clinical characteristics and reasons for switching to LA therapy from a PLHIV and healthcare provider (HCP) perspective in a real-world setting.

Methods: Clinical characteristics were collected from medical records. Reasons for switching were assessed through surveys administered at baseline.

Results: Between May-Dec 2021,236 PLHIV initiated CAB+RPV LA across 19 sites in accordance with the SmPC. Median age was 42.5 (interquartile range (IQR);36.0-49.5), 95.3% (225/236) were male (Table1).

From the HCP perspective, the main reason (92.4%; n=218/236) for switching to CAB+RPV LA was "patient wish" (Fig1). Among PLHIV, "convenience" (62.8%; n=140/223) and "pill fatigue" (52.5%; n=117/223) were the most often cited reasons for choosing LA therapy. Prior to switching, 23.1% (50/216) of PLHIV reported having been often/always "worried about unintentional disclosure of their HIV status through oral therapy", 27.8% (n=60/216) often/always "worried about forgetting daily ART" and 29.6% (64/216) often/always felt "taking daily oral ART was an uncomfortable reminder of their HIV status".

The majority of PLHIV (84.7%;n=200/236) were started with an oral lead-in (OLI) phase prior to the injectables. For those choosing no OLI, "patient preference" was the main rationale provided (86.1%;n=31/36).

Conclusions: Switching to CAB+RPV LA in routine clinical care is primarily driven by patient choice with convenience and pill fatigue being the most often cited reasons for switching in this cohort.

	Total	Observed data
Sex, male, % (n)	95.3 % (225)	236
Age, years, median (interquartile range; IQR)	42.5 (36.0-49.5)	236
Age categories <50; 50-65; >65, % (n)	 75.0 % (177); 24.6 % (58); 0.4 % (1)	236
BMI ≥30 kg/m², % (n)	10.5 % (19)	181
CD4 T-cell count, cells/µL, median (IQR)	714.5 (543 – 986)	228
History of AIDS (CDC C), % (n)	7.6 % (18)	236
Time on ART, years (median, IQR)	8.1 (4.9-11.7)	210
Number of previous regimens ≥3, % (n)	43.2 % (102)	236

Long-acting cabotegravir+rilpivirine in older adults: pooled Phase 3 Week 96

E. Elliot[1], P.D. Benn[1], A. Clark[1], J.W. Polli[2], L. Garside[3], J. Roberts[4], R. D'Amico[2], S.L. Ford[5], S. Vanveggel[6], B. Baugh[7], J.A. Van Wyk[1]

[1]*ViiV Healthcare, Brentford, United Kingdom,* [2]*ViiV Healthcare, North Carolina, United States,* [3]*GlaxoSmithKline, London, United Kingdom,* [4]*GlaxoSmithKline, Mississauga, Canada,* [5]*GlaxoSmithKline, North Carolina, United States,* [6]*Janssen Research & Development, Beerse, Belgium,* [7]*Janssen Research and Development, Titusville, United States*

Background: Cabotegravir (CAB) + rilpivirine (RPV) is the first complete long-acting (LA) regimen for the maintenance of HIV-1 virologic suppression. With successes in HIV treatment, the proportion of people living with HIV aged ≥50 years (y) is increasing. Similar outcomes with CAB+RPV LA have been observed regardless of age through Week (W) 48. Here, longer-term outcomes through W96 are presented by age group.

Methods: Data from ATLAS-2M and FLAIR were pooled and stratified by age (<50 y and ≥50 y). Data from ATLAS-2M participants who transitioned from CAB+RPV in ATLAS were excluded. W96 efficacy endpoints were the proportion of participants with plasma HIV-1 RNA ≥50 (virologic non-response) and <50 copies/mL (virologic suppression). Incidence of confirmed virologic failure (CVF; two consecutive measurements of ≥200 copies/mL) and safety through W96 were also assessed.

Results: In total, 983 participants aged <50 y and 237 aged ≥50 y were randomized to receive CAB+RPV LA Q8W or Q4W, or continue oral ART (*Table*); 18 (LA, n=17; oral ART, n=1) were ≥65 y. Participants ≥50 y tended to have more comorbidities and co-medications at baseline vs. <50 y. Virologic outcomes were similar across arms and age groups; rates of virologic suppression were high (87–94%) and rates of non-response were low (1–3%). CVF rates were similarly low across arms and age groups (1–2%).
The frequency of drug-related adverse events (AEs), serious AEs, and AEs leading to withdrawal were comparable between age groups for both LA regimens. Injection site reactions were similar across age groups, most being mild to moderate. Outcomes were broadly comparable for participants ≥65 y.

‡Two consecutive measurements of HIV-1 RNA ≥200 copies/mL.
§No Grade 4 or Grade 5 events were reported.
AE, adverse event; ART, antiretroviral therapy; CAB, cabotegravir; CVF, confirmed virologic failure; ISR, injection site reaction;
LA, long-acting; Q4W, every 4 weeks; Q8W, every 8 weeks; RPV, rilpivirine; y, years.

Table. Pooled Outcomes From ATLAS-2M and FLAIR Stratified by Age (<50 y and ≥50y) at Week 96

Conclusions: CAB+RPV LA demonstrated high efficacy and acceptable safety and tolerability in participants aged <50 y and aged ≥50 y at W96. These data support the use of CAB+RPV LA as a complete maintenance regimen in adults irrespective of age.

EPB181

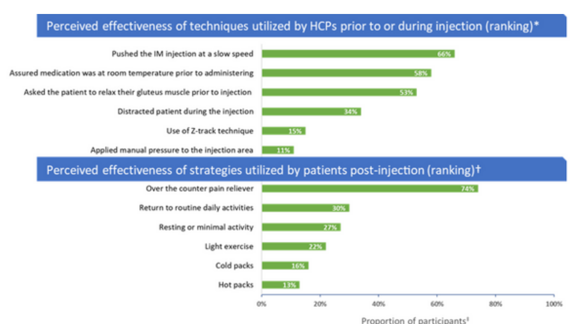
"Give it a Shot": best practices from HCPs for administering long-acting cabotegravir+rilpivirine

P. Teichner[1], E. Elliot[2], M. Pascual-Bernáldez[3], D. Merrill[1], C. Garris[1], R. D'Amico[1], R. Grove[4], R. Van Solingen-Ristea[5], B. Baugh[6], P. Patel[1], V. Vannappagari[1], J.A. van Wyk[2]
[1]ViiV Healthcare, North Carolina, United States, [2]ViiV Healthcare, Brentford, United Kingdom, [3]ViiV Healthcare, Madrid, Spain, [4]GlaxoSmithKline, London, United Kingdom, [5]Janssen Research & Development, Beerse, Belgium, [6]Janssen Research and Development, Titusville, United States

Background: Cabotegravir (CAB) + rilpivirine (RPV) dosed monthly or every 2 months is a complete long-acting (LA) regimen for the maintenance of HIV-1 virologic suppression. LA intramuscular (IM) gluteal injection is a novel antiretroviral delivery method that can cause discomfort/pain.
We surveyed injectors in the CAB+RPV development program on optimal administration techniques in order to inform clinical practice and improve patient/provider experience with gluteal injections.

Methods: Primary injectors across the Phase 3/3b program were invited to participate in an anonymous, self-administered online questionnaire containing 15 items with pre-defined response options and one open-ended item. Topics included provider demographics, clinical and injection experience, techniques used to minimize pre-/post-injection discomfort, and the perceived effectiveness of these techniques. Data were captured electronically and summarized using descriptive statistics.

Results: Surveys were sent to 161 sites in 15 countries. Overall, 181 providers returned the survey; 76% had administered ≥50 CAB+RPV injections. Among respondents utilizing ≥1 injection technique (n=169), the most commonly used and ranked as the most effective in minimizing pre-/post-injection pain were (*Figure*): pushing the IM injection at a slow speed (66%), bringing the medication to room temperature (58%), relaxing the gluteus muscle prior to injection (53%), and distracting the patient (34%).



*Data based on n=169 HCPs (93% of sample) who reported utilizing at least one technique prior to/during injections that successfully minimized pain/discomfort. n=12 HCPs (7% of sample) reported no techniques and were excluded from the base.
†Data based on n=145 HCPs (80% of sample) who reported study participants trying at least one post-injection strategy that successfully minimized pain/discomfort.
‡Percentages reflect the proportion of HCPs/participants who ranked each strategy as first, second, or third most effective at minimizing injection-associated pain/discomfort.
HCP, healthcare professional; IM, intramuscular.

Figure. Most effective techniques in minimizing pain/discomfort.

Overall, 60% of injectors felt that a prone position provided optimal patient comfort and 41% had no preference on injection order (CAB vs. RPV). Post-injection, the techniques ranked by injectors as most effective in minimizing pain, as reported to them by patients, were over the counter pain relievers (74%) and returning to routine daily activities (30%).

Conclusions: In the Phase 3/3b studies, CAB+RPV LA injections were well tolerated, associated with low rates of treatment discontinuation due to injection site reactions, and preferred by patients over daily oral therapy. These data support that simple techniques, routinely used by injectors, help optimize the administration of CAB+RPV LA.

EPB182

Long-acting cabotegravir+rilpivirine injection site reactions: pooled Week 96 results

N. Chamay[1], E. Elliot[1], S. Dakhia[1], J.W. Polli[2], L. Garside[3], P. Teichner[2], S. Thiagarajah[3], R. D'Amico[2], R. Van Solingen-Ristea[4], E. Birmingham[5], B. Baugh[6], J.A. van Wyk[1]

[1]ViiV Healthcare, Brentford, United Kingdom, [2]ViiV Healthcare, North Carolina, United States, [3]GlaxoSmithKline, London, United Kingdom, [4]Janssen Research & Development, Beerse, Belgium, [5]Janssen Research & Development LLC, Raritan, United States, [6]Janssen Research and Development, Titusville, United States

Background: Long-acting cabotegravir + rilpivirine (CAB+RPV LA) administered monthly or every 2 months is the first complete LA regimen recommended by treatment guidelines for the maintenance of HIV-1 virologic suppression. Across Phase 3/3b trials, the most frequently reported adverse events were injection site reactions (ISRs).

Here, we present pooled ISR outcomes by regimen, sex, and body mass index (BMI) from the ATLAS-2M and FLAIR studies through Week (W) 96.

Methods: Data from participants receiving CAB+RPV LA in ATLAS-2M and FLAIR were pooled and stratified by dosing regimen, sex at birth, and baseline BMI category. Data from ATLAS-2M participants who transitioned from CAB+RPV in ATLAS were excluded. ISR characteristics were evaluated through W96.

Results: A total of 920 (Q8W, n=321; Q4W, n=599) participants received ≥1 injection of CAB LA/RPV LA across ATLAS-2M and FLAIR, representing 34,939 injections through W96 (Q8W, n=7954; Q4W, n=26,985) (**Table**). Overall, 8453 ISRs (Q8W, n=2345; Q4W, n=6108) were reported by 801 participants (Q8W, 89% [n=285]; Q4W, 86% [n=516]). Most were mild to moderate in severity (Grade 1, 83%; Grade 2, 16%; Grade 3, 1%), with a median (interquartile range) duration of 3 days (2–4), and 86% had a duration ≤7 days. The most commonly reported ISRs (% of injections) were pain (20%), nodule (1%), and discomfort (1%). ISRs decreased in incidence over time, being reported by 71%, 24%, and 15% of participants at W4, W48, and W96, respectively. Withdrawals due to ISR-related reasons were infrequent and comparable between dosing regimens, occurring in 2% (n=20/920) of participants (majority were injection intolerability [n=10]). ISR profiles over 96 weeks were generally comparable across regimen, sex, and baseline BMI category.

	Dosing Regimen			Sex at Birth		Baseline BMI Category

Week 96 weight and lipid changes from baseline among participants receiving cabotegravir and rilpivirine long-acting or comparator therapy in the ATLAS-2M and FLAIR studies

P. Patel[1], E. Elliot[2], R. D'Amico[1], L. Garside[3], C. Smith[4], J. Roberts[5], J.W. Polli[1], R. Van Soligen-Ristea[6], C. Orkin[7], E.T. Overton[8], S. Swindells[9], B. Baugh[10], J.A. van Wyk[2]
[1]ViiV Healthcare, North Carolina, United States, [2]ViiV Healthcare, Brentford, United Kingdom, [3]GlaxoSmithKline, London, United Kingdom, [4]Parexel International, Sheffield, United Kingdom, [5]GlaxoSmithKline, Mississauga, Canada, [6]Janssen Research & Development, Beerse, Belgium, [7]Queen Mary Univeristy, London, United Kingdom, [8]University of Alabama, Birmingham, United States, [9]University of Nebraska Medical Center, Omaha, United States, [10]Janssen Research and Development, Titusville, United States

Background: Long-acting cabotegravir + rilpivirine (CAB+RPV LA) administered monthly or every 2 months is the first and only complete LA regimen recommended by treatment guidelines for the maintenance of HIV-1 virologic suppression. In pooled Phase 3/3b studies, weight and lipid changes from baseline were modest in participants receiving CAB+RPV LA or comparator antiretroviral regimen (CAR) through Week (W) 48. Weight and lipid changes from baseline to W96 in the ATLAS-2M and FLAIR studies are presented.

Methods: Data from 1220 participants naive to CAB+RPV in ATLAS-2M and FLAIR were pooled; 937 were randomized to CAB+RPV LA (every 4 or 8 weeks). Data were compared with 283 participants randomized to CAR (abacavir/dolutegravir/lamivudine; FLAIR only). Changes from baseline in weight, BMI, and lipids at W96 were analyzed.

Results: Median (range) weight change from baseline to W96 was +1.80kg (−24.6, 25.4) in the pooled LA arms and +2.00 kg (−17.3, 35.7) in the CAR group (*Table*).

Weight increases of ≥5% and ≥10% occurred in 32% (n=261/825) and 12% (n=103/825) of participants, respectively, in the pooled LA arms compared with 34% (n=86/255) and 13% (n=33/255) in the CAR group. At W96, 16% (n=75/460) of pooled LA participants and 20% (n=32/160) of CAR participants shifted BMI category from normal to overweight, and 12% (n=37/311) and 11% (n=8/75) of overweight participants shifted to obese, respectively. A higher proportion of participants with ≥10% weight gain were female and Black. There were no clinically relevant changes in lipid profiles between groups.

Conclusions: Median weight changes remained modest and comparable between CAB+RPV LA and CAR participants at W96. Weight increases of ≥10% and upward BMI shifts were uncommon, with no significant lipid changes observed. A study comprehensively evaluating potential for weight and metabolic changes with oral and LA INSTI-based regimens is ongoing.

Injection site reaction experience in clinical studies of people using lenacapavir for HIV treatment

P. Kumar[1], S. Gupta[2], S. Segal-Maurer[3], O. Ogbuagu[4], C. McDonald[5], C. Brinson[6], A. Chester[7], H. Wang[7], H. Dvory-Sobol[7], M. Rhee[7], J. Baeten[7], J.-M. Molina[8]
[1]*Georgetown University Medical Center, Washington, United States,* [2]*Indiana University, Indianapolis, United States,* [3]*New York Presbyterian Queens, Flushing, United States,* [4]*Yale University School of Medicine, New Haven, United States,* [5]*Texas Centers for Infectious Disease Associates, Fort Worth, United States,* [6]*Central Texas Clinical Research, Austin, United States,* [7]*Gilead Sciences, Foster City, United States,* [8]*Hopital Saint Louis, Paris, France*

Background: Lenacapavir (LEN), a potent first-in-class capsid inhibitor, is in development as a 6-monthly subcutaneous (SC) injection for treatment and prevention of HIV-1 infection. In animals, SC injection led to reversible chronic granulomatous inflammation at the injection site as a foreign body response to LEN drug depot.

Methods: We characterized the injection site reactions (ISRs) in participants who received at least one dose of subcutaneous (SC) LEN 927 mg (2 x 1.5 mL) in clinical studies in heavily treatment experienced (CAPELLA) and in treatment naïve (CALIBRATE) people with HIV (PWH).

Results: In CAPELLA, 72 participants received at least one and 70 two doses of SC LEN. In CALIBRATE, 103 received at least one and 95 two doses. The median duration of follow up was 376and 449 days, respectively. Most ISRs (97%, 99/102 participants) were Grade 1 or 2, rarely leading to discontinuation (4 participants: 1 [nodule], 2 [induration] 1 [erythema/swelling]). Common ISRs (any ISR ≥10% in both studies) were swelling, erythema, pain, nodule and induration, which generally occurred less frequently with subsequent injection (Table).

Swelling, erythema and pain generally resolved within days; nodule and induration resolved over months. Investigators reported nodules and induration as generally palpable, not visible, non-erythematous, nonpainful.

	CAPELLA			CALIBRATE		
ISR types	1st SC (n=72) %	2nd SC (n=70) %	Median duration (days)	1st SC (n=103) %	2nd SC (n=95) %	Median duration (days)
Swelling	26%	13%	12	14%	12%	11
Erythema	24%	11%	6	14%	18%	5
Pain	22%	21%	3	15%	9%	4
Nodule	22%	11%	180	11%	8%	195
Induration	11%	10%	118	9%	6%	202

Table.

Conclusions: Among PWH using SC LEN, ISRs were generally mild to moderate, rarely leading to discontinuation, and decreased in frequency with subsequent injection. Most ISRs resolved within days, while induration and nodules gradually improved over months but were generally not visible or painful. The pattern and nature of ISRs is consistent with preclinical experience.

EPB185

Preference for long acting injectable (LAI) antiretrovirals for HIV treatment or PrEP in Argentina

S. Sciannameo[1], V. Zalazar[1], L. Spadaccini[1], M. Duarte[1], I. Aristegui[1], P. Cahn[1], O. Sued[2]
[1]*Fundación Huésped, Research Department, Buenos Aires, Argentina,* [2]*PAHO, HT Unit, Washington DC, United States*

Background: Information on long acting injectable (LAI) antiretrovirals preference is limited in Latin America. This study assessed preference for LAI antiretrovirals (ARV) and its correlations, among people living with HIV (PLHIV) and people willing to receive PrEP in Argentina.

Methods: An online survey was conducted, addressing HIV negative people willing to use PrEP and also PLHIV already on oral treatment. The sample was divided into: cisgender women (CW), trans and non-binary (TNB) and cisgender men (CM), identified as heterosexual (HCM) and gay, bisexual or queer (GBQ). Descriptive statistics were used to summarize data.

Results: The survey was responded by 1676 participants (M= 33 years, IQR: 28–41), including 786 CW, 88 TNB and 802 CM, of whom 85 self-identified as HCM and 717 as GBQ men. Among the 804 PLHIV, the majority (91.5%) preferred LAI (13.4% bimonthly and 78.1% six-monthly).

Preference for LAI was high in all groups: CW 86.7%, HCM 84.6% , CBQ 94.8%, and TNB 85.1%. Common reasons for preferring LAI over pills were discretion and no need to remember taking pills.

There was a positive association between LAI preference and identifying as GBQ cis men (Z=4,3; p<.05) and negative for cis women (Z = - 2,9; p< .05). Also, there was a positive association with respondents who have a higher educational level (Z = 4,3; p <; .05) and those who used injectable medication before (Z = 2,6; p< .05). Concerning PrEP, among 894 HIV negative participants, 68% preferred LAI (10.8% bimonthly and 57.2% six-monthly). Preference for LAI PrEP was similar in all groups: CW 68.8%, HCM 72.7%, GBQ 65.6%, TNB 65.9%.

Common reasons for choosing LAI PrEP were not wanting to take pills every day and fear of forgetting them. LAI preference for PrEP was positively associated with having had a good experience using injectable medication before (Z = 3,4; p< .05).

Conclusions: Overall, acceptance of LAI was high for both potential PrEP users and PLHIV based on its convenience, particularly among those with previous experience. Still more information is needed related to its implementation in our context and to the perspective of decision makers and health care providers.

Early implementation and clinical outcomes of long-acting injectable cabotegravir and rilpivirine in a safety-net HIV clinic

K. Christopoulos[1], J. Grochowski[1], M. Hickey[1], E. Imbert[1], J. Szumowski[1], S. Dilworth[1], J. Briggs[1], J. Oskarsson[1], M. Shiels[1], F. Mayorga-Munoz[1], D. Havlir[1], M. Gandhi[1]
[1]*University of California San Francisco, San Francisco, United States*

Background: Registrational trials of long-acting cabotegravir-rilpivirine (CAB/RPV-LA) required viral suppression (VS) on oral antiretrovirals, but CAB/RPV-LA may benefit patients who are unable to attain VS due to adherence challenges. We sought to assess the feasibility and early clinical outcomes of CAB/RPV-LA implementation in a large safety-net HIV clinic.

Methods: Informed by the capability-opportunity-motivation behavior (COM-B) model, Ward 86 in San Francisco developed a pilot program to support provider initiation and patient adherence to CAB/RPV-LA. Provider supports included education/training and a clinic pharmacy team for review, insurance authorization, and initiation. Patient referral eligibility consisted of regular clinic attendance, no RPV and ≤1 integrase inhibitor mutation, and locator information. Patient-centered supports included education, a direct-to-inject option, and reminder/follow-up phone calls/texts.

Additionally, patients without VS had individualized plans, including identification of community-based supports (e.g. case managers), community-based injection sites, and financial incentives. Appointment attendance and viral load (VL) monitoring for all patients were aided by electronic medical record reports and reviewed in multidisciplinary (MD/RN/pharmacy) case conferences. We defined viral suppression as VL<40 copies/mL.

Results: From February-November 2021, providers referred 70 patients, of whom 16 are in process and 29 are on hold due to patient/provider preference. Of 25 patients who started CAB/RPV-LA, median age was 46; 8% were cis-women, 20% Black, 16% Latinx, 36% experiencing homelessness/unstable housing, and 56% currently using stimulants. Twenty-three (92%) patients have had 100% on-time injection attendance, defined as within +/- 7 days of a 28-day injection cycle, with the other two patients late for only one injection each. Of 14 starting with VS (median CD4 680), 11 (79%) direct-to-inject, with median 4 injections (2-6 injections), 13 (96%) have maintained VS and 1 patient is without follow-up VL due to unexpected travel. Of 11 starting without VS (median CD4 135, mean log10 VL 4.93), all direct-to-inject, with median 4 injections (3-8 injections), 8 (73%) have achieved VS. For the 3 patients without VS, 100% have had a two-log VL decline by median 22 days.

Conclusions: Our data demonstrate the feasibility and promise of a patient-centered approach for CAB/RPV-LA implementation for both those with VS and those with challenges adhering to oral therapy.

Adherence

EPB187

Viral load suppression after intensive adherence counselling among HIV infected adults at Kiswa health centre, Kampala: a retrospective cohort study. Secondary data analysis

C. Nakaye[1]
[1]*Makerere University - Johns Hopkins University (MU-JHU) Research Collaboration/MU-JHU CARE LTD, Clinic, Kampala, Uganda*

Background: The Joint United Nations Programme on HIV/AIDS through the 95-95-95 target requires 95% of people with HIV infection (PWHIV) on antiretroviral treatment (ART) to be virally suppressed. Viral Load (VL) non-suppression has been found to be associated with suboptimal ART adherence, and intensive adherence counselling (IAC) has been shown to lead to VL re-suppression by over 70% in PWHIV on ART. Currently, there is data paucity on VL suppression after IAC in adult PWHIV in Uganda.

This study aimed to evaluate the proportion of VL suppression after IAC and associated factors among adult PWHIV on ART at Kiswa health centre in Kampala, Uganda.

Methods: Study was a retrospective cohort design and employed secondary data analysis to review routine program data. Medical records of adult PWHIV on ART for at least six months with VL non-suppression from January 2018 to June 2020 at Kiswa HIV clinic were examined in May 2021. Descriptive statistics were applied to determine sample characteristics and study outcome proportions. Multivariable modified Poisson regression analysis was employed to assess predictors of VL suppression after IAC.

Results: Analysis included 323 study participants of whom 204 (63.2%) were female, 137 (42.4%) were between age of 30 and 39 years; and median age was 35 years (interquartile range [IQR] 29-42).

Participant linkage to IAC was 100%. 48.6% (157/323) of participants received first IAC session within 30 days or less after unsuppressed VL result. 66.78% (205/307) of participants who received recommended three or more IAC sessions achieved VL suppression. 34% of participants completed three IAC sessions in recommended 12 weeks.

Receipt of three IAC sessions (ARR = 1.33, 95%CI: 1.16-1.53, p<0.001) and having baseline VL of 1,000 - 4,999 copies/ml (ARR =1.47, 95%CI: 1.26-1.73, p<0.001) was significantly associated with VL suppression after IAC.

Conclusions: VL suppression proportion of 66.78% after IAC in this population was comparable to 70%, the percentage over which adherence interventions have been shown to cause VL re-suppression.

However, timely IAC intervention is needed from receipt of unsuppressed VL results to IAC process completion. Resistance testing should be performed for PWHIV with persistent VL non-suppression after IAC for apt ART regimen switch.

EPB188

Antiretroviral Therapy (ART) use among pregnant enrollees receiving medicaid managed care

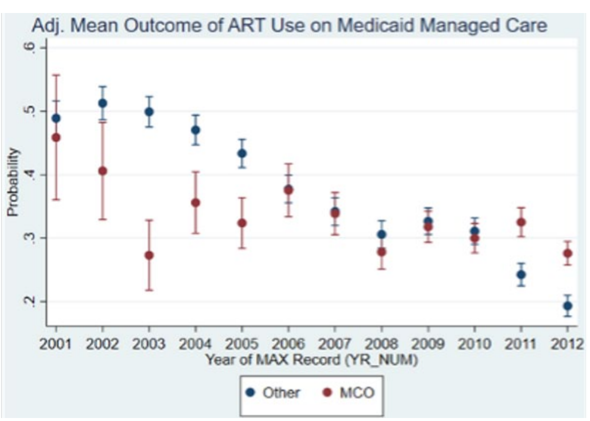
K.D. Thompson[1], D.J. Meyers[1], J. Ellison[1], I.B. Wilson[1]
[1]*Brown University, Providence, United States*

Background: Medicaid is a critical source of care, including ART, for vulnerable HIV+ pregnant women. Between 2001-2012 the number of persons with Medicaid covered by capitated managed care organizations (MCOs) increased dramatically. We address 2 questions in this abstract:

1. Overall, what is the trend in ART use among pregnant women with Medicaid between 2001–2012; and
2. What is the relationship between this trend and MCO, versus other (mostly fee-for-service) coverage.

Methods: In this observational study, we used 12 years (2001-2012) of Medicaid Analytic eXtract (MAX) data from the 14 states with the highest prevalence of HIV (CA, FL, GA, IL, LA, MA, MD, NC, NJ, NY, OH, PA, TX, VA) to examine ART use among pregnant mothers enrolled in an MCO. We fit a multivariable logistic regression model, adjusting for patient characteristics (age, race/ethnicity, state, eligibility, rurality, prenatal care visits, substance use, and comorbid conditions), and an interaction between MCO status and year to measure the association between MCO enrollment and ART use over time.

Results: Among 30,656 deliveries from 23,755 HIV+ Medicaid enrollees, we identified 10,565 [34.5%] with any ART use 12 months prior to delivery. Overall, rates of ART use fell from 37.7% in 2001 to 27.18% in 2012. Trends by coverage type are shown in the Figure. Early on, ART use was higher in those with non-MCO coverage, but in 2011 and 2012 ART use was higher in MCO.



Conclusions: ART use declined among pregnant women in Medicaid 2001-2012, and after adjustment the decline was greater for women with non-MCO coverage than for those with MCO coverage. The observed decline in ART use cannot be explained by the expansion of MCO coverage or patients' clinical characteristics. Additional analysis is needed to assess drivers of low adherence in this population and the role of MCOs in HIV care engagement.

EPB189

Construction and validation of a questionnaire to measure adverse effects of antiretrovirals in the Mexican population

V. Rodríguez Pérez[1]
[1]*Condesa Specialized Clinic, Antiretrovirals Adherence & Polypharmacy Clinic, CDMX, Mexico*

Background: Until now, there wasn't a validated questionnaire that records adverse events on antiretroviral therapy (ART) in the Mexican population. With polypharmacy, adverse events are critical for adherence to ART. The terminology of each report varies; therefore, it is convenient to document the discomfort through a validated questionnaire that can be self-applied and standardized to the main events with current therapies. We aimed to perform and validate a self-reported questionnaire of adverse events with ART use.

Methods: We performed the bibliographic review of ART's adverse events and formulated 57 questions. The importance and relevance were performed with the content validity by the method by 13 judges.

A pilot study was conducted with ten patients of different socioeconomic levels to evaluate whether the questions were understandable and culturally relevant. The psychometric statistical analysis was performed with 377 patients who completed 57 items.

We performed an internal consistency analysis to eliminate the redundant items. With a factorial analysis with orthogonal rotation, a principal components method to the 57 questions three times, we excluded those items with factorial charges less than .40 and preserved the statistically significant items.

Results: Only 23 to 57 questions were grouped in five factors (mean intercorrelations r= 0 40, KMO of 0. 917): sleeping and productivity disorders, neuropsychiatric area, general discomfort, weight gain & digestion disorders, and cognitive area, with 34.6%, 9.5%, 5.96%, 5.35%, 5.10% of explained variance, respectively.

The Cronbach's Alpha for the questionnaire was 0.90 and from 0.70-0.86 by factors & 60.5% of the total explained variance.

Factor (items number)	Cronbach's Alpha (reliability coefficient)	Explained Variance (%)	Item- total correlations
"Sleeping and productivity disorders" (6)	0.86	34.6%	0.52-0.75
Neuropsychiatric area (5)	0.77	9.5%	0.38-0.66
"General discomfort" (5)	0.70	5.96%	0.40-0.69
Weight gain & Digestion disorders (4)	0.84	5.35%	0.43-0.70
Cognitive area (3)	0.70	5.10%	0.39-0.65
Questionnaire Total (23)	0.90	60.5 %	0.40-0.75

Table 1. Reliability and validity for the factors & total questionnaire.

Conclusions: The development of the questionnaire has the methodological support to be applied in the Mexican population in ART. The measurement index was adequate and useful to have homogenized reports of adverse events in different therapeutically ART groups.

Sex-specific (including cis- and transgender) issues of ART efficacy, adverse reactions and complications

Do ART and chemsex drugs get along? Potential drug-drug interactions in a cohort of HIV-positive chemsex users

L. De La Mora[1], M.J. Nebot[2], E. De Lazzari[1], M. Tuset[3], M. Laguno[1], A. Ugarte[1], A. Inciarte[1], B. Torres[1], A. González-Cordón[1], J. Ambrosioni[1], E. Martinez[1], J.L. Blanco[1], D. Short[4], J. Mallolas[1], M. Martinez-Rebollar[1]
[1]Hospital Clinic of Barcelona, Infectious Diseases, Barcelona, Spain, [2]Universidad de Barcelona, Faculty of Medicine, Barcelona, Spain, [3]Hospital Clinic of Barcelona, Pharmacology, Barcelona, Spain, [4]ViiV Healthcare, Brentford, United Kingdom

Background: HIV infection has evolved into a chronic condition requiring life-long antiretroviral treatment (ART), exposing people living with HIV (PLWH) to potential drug-drug interactions (pDDIs) with co-administered substances. There is an increased risk of pDDIs among PLWH chemsex users, due to intake of recreational illicit drugs alongside a chronic ART.
This study aims to characterize potential ART and chemsex drugs pDDIs and evaluate their association with unscheduled relevant medical and psychiatric hospital consultations and admissions.
Methods: Single-centre, retrospective, observational study of pDDIs between ART and recreational drugs in a series of gbMSM (gay, bisexual and other men who have sex with men) PLWH who practice chemsex attending a tertiary hospital from march 2017 through march 2020. In order to study associations between all recorded pDDIs and relevant clinical events related to the individuals detected in the unscheduled medical visits, we estimated the incidence rate (IR) per 100 person-years of those events and compared it between patients with green (absence of pDDI) and orange-flag (moderate severity pDDI) or red-flag (high severity pDDI) using the Incidence Rate Ratio (IRR).
Results: A total of 172 PLWH chemsex users were included. ART regimens were mostly based on integrase inhibitors (44%). The most frequently used substances and recreational drugs were erectile dysfunction agents (83%), methamphetamine (79%), GHB (77%) and alkyl nitrites (71%). Polydrug use was reported in 52% of the participants. Of the 2048 pDDIs found, 23% were orange flag pDDIs; 88% related to boosted ARTs and 8% to non-nucleoside reverse transcriptase inhibitors. The IR of the 285 unscheduled relevant episodes in patients with orange-flag pDDIs was 64.67 (95%CI: 40.07; 89.28), and the IRR relative to green flag pDDIs was 1.05 (95%CI: 0.60; 1.8, p=0.876).
Conclusions: Despite the fact that one in four chemsex users present pDDIs between drugs and ART, mainly with boosted-ARTs, we have not found evidence of an increased incidence of unscheduled relevant medical and psychiatric consultations among exposed patients.
Further research should be conducted on this subject and a multidisciplinary approach to these patients is recommended.

EPB191

Periconceptional dolutegravir use and risk of adverse pregnancy outcomes in Kenya

J. da Silva[1], K. Masamaro[2], J. Githuku[3,3], B. Ochieng[4], C. Mai[5], J. Williams[5], P. Akinyi[6], P. Wekesa[7], S. Okutoyi[8], L. Momanyi[9], I. Mukui[10], M. Kimani[10], A. Katana[2], C. Toroitich-Ruto[2], J. Muthusi[2], E. Ngugi[2], L. Nganga[2,2], T.-H. Chen[2]
[1]Centers for Diseases Control and Prevention, Division of Global HIV and Tuberculosis, Atlanta, United States, [2]Centers for Diseases Control and Prevention, Division of Global HIV and Tuberculosis, Nairobi, Kenya, [3]Field Epidemiology and Laboratory Training Program, Nairobi, Kenya, [4]Ministry of Health, Division of Adolescent and School Health, Nairobi, Kenya, [5]Centers for Diseases Control and Prevention, Division of Birth Defects and Infant Disorders, Atlanta, United States, [6]University of Nairobi, Nairobi, Kenya, [7]Center for Health Solutions, Nairobi, Kenya, [8]United States Agency for International Development, Nairobi, Kenya, [9]Ministry of Health, National AIDS & STI Control Program (NASCOP), Nairobi, Kenya, [10]Drugs for Neglected Diseases Initiative, Nairobi, Kenya

Background: Previous studies suggested an association between periconceptional dolutegravir (DTG) use among women of childbearing age (WCBA) and neural tube defects (NTDs) in the offspring. This safety signal, which prompted countries to delay or suspend plans to transition WCBA to DTG regimens. While the initial safety signal observed was not confirmed in subsequent data, many countries continued to be hesitant to use DTG in WCBA. We conducted a nested cohort study at 23 sites in Kenya that had WCBA on DTG regimens to assess the relationship between exposure to DTG and NTDs.
Methods: We identified 198 women periconceptionally exposed to DTG from July 1, 2017– July 5, 2019 and matched them to 398 women periconceptionally exposed to efavirenz (EFV) by maternal age, last menstrual period date and facility type. Data were collected through interviews and medical records abstraction. The subset of women pregnant at the time of the study were prospectively fol-

lowed through monthly phone calls until birth, and infant exams were conducted at delivery. Outcomes captured include NTDs, stillbirths, prematurity, and small for gestational age (SGA). We compared proportions in different risk categories using chi-square test.

Results: No NTDs were identified among women exposed to DTG or EFV. One case of cleft lip and palate was detected in the EFV cohort. There was no statistically significant difference of any adverse pregnancy outcomes (stillbirths, prematurity, SGA) between DTG and EFV cohorts (DTG: 28.8%, EFV: 26.0% p=0.54), pretermdelivery (DTG: 9.6%, EFV: 12.0%, p=0.46) small for gestational age (DTG: 16.2, EFV: 13.3%, p=0.41) or stillbirth (DTG 3.0%, EFV: 1.3%p=0.24).

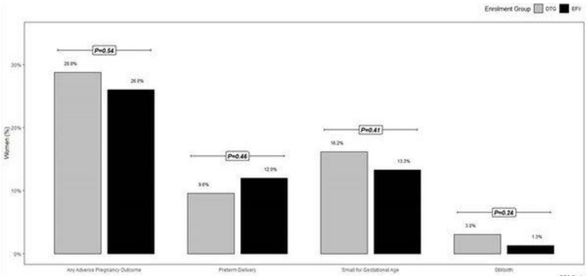

Figure. Pairwise comparison of adverse pregnancy outcomes by enrolment group.

Conclusions: We did not find a NTD signal or a difference in adverse pregnancy outcomes between DTG and EFV cohorts. These findings are consistent with other published studies and support current WHO guidelines to use DTG as a preferred first-line ARV drug in all populations.

Pregnancy (clinical management issues and pharmacokinetics) and contraception

EPB192
Impact of mother mentors' model to improve retention in PMTCT services in health facilities supported by Global Funds. a case from Christian Social Services Commission (CSSC)-AMREF, Tanzania

A. Kosia[1], A. Godwin[1], D. Kajoka[2], N. Makyao[3]
[1]Christian Social Services Commission, Health, Dar es Salaam, Tanzania, The United Republic of, [2]Ministry of Health Gender Elderly and Children, PMTCT unit, Dodoma, Tanzania, The United Republic of, [3]AMREF - AFRICA, Health, Dar es Salaam, Tanzania, The United Republic of

Background: Social Stigma and gender-based violence against people living with HIV/AIDS is still prevalent among the communities in Tanzania. This situation has exacerbated lack of access to quality prevention of Mother to Child Transmission (PMTCT) services to women and adolescent girls living with HIV/AIDS. The Global Fund's (PMTCT) project (2021-2023) is implemented by CSSC--AMREF at the rural areas and non-supported health facilities in 8 regions of Arusha, Lindi, Pwani, Morogoro, Tabora, Shinyanga, Mwanza and Geita where the project covers using Mother Mentor's model.

Description: The project trained 606 mother mentors and 264 health care workers who acts as their supervisors in all regions for ten days based on the national PMTCT mother mentor's curriculum in June and July 2021. A monthly monitoring and evaluation tracking tools were developed and were given to mother mentors.

Additionally, others mentors are supported with monthly transport allowances to facilitate their movement during sensitization, awareness creation campaign and tracking pregnant and breastfeeding women, children, and adolescents with HIV/AIDS to attend PMTCT services as part of strengthening the linkage between community and health facility in ensuring they reduce HIV transmission and mortality in the respective regions.

The use of Mother Mentors is reportedly to have significantly contributed to some positive results in the targeted communities. The GF PMTCT project's quarterly report revealed that, a total of 494 PMTCT clients lost to follow up were linked to care, 446 clients were linked to psychosocial and income generating activities (PSAG), thirdly 136 PSAG groups comprising of 940 members were formed of which 582 are PMTCT members.

Lessons learned: Mother Mentors plays a significant role in improving retention of mother baby pair between community and health facilities level. They need to be supervised and supported both technically and financially to be able to assist PMTCT cascades at the community setting.

Conclusions/Next steps: MM need to be scaled in other countries.

EPB193
Associations between HIV/ART exposure during pregnancy and adverse maternal and infant outcomes in the MANGO cohort in western Kenya

R. Patel[1], J. Humphrey[2], A. Chepkemoi[3], M. McPherson[2], M. Alera[4], S. Brown[2], A. Monroy[2], J.G. Carlucci[2], W. Kosgei[3], M. McHenry[2], C. Bernard[2], L. Oyiengo[5], B. Ochieng[5], B. Musick[2], C. Yiannoutsos[2], K. Wools-Kaloustian[2], E. Were[3]
[1]University of Washington, Seattle, United States, [2]Indiana University, Indianapolis, United States, [3]Moi Teaching and Referral Hospital, Eldoret, Kenya, [4]Academic Model for Providing Access to Healthcare, Eldoret, Kenya, [5]Ministry of Health, Nairobi, Kenya

Background: Data eliciting associations betweenantiretroviral treatment (ART) exposure and adverse maternal and newborn outcomes, including congenital abnormalities, are limited. We explored these outcomes within theMeasuring Adverse Pregnancy and Newborn Congenital Outcomes (MANGO) study in western Kenya.

Methods: MANGO is a cohort study that uses mixed prospective and retrospective data collection to ascertain delivery outcomes among pregnant women living with

HIV (WLHIV) and not living with HIV (WNLHIV) enrolled in care or delivering at a tertiary referral facility in western Kenya. For this analysis, women with singleton pregnancies from 9/2020 to 11/2021 werestratified by HIV status and ART exposure (i.e., WLHIV on dolutegravir [DTG] versus WLHIV on non-DTG-containing ART).

We utilized multivariate logistic regression models to determine factors associated with our composite outcome ofadverse maternal (i.e., emergency c-section delivery) and infant outcomes (i.e., stillbirth, preterm birth [<37 weeks gestation], low birth weight [<2.5 Kg], congenital abnormality, and neonatal death).

Results: Among 7,075 women with a documented delivery, 6910 (98%, median age 26 years) had singleton pregnancies and 344 (5%) were WLHIV. Among 176 WLHIV with recorded ART exposure, 149 (85%) were on DTG- and 27 (15%) were on non-DTG-containing ART. The composite outcome occurred in 2,846 (40%) of women overall, and by group: WNLHIV (40%), WLHIV (40%), WLHIV on DTG (34%), WLHIV on non-DTG-containing ART (41%).

Neither HIV status (aOR 0.970, 95% CI 0.78-1.21) nor DTG exposure (aOR 0.54, 95% CI 0.21-1.40) were associated with the composite outcome. Transferring into the study facility for delivery was associated with increased odds of the composite outcome regardless of HIV status (aOR 3.82, 95% CI 3.17-4.61).

Variable	All WLHIV (regardless of ART) and WNLHIV (n=6910)		WLHIV on DTG and WLHIV on non-DTG ART (n=176)	
	uOR (95% CI)	aOR[1] (95% CI)	uOR (95% CI)	aOR[2] (95% CI)
Age at delivery	1.004 (0.996-1.012)	1.002 (0.991-1.013)	**0.950 (0.905-0.908)**	0.980 (0.920-1.043)
Gravidity	1.028 (0.993-1.064)	1.010 (0.963-1.060)	0.807 (0.641-1.016)	0.883 (0.664-1.176)
Transfer in	**3.869 (3.212-4.660)**	**3.822 (3.171-4.607)**	**4.037 (1.164-14.00)**	3.623 (0.988-13.29)
Years on ART	n/a	n/a	0.966 (0.904-1.033)	0.963 (0.664-1.176)
HIV positive status (positive vs. negative)	0.970 (0.777-1.211)	0.934 (0.743-1.174)	n/a	n/a
DTG exposure	n/a	n/a	0.757 (0.327-1.752)	0.541 (0.210-1.396)
aOR=adjusted odds ratio; ART=antiretroviral therapy; CI=confidence interval; DTG, dolutegravir; uOR=unadjusted odds ratio; WLHIV=women living with HIV; WNLHIV=women not living with HIV; Note: Statistically significant factors in bold type; [1] Calculated with a logistic regression model among the cohort of WLHIV (regardless of ART exposure) and WNLHIV, adjusting for the other variables, as applicable, in the table; [2] Calculated with a logistic regression model among the cohort of WLHIV on DTG and WLHIV on non-DTG ART, adjusting for the other variables, as applicable, in the table.				

Conclusions: Transfer status, a likely indicator of women at increased risk of adverse pregnancy outcomes, should be accounted for when implementing pharmacovigilance programs at tertiary facilities. Pharmacovigilance programs need to continue monitoring adverse outcomes as new antiretrovirals become available in resource-limited settings.

EPB194

A multicentre observational study to determine the safety and effectiveness of dolutegravir (DTG) use during pregnancy: data from DOLOMITE-NEAT ID Network study

J. Kowalska[1], S. Antoniak[2], L. Assoumou[3], A. Pozniak[4], T. Rybak[5], S. De Wit[6], A. Milinkovic[4], S. Roedling[7], A. Duffy[8], C. Fletcher[8], L. Ragone[9], C. Thorne[10], V. Vannappagari[9]

[1]Medical University of Warsaw, Hospital for Infectious Diseases, Warsaw, Poland, [2]Gromashevsky Institute of Epidemiology and Infectious Diseases, Viral Hepatitis and AIDS Department, Kyiv, Ukraine, [3]INSERM, Paris, France, [4]Chelsea & Westminster Hospital, London, United Kingdom, [5]Odesa Regional Centre of Socially Significant Diseases, Odesa, Ukraine, [6]CHU Saint-Pierre, Brussels, Belgium, [7]Mortimer Market Centre, London, United Kingdom, [8]Research Organisation (Kings Cross) Ltd, London, United Kingdom, [9]ViiV Healthcare, Research Triangle Park, United States, [10]Fondazione Penta Onlus, Padua, Italy

Background: This analysis assessed real-world outcomes from women living with HIV on DTG based regimen (DBR) during pregnancy according to exposure trimester, using data from clinical sites participating in DOLOMITE -NEAT ID Network study.

Methods: Data were included from woman in Europe and Canada who were exposed to DBR during pregnancy for at least one day. Exposure was categorised by trimester, overall days and days per trimester. No adjusted analysis was performed because of the small number of events observed except maternal VL at delivery and birth weight.

Results:

1	Characteristics at DTG first exposure in pregnancy	Any trimester N=138	1st Trimester, N=92 (66.7%)	2nd or 3rd trimester N= 46 (33.3%)	P-value
2	Age, years, median (IQR)	32 (27-37)	33 (28-37)	30 (26-36)	0.229
3	Ethnicity, n (%): White; Black; Other/Unknown.	56 (40.6); 55 (39.9); 27 (19.6)	33 (35.9); 40 (43.5); 19 (20.7)	23 (50.0); 15 (32.6); 8 (17.4)	0.275
4	Time since HIV diagnosis, years, median (IQR)	9.1 (4.3-15)	9.4 (5.2-15.5)	5.2 (2.2-10.8)	0.003
5	Prior AIDS defining illness, n (%)	23 (16.8)	17 (18.5)	6 (13.3)	0.438
6	CD4 count, median (IQR) cells/mm³	545 (327-782)	537 (328-777)	564 (294-786)	0.933

Table 2.

The analysis included 138 DTG exposed pregnancies with 120 pregnancies resulting in 131 live neonates (8 multiples), 2 still births and 16 miscarriages or abortions. At baseline 109 (79.0%) women were on treatment experienced and 91 had undetectable VL (<50) (Table 1).

Of 92 (66.7%) women exposed to DTG during 1st trimester, 77 conceived while on DTG, four within the first six weeks after conception and ten after 6 weeks (one with missing information).

In 5 cases of live births, a birth defect was recorded; no birth defects were seen in stillbirths (Table 2). There were 3 TORCH infections (1 in 1st trimester, 2 in 2nd/3rd trimester). There were no reports of HIV infected infants (17.6% unknown), neural tube defects, maternal SARs or deaths.

Conclusions: While the numbers are too small to make definitive conclusions, no significant difference in frequency of birth defects was observed for first trimester exposures compared to 2nd/3rd trimester exposures with no neural tube defects in either. Most achieved viral suppression at delivery.

EPB195

Impact of point-of-care HIV viral load and drug resistance testing among pregnant and postpartum women living with HIV in Western Kenya: apre- and post-intervention study

R. Patel[1], P. Oyaro[2], K.K. Thomas[1], G.W. Basha[1], E. Brown[3], J. Wagude[4], I. Mukui[5], F. Oluoch[6], F. Odhiambo[7], B. Oyaro[8], L. Kingwara[9], N. Yongo[3], E. Karauki[3], L. Otieno[7], S. Hassan[1], G. John-Stewart[1], L.L. Abuogi[10]

[1]University of Washington, Seattle, United States, [2]Health Innovations Kenya, Kisumu, Kenya, [3]UW Kenya, Nairobi, Kenya, [4]Department of Health, Siaya, Kenya, [5]Ministry of Health, Nairobi, Kenya, [6]Department of Health, Kisumu, Kenya, [7]KEMRI, Nairobi, Kenya, [8]KEMRI-CDC, Kisian, Kenya, [9]National HIV Reference Laboratory, Nairobi, Kenya, [10]University of Colorado Denver, Denver, United States

Background: Ensuring viral suppression (VS) is critical among pregnant/postpartum women for their own outcomes and reduction of mother-to-child transmission. The goal of the Opt4Mamas study was to determine the impact of point-of-care (POC) viral load (VL) and targeted drug resistance mutation (DRM) testing in improving VS among pregnant/postpartum women on antiretroviral therapy (ART) in Kenya.

Methods: We conducted a prospective, double cohort, pre- and post-intervention study among pregnant women on ART followed postpartum at five health facilities in Kisumu, Kenya from February 2019-August 2021. Pre-intervention women underwent standard-of-care (VL testing every 6 months, DRM restricted to second line ART failure via centralized approvals), while post-intervention women received POC VL every 3 months during pregnancy, at delivery, and every 3 months postpartum, and targeted DRM testing if VL≥1000 copies/mL. Our primary outcome was VS (VL <1000 copies/mL) 6 months postpartum.

Results: Of 820 women enrolled, the median age was 29 years (interquartile range [IQR] 24, 33), gestational age 19 weeks (IQR 13, 25), gravida 3 (IQR 2, 4), CD4 count 523 (IQR 370, 709), and time on ART 3 years (IQR 1, 6). At 6 months postpartum, 97.7% (304/311) of post-intervention and 97.4% (333/342) of pre-intervention women had VS (risk ratio (RR) 1.0, 95% confidence interval [CI] 0.98, 1.03). VS at a lower threshold of <40 copies/mL remained similar between the groups (90.7% vs. 89.8% in post- vs. pre-intervention women, respectively). Sustained VS (i.e., VL<1000 on all VLs in those with≥2 VL results) was also similar between the groups (87.8% vs. 88.9% in post- vs. pre-intervention women, respectively). 54 episodes of viremia were identified among intervention women, of which 46 (85%) samples successfully underwent DRM testing with major DRMs identified in 20 (46%).

Conclusions: Overall,VS was high in both groups and was not significantly improved among women undergoing our intervention of POC VL and targeted DRM testing. Among those with viremia, nearly half had major mutations, underscoring the need to robustly scale up DRM testing for this population, which has the additional implication for transmitted resistance to infants. Further research is needed to evaluate combination interventions that best optimize VS for pregnant/postpartum women.

EPB196

Adverse perinatal outcomes associated with protease inhibitor-based antiretroviral therapy in pregnant women living with HIV: systematic review and meta-analysis

K. Beck[1], I. Cowdell[1], C. Portwood[1], H. Sexton[1], M. Kumarendran[1], Z. Brandon[1], S. Kirtley[2], J. Hemelaar[1]

[1]University of Oxford, National Perinatal Epidemiology Unit, Nuffield Department of Population Health, Oxford, United Kingdom, [2]University of Oxford, Centre for Statistics in Medicine, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom

Background: International guidelines advice against the use of protease inhibitor (PI)-based highly active antiretroviral therapy (HAART) in pregnant women living with HIV (WLHIV), in particular lopinavir/ritonavir(LPV/r)-based HAART, citing an increased risk of preterm birth (PTB).

We aimed to assess the risk of adverse perinatal outcomes in WLHIV receiving PI-HAART and the comparative risks associated with different PI-HAART regimens.

Methods: We conducted a systematic literature review by searching PubMed, CINAHL, Global Health, and EMBASE for studies published between Jan 1, 1980, and April 20, 2020. Two investigators independently selected studies and extracted data from studies reporting on the association of pregnant WLHIV receiving PI-HAART with 11 perinatal outcomes: preterm birth (PTB), very PTB (VPTB), spontaneous PTB (sPTB), low birth weight (LBW), very LBW (VLBW), term LBW, preterm LBW, small for gestational age

(SGA), very SGA (VSGA), stillbirth, and neonatal death. Pairwise random-effects meta-analyses examined the risk of each adverse perinatal outcome in WLHIV receiving PI-HAART compared to non-PI-based HAART (non-PI-HAART), and comparisons of different PI-HAART regimens.

Quality assessments of studies were performed, subgroup and sensitivity analyses were conducted based on country income status and study quality, and the effect of adjustment for confounding factors assessed. The protocol is registered with PROSPERO, numberCRD42021248987.

Results: Of 94,594 studies identified, 35 cohort studies including 57,672 women met the inclusion criteria. Random-effects meta-analyses showed that PI-HAART was associated with a significantly increased risk of SGA (RR 1.24, 95% CI 1.08-1.43) and VSGA (1.40, 1.09-1.81), but not PTB (1.10, 0.96-1.25), VPTB (1.30, 0.78-2.18), sPTB (1.91, 0.61-5.99), LBW (1.04, 0.86-1.26), VLBW (0.72, 0.37-1.43), term LBW (0.94, 0.30-3.02), stillbirth (1.04, 0.60-1.79), and neonatal death (1.82, 0.97-3.40), compared to non-PI-HAART.

We found no significant differences in perinatal outcomes between HAART regimens containing LPV/r, atazanavir/ritonavir (ATV/r), and darunavir/ritonavir (DRV/r), which are the most commonly used PIs.

Conclusions: PI-HAART is associated withan increased riskof SGA and VSGA, but not PTB or other perinatal outcomes. No significant differences in perinatal outcomes were found between LPV/r, ATV/r, and DRV/r.

These findings should inform clinical guidelines and further studies are urgently needed to better understand the association of different HAART regimens with adverse perinatal outcomes.

EPB197

Adverse perinatal outcomes associated with highly active antiretroviral therapy and monotherapy in women living with HIV: a systematic review and meta-analysis

C. Portwood[1], H. Sexton[1], M. Kumarendran[1], Z. Brandon[1], S. Kirtley[2], J. Hemelaar[1]

[1]University of Oxford, National Perinatal Epidemiology Unit, Nuffield Department of Population Health, Oxford, United Kingdom, [2]University of Oxford, Centre for Statistics in Medicine, Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, Oxford, United Kingdom

Background: Maternal HIV infection is associated with an increased risk of adverse perinatal outcomes. The global number of pregnant women living with HIV (WLHIV) receiving highly active antiretroviral therapy(HAART) is increasing and zidovudine (AZT) monotherapy has been phased out. We aimed to assess the risk of adverse perinatal outcomes in WLHIV receiving HAART or AZT monotherapy, compared to ART-naïve WLHIV and HIV-negative women.

Methods: We conducted a systematic literature review by searching PubMed, CINAHL (Ebscohost), Global Health (Ovid), and EMBASE (Ovid) for studies published between Jan 1, 1980, and April 20, 2020. Two investigators independently selected studies and extracted data from studies reporting on the association of pregnant WLHIV receiving HAART or AZT monotherapy with 11 perinatal outcomes: preterm birth (PTB), very PTB (VPTB), spontaneous PTB (sPTB), low birth weight (LBW), very LBW (VLBW), term LBW, preterm LBW, small for gestational age (SGA), very SGA (VSGA), stillbirth, and neonatal death.

Random-effects meta-analyses examined the risk of adverse perinatal outcomes in WLHIV receiving HAART or AZT monotherapy compared to ART-naïve WLHIV and HIV-negative women.

Quality assessments of studies were performed, subgroup and sensitivity analyses were conducted based on country income status and study quality, and the effect of adjustment for confounding factors assessed. The protocol is registered online with PROSPERO, number CRD42021248987.

Results: Of 94,594 studies identified, 61 cohort studies including 409,781 women met the inclusion criteria. Random-effects meta-analyses showed that WLHIV receiving AZT monotherapy were associated with a significantly decreased risk of PTB(RR 0.70, 95%CI 0.62-0.79) and LBW(0.77, 0.67-0.88), and comparable risk of SGA, compared to ART-naïve WLHIV. WLHIV receiving AZT monotherapy had a comparable risk of PTB and LBW, and an increased risk of SGA(1.16, 1.04-1.30) compared to HIV-negative women.

In contrast, WLHIV receiving HAART were associated with a comparable risk of PTB and LBW, and increased risk of SGA(1.38, 1.09-1.75), compared to ART-naïve WLHIV. WLHIV receiving HAART were associated with a significantly increased risk of PTB(1.55, 1.38-1.74), sPTB(2.09, 1.48-2.96), LBW(1.79, 1.51-2.13), termLBW(1.88, 1.23-2.85), SGA(1.80,1.34-2.40), and VSGA(1.22, 1.10-1.34), compared to HIV-negative women.

Conclusions: Pregnant WLHIV receiving HAART have a significantly increased risk of a wide range of perinatal outcomes compared to HIV-negative women.

ARV management strategies in paediatric and adolescent populations

EPB198

Optimizing ART for CALHIV by shifting PI-based ART to dolutegravir-based ART maintained and achieved viral load suppression

J. Bacha[1,2,3], S. Dlamini[2,4], F. Anabwani[4], J. Gwimile[5], J. Kanywa[6], J. Farirai[7], M. Bvumbwe[8], M. Tsotako[9], T. Steffy[1,2,9], D. Nguyen[1,2,10], H. Haq[1,2]
[1]Baylor College of Medicine, Pediatrics, Houston, United States, [2]Baylor College of Medicine International Pediatric AIDS Initiative (BIPAI) at Texas Children's Hospital, Houston, United States, [3]Baylor College of Medicine Children's Foundation - Tanzania, Mbeya, Tanzania, The United Republic of, [4]Baylor College of Medicine Children's Foundation - Eswatini, Mbabane, Eswatini, [5]Baylor College of Medicine Children's Foundation - Tanzania, Mwanza, Tanzania, The United Republic of, [6]Baylor College of Medicine Children's Foundation - Uganda, Kampala, Uganda, [7]Botswana-Baylor Children's Clinical Centre of Excellence Trust, Gabarone, Botswana, [8]Baylor College of Medicine Children's Foundation - Malawi, Lilongwe, Malawi, [9]Baylor College of Medicine Children's Foundation - Lesotho, Maseru, Lesotho, [10]Baylor College of Medicine, Department of Education, Innovation, and Technology, Houston, United States

Background: Dolutegravir (DTG) is recommended by the World Health Organization for children and adolescents living with HIV (CALHIV); however concerns exist around effectiveness of shifting CALHIV from protease inhibitors (PI)-based to DTG-based antiretroviral therapy (ART).
We describe the effectiveness of this approach on viral load suppression (VLS) in CALHIV across six countries in East and Southern Africa.
Methods: Retrospective chart review between 2017 and 2020 of clinical characteristics and VLS rates of CALHIV ages 10-19 years that were optimized from PI-based ART to DTG-based ART at BIPAI clinics in Botswana, Eswatini, Lesotho, Malawi, Tanzania, and Uganda. VLS was defined as VL<1000 copies/mL. Routine HIV genotyping was not available.
Results: A total of 1475 CALHIV on PI-based ART were shifted to DTG.The cohort was 45.5% (670/1475) female, median age 14.0 years (0.7% <5yo; 21.1% 5-9yo; 35.6% 10-14yo; 42.6% 15-19yo), and median time on ART prior to DTG was 9.8 years. 71.9% (1060/1475) were on lopinavir (LPVr)-based ART and 28.1% (415/1475) atazanavir (ATVr)-based ART. Average follow up period after shifting to DTG was 212 days.
By study end, 97.4% 1436/1475) remained active in care, 1.8% (27/1475) transferred out, 0.7% (11/1475) lost to follow up, and 0.07% (1/8091) died. VLS was maintained in the cohort with no loss of VLS when shifting from PI- to DTG-based ART (88.9% vs 89.8%, p=0.46). Similarly, maintenance of VLS without significant loss was seen across all subgroups of CALHIV, including analyses of prior PI regimen [LPVr to DTG (89.2% vs 91.1%, p=0.18), ATVr to DTG (88.4% vs 86.0%; p=0.34)], sex [females (87.2% vs 86.4%, p=0.69), males (90.4% vs 92.7%, p=0.13)], and age groups [5-9 year olds (93.5% vs 94.0%, p=0.82), 10-14 year olds (90.1% vs 91.4%, p=0.50), and 15-19 year olds (85.5% vs 86.9%).
Using a VLS cutoff of VL<400cp/mL produced similar findings. Among previously unsuppressed CALHIV, 67.8% (80/118) achieved VLS after shifting to DTG.
Conclusions: Shifting from PI-based to DTG-based ART was effective at maintaining and achieving VLS in CALHIV, and no loss of VLS was observed. These results support programmatic efforts to shift CALHIV from PI-based to DTG-based regimens, especially if unsuppressed on PI-based ART.

EPB199

HIV care preferences among young people living with HIV in Lesotho: a secondary data analysis of the PEBRA cluster randomized trial

O. Seiler[1], M. Kopo[2], M. Kao[2], T.I. Lejone[2], N. Tschumi[3,4], T.R. Glass[3,4], J.A. Brown[3,4], N.D. Labhardt[3,4,5], A. Amstutz[3,4,5]
[1]University of Zurich, Switzerland, Zurich, Switzerland, [2]SolidarMed, Maseru, Lesotho, [3]Swiss Tropical and Public Health Institute, Basel, Switzerland, [4]University of Basel, Basel, Switzerland, [5]University Hospital Basel, Basel, Switzerland

Background: Sub-Saharan Africa is home to 89% of all young people living with HIV.Young people living with HIV are a vulnerable subpopulation that face distinctive challenges and therefore need special attention. To offer suitable programs and better support for this population group, in-depth knowledge of their service preferences is required.
We evaluated HIV care preferences among young participants of a cluster-randomized trial longitudinally over the 12-month trial period.
Methods: This study is based on secondary data from the PEBRA (Peer-Educator Based Refill of ART) trial that investigated the PEBRA model vs standard of care among young people living with HIV, in care at 20 health facilities across 3 districts in Lesotho, Southern Africa. In the PEBRA model, a peer-educator regularly assessed participant preferences regarding antiretroviral therapy (ART) refill location, SMS notifications (adherence, refill, viral load) and general care support options, and delivered services accordingly. We present changes in preferences over time in Sankey diagrams.
Results: At enrolment, 44 of 123 (33.3%) chose ART refill outside the health facility, compared to 9 of 123 (7.3%) after 12 months. At the facility 70 of 123 (56.9%) respectively 57 of 123 (46.3%) picked up their medication within the Saturday clinic club. The number of participants who wished to receive an SMS reminder for adherence and/or ART refill was 51 of 123 (41.5%) at enrolment and 54 of 123 (44.7%) at the last assessment. Support by the peer-educator (i.e.

phone call, home visit) was chosen by 110 of 123 (89.4%) at the beginning of the study and by 85 of 123 (69.1%) at the end. Support by the nurse at the facility only was chosen by 13 of 123 (10.6%) participants at the first assessment and 21 of 123 (17.1%) at the last assessment.

Conclusions: Our longitudinal preference assessment among young people living with HIV showed a sustained interest in SMS notifications for adherence and refill visits as well as additional support by a peer educator.

However, ART refill outside the health facility was not as popular as expected; instead, medication pick-up at the facility, especially during Saturday clinic clubs,was favored.

EPB200

Cracking the code to increase viral suppression in children at Foyer Saint Camille Hospital from October 2020 to November 2021

P. Laurent[1], S. Porfil[2], M. Jasmin[3]

[1]Foyer Saint Camille Hospital, Medical Director/Program Manager, HIV-TB-Covid, Croix des Bouquets, Haiti, [2]Foyer Saint Camille Hospital, PMTCE Nurse, Croix-des-Bouquets, Haiti, [3]University of San Francisco, Healthqual, San Francisco, United States

Background: At Foyer Saint Camille Hospital, October 2020 data report showed that only 83.9 % of 81 children on HAART were virally suppressed. In January 2021, the coordination of ALESIDA project of Foyer Saint Camille Hospital launched a project aiming increasing viral suppression in children less than 15 years of age from 83.9% to over 95% by September, 30 2021

Description: In January 2021, a cohort of 13 children with detectable viral load was selected. Their parents and guardians were contacted and their agreement confirmed to register in for the project.

Training on pediatric HIV care and treatment with emphasis HAART administration, adherence and viral load suppression was provided to both parents and community field workers.

Parents were involved in selecting the best person to administer ART to children which will be conducted through directly observed therapy (DOT).

The option of DOT by field agents was proposed to unavailable parents. DOT was daily monitored by phone calls and through community field agent's reports. Data was collected in an excel file for daily monitoring.

Lessons learned: All 13 children virally suppressed by November 2021. Pediatric viral suppression increased over time from 83.95% in October 2020 to 98.7% in September 2021. 46% of these 13 children received DOT through parents, precisely their mother, and 56% of 13 children on DOT with field agents.

Parental involvement of child care decisions and better education in VIH pediatric care and treatment had a positive impact in viral suppression.

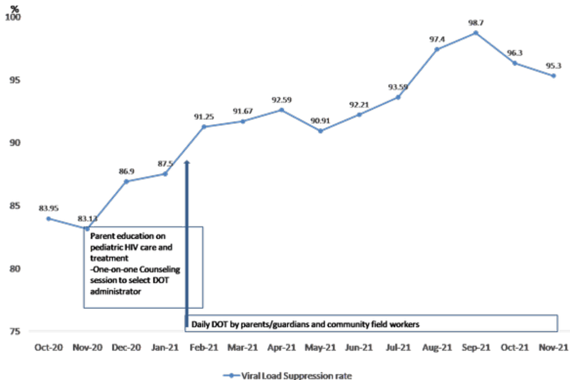

Figure. Trend of pediatric viral load suppression rate, Oct 20 - Nov 21

Conclusions/Next steps: Pediatric viral suppression can be effectively improved to achieve UNAIDS third „95" goal by offering DOT therapy to children under 15 with detectable viral load. The use of data collection tool enables data analysis to improve performance and prioritize program activities. The next phase of our intervention is the extension this strategy to all newly-enrolled HIV-infected children.

EPB201

Continuity of care among HIV-positive children and adolescents on antiretroviral therapy in Lesotho: early transfers and relocations pose challenges for follow-up

M. Masitha[1], L. Greenberg[2], V. Tukei[1], L. Masenyetse[1], M.M. Gill[2], M. Mokone[1], R. Machekano[2], M. Mokone[1], M. Sekese[1], A. Tiam[2]

[1]EGPAF, Maseru, Lesotho, [2]EGPAF, Washington DC, United States

Background: HIV continuity of care is essential for the long-term health of children/adolescents on antiretroviral therapy (ART). Transfers between health facilities and relocation may affect the continuum of care from HIV testing and ART initiation to long-term treatment retention. We reviewed patient retention data from an observational cohort of HIV-positive children/adolescents aged 0-19 years, newly initiating ART between January 2018-December 2020.

Methods: Patient characteristics, clinic visits, and outcomes were abstracted from clinical records. Participants/caregivers were interviewed every 3-months. Patients who did not return to the original care facility beyond 6 months of ART were categorized as having discontinued care early, and reasons for early discontinuation were categorized as lost to follow-up, relocation, or death. Chi-square tests and multivariable logistic regression were used to explore associations between early discontinuity of care and age, sex, district and year of ART initiation.

Results: Of 696 cohort participants, 277 (40%) were not seen again at their original care facility 6 months post-initiation; of these, 169 (61%) never returned after ART initiation. Among those who discontinued early, 139

(50%) had relocated. Loss to follow-up was highest (43%) among 15–19-year-old adolescents and mortality was highest among children 0-4 years (21.7%) (Table). Children (0-4) and older adolescents (15-19) had similar high early discontinuation rates (>=44%) compared to those 5-9 (25%, p=0.006) and 10-15 (16%, p<0.001) years. Females had significantly higher early discontinuation compared to males (43% vs 28%, respectively; adjusted odds ratio 1.6 95% CI 1.1-2.6).In adjusted analyses, age, gender, district/ region and ART initiation year were significantly associated with odds of early discontinuation from care.

N (%)	0 – 4 years (n = 60)	5 – 9 year (n = 19)	10 – 14 years (n = 14)	15 – 19 years (n = 184)	Total (N= 277)
Participant relocated	30 (50.0)	12 (63.2)	6 (42.9)	91 (49.5)	139 (50.2)
Participant died	13 (21.7)	2 (10.5)	0 (0.0)	1 (0.5)	16 (5.8)
Lost to follow – up	14 (23.3)	2 (10.5)	5 (35.7)	79 (42.9)	100 (36.1)
Other/ Unknown	3 (5.0)	3 (15.8)	3(21.4)	12 (6.5)	22 (7.9)

Table: Status of patients discontinued early

Conclusions: We found high rates of discontinuation of care from ART initiation facilities largely due to relocation and loss to follow-up. Mortality was high among children <5 years. These data underscore the importance of strengthening facility transfer procedures and community structures for retention and tracking, and leveraging technologies like multi-site electronic health registers, particularly for sub-groups with higher levels of early discontinuation.

Jackson Foundation for the Advancement of Military Medicine, International HIV Treatment and Prevention, Bethesda, United States, [6]HJF Medical Research International, Kisumu, Kenya, [7]The Uniformed Services University of the Health Sciences, Pediatrics, Bethesda, United States

Background: Virologic suppression (VLS) is the primary goal of antiretroviral therapy (ART), but children and adolescents living with HIV (CALHIV) often have worse VLS and other outcomes compared to adults. Our objective was to estimate the proportions of CALHIV with VLS and determine factors associated with VLS in our Kenya and Tanzanian programs.

Methods: This cross-sectional study was conducted at public facilities supported by the U.S. Military HIV Research Program between 2018-2021. CALHIV (1-19 years) on ART for >6 months were enrolled. Sociodemographic and medical information were obtained, and participants underwent viral load (VL) testing at enrollment. VLS (defined as VL <1000 copies/mL) was estimated using the Wilson score method. Multivariable robust Poisson regression models were used to estimate adjusted prevalence ratios (aPRs) with 95% confidence intervals (CIs) for associations between potential predictors of VLS.

Results: Of 1,394 complete cases included in analyses, 935 (67.1%) were from Kenya. The mean age was 12±4 years, 737 (52.9%) were female, and 1,251 (89.7%) had been on ART for >24 months. 595 (42.7%), 430 (30.8%), and 369 (26.5%) were on NNRTI, PI, and iNSTI-containing regimens respectively. Prevalence of VLS was 82% (95% CI: 80%-84%), and varied by country (85.6% vs 80.2% for Tanzania and Kenya; p=0.01), ART regimen (89.7%, 81.3%, and 76.3% for iNSTI, NNRTI, and PI; p<0.001), number of missed ART doses in the past month (83.6%, 78.1%, and 64.5% for none, 1-2, and ≥3 missed doses; p<0.001), and maternal viral load (85.4%, 59.3%, and 81.1% for <1000c/ml, >1000c/ml, and unknown VL status; p=0.001). After adjustment, CALHIV on iNSTI-containing regimens were more likely to be virally suppressed compared to other regimens (aPR=1.14; 95% CI: 1.05-1.23). High maternal VL (aPR=0.72; 95% CI: 0.52-0.99), unknown maternal VL (aPR=0.95; 95% CI: 0.90-0.99), and 3 or more missed doses of ART in the past month (aPR=0.77; 95% CI: 0.66-0.91) were inversely associated with VLS.

Conclusions: In this study of CALHIV in routine HIV care, use of integrase inhibitor-containing regimen was associated with VLS, lending credence to the value of pediatric ART optimization. Strategies to improve CALHIV adherence and maternal VL suppression are needed to improve patient- and program-level outcomes.

Uptake of raltegravir granules in newborns diagnosed with HIV in Zimbabwe during the COVID-19 pandemic

L. Denoeud-Ndam[1], C. Stecker[2], P. Andifasi[3], A. Mushavi[3], T. Maphosa[4], M. Zondo[5], M. Murandu[5], G. Gombakomba[5], L. Katirayi[6], M. Mungati[5], R. Bailey[1], R. Weber[4], E. Rivadeneira[7], S. Hrapcak[7]
[1]Elizabeth Glaser Pediatric AIDS Foundation, Geneva, Switzerland, [2]Catholic Relief Services, Baltimore, United States, [3]Ministry of Health and Child Care, Harare, Zimbabwe, [4]Centers for Disease Control and Prevention, Harare, Zimbabwe, [5]Elizabeth Glaser Pediatric AIDS Foundation, Harare, Zimbabwe, [6]Elizabeth Glaser Pediatric AIDS Foundation, Washington D.C., United States, [7]Centers for Disease Control and Prevention, Atlanta, United States

Background: Options for newborn antiretroviral therapy (ART) are currently limited. In 2020, Zimbabwe adopted the World Health Organization recommendation to use raltegravir (RAL) granule-based regimens in newborns identified through birth testing. Implementation and lessons learned during roll-out of this formulation during the COVID-19 pandemic are described.

Description: RAL granules were introduced in 14 health facilities with capacity for point-of-care (POC) HIV birth testing in Zimbabwe. Healthcare workers (HCW) were trained on RAL use and on counseling caregivers on preparation and administration of RAL to HIV-positive newborns. Retrospective data collected from facility registers between June 2020 and July 2021 provided numbers of HIV-exposed newborns tested, HIV-positive newborns, and numbers initiated on RAL.

Lessons learned: During implementation, 3,172 (45.4%) of 6,989 HIV-exposed newborns received POC birth test results at 14 facilities (Figure).

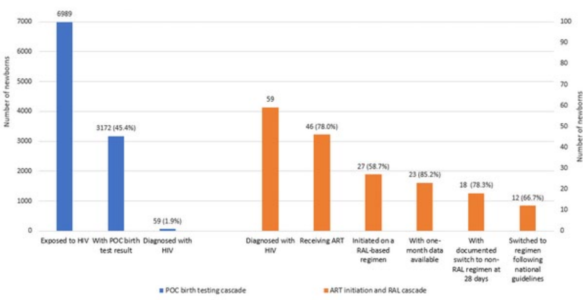

Figure. Point-of-care birth testing, ART initiation and RAL treatment cascade; N=6,989 newborns HIV-exposed in 14 health facilities.

Fifty-nine newborns (1.9%) were HIV-positive; 46 (78.0%) initiated ART at median age of 5 days. Twenty-seven (58.7%) were initiated on RAL and 19 on non-RAL regimens (nevirapine-based n=9, lopinavir/ritonavir-based n=9, dolutegravir-based n=1). Of 27 infants on RAL, 23 (85.2%) had one-month switch data; 18 (78.3%) had switched to non-RAL regimen at 28 days, 12 of whom switched to a national guideline-approved regimen. COVID-19 supply chain disruptions impacted availability of POC testing cartridges, RAL granules, and AZT/3TC backbone, which delayed testing, ART initiation, and use of alternative treatment regimens. COVID-19 resulted in shortages of trained HCW and travel restrictions limiting in-person mentorship and supervision visits.

Conclusions/Next steps: Lower than expected birth testing uptake and RAL usage were observed, in large part due to inconsistent supply chain and trained human resources shortages during COVID-19. Addressing health systems gaps for supply chain, staffing (training, retention, mentorship, and supervision), and ability to track HIV-positive newborns is needed to improve birth testing services and outcomes for HIV-exposed infants, timely ART initiation, and follow-up on optimized regimens.

EPB204

High rate of HIV virologic failure in children under the age of five in Tanzania

K. McKenzie[1,2,3], W. Olomi[4], M. Chodota[2], L. Mwita[2]
[1]Baylor College of Medicine, Houston, United States, [2]Baylor College of Medicine Children's Foundation - Tanzania, Mbeya, Tanzania, The United Republic of, [3]Baylor International Pediatric AIDS Initiative (BIPAI) at Texas Children's Hospital, Houston, United States, [4]NIMR-Mbeya Medical Research Centre (MMRC), Mbeya, Tanzania, The United Republic of

Background: While many high-HIV-burden countries continue to announce freedom from maternal-to-child transmission, Tanzania still struggles with new infections among infants. Moreover, despite multiple advances in the care of HIV in young children, including increased variety of antiretroviral therapy (ART) drug formulations, children under the age of 5 years (U5) continue to lag behind older children in terms of viral suppression.

Methods: A retrospective chart review up was performed at the Baylor College of Medicine Children's Foundation – Tanzania sites in Mbeya and Mwanza. All children aged 0-15 years old who had been on ART for at least 6 months and had at least one viral load (VL) measurement recorded by July 2021 were included in the study. Viral suppression was defined as VL<1000 copies/ml.

Results: A total of 1725 children were included in the study, average age was 8.9 (SD=4.0), 50.9% were female, 66.8% had were WHO stage III/IV, and 2.9% had moderate or severe malnutrition. Most of the caregivers were parents (62.0%), 48.5% were on a dolutegravir-containing regimen, 11.6% had active TB, only 2.0% had a CD4<200 cells/mm^3, and the median age at ART initiation was 31.5 months. Overall, 10.7% of children were unsuppressed but among U5, 21.9% were unsuppressed. On multivariate analysis, U5 were 82% more likely to be unsuppressed than older children (AOR=1.82; 95%CI, 1.10-3.03; P=0.02). Compared to older children, U5 were more likely to have malnutrition (P=0.03), WHO stage III or IV (P=0.0003), be on

a protease inhibitor regimen (P<0.0001), be in the care of a parent (P<0.0001), and have severe immunosuppression (P=0.024). Among unsuppressed children, U5 started ART earlier (10.9 versus 57 months; P<0.00001), were on ART for less time (P<0.00001), and were less likely to be on dolutegravir (P<0.00001). Among U5, having TB (AOR=0.29; 95%CI, 0.1-0.8; P=0.021) and <1 year on ART (AOR=0.39; 95%CI, 0.17-0.91; P=0.028) were more likely to be associated with viral failure.

Conclusions: Young children should be considered vulnerable in terms of HIV viral failure. Providers should be prepared to address comorbidities in these children, especially TB and malnutrition. Finally, advocacy for availability of pediatric drug formulations, especially dolutegravir, will likely benefit young children.

EPB205

A community-driven approach to pediatric Dolutegravir (pDTG) based regimen transition among children of key populations living with HIV in Nigeria

A. Oguntonade[1], G. Emmanuel[2], N. Mwoltu[1], C. Anya[1]
[1]Heartland Alliance Ltd/Gte, Programs, Uyo, Nigeria, [2]Heartland Alliance Ltd/Gte, Key Populations Community HIV Action and Response Project, Abuja, Nigeria

Background: In September 2021, Nigeria adopted and made available pDTG, a clinically superior, more tolerable drug formulation with the potential to improve adherence to ART and treatment outcomes in children living with HIV (CLHIV) weighing 3kg to less than 20kg. This followed the recent WHO recommendation positioning DTG-based regimens as the preferred first line for CLHIV from lopinavir/ritonavir-based regimens.

Due to poor adherence to existing pediatric ARV including less than optimal viral load suppression rates (87%), Heartland Alliance LTD/GTE (HALG) Nigeria rolled out a family centered community driven differentiated service approach to ART initiation and refills for Children of Key Populations (KPs) to achieve rapid transition to pDTG in three states: Akwa-Ibom, Cross River and Lagos states under the USAID funded Key Populations Community HIV Actions and Response (KP-CARE 1) project.

Methods: The Retention and Audit Determination Tool (RADET) was utilized from the programme' s electronic database to determine eligibility for the transitioning at the onset in October 2021. Eligible Children weighing 3kg to less than 20kgi imitated on ART with non-DTG based regimen between January and December 2021 were identified and profiled for their refill due date and location. Schedules were then drawn for Community ART teams (cART) to deliver the pDTG to the CLHIV on ART based on the profiles.

Also, those living within proximity were clustered and refilled ahead of their refill due dates considering the dynamics of the socio-economic environment of their caregivers.

Results: A total of 134 children aged less than 14years were active on ART of out of which there were 69 females (52%), and 65 males (48%). Those with weight less than 20kg were 51 with 46(90%) being initiated on Lopinavir based regimen and a total of 46 (100%) were transited to pDTG by December 2021.

Conclusions: This evidence demonstrates that a KP family-centered and community-driven ARV delivery mechanism is an effective approach to rapid transitioning to PDTG Based regimens for CLHIV of key population.There is need to compare this approach with other methods in further study.

EPB206

A comparison of antiretroviral therapy outcomes among adolescents in Teen Clubs and Standard Care Clinics: Blantyre, Malawi

M. Alibi[1]
[1]Blantyre City Council, Health and Social Services, Blantyre, Malawi

Background: HIV treatment outcomes are still poor among adolescents compared to adults. Different service delivery models are being implemented to address this, and one of them is the Teen Club model. Currently, it is clear that Teen Clubs improves adherence to treatment (short-term impact), but the gap is on the long-term impact.

The objective of the study was to compare virological suppression and virological failure rates among adolescents in Teen Clubs with those on the Standard Care model.

Methods: This was a retrospective cohort study. A total of 110 in Teen Clubs and 123 in Standard of Care from 6 Health facilities were selected using stratified simple random sampling.

The participants were followed up for 24 months. STATA, v16.0 was used for data analysis. Univariate analyses were performed for demographic and clinical variables.

A chi-squared test was used to assess the difference between proportions. Crude and adjusted relative risks were calculated using a binomial regression model. retrospective cohort study.

Results: At 24 months 56% of adolescents in the Standard of Care (SoC) arm had viral load suppression compared to 90% in the Teen Club arm.

Of those who achieved viral load suppression at 24 months, about 22.7% (SoC) and 76.4% (Teen Club) achieved undetectable viral load suppression rates. Adolescents in Teen Club were less likely to have high viral load compared to those in the SoC arm Adjusted RR 0.23, 95%CI: 0.11-0.61;*p*=0.002 adjusted for age and sex. The virological failure rates among adolescents in Teen Clubs and SoC were (3.1% vs 10.9%).

The adjusted RR 0.16, 95%CI: 0.03-0.78; *p*=0.023, those in Teen Clubs were less likely to have virological failure compared with those in SoC after controlling for age, sex, and place of residence.

Conclusions: After identifying the impact of the Teen Club model, results can be used to advocate for the rollout of the model to other health facilities

EPB207

The *'magic bullet'* for HIV viral suppression? How fixed-dose combination Dolutegravir (DTG) antiretrovirals are improving viral suppression among children aged 10-14 years on antiretroviral therapy (ART) in Zambia

A. Ndhlovu[1], K. Mwanda[1], M. Chikuba-McLeod[1], M. Musonda[2], L. Ciccio[1], L. Kawanga[1], M. Banda[1], S. Mbozi[1]
[1]*JSI Research & Training Institute, Inc. (JSI), Lusaka, Zambia,* [2]*United States Agency for International Development (USAID)/Zambia Mission, Lusaka, Zambia*

Background: The critical endpoint to achieving HIV epidemic control is attainment of the third 95 cascade target, viral suppression, among people living with HIV, who know their status and are on treatment (UNAIDS, 2015). Globally, only 40% of children living with HIV (CLHIV) are virally suppressed (UNAIDS, 2021).
Before the change in pediatric ART guidelines in 2020, Zambia faced a similar challenge, which was compounded by limited availability of the more palatable and highly efficacious fixed-dose combination DTG-containing antiretrovirals.
Methods: In November 2020, with increased availability of pediatric DTG-containing antiretrovirals in the national ART program, the USAID DISCOVER-Health Project, implemented by JSI, started initiating on and transitioning 10–14-year-old CLHIV to DTG-containing regimens, in line with national HIV care and treatment guidelines. The data were entered into SmartCare in supported clinics in Copperbelt, North-western and Central Provinces.
Project level SmartCare data were analysed using the International Business Machine Corporation Statistical Product and Service Solutions (IBM SPSS®).
Results: The table below summarizes the findings.

Time period	CLHIV on ART	CLHIV on DTG	Virally suppressed	Not Virally suppressed	Viral Load (copies/mL)
November 2020	824	41% (n=338)	82% (n=671)	18% (n=153)	Mean=14,587, median=27, range=0-1.35 million
September 2021	697	89% (n=620)	93% (n=648)	7% (n=49)	Mean=3,865, median=20, range=0-345,983
OR 3.01, 95% CI 2.14-4.23; p=0.002					

Table.

In November 2020, 824 CLHIV, aged 10-14 years had viral load results on file ranging from 0- 1.35 million copies/mL with viral suppression at 82%. Only 41% of the CLHIV at the time were on antiretrovirals (ARVs) containing DTG.
As of September 2021, after ten months of implementation: 89% CLHIV were on DTG-containing ARVs; 971 eligible CLHIV had a VL result on file ranging from 0-345,983 copies/mL with 93% virally suppression. With a higher proportion of CLHIV on ART accessing DTG-containing ARVs, viral suppression was significantly higher than at baseline.
Conclusions: Expanded access to DTG-containing regimens is an important intervention for increasing viral suppression rates in CLHIV for good individual health outcomes, and for fast-tracking achievement of HIV epidemic control.

EPB208

Improving viral load suppression rate among paediatricpatientson anti-retroviral therapy in Central Province, Zambia

M. Sichamba[1], B. Kafulubiti[1], S. Zulu[1], R. Makufele[1], T. Pwele[1], D. Dixon[1], M. Chanda[1], T. Tuhuma[1]
[1]*JSI - SAFE, International Division, Kabwe, Zambia*

Background: The aim of Antiretroviral Therapy (ART) is to attain and maintain Viral Suppression (VL) among People living with HIV(PLHIV). USAID SAFE program (SAFE) collaborated with the Ministry of Health (MOH) in Zambia to support facilities to ensure 95% of PLHIV on ART are virally suppressed.
The suppression rate in SAFE supported facilities differs by age, with children below 15 years having lower suppression rate than adults. USAID SAFE worked with MOH to identify and address factors that were contributing to low viral suppression among children
Description: All Children files were reviewed in 31 selected SAFE supported facilities and the following factors were identified:
1. Health Facility related factors: such as suboptimal regimens, drug under dosing and underlying infections.
2. Client related factors: Such as poor drug storage, missing of drug dosages if no food available, if caretaker not home at the scheduled time of drugs to be taken, if a parent has not disclosed the HIV status of the child to a new spouse/partner, under dosing during drug administration.
SAFE implemented following interventions to address the problems:
1. Eligible children transitioned from Efavirenz (EFV) based regimen to more efficacious Dolutegravir (DTG) based regimen.
2. Pairing unsuppressed children with specific Community Based Volunteers (CBVs) for Enhanced Adherence Counselling sessions.
3. Home visits by Clinician and Community Based Volunteer to identify factors at home.
4. Specific days for paediatric clinics for virally unsuppressed children.
5. Pairing up Mother/Caretaker clinical appointment with the child's appointment.
6. Aligning clinical appointments for paediatrics with the school calendar and conducting after hours and weekend clinics.

Lessons learned: In October 2020, out of 2,160 children infected with HIV and enrolled on ART, only 1,746 (81%) were virally suppressed and 414 (19%) were unsuppressed. Following implementation of the above interventions, the VL steadily improved to 1,590 (90%) children were virally suppressed with 183 (10%) unsuppressed children.

Conclusions/Next steps: While children may be managed at the health facility, client level factors are also key to attaining viral suppression. Therefore, MoH and all HIV treatment partners should work to identify and address both facility level and client level factors.

Cure strategies in paediatric and adolescent populations

EPB209

Joint evolution of CD4 and viral load trajectories over 2 years in an early-treated pediatric African cohort

S. Dominguez Rodriguez[1], Á. Ballesteros[1], L. Kuhn[2], T. Nhampossa[3], K. Otwombe[4], S. Shaun Barnabas[5], N. Klein[6], M.G. Lain[7], C. Giaquinto[8], P. Rossi[9], P. Rojo[1], A. Tagarro[1], EPIICAL Consortium

[1]Fundación para la Investigación Biomédica del Hospital 12 de Octubre, Pediatric Infectious Diseases Unit, Madrid, Spain, [2]Gertrude H. Sergievsky Center, Vagelos College of Physititlcians and Surgeons, Columbia University Irving Medical Center, New York, United States, [3]Barcelona Institute for Global Health (ISGLOBAL), Barcelona, Spain, [4]Perinatal HIV Research Unit, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa, [5]Family Centre For Research With Ubuntu (FAMCRU), Stellenbosch University, Cape Town, South Africa, [6]Africa Health Research Institute (AHRI), Durban, South Africa, [7]Fundação Ariel Glaser contra o SIDA Pediátrico, Maputo, Mozambique, [8]University of Padova, Department of Surgery, Oncology and Gastroenterology, Section of Oncology and Immunology, Padova, Italy, [9]Ospedale Pediatrico Bambino Gesu, Division of Immune and Infectious Diseases, Istituto di Ricovero e Cura a Carattere Scientifico, Rome, Italy

Background: In response to antiretroviral therapy (ART), some patients experience a discordant response, characterized either by a high CD4+ cell count despite persistent viremia or by viral suppression with low CD4+ cell count. Little is known about the meaning of discordant responses in children reported to be 10-20%. In this study, we analyze virologic and immunologic phenotypes, including a discordant response based on trajectories instead of arbitrary thresholds.

Methods: This study was done within the EARTH Cohort, a prospective cohort enrolling perinatally HIV infected infants diagnosed in the first 3 months of life and treated after diagnosis, in Mozambique and South Africa. During 2-years of follow-up, the trajectories of CD4 and VL were calculated using KmL3D R package that implements k-means dedicated to clustering joint-trajectories. Optimum number of clusters was based on the Calinski-Harabatz criterium. Comparisons between clusters were assessed by the Kruskal-Wallis and Fisher test.

Results: A total of 59 patients with at least 5 measurements of CD4 and VL were included in this study. Four robust clusters were selected.

The participants in Cluster A (23/59 (39.0%)) presented virological failure and poor %CD4 reconstitution after treatment. They were treated later, and they had high VL and low %CD4 at ART initiation.

Cluster B (19/59 (32.2%)) had participants who achieved viral suppression and had consistently high %CD4. A total of 17/59 (28.8%) patients presented discordant responses. Patients included in Cluster C (16/59 (27.1%)) presented a viral failure and high good CD4 reconstitution, and patients included in Cluster D (1/59 (1.7%)) also presented discordant response, in this case, viral suppression and poor CD4 reconstitution. Despite acceptable CD4 levels, patients with discordant responses presented higher rates of clinical progression (37.5%) (WHO stage III-IV) than those with viral suppression and good CD4 response (1/19 (5.3%)), p=0.015. Patients with discordant responses were more frequently treated with ART regimens including protease inhibitors (p=0.047).

Conclusions: A higher rate of discordant responses was present in this study (28.8%) compared to previous reports. The characterization of immunologic and virologic status of the patients could help in the design of personalized therapeutic interventions and in identifying patients for trials.

Adherence in paediatric and adolescent populations

EPB210

Factors associated with non-adherence among children on antiretroviral therapy in Akwa Ibom, Nigeria

E. Nwanja[1], U. Akpan[2], T. Otoyo[2], O. Onwah[3], P. Nwaokoro[4], T. Badru[5], A. Idemudia[6], O. Sanwo[5], H. Khamofu[5], S. Raj Pandey[5], M. Bateganya[7], E. James[8], I. Igbemi[9]

[1]Achieving Health Nigeria Initiative, Monitoring and Evaluation, Research and Learning, Uyo, Nigeria, [2]Achieving Health Nigeria Initiative, Uyo, Nigeria, [3]Achieving Health Nigeria Initiative, Awka, Nigeria, [4]FHI 360, Akwa Ibom, Nigeria, [5]FHI 360, Abuja, Nigeria, [6]Achieving Health Nigeria Initiative, Abuja, Nigeria, [7]FHI 360, Durham, United States, [8]USAID, Abuja, Nigeria, [9]Agency for the Control of AIDS, Uyo, Nigeria

Background: Adherence to antiretroviral therapy (ART) is a principal determinant of virologic suppression. We assessed factors associated with nonadherence among children living with HIV (CLHIV) with unsuppressed viral load (VL) in Akwa Ibom, Nigeria.

Methods: This retrospective study conducted by the PEPFAR/USAID-funded Strengthening Integrated Delivery of HIV/AIDS Services (SIDHAS) project, used routine program data of virally unsuppressed (VL ≥1,000 copies/mL) CLHIV ages 0–14 years). Data were collected during enhanced adherence counseling (EAC) sessions in 53 health facilities from January through March 2021. Reasons for nonadherence—missed drug intake for up to two or more days in the last 30 days—as reported by caregivers of CLHIV, were analyzed.

Caregivers were categorized as:

1. First-degree relatives (FDRs) including father, mother, and siblings;
2. Second-degree relatives (SDRs) such as grandparents, uncles, and aunts; and,
3. Third-degree relatives (TDRs), i.e., other relatives and nonrelatives.

Chi-squared statistic was used to analyze differences.

Results: Among the 343 unsuppressed CLHIV, 50.7% (n=174) were males, and 29% (n=101), 40% (n=138), and 30% (n=104) were <5 years, 5–9 years, and 10–14 years, respectively. Median (IQR) duration on ART was 21 months (14–47 months). Of the 343 caregivers, 71.7% (n=246), 16.6% (n=57), and 11.7% (n=40) were FDR, SDR, and TDR, respectively.

Among caregivers, 69.9% (172/246) of FDR, 3.5% (2/57) of SDR, and 20% (8/40) of TDR were HIV positive. Nonadherence was 98% (39/40) among children under the care of TDR, 95% (54/57) among those under SDR care, and 93% (229/246) among those under FDR care (p=0.535).

Common reasons for missing ART doses were caregivers' unavailability to administer medication (59.7%), lack of food (11%), and pill burden (9%) (FDR); caregivers' unavailability (45.6%), lack of food (25%), pill burden (9%), and unpalatability (7%) (SDR); and caregivers' unavailability (50%), lack of food (20%), pill burden (11%), and lack of transport fare (23%) (TDR) (p<.001).

Conclusions: Caregivers' unavailability to administer drugs was the main reason for ART nonadherence among virally unsuppressed children undergoing EAC. Caregiver HIV status was not associated with nonadherence. Program implementers should emphasize the role of caregivers in the management of ART for CLHIV.

EPB211

Feasibility and acceptability of video-assisted directly observed therapy for high-risk youth living with HIV

A. Newman Jr.[1]

[1]Emory University, Rollins School of Public Health, Atlanta, United States

Background: Adolescents and young adults (ages 18-34) are disproportionately impacted by HIV, and often have poor adherence to antiretroviral therapy. Directly observed therapy (DOT) as used for the treatment of tuberculosis may help to improve adherence; however, logistical challenges may be a barrier to implementation.

We conducted a pilot trial of video-assisted DOT (Video Observed Therapy [VOT]) to closely monitor youth, support efforts to develop positive adherence patterns, and improve clinical outcomes for youth enrolled at a comprehensive HIV care center in Atlanta, Georgia, USA.

Description: We enrolled 14 youth with adherence challenges and/or a detectable HIV viral load into our pilot VOT program. The VOT coach (a trained coordinator, also living with HIV) worked with participants to set a time and choose a platform (e.g., FaceTime, Zoom) for daily video calls. Participants were scheduled to receive daily (Monday-Friday) video calls for three months wherein the coach would directly observe the participant taking medication.

In addition to observation, the coach would also ask participants about medication problems or side effects and provide feedback and emotional support. We conducted post-session surveys and qualitative interviews to assess participants' experiences and provide data on VOT acceptability.

Lessons learned: The mean age of participants was 25 years, 75% were male, 89% were Black, and 69% acquired HIV through horizontal transmission. Psychosocial barriers were prominent: 42% cited transportation difficulties getting to clinic, 44% described residential instability, and 69% met clinical cutoff for depression.

Despite initial interest, most (64.3%) participants presented for fewer than half of scheduled video appointments over the three-month period. Those who did participate described VOT as feasible and acceptable in follow-up surveys (mean scores >4/5); and specifically mentioned

the importance of peer support from a coach living with HIV in interviews. Some cited physical illness and competing demands (i.e. jobs) as barriers to more active participation.

Conclusions/Next steps: Structural barriers limited uptake of VOT;however, the intervention was highly acceptable among those who did participate. Future interventions should integrate VOT with rigorous mental health and social service support to help participants navigate structural challenges as a strategy for providing additional adherence support to youth.

EPB212

Facilitators and barriers to delivery of dispensing messages to caregivers of children living with HIV at four HIV care centres in Kampala: a qualitative study

E. Namusoke-Magongo[1], P. James Elyanu[2], D. Kalibbala[2], F.C. Semitala[3,4], C. Mulowoza[2], J. Rujumba[3], M.R. Kamya[3,5]
[1]Ministry of Health, AIDS Control Program, Kampala, Uganda, [2]Baylor College of Medicine Children's Foundation, Kampala, Uganda, [3]Makerere University College of Health Sciences, Kampala, Uganda, [4]Makerere Joint AIDS Program (MJAP), Kampala, Uganda, [5]Infectious Disease Research Collaboration (IDRC), Kampala, Uganda

Background: In Uganda, despite optimisation of children to more efficacious Lopinavir/ritonavir (LPV/r) based regimen like LPV/r pellets, viral suppression rates among children remain low, at 77%, way below the UNAIDS target of 95%. Moreover, viral suppression among children <5 years is even much lower at 60% and a major cause has been poor adherence to medicine. Uptake and administration of LPV/r pellets is hindered by low literacy levels among caregivers regarding how to administer the pellets. We explored facilitators and barriers to delivery of dispensing messages to caregivers at four HIV care centres in Kampala, Uganda.

Description: We conducted a qualitative study at four HIV clinics in Kampala: Baylor-Uganda clinical centre of excellence, Kisenyi HC III, Kawala HC III and Mulago National Referral Hospital- MJAP ISS Clinic. Data were collected through 7 FGDs of 6-9 participants each and 12 key informant interviews with health care workers involved in care for children between 19th October–2nd November 2021. Data was analysed using content thematic approach informed by the Capability, Opportunity and Motivation Model of Behaviour (COM-B model).

Lessons learned: Availability of skilled and knowledgeable health workers, visual messages especially flip charts, drug demonstrations on administration, use of toll-free telephone, and short message service reminders were noted as facilitators. The barriers noted included: shared counselling and clinical rooms that impede confidentiality, dispensing messages not provided routinely but targeting those initiating or not adhering to ARVs, negative attitude of some health workers, heavy client load limiting the time spent with caregivers to offer dispensing messages, lack of mentorship on dispensing messages, negative beliefs, inadequate audio-visual messages on drug administration and effects of none adherence, and COVID-19 pandemic related restrictions.

Conclusions/Next steps: There are major barriers to the delivery of dispensing messages to caregivers of children Living with HIV. Initiatives to improve dispensing messages should build on the existence of skilled and experienced health care workers at all HIV clinics and a network of expert clients who draw on their own experiences taking ARVs to educate others. Advocacy to address the broader health system challenges such as space and health workforce constraints will be critical as well.

EPB213

Association between caregivers' depression with adherence and viral suppression among HIV infected children aged < 10 years on follow up at Kenyatta National Hospital in Kenya

A.W. Kihiu[1], B. Mutai[2], R. Nduati[2], M. Kumar[3]
[1]County Government of Nyeri, Mukurue-ini Sub County Hospital, Nyeri, Kenya, [2]University of Nairobi, Department of Pediatrics and Child Health, Nairobi, Kenya, [3]University of Nairobi, Department of Psychiatry, Nairobi, Kenya

Background: Depression is well described among caregivers of children with chronic illnesses and may impact the quality of care of the affected child. HIV presents unique challenges because the caregiver often is infected as well.

A study was carried out to determine the prevalence of depression among caregivers of HIV infected children, and its impact on the child's well being measured by viral suppression, adherence to ART and retention in care among children on follow up at Kenyatta National Hospital.

Methods: Using a cross-sectional study design, study participants were recruited from the hospital HIV clinic. Depression was assessed using the PHQ-9 questionnaire. Pill count record was used to assess for ART adherence among children. Children's viral load and clinic attendance were abstracted from the hospital's electronic records. Children of women with and without depression were compared to determine effect of depression on viral suppression, adherence to ART and retention in care

Results: There were 117 caregivers-child dyads and 110 (94.02%) of the care givers were female. The median age of caregivers was 35 years (IQR 31-42 years), 78 (66%) were married and 52 (44%) had secondary school level education. Regarding occupation, 38 (34.23%) were casual labourers, 38 (34.23%) self-employed, 26 (23.42%) unemployed and 9 (8.11%) formally employed.

The children's median age was 5 years (IQR 3-7 years) and 95 (81.19%) had a parent as the primary caregiver. Overall 75 (64.1%) of the children had a viral load less than 1000 copies/ml, 95 (81.2%) were adherent to ART and 113

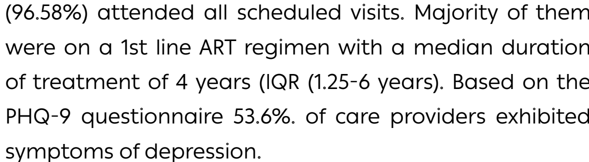
Poster exhibition

E-posters

Late-breaker abstracts

Author Index



(96.58%) attended all scheduled visits. Majority of them were on a 1st line ART regimen with a median duration of treatment of 4 years (IQR (1.25-6 years). Based on the PHQ-9 questionnaire 53.6%. of care providers exhibited symptoms of depression.
Caregivers with moderate and moderately-severe depression had lower odds of having children with ≥ 95% adherence to ART, Adjusted odds ratio (AOR) 0.015 [(0.001, 0.135) p=0.000)] and increased odds of having children with viral load of >1000 copies/ml AOR=107.8 [(19.4, 599.1) p=0.000] compared to those without depression.
Conclusions: The high prevalence of depression among the caregivers of HIV infected children adversely impacts children's level of adherence and viral suppression.

EPB214

Comparison of outcomes among HIV infected children by caregiver type in Western Kenya

A. Wasilwa[1], E. Amadi[1], D. Riedel[2], A. Ndaga[1], R. Oyuga[1], F. Ogero[3], D. Oneya[4], L.O. Nyabiage[5], C. Ng'eno[1]
[1]Center for International Health, Education, and Biosecurity (CIHEB), University of Maryland, Baltimore (UMB), Nairobi, Kenya, [2]CIHEB, University of Maryland, Baltimore, United States, [3]Kisii County, Department of Health, Kisii, Kenya, [4]Migori County, Department of Health, Migori, Kenya, [5]Division of Global HIV&TB (DGHT), Center for Global Health, U.S. Centers for Disease Control and Prevention (CDC), Kisumu, Kenya

Background: Antiretroviral (ART) compliance among children living with HIV (CLHIV) is dependent on caregivers. Globally, prior studies have evaluated ART outcomes among CLHIV with knowledge gaps on impact of specific caregiver types on treatment outcomes.
This study compared viral suppression (VS) and continuity in treatment among CLHIV with primary versus alternative caregivers.
Methods: We conducted a retrospective analysis to assess VS and continuity in treatment (retention in care) of CLHIV (0-14 years) in 34 public facilities supported by University of Maryland, Baltimore in Kisii and Migori counties by caregiver type. Primary caregivers were defined as biological parents while alternative caregivers as other guardians. CLHIV with ≥1 clinical visit between July 2017 and August 2021 and a documented caregiver type were included. Chi-square tests were used to test for association between caregiver type and outcomes while generalised linear models with logit link used to assess differences in outcomes by caregivers.
Results: 549 children were included, 51% (282) were female and median age at enrolment was 4.1 years (interquartile range [IQR] 2.0-6.9). Cumulatively, 256 (47%) had alternative caregivers of whom 81% (191) were aunts, 16% (37) uncles and 12% (28) siblings. At ART enrolment, 8% (18/201) and 16% (30/191) of children with primary and alternative caregivers presented with advanced HIV disease respectively. Proportion that achieved VS increased to 90% from a baseline of 70% for those with primary caregivers compared to an increase to 91% from 68% for alternative caregivers.
Overall, 97% (283) and 96% (245) of children with primary and alternative caregivers respectively continued in care as of August 2021. Children with primary caregivers were less likely to present with advanced HIV disease at enrolment (Risk Ratio (RR) 0.53, 95% CI (0.28–0.98)).
However, there was no difference in baseline VS (p=0.587), VS at last visit (p=0.671), or continuity in care (p=0.59) by caregiver type.
Conclusions: Continuity of care and proportion of children that achieved VS was high irrespective of caregiver type. However, CLHIV with alternative caregivers were more likely to present with advanced HIV disease at enrolment; hence, the need for enhanced strategies for early identification and ART initiation in this population.

EPB215

Using programmatic data to assess pediatric service coverage and HIV treatment cascades in Western region, Ghana

S. Benefour[1], T. Ayuomah[2]
[1]JSI Research & Training Institute, Inc., USAID Ghana Strengthening the Care Continuum Project, Takoradi, Ghana, [2]Ghana Health Service, Effia Nkwanta Regional Hospital, Sekondi-Takoradi, Ghana

Background: In 2019, 2,972 (15%) of new 20,068 HIV infections in Ghana were in children under the age of 14. Out of the estimated number of 13,616 annual deaths, 2,441 (18%) were children. To address this critical issue, opportunities for identifying and supporting infants and young children living with HIV early cannot be missed.
There is need to review program data to inform innovative strategies for testing and putting pediatrics and adolescents left behind on HIV treatment.
Methods: The USAID Strengthening the Care Continuum project (Care Continuum), implemented by JSI Research & Training Institute, Inc. reviewed program data of pediatric clients on ART from January 2019 to December 2021. Within the period we analyzed the number of: pediatric HIV testing for males and females, positivity rates, linkage and yield; ART facilities and the number offering pediatric ARVs; pediatrics who received VL results; and suppressed and unsuppressed clients.
Results: We assessed service utilization in 58 ART pediatric service facilities out of 76 ART sites (76%), testing 8,539 females and 7,601 males. The data for females and males were as follows, respectively: positivity rates of 1.98% (n=169) and 2.26% (n=172); initiation rates of 2.1% (n=179) and 2.49% (n=189); HIV yield of 28% and 26%; average linkage rate of 193.5% and 218.4%; VL suppression rates of 91% (n=597) and 88% (n=304); and pediatric client unsuppressed VL of 26% and 42%.

Data were collected through the District Health Information Management System (DHMIS), which aggregates clients who were identified as positive, plus new positive clients. This accounts for higher percentage of initiated clients than new positive clients.

Conclusions: Early initiation of antiretroviral drugs in infants with HIV can save lives. However, coverage of essential interventions remains low. This study illuminates that late VL sample receipt of VL results due to faulty PCR machines and sample transport delays VL result entry, leading to inflated linkage rates and skewed VL coverage data. This impacts decision-making. ANC units can address this by sending client folders to RCH when mothers transition to RCH for services.

EPB216

Effect of poor adherence on virological failure and genotypic changes in vertically-infected adolescents in Yaoundé: Evidence from an EDCTP prospective cohort study

D. Njume[1], J. Fokam[1], W. Pabo[1], C. Chenwi[1], F. Abdullah[2], F.-X. Mbopi Keou[3]

[1]'Chantal Biya' International Reference Centre for Research on HIV Prevention and Management, Virology, Yaounde, Cameroon, [2]South African Medical Research Council (SAMRC), AIDS and TB, Pretoria, South Africa, [3]Faculty of Medicine and Biomedical Sciences, University of Yaoundé 1, Yaounde, Cameroon

Background: HIV affects 1.7 million adolescents worldwide, with 88% in Sub-Saharan Africa (SSA) and 2% in Cameroon. Antiretroviral therapy (ART) has decreased HIV-associated mortality, but poor adherence and HIV drug resistance (HIVDR) emergence remain setbacks for treatment response in adolescents living with perinatal HIV infection (ALPHI); prompting assessment of the effect of adherence on virological response to ART and acquired HIVDR patterns in ALPHI in two hospitals in Yaounde.

Methods: A prospective cohort study was conducted amongst ALPHI aged 10-19. 214 participants were enrolled at baseline and followed up for two phases over 16 months.

Self-reported adherence (% missed doses in last 30 days) was assessed and plasma viral load (PVL) performed at each phase. If virological failure/VF (PVL>1000copies/ml), genotypic resistance testing(GRT) was performed, interpreted using the Stanford Algorithm(v.8.8). Rates of VF, once-daily ART dosing and HIVDR were compared for adherent and non adherent participants.

Statistical analysis was done on EpiInfov.7.2.4.0, using Chi-square/Fisher-exact test(categorical data), Mann-Whitney test(quantitative data).

Results: Of 214 participants, 196 and 176 were followed at second and third phases. Median age was 15±3 years; with 55.4% in the older age group (15-19 years). Self-reported adherence was 78.5%, 66.8% and 67.1% respectively. At baseline and 2nd phase, poor adherence was associated with older age; (OR=3, p=0.004; RR=1.2, p= 0.01) and once-daily regimen use (OR=3, p=0.01; RR=1.3, p=0.006). VF decreased from 41.6% to 26.1% (p=0.002), indicating increased viral suppression (VS) [58.7%-73.8%]. VF was two-fold higher with poor adherence (RR=2, p=0.0002; RR=2, p=0.004) at 2nd and 3rd phases. GRT performance increased from 75%-97.8%, with poor prescription practice from 36.2%-48.3% (p=0.15); underscoring retention on poorly-active regimens, limiting VS and prompting DRM accumulation. DRM rates were 90.9%, 79.9% and 71.1% and were higher with good adherence at 3rd phase (RR=1.7, p=0.004).

Conclusions: ALPHI in Cameroonian urban setting-shavedwindling adherence levels, worsened by older age and single-dose regimens. VF is worsened two-fold by single-dose regimens. VF decreased due to improved adherence counselling and GRT. Poor adherence increased VF two-fold and HIVDR remained high in both adherent and non-adherent adolescents on sub-optimal therapy. Poor GRT prescription practice, limits VS attainment. Hence, capacity-building on GRT result use and reinforced adherence, particularly in older adolescents and those on single-dose regimens, is paramount for VS.

HIV complications and co-morbidities in paediatric and adolescent populations

EPB217

Prevalence of malnutrition and its association with HIV-Exposure among young children in Kenya: results from the 2018-2019 Kenya Population-based HIV Impact Assessment (KENPHIA)

M.V. Robinson[1,2], J. Favaloro[3], A. Waruru[1], M. Ochwoto[4], M. Schmitz[1], M. Barasa[1], L.N. Omoto[1], M.N. Njeru[1], M. Bronson[3], T. Dobbs[3], S. Jonnalagadda[1], C. Toroitich-Ruto[1]

[1]U.S. Centers for Disease Control and Prevention, Division of Global HIV & TB, Center for Global Health, Nairobi, Kenya, [2]Public Health Institute, PHI/CDC Global Health Fellowship, Oakland, United States, [3]U.S. Centers for Disease Control and Prevention, Division of Global HIV & TB, Center for Global Health, Atlanta, United States, [4]Kenya Medical Research Institute (KEMRI), Nairobi, Kenya

Background: Malnutrition among HIV-exposed children is associated with higher risk of physiological and cognitive disability and death. We estimated malnutrition prevalence among HIV-exposed (HEC) and -unexposed (HUC) children using data from the Kenya Population-based HIV Impact Assessment (KENPHIA) 2018-2019, a nationally representative two-stage cross-sectional household-based survey.

Methods: Mid Upper Arm Circumference (MUAC) was measured among children aged 6-59 months in the sampled households. Child HIV exposure was determined us-

ing confirmed maternal HIV status. Sex and age-adjusted MUAC Z-scores were calculated by HIV exposure and categorized into 'severe malnutrition' (SM) [Z-score ≤−2 standard deviations (SD] or 'severe acute malnutrition' (SAM) [Z-score ≤−3 SDs] using WHO Growth Standards. Weighted prevalence of SM and SAM were calculated. Multiple linear regression of Z-scores from 1,949 children was conducted to identify demographic and household characteristics associated with a decrease/increase in Z-score, stratified by HIV exposure. Analyses accounted for survey design and non-response.

Results: SM prevalence was greater by 2.0% among HEC (6.4%, 95% CI: 3.4-11.9) compared to HUC (4.4%, CI: 3.3-5.8). SAM was greater by 0.8% among HEC (1.2%, CI: 0.8-1.6) compared to HUC (0.4%, CI: 0.2-0.8). Among HEC, one year increase in maternal age corresponded to a decrease in Z-score by 0.04; each additional child living in the same household was associated with an increase in Z-score by 0.26. Among HUC, one month increase in child's age corresponded to a decrease in Z-score by 0.02; those in households in the highest wealth quintile had a Z-score greater by 0.41 compared to households in the lowest quintile (Table).

	HIV-Exposed (N=110)	Adj. Coeff[2]	95% CI	p-value	HIV Un-Exposed (N=1,839)	Adj. Coeff[2]	95% CI	p-value
Male	56	0.205	-0.232, 0.641	0.34	1,001	-0.072	-0.195, 0.051	0.24
Child's Age (mos.)(Continuous)	110	-0.013	-0.029, 0.002	0.09	1,839	-0.016	-0.020, -0.013	P<0.01
Mother's Age (Continuous)	110	-0.042	-0.073, -0.011	0.01	1,839	-0.006	-0.018, 0.005	0.25
Household in highest wealth quintile(5) **compared to lowest**(1)	5	-0.085	-0.689, 0.518	0.77	151	0.409	0.122, 0.696	0.01
Household experienced food insecurity in previous 4 weeks	40	0.061	-0.297, 0.420	0.73	389	-0.031	-0.257, 0.194	0.78
# of children in household (Continuous)	110	0.263	0.151, 0.375	0.00	1,839	-0.009	-0.060, 0.043	0.73

[1] Total N (N=1,939) is less than total N with MUAC measurements (N=1,949) due to incompleteness of covariates in the model
[2] Models were adjusted for all variables shown in table above as well as household residence (urban vs. rural), wealth quintiles 2-4, household water source treatment, household sharing toilet with other households, and household head being sick (not shown above)

Table 1. Association between malnutrition, sex, age, and other variables stratified by HIV exposure among children 6-59 months old with MUAC measurements (N=1,939)[1], KENPHIA 2018.

Conclusions: Higher malnutrition prevalence was observed in HEC compared to HUC. Maternal age and number of children in the household were associated with malnutrition (lower Z-scores) among HEC, indicating higher risk for poor health outcomes.

These findings may help address gaps in child nutrition programming to improve child growth outcomes, especially among HEC.

EPB218

Hospitalisation patterns among infants with HIV in the era of universal antiretroviral therapy in South Africa

K. Anderson[1], V. Iyun[1], B. Eley[2], H. Rabie[3], T. Ferreira[4], J. Nuttall[2], L. Frigati[3], N. Van Dongen[4], M.-A. Davies[1,5]

[1]*University of Cape Town, Centre for Infectious Disease Epidemiology and Research, School of Public Health & Family Medicine, Cape Town, South Africa,* [2]*Red Cross War Memorial Children's Hospital, University of Cape Town, Paediatric Infectious Diseases Unit, Department of Paediatrics and Child Health, Cape Town, South Africa,* [3]*Tygerberg Hospital, Stellenbosch University, Department of Paediatrics and Child Health, Stellenbosch, South Africa,* [4]*Rahima Moosa Mother and Child Hospital, University of the Witwatersrand, Empilweni Services and Research Unit, Department of Paediatrics and Child Health, Johannesburg, South Africa,* [5]*Western Cape Department of Health, Directorate of Health Impact Assessment, Cape Town, South Africa*

Background: The shift to earlier antiretroviral therapy (ART) initiation in infants is expected to reduce morbidity and mortality. Studies examining hospitalisation among infants with HIV in resource-limited settings in the context of early infant diagnosis and early ART initiation are limited.

Methods: We used routinely collected data of infants who initiated ART aged <3 months (Western Cape province, South Africa; 2013-2017). We described hospitalisation from birth until 12 months post-ART initiation. Record reviews were performed in a subset of infants who attended two tertiary-level facilities.

Results: Among 840 infants, 577 (69%) were hospitalised; 297 (35%) had >1 hospitalisation. Median ART initiation age decreased from 57 days (IQR 22-74) (2013-2015) to 19 days (IQR 5-54) (2016-2017). Mortality was 4%. Early neonatal hospitalisation (age <7 days) occurred in 270 infants (32%; 164 (20%) initiated ART during hospitalisation); and represented 24% of hospitalisations (271/1125).

Overall, 441 infants (53%) were hospitalised at age ≥7 days, including 235 infants (28%) with 262 hospitalisations pre-ART initiation (210 (25%) initiated ART during hospitalisation) and 334 infants (40%) with 592 hospitalisations post-ART initiation.

Excluding early neonatal hospitalisations, infants who initiated ART at age 29-91 days vs earlier had higher hospitalisation risk (RR= 1.52; 95% CI 1.31-1.77) and fewer achieved viral load (VL) <100 copies/ml at 12 months (RR=0.79; 95% CI 0.64-0.97). Among infants with available results, 43% (187/440) and 45% (190/419) had VL <100 copies/ml at 6 and 12 months respectively. Hospitalisation post-ART initiation was more common in infants with VL ≥100at 12 months (RR=1.36, 95% CI 1.09-1.68).

Among infants whose hospital records were reviewed, reasons for early neonatal hospitalisations mostly related to prematurity or low birthweight (n=37/43; 86%) whereas

hospitalisations at age ≥7 days were mostly due to infections (n=176/210; 84%). Excluding early neonatal hospitalisations, infants who initiated ART at age 29-91 days vs earlier had higher infectious-cause hospitalisation risk (86% vs 29%, p<0.001; RR=2.95; 95% CI 2.09-4.18); intensive care was required in 22% of hospitalisations.
Conclusions: Earlier ART initiation is associated with higher viral suppression rates at 12 months and lower hospitalisation risk. High hospitalisation incidence observed pre- and post-ART initiation despite initiation age <3 months is concerning.

EPB219
Effects of integrase strand transfer inhibitors (INSTIs) on body mass index and blood pressure in children living with HIV

K. Baba[1], T. Lee[2], F. Kakkar[3], M. Hawkes[4], L. Samson[1], S. Read[5], H. Soudeyns[6], A. Bitnun[5], J. Brophy[1], EPIC4
[1]Children's Hospital of Eastern Ontario, University of Ottawa, Ottawa, Canada, [2]CIHR Canadian HIV Clinical Trials Network, Vancouver, Canada, [3]Centre de Recherche du CHU Sainte-Justine, Montreal, Canada, [4]Stollery Children's Hospital, University of Alberta, Edmonton, Canada, [5]Hospital for Sick Children, University of Toronto, Toronto, Canada, [6]Unité d'Immunopathologie Virale, Centre de Recherche du CHU Sainte-Justine, Montreal, Canada

Background: Integrase strand transfer inhibitors (INSTIs) have been associated with excess weight gain in adults. This study assessed the effect of INSTIs on body mass index (BMI) percentile and blood pressure (BP) of children living with perinatally acquired HIV (CLWPH).
Methods: EPIC4 prospectively enrolled and followed CLWPH from 7 Canadian centres from 2014-2018. Spline regression analysis was used to compare trends in BMI for patients with INSTI containing regimens versus age- and sex-matched INSTI naive patients. Percentages with worsening BP category (normal/elevated/stage 1/2 hypertension) were also compared using Chi-square test. Data points were assessed at time of initiation and 1 & 2 years before and after starting INSTI containing regimens.
Results: 197 children (113 INSTI-exposed; 84 controls) were included, with median age 13 years at start of INSTI (range 0.4-18.5); 53% were female. 75% had normal BMI at baseline; 20% were overweight or obese, 5% were underweight. Dolutegravir, raltegravir and elvitegravir were prescribed for 33 (29%), 43 (38%), and 37 (33%), respectively.
Viral load was detectable in 43/113 (39%) in INSTI group versus 9/84 (11%) in non-INSTI group at baseline, and in 7/61 (11.5%) and 13/73 (17.8%) after 2 years. Median CD4 count was 694 cells/uL in INSTI group vs 772 in non-INSTI group at baseline, and 772 vs 780 after 2 years.
Comparing BMI percentile over time, modest increases in BMI percentile from baseline were noted in both groups. Regression analysis demonstrated no difference in BMI percentiles between INSTI and non-INSTI groups (p=0.276), except in those taking INSTI plus protease inhibitors (n=27; difference in change in BMI percentile compared to non-INSTI at 1 and 2 years of 0.05 [p=0.014] and 0.12 [p=0.014], respectively). Percentages with stage 1/2 hypertension were not different between INSTI vs non-INSTI over time (baseline 25% vs 17%, p=0.292; 1yr 32% vs 23%, p=0.256; 2yrs 24% vs 24%, p=0.965).
Conclusions: INSTI-containing regimens do not appear to be associated with increases in BMI percentile or BP in CLWPH in Canada.

HIV-associated co-infections and malignancies in paediatric and adolescent populations

Believe it or not: children and adolescents living with HIV receiving antiretroviral therapy can still present with severe forms of Kaposi sarcoma

L. Campbell[1,2,3], A. Silverstein[4], E. Peckham-Gregory[2,5], B. Malingoti[3], H. Adinani[6], A. Kapesa[3], J. Bacha[1,2,3], N. El-Mallawany[2,7]
[1]Baylor College of Medicine International Pediatric AIDS Initiative at Texas Children's Hospital, Houston, United States, [2]Baylor College of Medicine, Pediatrics, Houston, United States, [3]Baylor College of Medicine Children's Foundation - Tanzania, Mbeya, Tanzania, The United Republic of, [4]University of Tennessee Health Science Center, Hospice and Palliative Medicine, Memphis, United States, [5]Center for Epidemiology and Population Health, Baylor College of Medicine, Pediatrics, Houston, United States, [6]Department of Health and Social Welfare, Tanzania Ministry of Health, Community Development, Gender, Elderly and Children, Mara, Tanzania, The United Republic of, [7]Texas Children's Cancer and Hematology Centers, Texas Children's Hospital, Global HOPE (Hematology-Oncology Pediatric Excellence), Houston, United States

Background: In regions with high seroprevalence of *Human gammaherpesvirus* 8, children and adolescents living with HIV (CALHIV) can present with severe forms of Kaposi sarcoma despite treatment with antiretroviral therapy (ART).
Methods: Retrospective review was conducted of CALHIV diagnosed with KS between 1 March 2011 and 30 March 2020 at the Baylor College of Medicine Children's Foundation - Tanzania in Mbeya, Tanzania. Patients were treated with chemotherapy [bleomycin and vincristine (BV), BV and doxorubicin (ABV), and/or paclitaxel depending on KS disease severity] and ART.
Results: A total of 69 CALHIV were diagnosed with KS, median age of 12.6 years (IQR 9.4-15.5) and 40.6% (28/69) female. At KS diagnosis, 78.3% (54/69) were receiving ART for

a median of 6.2 months (IQR 1.3-43.7). 60.6% (40/66) met criteria for WHO severe immunosuppression, 67.6% (23/34) had viral load > 1000 cp/mL, 40.6% (28/69) had severe acute malnutrition, 27.5% (19/69) had severe anemia, and 22.7% (15/66) had severe thrombocytopenia.

T1 KS disease was observed more frequently among patients on ART > 6 months (24/29; 82.8%, *p*-value 0.0147) and lymphadenopathic predominant disease was observed more frequently among patients on ART ≤ 6 months (11/25; 44%,*p*-value 0.0467) (Table 1).

Chemotherapy was given to 94.2% (65/69) with initial regimens of BV [56.9% (37/65)], ABV [40.0% (26/65)], or paclitaxel [3.1% (2/65)]; 5.8% (4/69) died before initiating chemotherapy. 95.7% (66/69) of CALHIV received ART; 4.3% (3/69) died before ART initiation. At censure, 71.0% (49/69) were alive, none abandoned treatment, and 28.9% (20/69) died.

Median follow up was 22.6 months (IQR 7.5-51.8). At completion of initial chemotherapy, 83.3% (45/54) had HIV viral load < 1000 cp/mL, and 23.5% (12/51) had severe immunosuppression.

Clinical characteristic	Not on ART (n=15)	On ART≤ 6 months (n=25)	On ART > 6 months (n=29)	*p*-value
T1	6/15 (40.0%)	15/25 (60.0%)	24/29 (82.8%)	0.0147
I1	9/14 (64.3%)*	12/24 (50.0%)*	17/28 (60.7%)*	0.6281
SI	9/15 (60.0%)	17/25 (68.0%)	16/29 (55.2%)	0.6281
Pediatric Lilongwe Stage 1A and 1B (mild mucocutaneous disease)	3/15 (20.0%)	1/25 (4.0%)	1/29 (3.4%)	0.1184
Pediatric Lilongwe Stage 2 (lymphadenopathic disease)	5/15 (33.3%)	11/25 (44.0%)	4/29 (13.8%)	0.0467
Pediatric Lilongwe Stage 3 (woody edema)	3/15 (20.0%)	5/25 (20.0%)	13/29 (44.8%)	0.0867
Pediatric Lilongwe Stage 4 (disseminated mucocutaneous and/or visceral disease)	4/15 (26.7%)	8/25 (32.0%)	11/29 (37.9%)	0.7408
Died	5/15 (33.3%)	7/25 (28.0%)	8/29 (27.6%)	0.9139

Table 1: Comparison of clinical characteristics of CALHIV at KS diagnosis and outcomes depending on time on ART (n=69)

*1 individual missing CD4 data

Conclusions: In our cohort, treatment with ART did not preclude CALHIV from presenting with severe KS disease, but positive outcomes were feasible with chemotherapy and ART.

EPB221

"Children are not just little lymphadenopathic adults" – describing the unique clinical challenges of children with lymphadenopathic Kaposi sarcoma

L. Campbell[1,2,3], A. Silverstein[4], E. Peckham-Gregory[2,5], W. Kamiyango[6,7], J. Villiera[6,7], C. McAtee[2,6,7,8], J. Bacha[1,2,3], C. Kovarik[9], P. Mehta[2,8], T. Chanroo[2,6,7], A. Kapesa[3], B. Malingoti[3], R. Mzikamanda[6,7], N. Ozuah[2,6,7,8], P. Kazembe[6], C. Allen[2,8], M. Scheurer[2,5], N. El-Mallawany[2,8]

[1]Baylor College of Medicine International Pediatric AIDS Initiative at Texas Children's Hospital, Houston, United States, [2]Baylor College of Medicine, Pediatrics, Houston, United States, [3]Baylor College of Medicine Children's Foundation - Tanzania, Mbeya, Tanzania, The United Republic of, [4]University of Tennessee Health Science Center, Hospice and Palliative Medicine, Memphis, United States, [5]Center for Epidemiology and Population Health, Baylor College of Medicine, Pediatrics, Houston, United States, [6]Baylor College of Medicine Children's Foundation Malawi, Lilongwe, Malawi, [7]Texas Children's Cancer and Hematology Centers Global HOPE (Hematology-Oncology Pediatric Excellence) Program, Lilongwe, Malawi, [8]Texas Children's Cancer and Hematology Centers, Texas Children's Hospital, Global HOPE (Hematology-Oncology Pediatric Excellence), Houston, United States, [9]University of Pennsylvania, Philadelphia, United States

Background: The AIDS Clinical Trial Group Kaposi sarcoma (KS) tumor (T) 0 staging encompasses individuals with mild-moderate mucocutaneous disease (non-nodular oral involvement) and with lymphadenopathic disease; however, children with these presentations can experience divergent outcomes. We aim to validate that pediatric specific KS staging more precisely risk-stratifies children with KS.

Methods: Characteristics and survival of children diagnosed with KS at either the Baylor Malawi (1 July 2013 to 31 March 2020) or Baylor Tanzania Mbeya Center of Excellence (1 March 2011 to 31 Dec 2017) were analyzed. The modified Lilongwe pediatric KS staging classification was utilized in which mild-moderate mucocutaneous disease corresponded to stage 1 and lymphadenopathic predominate disease corresponded to stage 2.

Results: Of 171 children with KS, 18% (31/171) had stage 1 disease, and 33% (56/171) had stage 2 disease (Table 1). T0 classification was assigned to 77% (24/31) of those with stage 1 disease and 87% (49/56) of those with stage 2 disease. All who received T1 classification with stage 1 (7) or stage 2 disease (7) had nodular oral involvement.

Stage 1 two-year overall survival was 87% (95% CI: 69%-95%) and stage 2 was 63% (95% CI: 48-75%). Among those with stage 1 disease, 81% (25/31) achieved complete clinical remission (CCR) after initial chemotherapy. Of the remaining 6, 2 relapsed/progressed but survived after salvage chemotherapy, 1 died off- therapy, and 3 died with KS progression.

Among those with stage 2 disease, 55% (31/56) achieved CCR. Of the remaining 25, 4 died within 7 days of KS diagnosis, 6 died during initial chemotherapy, and 3 died off-therapy. Twelve relapsed/progressed, 6 survived after salvage chemotherapy and 6 died with KS progression.

	Stage 1: Mild-moderate mucocutaneous disease (n=31)	Stage 2: Lymphadenopathic disease (n=56)	Stage 3: Woody edema disease (n=33)	Stage 4: Severe mucocutaneous and/or visceral disease (n=51)	*P*-value
Age in years, median (range)	9.6 (3.6 - 19.9)	4.4 (1.7 - 20.8)	12.2 (3.5 - 22.1)	9.5 (1.9 - 20.2)	<0.01
T1 Stage, n (%)	7 (23%)	7 (13%)	33 (100%)	43 (84%)	<0.01
Hyperpigmented Skin Lesions, n (%)	19 (61%)	19 (34%)	21 (63%)	38 (75%)	<0.01
Oral Involvement, n (%)	16 (52%)	17 (30%)	8 (24%)	30 (59%)	<0.01
Nodular Oral Involvement, n (%)	7 (23%)	7 (13%)	1 (3%)	15 (29%)	0.28
Hemoglobin < 8, n (%)	4 (13%)	24 (43%)	7 (21%)	17 (33%)	0.02
Platelets < 50, n (%)	3 (10%)	23 (41%)	2 (6%)	14 (27%)	<0.01
CD4 < 200, n (%)	13 (72%)	8 (31%)	10 (30%)	18 (56%)	0.04
On ART, n (%) with denominator HIV+ only	16 (59%)	19 (45%)	25 (78%)	36 (75%)	0.01

Table 1.

Conclusions: Survival among children with lymphadenopathic KS, most of whom were classified as T0, was suboptimal, emphasizing the aggressive nature of KS in children and the need for improved treatment strategies.

Behavioural health outcomes in paediatric and adolescent populations

EPB222

Participant Acceptability and Clinician Satisfaction of Cognitive Behavioral Therapy and a Medication Management Algorithm Compared with Enhanced Standard Care for Treatment of Depression among Youth Living with HIV

L. Bergam[1], K. Baltrusaitis[2], B. Kennard[3], G. Emslie[4], C. Krotje[5], K. Knowles[5], S. Buisson[6], J. Deville[7], E. Barr[8], S. Gillespie[9], M. Shikora[10], L. Levy[6], E. Townley[11], D. Shapiro[2], L. Brown[12]

[1]Harvard T.H. Chan School of Public Health, Center for Biostatistics in AIDS Research, Boston, United States, [2]Harvard University T.H. Chan School of Public Health, Center for Biostatistics in AIDS Research, Boston, United States, [3]University of Texas Southwestern Medical Center, Dallas, United States, [4]University of Texas Southwestern, Medical Center, Dallas, United States, [5]Frontier Science Foundation, Amherst, United States, [6]FHI 360, Durham, United States, [7]David Geffen School of Medicine at the University of California, Los Angeles, United States, [8]University of Colorado School of Medicine Children's Hospital, Aurora, United States, [9]Texas Children's Hospital/ Baylor College of Medicine, Houston, United States, [10]SUNY Stony Brook NICHD, Stony Brook, United States, [11]National Institute of Allergy and Infectious Diseases, National Institute of Health, Rockville, United States, [12]Rhode Island Hospital, Alpert Medical School of Brown University, Providence, United States

Background: Primary results of the International Maternal Pediatric Adolescent AIDS Clinical Trials Network (IMPAACT) 2002 trial showed that a Cognitive Behavioral Therapy (CBT) and Medication Management Algorithm (MMA) (COMB-R) significantly improved depression outcomes in Youth Living with HIV (YLWH) compared with Enhanced Standard Care (ESC).

Because participant perspectives and experiences of CBT are an important complement to treatment efficacy (Olsson, JBCT, 2021), we examined and compared the acceptability and satisfaction of these approaches among study participants and clinicians.

Methods: Between March 2017 and March 2019, 13 U.S. sites enrolled YLWH, ages 12-24, diagnosed with nonpsychotic depression. Using restricted randomization to balance site characteristics, sites were randomized to either COMB-R (CBT administered by a therapist and a licensed prescriber trained in the MMA) or ESC (standard psychotherapy and medication management).

After intervention conclusion at Week 24, participants and clinicians (licensed prescribers and therapists) rated their acceptability and satisfaction of the treatment in multiquestion surveys, with higher ratings indicating more desirable outcomes. Site-level means were compared using Wilcoxon tests.

Results: Overall, 69 participants were in COMB-R and 71 were in ESC. The mean age was 21.4 years, 53% were female, and 54% were living with perinatally acquired HIV. Baseline age, sex, depression levels, RNA viral load, and CD4 count were similar between groups. The distribution of site-level mean participant acceptability (quality, expectations, and overall satisfaction with treatment) was greater in COMB-R compared with ESC (Table 1).

The distribution of site-level mean licensed prescriber satisfaction (ease of using the intervention and improvement of participants' symptoms) was also greater in COMB-R compared with ESC. The distribution of site-level mean therapist satisfaction did not differ between groups.

Survey	Survey Description	COMB-R (6 sites)	ESC (7 sites)	P-value (Wilcoxon Test)
Participant acceptability	8 questions; scale from 1 to 4	3.7 (3.5, 3.9)	3.4 (3.3, 3.7)	0.04
Prescribing clinician satisfaction	2 questions; scale from 0 to 4	3.2 (2.5, 3.4)	2.4 (2.0, 3.0)	0.01
Counseling clinician satisfaction	6 questions; scale from 0 to 3	2.1 (1.9, 2.8)	2.3 (2.0, 2.6)	0.52

Table 1. Median (Minimum, Maximum) of site-level mean participant acceptability and clinician satisfaction

Conclusions: We found that mean acceptability and satisfaction for participants and licensed prescribers were significantly higher at COMB-R sites compared with ESC sites. These results further support the use of CBT and MMA in treating depression among YLWH.

Mental health and neurocognition in paediatric and adolescent populations

EPB223

Childhood adversity and depression in Ugandan adolescents with perinatally-acquired HIV: differences by HIV status and adversity exposure

A.F. Santoro[1], A. Nanteza[2], J.L. Gumikiriza-Onoria[2], C. Ferraris[1], S. Dirajlal-Fargo[3], R.N. Robbins[1]

[1]*Columbia University and the New York State Psychiatric Institute, New York, United States,* [2]*Makerere University, Kampala, Uganda,* [3]*Case Western Reserve University, Cleveland, United States*

Background: Adverse childhood experiences (ACEs; abuse, neglect, household dysfunction) have been shown to predict psychiatric symptoms in adults with HIV; however, less is known about ACEs' impact on mental health among youth with HIV.

This study examined associations between ACEs and depressive symptoms and differences by HIV status and ACE exposure in Ugandan adolescents (12-20 years) with perinatally-acquired HIV (PHIV) and HIV-negative controls.

Methods: 59 adolescents (36 PHIV; 23 controls; M_{age}=15.75; 50.8% female) recruited from Kampala, Uganda completed measures of ACEs (Adverse Childhood Experiences scale) and depressive symptoms (Patient Health Questionnaire-9 [PHQ-9]). Participants were grouped by ACE exposure (Low: 0-2 ACEs; High: ≥3 ACEs) and HIV status creating four groups: PHIV Low-ACE, PHIV High-ACE, Controls Low-ACE, Controls High-ACE.

Regressions examined associations between ACEs and depressive symptoms, adjusting for covariates (age, sex, HIV status). Fisher's exact tests and Brown-Forsythe ANOVAs assessed differences across HIV-ACE groups.

Results: 83.1% of participants reported ≥1 ACE, with 37.3% (41.7% PHIV; 30.4% Controls) reporting high ACE exposure (≥3 ACEs). 10.2% of participants (13.9% PHIV; 4.3% Controls) reported clinically significant depressive symptoms (PHQ-9 scores ≥10).

Additionally, 23.7% of participants (27.8% PHIV; 17.4% Controls) reported depression in the last year. Adjusting for covariates, ACEs predicted PHQ-9 scores (B=1.48, *p*=.001), explaining 37% of the unique variance. Significant differences across HIV-ACE groups (Table 1) were found for PHQ-9 scores, $F(3, 23.35)=8.63$, $p<.001$, with the PHIV High-ACE group exhibiting higher scores than all other groups (*ps*=.001-.03).

Compared to the PHIV Low-ACE group, greater proportions of the PHIV High-ACE group had clinically significant depressive symptoms (0% vs. 33.3%, *p*=.008, OR=1.50) and depression in the last year (9.5% vs. 53.3%, *p*=.007, OR=10.86).

		PHIV (*n*=36)		Controls (*n*=23)	
		Low ACE (*n*=21)	High ACE (*n*=15)	Low ACE (*n*=16)	High ACE (*n*=7)
PHQ-9 Total	M (SD) [Range]	0.67 (0.97) [0–3]	6.27 (5.47) [0–14]	1.06 (1.81) [0–6]	2.00 (3.61) [0–10]
Clinically Sig. Depressive Symptoms (PHQ-9 ≥10)	% (n)	0.0% (0)	33.3% (5)	0.0% (0)	14.3% (1)
Depression (Past year)	% (n)	9.5% (2)	53.3% (8)	18.8% (3)	14.3% (1)

Table 1. Depression outcomes by HIV status and ACE-exposure. High-ACE was categorized as ACE scale total scores ≥3. PHIV=Perinatally-acquired HIV; ACE=Adverse childhood experiences; PHQ-9=Patient Health Questionnaire-9 scale.

Conclusions: ACEs are common among Ugandan adolescents and may increase risk of depression in adolescents with PHIV. Among PHIV participants with high ACEs, one-third reported clinically significant depressive symptoms and half reported depression within the year, suggesting screening for ACEs may be useful in identifying adolescents with PHIV at-risk for mental health struggles.

Transition of adolescents into adult care

EPB224

Trust, telehealth, and transition: factors affecting telehealth and engagement in care during health care transition of young adults with HIV during the COVID-19 pandemic

E. Barr[1], H. Dunlevy[1], D. Kacanek[2], C. Glenny[1], M. Snyder[1], S.M. Reed[3], L. Silviera[1], P. Cook[3]
[1]University of Colorado, School of Medicine, Aurora, United States, [2]Harvard T.H. Chan School of Public Health, Boston, United States, [3]University of Colorado, College of Nursing, Aurora, United States

Background: Approximately 5 million adolescents and young adults with HIV (YALWH) will transition to adult care globally in the next decade, yet only 40-50% remain in care at a year, creating public health risks and affecting long-term health. The Covid-19 pandemic demanded a shift to telehealth yet there is limited literature on trust in telehealth. We evaluated patient-provider trust and telehealth use with respect to viral load, HIV stigma, transition status, and demographic factors.

Methods: This cross-sectional study assessed patient-provider trust using the Health Care Relationship Trust scale and the Watson Patient Caring Score. Trust in telehealth was assessed using the Patient Trust Assessment Tool. Stigma was evaluated with the HIV Stigma Scale. HIV RNA PCRs and the number and types (telehealth/in-person) of visits were collected via chart abstraction for 8 months before and after Covid-19 began in Colorado, USA (3/15/2020). Data were analyzed with linear or logistic regression.

Summary of Predictors of Trust and Telehealth Use

Outcome Variable	Predictor	β	R^2	($p < .05$)	Explanation
Trust in Telehealth (PATAT[a])	Patient-provider trust (HCR[b] Trust)	0.43	0.54	< .001	As HCR Trust and WPCS increased, trust in telehealth increased
	Patient-provider trust (WPCS[c])	0.37	0.54	< .001	
Patient-provider trust (HCR Trust)	High School or GED	0.25	0.52	0.035	High school or GED had higher HCR Trust than those with higher education
Patient-provider trust (WPCS)	HIV stigma scale	-0.23	0.54	0.005	As HIV stigma increased, WPCS decreased
HIV RNA PCR (pre- and post-Covid-19 combined)	Post-transition	-0.27	0.42	0.009	Those post-transition, had SHIV and had at least one telehealth visit were more likely to be HIV-undetectable across the whole time period
	SHIV[d]	-0.24	0.42	0.021	
	Telehealth use	-0.58	0.42	< .001	
HIV RNA PCR in 8 mos. Post- Covid-19	Telehealth use	-0.42	0.32	0.002	Those with at least one telehealth visit were more likely to be HIV-undetectable post Covid-19
Total visits (pre- and post-Covid-19)	Telehealth use	-0.20	0.16	0.042	Those with at least one telehealth visit had higher total visits

Note : [a]Patient Trust Assessment Tool (PATAT), [b]Health Care Relationship Trust scale (HCR), [c]Watson Patient Caring Score (WPCS), [s]ituationally acquired HIV (SHIV)

Results: Participants (*N*= 109) were 60% male, 61% non-white, 39% living with perinatally acquired HIV, and 58% post-transition. Greater patient-provider trust was associated with higher trust in telehealth. College graduates, higher income, and people with higher HIV-stigma had lower patient-provider trust. Those who felt telehealth was "easier" were 2.88 times more likely to use telehealth. Participants who had at least one telehealth visit were more likely to have additional telehealth visits, to have more total visits (in-person and telehealth), and to have an undetectable HIV viral load (<40 copies/ml) overall.

Conclusions: During the Covid-19 pandemic, YALWH with higher patient-provider trust were more likely to trust telehealth, and those who found telehealth easier were more likely to use telehealth, which was associated with HIV viral suppression. Strengthening trusted patient-provider relationships and increasing ease of use may increase telehealth uptake which may improve engagement in care resulting in greater HIV viral suppression when transitioning care.

Clinical issues in sex workers

EPB225

Same-day testing and treatment of sexual transmission infections among female sex workers using Nucleic Acid Amplification Test (NAAT) at a point of care

J. Valencia[1,2,3], L. Vázquez Guillamet[4], G. Cuevas[2], J.V. Lazarus[4], J. Torres-Macho[2], J. Domingorena[3], L.E. Jimenez[1], P. Ryan[2]
[1]Madrid Positivo NGO, Clinical Projects, Madrid, Spain, [2]Infanta Leonor Teaching Hospital, Internal Medicine, Madrid, Spain, [3]Harm Reduction Unit „SMASD", Mental Health and Addiction Department, Community of Madrid, Madrid, Spain, [4]Barcelona Institute for Global Health (ISGlobal), Hospital Clinic, University of Barcelona, Barcelona, Spain

Background: Undiagnosed and undertreated sexually transmitted infections (STIs), lead to spread of these STIs in the community and facilitate the HIV acquisition.

Methods: We carried out a cross-sectional study among female sex workers (FSWs) from Madrid, Spain. A mobile unit (MU) was used to screen Chlamydia trachomatis (CT), Neisseria gonorrhoeae (NG) and Trichomonas vaginalis (TV) using a NAAT obtained from either urine or vaginal fluid swab samples at a MU with results in 90 minutes. Participants with a positive result received on site same day treatment. Further, HIV, HCV and syphilis were screened using rapid tests.

Results: 49 FSWs were included. Baseline characteristic are showed in Table 1. Three patients self-reported HIV diagnosis and were on antiretroviral therapy, and seven had HCV antibodies (three of them viremic). Excluding three HIV infected FSWs,4 (8.7%) reported any knowledge on pre-exposure prophylaxis (PreP), and none had ever taken PreP.

The prevalence of CT/NG/TV and syphilis were 15.6%, 13.0%, 45.5% and 16.7%, respectively and the prevalence of all screened STI was higher in FSW who use drugs (Figure 1). The infections produced by CT/NG/TV/syphilis were

asymptomatic in 71.4%, 50%, 70% and 62.5%, respectively. All infections except one were treated. In the multivariate logistic regression analysis, the use of drugs among FSWs was associated with the likelihood of being diagnosed with at least one STI (aOR11.7(CI 95% 1.5-90.9; P= 0.01).

	Overall (n=49)	Use of drugs (n= 39)	Non-use of drugs (n= 10)	p-value
Age, median (IQR)	40.0 (33-48)	41.0 (33-49)	37.0 (29.5-43)	0.25
Nationality: Spaniards	24 (49%)	23 (59%)	1 (10%)	0.006
Type of residence: homeless	25 (51.0%)	25 (64.1%)	0	0.001
Employment: Unemployed	46 (93.9%)	36 (92.3%)	10 (100%)	0.84
Prison history	19 (38.8%)	17 (43.6%)	2 (20%)	0.17
Ever physical or sexual violence	30 (61.2%)	27 (69.2%)	3 (30%)	0.02
Unconsistent use of condoms	27 (55.1%)	22 (56.4%)	5 (50%)	0.71
Genito-urinary symptoms	18 (36.7%)	12 (30.8%)	6 (60%)	0.08

Table.

Figure. Prevalence of sexually transmitted infections (STI) among female sex workers (FSW) from the study cohort.

Conclusions: We identified a very high prevalence of undiagnosed and asymptomatic STIs among FSWs who use drugs. STIs periodic screening using NAAT based testing and same-day result-based treatment at a MU allow avoid diagnoses delays and undertreated STIs.

EPB226

Understanding the impact of COVID-19 on retention of female sex workers on HIV treatment in Malawi

A. Abubakar[1], C. Trapence[1], A. Worku[1], G. Zomba[1], T.V. Boven[1], C. Lau[1], C. Mhango[1], A. Mganga[1], A. Mtimuni[1], V. Kanje[1]

[1]*USAID Malawi, Health Population and Nutrition, Lilongwe, Malawi*

Background: Concerns have been raised about the impact of the COVID-19 pandemic on public health interventions. One program that seems to be highly vulnerable is the HIV treatment program. Using female sex workers (FSW) as a subgroup, we assessed the effects of COVID-19 on HIV treatment in Malawi.

Methods: We conducted a retrospective descriptive study using the HIV program data generated through reported using the district health information system (DHIS2) from 4 districts in the country with FSW intervention. We looked at the interruption of treatment for FSW on HIV care and treatment three months before the COVID 19 pandemic (January to March 2020), known as the pre-COVID period, and three months after the first case of COVID was reported (April to June 2020), known as the post-COVID period. We observed the proportion of FSWs interrupting treatment to see if a huge disparity exists.

Results: The result is reported at the country level. The proportion of FSW interrupting treatment increased significantly (pre=4%, post=22%) with a difference of 18%.

Conclusions: A significant increase in FSWs Interrupting of treatment during COVID-19 was observed and it will be worth exploring the determinants of these interruption. There is a need to review the effectiveness of policies such as multi-month dispensing (MMD), differentiated service delivery (DSD), in order to pivot to a more effective and innovative patient-centered approach for addressing interruption in treatment and optimizing retention among FSWs.

Clinical issues in transgender people

EPB227

Acceptability and uptake of self-sampling for etiological diagnosis of sexually transmitted infections (STIs) among transgender women in Brazil

D. McCartney[1], K.C. Bassichetto[2], A.R. Coimbra Motta Castro[3], A. Fachel Leal[4], D. Knauth[4], I. Dourado[5], L. Magno[6], L. Galan[2], P.A. Morelli Fonseca[7], R.S. Bacuri de Queiroz[7], R.J. Carvalho da Silva[8], M.A. Veras[2,9], P. Mayaud[1]

[1]*London School of Hygiene & Tropical Medicine, Department of Clinical Research, London, United Kingdom,* [2]*Núcleo de Pesquisa e Direitos Humanos em Saúde da População LGBT+, São Paulo, Brazil,* [3]*Universidade Federal de Mato Grosso do Sul, Campo Grande, Brazil,* [4]*Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil,* [5]*Instituto de Saúde Coletiva - Universidade Federal da Bahia, Salvador, Brazil,* [6]*Universidade do Estado da Bahia, Salvador, Brazil,* [7]*Instituto Leônidas e Maria Deane - Fiocruz Amazônia, Manaus, Brazil,* [8]*Centro de Referência e Treinamento em DST/Aids - Secretaria de Estado da Saúde de São Paulo, São Paulo, Brazil,* [9]*Faculdade de Ciências Médicas da Santa Casa de São Paulo, São Paulo, Brazil*

Background: Sexually transmitted infections (STIs) disproportionately affect transgender women (TGW), who often lack access to healthcare due to stigma and marginalization. This study aimed to evaluate the choice of self- or provider-collection of samples from potential infection sites for testing of STIs among TGW in Brazil.

Methods: TransOdara was a cross-sectional study among TGW conducted in five capital cities representing all Brazilian regions from December 2019 to July 2021.

A total of 1317 participants aged 18 years and older were recruited using Respondent Driven Sampling, completed a standard questionnaire, and swab samples from multiple sites (genital, anorectal, oropharyngeal, and neovaginal) collected and tested for chlamydia, gonorrhea, and HPV. Participants could choose whether sample was self-collected (following instructional diagrams) or provider-collected.

Results: The preferred choice was for self-collection of anorectal swabs (75%; n=1252) (95%CI 72.8-77.6) and genital swabs (77%; n=1236) (95%CI 74.3-79.2). A lower preference for self-collection of oropharyngeal swabs (50%; n=1270) (95%CI 47.1-52.6) and neovaginal swabs (40%; n=15) (95%CI 16.3-67.7) was observed. Those who chose self-collection reported that the sample collection was 'easy' for oropharyngeal (93%; n=623), anorectal (93%; n=930), genital (97%; n=927), and neovaginal (80%; n=5) sites, and almost all indicated that the instructional diagrams were 'easy' to follow. Those who chose provider-collection reported feeling 'comfortable' with the sample collection from oropharyngeal (89%; n=617), anorectal (84%; n=299), genital (93%; n=278), and neovaginal (100%; n=9) sites.

SWAB TYPE Collection modality	Campo Grande		Manaus		Porto Alegre		Salvador		São Paulo		TOTAL

Provider-collected	-	-	-	-	-	-	1	100	8	72.7	9	60.0	32.3-83.7
Total	-	-	-	-	3	100	1	100	11	100	15	100	

Table 1: Preference of study participants on the modality of swab collection, according to anatomical site

Conclusions: Overall, TGW chose self-sampling for testing of STIs from potential infection sites when given the opportunity and guided by illustrated instructions.

STI screening should be integrated into services for HIV and other sexual health services with self-collection methods (with appropriate guidance) offered as a choice for sample collection among TGW who seek healthcare services.

Clinical issues in people who use drugs

EPB228

Integrated STI and abscess management among PWIDs at government health facilities: a simple approach towards a great mission

D. Dey[1], M. Shahidul Islam[1], S. Farid[1]
[1]*Save the Children in Bangladesh, Health, Nutrition and HIV/AIDS, Dhaka, Bangladesh*

Background: Background: Clinical services for the PWIDs in Bangladesh have been covered primarily by NGOs. To mainstream PWIDs into government facilities, a major shift was made by introducing health service outlet modalities with limited clinical services to replace drop-in centers. The change is significant in terms of the larger population and geographical coverage attainable, which requires integrating clinical services with government Facilities.

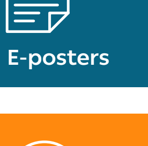
Description: Description: Integration of STI and abscess management with government health facilities started in April 2021. Previously only non-responsive and complicated cases were referred to these facilities. In this new modality, PWIDs are informed, sensitized, and motivated to go to nearby government Centers for STI and abscess management. Simultaneously, health care professionals of these centers are contacted regularly by outlet team to ensure PWIDs are treated well.

Despite these protocols, during Apr-June 2021 no PWIDs were managed through integration. In the next quarter, 17 STI and 10 abscess cases were managed through integration, and numbers increased significantly during Oct-Dec 2021 with 43 STI and 36 abscess cases managed.

Moreover, PWIDs received regular abscess dressing in government facilities resulting in cure. Challenges faced by PWIDs included long wait times, insufficient time to meet with providers, requirement to purchase some medicines, and inability to maintain follow-up appointments. Frequent change of physicians at the government hospital was also a challenge.

Lessons learned: Lessons learned: Despite some major challenges, the service uptake from the government facilities has gradually increased. Providing proper guidance to the PWIDs increased their health care seeking behavior, complemented by effective communication with government facilities ensuring a welcoming environment. SACMOs were trained on how to integrate these services smoothly.

Conclusions/Next steps: Conclusions: Scaling up integration of clinical services with government facilities will play a vital role in mainstreaming PWIDs into the health care system. Advocacy and sensitization of the relevant government healthcare professionals needs to be strengthened to ensure acceptance of PWIDs without stigma. PWIDs will also be motivated to seek health care like general populations.



EPB229

No pharmacokinetic interaction between islatravir and methadone

R. Matthews[1], W. Handy[1], W. Ankrom[1], M. Patel[1], C. Matthews[1], Z. Xu[1], K. Gravesande[2], S. Searle[3], H. Schwartz[4], M. Iwamoto[1], A. Stoch[1]
[1]Merck & Co., Inc., Kenilworth, United States, [2]Insmed Inc., Bridgewater Township, United States, [3]ICON/PRA Health Sciences, Salt Lake City, United States, [4]CenExel RCA, Hollywood, United States

Background: Islatravir (ISL) is a deoxyadenosine analog that targets HIV reverse transcriptase. ISL has a long half-life and demonstrates activity against NRTI- and NNRTI-resistant variants. Use of injectable drugs continues to be a significant risk factor in becoming infected with HIV, despite the decline in HIV infections due to intravenous drug use. People on methadone maintenance therapy may benefit from ISL, either as treatment of HIV infection or as pre-exposure prophylaxis. This clinical study evaluated the effect of ISL administration on methadone PK.

Methods: This was a nonrandomized, open-label, drug-drug interaction study in adult male and female participants on stable methadone therapy (20-200 mg QD). Participants received their standard methadone therapy during a >/=14-day run-in phase. Following enrollment, participants continued their daily standard dose of methadone for at least 15 days; ISL was administered concomitantly on Day 2. Serial blood samples were collected for methadone PK on Day 1 and Day 2.

Results: Fourteen participants (5 female) aged 26-63 were enrolled; 13 completed. The geometric mean ratios (GMRs; 90% confidence interval [CI]; ISL+methadone/methadone alone) for S-methadone AUC0-24, Cmax, and C24 were 1.03 (0.99, 1.07), 1.01 (0.94, 1.09), and 1.08 (1.04, 1.13), respectively. For R-methadone AUC0-24, Cmax, and C24, the GMRs (90% CI) were 1.03 (1.00, 1.07), 1.02 (0.96, 1.09), and 1.06 (1.03, 1.10), respectively. The GMRs (90% CI) for total-methadone AUC0-24, Cmax, and C24 were 1.03 (0.99, 1.07), 1.01 (0.95, 1.08), and 1.07 (1.03, 1.11), respectively. Coadministration of a single dose of ISL with methadone was generally well tolerated.

Conclusions: Coadministration of a single dose of islatravir did not meaningfully affect methadone PK. Study results support coadministration of these two medications.

Cure interventions

The BAF complex inhibitor pyrimethamine induces HIV-1 transcription in ART-suppressed HIV-1-infected individuals

H. Prins[1], R. Crespo[2], C. Lungu[2], S. Rao[2], L. Li[3], R. Overmars[4], Y. Muller[5], P. Katsikis[5], J. van Kampen[4], D. van de Vijver[4], T. Mesplede[4], R. Gruters[4], B. Koch[3], A. Verbon[1], C. Rokx[1], T. Mahmoudi[2,6,7]
[1]Erasmus MC, Internal Medicine, Rotterdam, Netherlands, the, [2]Erasmus MC, Biochemistry, Rotterdam, Netherlands, the, [3]Erasmus MC, Pharmacology, Rotterdam, Netherlands, the, [4]Erasmus MC, Viroscience, Rotterdam, Netherlands, the, [5]Erasmus MC, Immunology, Rotterdam, Netherlands, the, [6]Erasmus MC, Pathology, Rotterdam, Netherlands, the, [7]Erasmus MC, Urology, Rotterdam, Netherlands, the

Background: A central approach to eradicate the HIV-1 reservoir is the shock and kill strategy, that aims at pharmacological reactivation of latent HIV-1 transcription followed by strategies that lead to purging of infected cells in the presence of cART. Previously, we showed that inhibition of the BAF complex, a key promotor of HIV-1 latency, by the clinically approved generic drug pyrimethamine, leads to latency reversal in cells obtained from people living with HIV (PLWH).

To evaluate the efficacy of BAF complex inhibition to reactivate HIV-1 reservoirs *in vivo*, and whether the effect is potentiated when combined with the HDAC inhibitor valproic acid, we conducted a proof-of-concept randomized controlled trial: LRAs United as a Novel Anti-HIV strategy.

Methods: Twenty eight HIV-1-infected adults on suppressive cART were randomized in a 1:1:1:1 ratio to one of four arms to receive valproic acid for 14 days; or pyrimethamine for 14 days ; or both valproic acid and pyrimethamine; or no intervention. The primary endpoint was the change in HIV-1 reactivation measured as the fold change in cell-associated (CA) unspliced (US) HIV-1 RNA. Secondary endpoints included the clinical safety and tolerability of the intervention regimen and the change in inducible HIV-1 reservoir size.

Results: No serious adverse events or suspected unexpected serious adverse reactions were observed during the trial. We observed a significant fold increase in the levels of HIV-1 RNA in CD4+ T-cells isolated from individuals treated with the BAFi pyrimethamine monotherapy, but not with the HDACi valproic acid. Concurrent treatment with both pyrimethamine and valproic acid did not lead to a synergistic increase in the levels of CA US HIV-1 RNA compared to monotherapy with pyrimethamine or valproic acid. Lastly, in our study, induction of HIV-1 transcription by the BAFi pyrimethamine did not lead to a reduction in the size of the inducible reservoir.

Conclusions: Our study is the first to show that pharmacological inhibition of the BAF complex reverses HIV-1 latency in PLWH. While treatment with pyrimethamine sig-

nificantly induced HIV-1 transcription *in vivo*, combination with the HDACi valproic acid did not lead to synergistic reactivation of HIV-1, warranting exploration of other potential combinatorial approaches using pyrimethamine.

EPB231

Inhibitory, KIR/HLA-mismatched, allogeneic NK and γδ-T cells as an HIV cure strategy: proof-of-concept in 3 patients

S. Gumrukcu[1,2], P. Musikanth[1], G. Howell[3], T. Nguyen[3], E. Aquino[1], S. Singh[1], M. Dybul[2], W.D. Hardy[3]

[1]Seraph Research Institute, Toluca Lake, United States, [2]Enochian Biosciences, Los Angeles, United States, [3]Seraph Research Institute & Enochian Biosciences, Los Angeles, United States

Background: NK and gamma/delta (γδ)-T cells are innate immune cells important in anti-HIV responses. Because antigen recognition is achieved outside of MHC-restriction in these cells, we studied inhibitory KIR/HLA-mismatched allogeneic NK and γδ-T cells as a potential adaptive cell therapy for HIV cure.

Methods:

Pre-clinical

- NK & γδ-T cells were isolated by CliniMACS from 3 HIV-seronegative volunteers, individually KIR/HLA-mismatched to 3 PWH; γδ-T cells were expanded using IL-2 & zoledronic acid.

Clinical

- IRB-approved individual-patient treatment protocol.
- Pts: 1) 41 y/o female; HIV+ 2003; pan-ART-intolerant; CD4+T cells=34/mm³; VL=1.4x10⁶cps/mL (off ART)

2) 39 y/o male; HIV+ 2002; VL<20cps/mL, ART-fatigue; CD4+ T cells=464/mm³; VL=26,000cps/mL (off ART)

3) 54 y/o male: HIV+ 1987; Long ART Hx (MDR; VL-200-1000 cps/mL); CD4+ T cells=670/mm³; VL=5025cps/mL (off ART)

Protocol: Days -5,-4,-3- fludarabine- 15mg/m²/day; Days -2,-1- IFNα- 3x10⁶IU/m²/day; Day 0- Cells infused; Days 0-4- Il-2- 6x10⁶IU/m²/day

- 25x10⁶/kg NK cells & 5x10⁶/kg γδ-T cells
- ART discontinued prior to treatment.

Results:

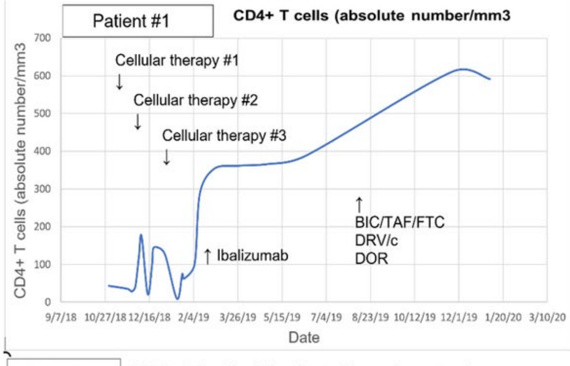
Clinical

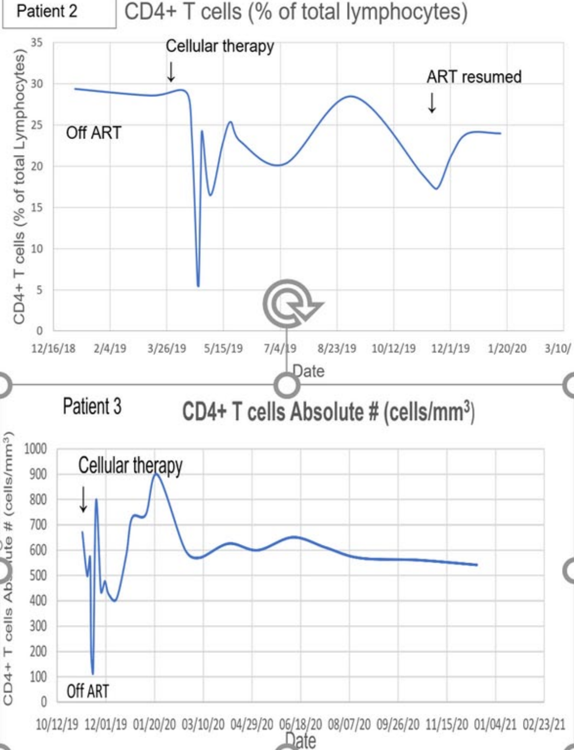
Pt 1: 3 cellular treatments (see figure). Developed IRIS-associated PJP post-treatment #2. Ibalizumab added w/ ↑ VL which suppressed <20 cps/mL on BIC/TAF/FTC +DRV/c + DOR with good tolerance.

Pt 2: VL <20 cps/mL x 16 wks, then rebounded following unprotected anal sex. ART resumed.

Pt 3: VL remained ≤ 20cps/mL x 12 mos, initiated ART to practice safe sex

All pts reported Gr 2/3 AEs typical of Il-2 treatment. All AEs resolved. No SAEs.





Conclusions: KIR/HLA-mismatched, allogeneic NK + γδ-T cell treatment is well-tolerated, suppressed HIV RNA without ART and increased CD4+ T cells. A phase 1, investigator-initiated, IND study will be submitted.

EPB232

In vitro evaluation of drug-loaded polymeric nanoparticles in the treatment of Human Immunodeficiency Virus

O. Obisesan[1], L. Katata-Seru[1], H. Mufhandu[1]

[1]Northwest University, Mafikeng, South Africa

Background: Human immunodeficiency virus is chronic infection known for its associated latency in the neurons and its potential for comorbidities. The use of antiretroviral therapy has significantly enhanced the quality of life of people living with HIV.

However, resistance has evolved with the use of antiretroviral therapy. Most FDA approved antiretroviral drugs do not cure the disease and no major breakthrough has been made with HIV vaccine production. The advent of nanotechnology has helped in the reformulation of exist-

ing HIV drugs to enhance drug delivery, increase drug efficacy and minimize potential side effects. Encapsulating antiretroviral drug (Tenofovir disoproxil fumarate) in biodegradable polymer will improve the delivery of the drug to the target sites; enhance HIV treatment and reduce drug resistance.

Methods: Double emulsion solvent evaporation method was used to formulate biodegradable polymeric nanoparticles containing antiretroviral drug (TDF-PCL NPs). The formulated nanoparticles were characterized with scanning electron microscope (SEM), malvern zetasizer and fourier transform infra-red spectroscopy (FTIR).

TDF-PCL NPs was assessed *in vitro* for cytotoxicity in Vero cell lines. Viral inhibition of HIV-1 infected cells treated with polymeric nanoparticles was determined using neutralization assay.

Results: Characterization of TDF-PCL NPs showed an average particle size, PDI and ZP of 152.9±1.7 nm, 0.275, -26.9±0.3 mV respectively with an encapsulation efficiency and drug loading capacity of 84.4% and 8.3% respectively. Furthermore, FTIR reports showed successful integration of TDF in the polymer while SEM revealed that the TDF-PCL NPs have spherical morphology. The cytotoxicity assay of TDF-PCL-NPs on Vero cells showed no significant toxic effect to the cells after 24 hours of treatment.

In addition, the *in vitro* release study of TDF-PCL-NPs in PBS (pH1.5 and 7.4) showed an extended drug release of more than 48 hours when compared with the free drug. The neutralization efficacy of TDF-PCL-NPs in infected HIV cells showed an IC_{50} value of 11.44 uglmL compared to the free drug of 29.19 uglmL.

Conclusions: It is apparent that polymeric nanoparticle may be a better treatment option for HIV-1 infection as it shows less cytotoxic effects, improves the delivery of the drug to the target sites, which may as well reduce drug resistance.

Nutrition

EPB233

Impact of HIV status on nutritional outcomes in hospitalized Mozambican children

E. Martey[1], E. da Conceição José Luís[2], O. Loquiha[3], A. Schindele[3], A. Seni[4], L. Samuel[3], D. Moçambique[2], M. Sequene[4], S. Martins[2], W.C. Buck[1,2]

[1]*University of California Los Angeles, David Geffen School of Medicine, Los Angeles, United States,* [2]*Hospital Central de Maputo, Maputo, Mozambique,* [3]*Clinton Health Access Initiative, Maputo, Mozambique,* [4]*Hospital Central de Beira, Beira, Mozambique*

Background: Hospitalization and HIV infection are known risk factors for worsening nutritional status in African children. The majority of the related literature has focused on specialized malnutrition wards, but little has been published about the prevalence of acute malnutrition and the impact of HIV on inpatient nutritional outcomes in other pediatric wards.

Methods: From 2020–2021, a quality improvement (QI) project focused on nurse-led nutritional screening was implemented on pediatric wards, not including neonatal or pediatric intensive care units or malnutrition wards, at two central hospitals in Mozambique. For the QI intervention, clinical and demographic data were collected after inpatient chart closure for patients selected by random sampling.

This is a preliminary, secondary analysis of the QI data for children aged 1 month-14 years with known HIV status. Anthropometric z-scores and nutritional classifications were determined using WHO standards.

Results: Of 2,217 children in the QI database, 1,608 (73%) had HIV status recorded, with 11%, 3%, and 85% HIV-positive, exposed, and negative, respectively. The prevalence of severe acute malnutrition at admission was highest in HIV-positive children (17%), followed by HIV-exposed (14%), (p< 0.001).

Overall, 24% of patients had moderate or severe acute malnutrition at admission. In patients hospitalized ≥5 days, 54% lost weight, with HIV-exposed infants most affected (74%), (p=0.049). There were no significant differences between serogroups for ≥5% body weight loss during hospitalization.

Variable	All patients	HIV-positive	HIV-exposed	HIV-negative	P-value

Author Index

Conclusions: Acute malnutrition is common in children hospitalized for reasons other than malnutrition, with higher prevalence in HIV-positive and exposed children. Weight loss during hospitalization is also common, especially among HIV-exposed infants. Enhanced nutritional care on non-malnutrition wards is needed, and introduction of admission nutritional risk-assessment tools and preventive nutritional therapy should be considered, regardless of HIV status.

EPB234

Preventing HIV positive childhood Malnutrition through mothers /caregivers' education on home-made high protein diet amongst Internally Displaced Persons (IDPs) in the conflict zone of the North West Region of Cameroon

J. Sama[1], D. Sama[2], A. Lukong[3], W. Abia[4], C. Rodriquez[5], R. Langsi[6]
[1]College of Technology, University of Bamenda, Department of Human Nutrition, Bamenda, Cameroon, [2]Sama Care Ltd, HIV Unit, Bamenda, Cameroon, [3]College of Technology, University of Bamenda, Department of Nutrition, Food and Bioresource Technology, Bamenda, Cameroon, [4]University of Yaoundé 1, Microbiology / Food toxicology, Yaoundé, Cameroon, [5]Saint Mary Soledad Hospital, HIV Care Unit, Bamenda, Cameroon, [6]University of Bamenda, Health Division, Bamenda, Cameroon

Background: Children living in a conflict zone are twice more likely to suffer from malnutrition than those living in a peaceful settings. This has an effect on physical and mental growth leading to about three out of every four kids experiencing stunted growth and mental retardation. The HIV positive child is already faced with nutritional challenges (breastfeeding challenges, loss of appetite, nausea and vomiting from drug side effects) and therefore the conflict situation only comes in to make a bad situation worse for the IDPs). This explains why majority of HIV positive children who are admitted in hospitals have malnutrition related conditions. Limited resources and ignorance play a great role in enhancing this situation.
This work aims at analysing the impact and mitigating the situation through education.
Description: The programmed was promoted by the by the Ministry of Public Health and local NGOs including the HIV Unit of Sama Care International. It ran for over 8 months targeting 20 households of IDPs with HIV positive children in three different locations in Bamenda, Cameroon. Semi-structured interviews were conducted with 05 selected members of staff and targeted 05 groups of 04 mothers and caregivers using audio-tapes. Touch point analysis was used to analyse information.
Lessons learned: NoBoth mother/caregivers presented similar views as to the dietary approach to managing HIV positive children. However, the 30% of mother had above secondary education presented pragmatic methods of composing high Protein diet from locally available foodstuff and fruit blends. A total of 20 different food arrangements were proposed to participants and 3 staff were designated to monitor and evaluate this implementation thereafter. 10 of these food plans are actively being used and the next planned phase is to grow them within the community and preservation methods included such as dried fruit like mango with cereal and peanut powder introduced.
Conclusions/Next steps: The impact of the study was observed in both economic and health terms. It minimised purchase of buying artificial protein diets and also health wise the children were generally healthier evidenced by less frequent admissions to hospital.

Resistance to ART

EPB235

Resistance mutations in the HIV integrase coding region among INSTI-naïve pregnant women in Argentina: a baseline survey

D. Cecchini[1], J. Sfalcin[2], I. Zapiola[3], A Gomez[2], S. Fernandez Giuliano[3], C. Rodriguez[1], L Mammana[3], A Seravalle[2], F Fay[2], G Bugarín[4], M.B. Bouzas[3]
[1]Hospital Cosme Argerich, Infectious Diseases Unit, Buenos Aires, Argentina, [2]CIBIC, Rosario, Argentina, [3]Hospital Francisco J. Muñiz, Virology Unit, Clinical Analysis Division, Buenos Aires, Argentina, [4]MSD Argentina, Munro, Argentina

Background: Argentina has reported overall moderate to high levels of drug resistance (mostly to NNRTIs) in naive HIV-infected population, including pregnant women. To date, no data exists regarding prevalence of resistance associated mutations (RAMS) in the integrase coding region in such population.
We aim to describe the prevalence of RAMS to integrase strand transfer inhibitors (INSTI) in an historical cohort of HIV-infected pregnant women, prior to INSTI use within the country, providing baseline data on this topic.
Methods: Retrospective analysis of a cohort of 89 INSTI-naïve HIV-infected pregnant women, whose pretreatment samples had been genotyped by TRUGENE (period 2008-2014) as part of a first interim survey on transmitted and acquired drug resistance. 56 samples were available for re-sequencing in the integrase coding region with Ultra Deep sequencing (UDS) using a Public Health Agency of Canada genotyping protocol on Miseq sequencer (Illumina). Bioinformatics analysis were performed by HyDRA software for a 20%, 10%, 5%, 2% and 1% UDS sensitivity threshold. INSTI-RAMS were identified according to Stanford algorithm (HIVdb version 9.0).
Results: Samples from 56 INSTI-naïve HIV-infected pregnant women were analyzed. Of them, 38 had no exposure to antiretroviral therapy (ART) and 18 had prior ART with

non-INSTI drug classes. Predominant HIV subtype was BF (78.5%). Prevalence of INSTI-RAMS (percentage) according to UDS sensitivity threshold is shown in table 1.

UDS threshold	20%	10%	5%	2%	1%
Major mutations					
Y143C	--	--	--	1.7%	1.7%
Y143S	--	--	--	1.7%	1.7%
T66I	--	--	--	1.7%	1.7%
E138K	--	--	--	--	1.7%
E92G	--	--	--	1.7%	1.7%
Accessory mutations					
T97A	3.5%	3.5%	3.5%	3.5%	3.5%
G163R	12.5%	12.5%	12.5%	12.5%	12.5%
G163K	7.1%	7.1%	8.9%	8.9%	8.9%
Other					
V151I	5.3%	7.1%	8.9%	8.9%	10.7%
L74I	1.7%	1.7%	1.7%	1.7%	1.7%

Table 1.

Conclusions: Using 20% UDS sensitivity threshold, a high overall prevalence (23.1%) of accessory mutations in the integrase coding gene was found, mostly at expense of G163K/R RAMS, with potential impact on susceptibility to first generation INSTIs. In addition, major INSTI-mutations were detected applying 1 and 2% sensitivity thresholds.
Our study provides first evidence of RAMS in the integrase coding region in pregnant women in Argentina prior to the use of INSTIs in clinical practice. Influence of circulating subtypes and impact on virological response merit further research.

EPB236
Transmitted HIV-1 drug resistance in a RAPID ART initiation cohort Panama 2018-2020

R.E. Morales[1], A.B. Arauz[2], A. Azmitia[1], C. Gutierrez[1], A. Martinez[3], J. Gondola[3], F. Diaz[2], J. Wright[1]
[1]*Center for Disease Control and Prevention, Guatemala City, Guatemala,* [2]*Hospital Santo Tomas, Panama City, Panama,* [3]*Instituto Conmemorativo Gorgas de Estudios de la Salud, Panama City, Panama*

Background: HIV-1 drug resistance (HIVDR) testing is not routinely available for clinical management in most low and middle-income countries [1].
We conducted a pilot study for Rapid ART initiation (RAPID) in ART-naïve patients initiating ART at Santo Tomas Hospital in Panama during February 2018 –June 2020. The goal was to improve the time to ART initiation from 8 weeks to less than 7 days. As part of RAPID, baseline CD4, viral load, and genotype data were obtained.
We assessed the prevalence of transmitted drug resistance mutations (TDRM) in this cohort of patients initiating ART in Panama.
Methods: A total of 762 patients were enrolled throughout the RAPID study. We conducted genotypic testing using an in-house protocol for protease, reverse transcriptase, and integrase sequencing in all patients piloting RAPID ART. Demographic and laboratory variables were collected from the clinic database. We performed a Pearson Chi-squared test with a significance level of 5% comparing patients with no TDRM to those with a least one. TDRMs were identified according to the Stanford HIV drug resistance database.
Results: Of 762 ART-naïve patients tested for HIVDR, 146 (19.2%) had any TDRM; 112 (14.8%) had mutations that confer resistance to NNRTI, 53 (7.0%) to NRTI, 25 (3.3%) to NNRTI+NRTI, and 8 (1.1%) to PI. K103N (5.8%) and M41L (2.6%) were the most frequent mutations for NNRTI and NRTI, respectively. No INSTI mutations were identified. Comparing patients without mutations to those with at least one TDRM, we found significant differences in among sexual orientation (p=0.0085), CD4 count (p=0.025), and educational attainment (p=0.014). Within sexual orientation, we observed a higher proportion of mutations among MSM compared to the remaining population.

Feature	Total (N=762)	TDRM (n=146)	P-value
MSM	351	82 (23%)	0.0085
Non-MSM	411	64 (16%)	0.0085
CD4+ T-cell >500	229	44 (20%)	0.025
CD4+ T-cell 200-499	386	63 (16%)	0.025
CD4+ T-cell <200	146	39 (27%)	0.025

Table

Conclusions: We found a high prevalence of TDRM among patients' initiating ART in Panama. The observed mutations highlight the importance to transition away from NNRTI-based regimens to integrase-based regimens.
It is important to continue drug resistance surveillance as new drug classes are rolled out in the region.

EPB237
Factors associated with Antiretroviral therapy failure among persons living with HIV in Zambia, 2013-2020 – A retrospective cohort study

C. Haabeenzu[1], M. Situmbeko[2], J.T. Prieto[3], E.S. Heilmann[4], N. Sinyange[2], I. Chiboma[5], J.Z. Hines[4], M. Ndhlovu[6]
[1]*Zambia Field Epidemiology Training Program, Lusaka, Zambia,* [2]*Zambia National Public Health Institute, Lusaka, Zambia,* [3]*Palantir Technologies, Paris, France,* [4]*Centers for Disease Control and Prevention, Lusaka, Zambia,* [5]*Ministry of Health, Lusaka, Zambia,* [6]*Levy Mwanawasa Medical University, Lusaka, Zambia*

Background: Zambia achieved high antiretroviral-therapy (ART) coverage among persons living with HIV (PLHIV), making the control of the epidemic within reach. However, unsuppressed viral load (VL) despite ART threatens Zambia's trajectory toward ending HIV. We assessed factors associated with ART treatment-failure in Zambia using national electronic health record (EHR).
Methods: A retrospective cohort study was conducted of PLHIV aged ≥15 years enrolled in the national EHR (called 'SmartCare') during 2013-2020 in Zambia. We defined treatment failure as ≥2 unsuppressed VLs ≥6 months after initiating ART and ≥6 months apart, or being switched from first- to second-line ART. We excluded participants

with unknown ART initiation dates, already on second-line ART at initiation, <2 documented VL results, and undocumented prescription lengths. Covariables included sex, age, province, rural/urban, and prescription length (categorized as <3 months, 3-5 months, and ≥6 months). We did multivariable logistic regression and Kaplan-Meier survival analysis in R.

Results: We analyzed 673,066 (55.6%) of the 1,210,156 PLHIV enrolled in SmartCare during 2013-2020. Mean age was 41 years and females comprised 65.8%. A total of 52,881 (7.86%) PHLIV failed treatment, with an incidence of 14.15/1,000 person-years. Fifty percent of those classified as failing treatment did so by 3.03 years. Compared with a prescription length of <3-months, 3-5 month and ≥6-month lengths had lower odds of treatment failure (adjusted odds ratio [aOR]: 0.49 [95% confidence interval (CI): 0.48-051]; 0.327 [95% CI: 0.27-0.29], respectively). Being male and living in an urban district were associated with higher odds of treatment failure (aOR: 1.37 [95% CI: 1.34-1.41]; aOR: 1.31, 95% CI: 1.26-1.34], respectively).

Conclusions: Longer ART prescription lengths were associated with lower treatment failure in Zambia. That PLHIV with well-controlled disease are often offered longer prescription lengths could explain lower failure among the longer prescription length groups. These findings could also be biased by the large number of excluded observations. Persons recently initiated on ART need close monitoring given that >50% failed within the first 3 years of treatment initiation. Increasing programs that target males and urban PLHIV might help improve HIV outcomes in Zambia.

EPB238

Temporal trends of pediatric HIV drug resistance and subtype in Brazil (2009-2020)

A.A.C.M. Ferreira[1], R.G.G. Pinho[2], N.M.C. Véras[2], A.R. Pascom[2], T.D. Barros[3], G.F.M. Pereira[2], V.I. Avelino-Silva[1,4]
[1]*Faculdade de Medicina da Universidade de São Paulo, Department of Infectious and Parasitic Diseases, São Paulo, Brazil,* [2]*Ministry of Health of Brazil, Department of Chronic Conditions and Sexually Transmitted Infections, Brasília, Brazil,* [3]*Ministry of Health of Brazil, PNI, Brasília, Brazil,* [4]*Faculdade Israelita de Ciencias da Saude Albert Einstein, São Paulo, Brazil*

Background: Strategies to reduce HIV mother-to-child transmission are essential but increase exposure to antiretroviral (ARV) in children born to women living with HIV. Management of resistance is challenging due to the limited number of drugs in the pediatric regimens. Hence, HIV-drug resistance (HIV-DR) remains a concern in children living with HIV (CLHIV). This study aimed to analyze HIV-DR and subtype in CLHIV from 2009 to 2020.

Methods: We analyzed temporal trends of HIV-DR and HIV-subtype between January 2009 - December 2020 using data from Ministry of Health of Brazil.

All CLHIV aged≤18 months with available genotyping tests were included. We used the Stanford HIVdb Program to assess HIV-DR and Rega HIV-Subtyping. HIV stage was categorized according to age-specific CD4⁺ counts.

Results: We included 1,191 CLHIV. Median age was 5 months (IQR 3-9). Most were girls (57.5%) and black/mixed race/skin-color (52.1%). Among those with available CD4⁺counts (n=747), 19.3% were in stage-1, 69.9% in stage-2, 10.8% in stage-3; Social Vulnerability Index was low for 54.1%, medium for 33.1%, and high for 12.8%[2].

Overall, 70% of the genotyping tests were fully susceptible; 19.4% had resistance to non-nucleoside reverse transcriptase inhibitors (NNRTI), 24.6% were resistant to at least one ARV from the pediatric regimen (nevirapine, abacavir, zidovudine, lamivudine, lopinavir). HIV-DR was higher in the 2015-2017 period, with NNRTI resistance increasing particularly after 2017. Subtype-B was the most prevalent. Resistance to integrase inhibitors was tested in 22 CLHIV, only one out of 7 tested in 2020 had mutations (Figure 1).

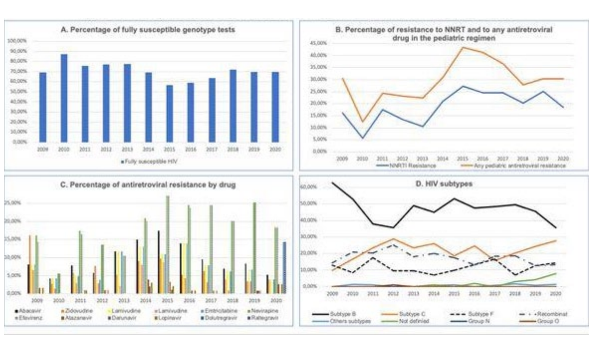

Figure 1. HIV drug resistance in children ≤18 months old living with HIV in Brazil, 2009-2020

Conclusions: The high prevalence of HIV-DR in this age group, especially to NNRTI, is concerning. Restrictions of integrase inhibitors to pregnant and women planning to conceive, along with the use of NNRTI for pediatric post-exposure prophylaxis may have contributed to those findings. Surveillance of HIV-DR in CLHIV is essential to guide treatment recommendations and to identify the impact of health policies.

EPB239

Resistance analysis of long-acting lenacapavir in treatment-naïve people with HIV at 54 weeks

L. VanderVeen[1], N. Margot[1], V. Naik[1], H. Dvory-Sobol[1], M. Rhee[1], C. Callebaut[1]
[1]*Gilead Sciences, Foster City, United States*

Background: Lenacapavir (LEN) is a first-in-class HIV-1 capsid (CA) inhibitor in clinical development for treatment and prevention of HIV-1 infection. CALIBRATE is an ongoing, open-label, phase 2 study evaluating subcutaneous (SC) and oral LEN, in combination with other antiretroviral agents, in treatment-naïve people with HIV-1. High rates of virologic suppression (87%) were achieved with

LEN-based regimens by FDA Snapshot analysis at Week 54 (WK54). Here we present interim resistance analyses through WK54.

Methods: Participants were randomized (2:2:2:1) to 1 of 4 treatment groups (TG). TG1 and TG2 both received SC LEN + oral daily (QD) emtricitabine/tenofovir alafenamide (F/TAF) for 28 weeks, after which virologically-suppressed participants continued a 2-drug regimen: SC LEN with oral QD TAF (TG1, n=52) or bictegravir (B, BIC) (TG2, n=53). TG3 (n=52) received oral QD LEN + F/TAF and TG4 (n=25) received oral QD B/F/TAF throughout.

Genotypic and phenotypic analyses of HIV-1 CA, protease, reverse transcriptase, and integrase were performed at confirmed virologic failure (HIV-1 RNA ≥50 copies/mL and <1 $\log_{10}$ reduction at WK10, or confirmed virologic rebound ≥50 copies/mL or >1 $\log_{10}$ increase from nadir at any visit).

Results: Through WK54, 6 of 182 participants met the criteria for resistance analysis, including 4 participants with no emerging resistance who resuppressed to HIV-1 RNA <50 copies/mL while continuing treatment.

One TG1 participant receiving SC LEN + F/TAF developed emergent resistance to LEN (Q67H+K70R in CA; LEN phenotypic fold change [FC]=20) and emtricitabine (M184M/I; FC >58) by WK10. One TG3 participant receiving oral LEN + F/TAF developed resistance to LEN (Q67H; FC=7) at WK54, with no emergent resistance to F/TAF components.

Conclusions: Emergent resistance to LEN was infrequent in treatment-naïve participants receiving SC or oral LEN (1.3%, 2/157) through one year of treatment, including when part of a multi-tablet regimen, consistent with the high rate of treatment success observed in the study. Resistance emergence was similar after 28 weeks (0.6%, previously reported) and 54 weeks of treatment.

These findings support the ongoing evaluation of LEN in combination and/or coformulation with other antiretrovirals for treatment and prevention of HIV.

EPB240

Resistance analysis of long-acting Lenacapavir in highly treatment-experienced people with HIV after 52 weeks of treatment

N. Margot[1], L. VanderVeen[1], V. Naik[1], H. Dvory-Sobol[2], M. Rhee[2], C. Callebaut[1]

[1]Gilead Sciences, Clinical Virology, Foster City, United States, [2]Gilead Sciences, Clinical Research, Foster City, United States

Background: Lenacapavir (LEN) is a first-in-class HIV-1 capsid (CA) inhibitor in clinical development for the treatment and prevention of HIV-1 infection. CAPELLA is a phase 2/3 study evaluating subcutaneous LEN in combination with other antiretrovirals in people with HIV (PWH) currently on a failing regimen with multidrug resistance. Resistance to ≥2 agents in ≥3 of the 4 main antiretroviral classes was required for enrollment. LEN in combination with an optimized background regimen (OBR) led to 83% virologic suppression at Week 52. Interim resistance analyses through Week 52 are described.

Methods: Genotypic and phenotypic analyses of HIV-1 CA, RT, protease and integrase (Monogram) were performed at virologic failure (VF: confirmed virologic rebound ≥50 copies/mL or <1 $\log_{10}$ decline from baseline at Week 4).

Results: This interim Week 52 analysis includes all 72 participants enrolled in the study, 45 of whom had data through Week 52. 21 of 72 participants met the VF criteria for resistance analysis, including 8 participants who re-suppressed HIV-1 RNA (<50 copies/mL) and were excluded from the resistance analysis population (RAP).

Of the 12 of 13 participants with data in the RAP, 8 (8/72, 11%) developed LEN-associated resistance mutations in CA: 6 participants developed the LEN-associated CA mutation M66I alone or with other substitutions (median LEN fold-change: 234), 1 participant developed the novel K70H mutation (LEN fold-change: 265), and 1 participant had emergence of Q67H + K70R mutations (LEN fold-change: 15).

All 8 participants with CA-resistance emergence either had poor and inconsistent adherence to the OBR (n = 4; drug levels measured in plasma) or did not have any fully active agents in the OBR (n = 4) at the time of resistance emergence (i.e. functional monotherapy with LEN). No emergent resistance to agents from the OBR was observed in the RAP.

Conclusions: Emergence of LEN-associated capsid mutations occurred in the setting of functional LEN monotherapy, reinforcing the general principle that treating people with limited options should include more than 1 fully active agent whenever possible and that adherence to OBR is key to controlling HIV-1. These data indicate that LEN is a promising option for HTE PWH.

EPB241

Minimal acquired resistance to dolutegravir and bictegravir in patients failing third-line ART in South Africa

K. Steegen[1,2], R. Lancaster[3], L. Hans[1,2]

[1]University of the Witwatersrand, Molecular Medicine and Haematology, Johannesburg, South Africa, [2]National Health Laboratory Service, Molecular Medicine and Haematology, Johannesburg, South Africa, [3]National Department of Health, Affordable Medicines Directorate, Pretoria, South Africa

Background: Raltegravir has been available as third-line antiretroviral treatment (TLART) in the South African public sector since 2013, with a gradual introduction of dolutegravir since 2014 and active requests to switch raltegravir to dolutegravir from 2018. In 2019, dolutegravir was introduced in first-line treatment. We assessed resistance profiles in patients failing integrase strand transfer inhibitors (INSTI)-based treatment.

Methods: Sequence data were obtained from patients with an INSTI resistance test request between January 2019 and June 2021 at the Charlotte Maxeke Johannesburg Academic Hospital laboratory. Sanger sequences were generated and submitted to Stanford HIVdb v9.0 for drug susceptibility predictions, with resistance defined as a score ≥15.

Results: Sequences were available for 43 unique patients failing TLART of which 68% were female (median age 41 years; IQR 28-48). The median viral load was 4.2 log copies/mL (IQR: 3.5-5.0). Eighteen patients were exposed to dolutegravir and 16 to raltegravir; three patients had prior exposure to INSTIs but not at the time of testing; and six patients had unknown treatment regimens.

INSTI-exposure duration was available for 25 patients (median 31 months; IQR: 21-49). Any INSTI resistance was less frequently detected in patients failing dolutegravir (3/18) versus raltegravir-based treatment (11/16, p=0.0045). In the raltegravir-exposed group, resistance to raltegravir and cabotegravir was commonly detected (n=11), whereas only six had cross-resistance to dolutegravir and bictegravir.

One patient in the dolutegravir group had high-level resistance to dolutegravir. No resistance was detected in three patients without current INSTI exposure, and one patient with unknown treatment history had INSTI resistance.

Conclusions: Given the low genetic barrier to raltegravir, a high prevalence of resistance is not unexpected in this group. However, cross-resistance to dolutegravir and bictegravir remained limited, confirming the need to replace raltegravir with dolutegravir.

Although only one dolutegravir-exposed patient presented with resistance to dolutegravir and bictegravir, three patients presented with resistance to raltegravir and cabotegravir. Despite the roll-out of dolutegravir as first-line treatment, no data from this group was available due to restricted resistance testing guidelines.

It is uncertain if similar resistance patterns will be observed in first-line dolutegravir failures, making resistance surveillance in this group essential.

EPB242

HIV genotypic drug resistance testing outcomes using Dry Blood Spot samples from patients failing second-line antiretroviral therapy and attending routine care in 3 rural districts of Zimbabwe

C. Kunzekwenyika[1], L. Ruckstul[2], C. Mupanguri[3], K. Madzeke[1], T. Shamu[4,5,6], M. Hobbins[2]

[1]SolidarMed, Masvingo, Zimbabwe, [2]SolidarMed, Lucerne, Switzerland, [3]Zimbabwe Ministry of Health and Child Care, Harare, Zimbabwe, [4]Graduate School of Health Sciences University of Bern, Bern, Switzerland, [5]ISPM University of Bern, Bern, Zimbabwe, [6]Newlands Clinic, Bern, Switzerland

Background: SolidarMed (SM), is an organization specializing in health system strengthening and assists the Ministry of Health of Zimbabwe in three rural districts. Within its larger program, SM supported HIV drug resistance testing (HIVDR) using DBS for patients requiring a switch to third-line antiretroviral (ART) regimen in routine practice, who would otherwise be unable to access such services due to logistical implications of fresh sample transport.

Methods: A cross-sectional descriptive study was done. DBS samples for HIVDR testing were collected from patients with virologic failure confirmed after 2 consecutive viral loads >1000 copies/ml and three enhanced adherence counseling sessions according to national guidelines. Viral loads were measured on plasma at Masvingo provincial hospital using Roche/Hologic panther platforms. DBS samples were collected by trained nurses at rural clinics, sent to SM offices within two weeks, and immediately shipped to a South African laboratory via courier services at ambient temperatures. Genetic resistance test (GRT) profiles were determined on proviral DNA from DBS samples using Sanger sequencing and results were communicated via secure email and relayed to clinics for further management. Proportions, medians, and interquartile ranges were used to describe the findings.

Results: 136 valid DBS samples went for testing and GRT was successful on 55% (75/136), from patients of a median age of 36 years (15-42) with 55% being women (n=39). Of these, 33(44%) were on a protease inhibitor (PI)-based second-line treatment regimen. PI drug Resistance associated mutations (RAMs) were found in 17 (52%) including atazanavir/ritonavir (52%), lopinavir/ritonavir (52%), and darunavir (24%) requiring regimen change. The median turnaround time, from blood collection to return of results, was 3.5 months (2.5 – 4).

Conclusions: HIVDR testing using DBS – despite a low sample success rate – was practical in this rural setting. Overall, a high proportion(52%) of the samples confirmed resistance to 2nd line treatment, underlining the validity of the national guidelines to identify treatment failure, and the importance of the availability of resistance testing in this setting to initiate 3rd line treatment.

The study also identified important challenges including sample transportation resulting in long turnaround time and delay in treatment switch showing the need for in-country HIVDR testing.

EPB243

Frequency of virologic factors possibly associated with CAB/RPV LAI failure

K. Scheibe[1], A. Urbańska[1], M. Parczewski[1]
[1]*Pomeranian Medical University, Department of Infectious, Tropical Diseases and Immune Deficiency, Szczecin, Poland*

Background: The long-acting injectable (LAI) cabotegravir (CAB) and rilpivirine (RPV) offers important advantages over oral ART. However, recent data shows that subtype A1/A6 and RPV/CAB resistance-associated mutations (RAMs) are related to CAB/RPV LAI failure. We aimed to describe the prevalence of these factors among naïve and treatment-experienced patients.

Methods: The study included 4,273 Caucasian patients (3,633 naïve, 640 non-naïve), treated in Polish centers in 1996-2021, from whom HIV-1 protease (PR) and reverse transcriptase (RT) sequences were obtained. Additionally, for 1,207 of this dataset (935 naïve, 272 non-naïve) integrase (INT) sequences were also analysed. The HIV-1 subtype was determined by phylogenetic analysis of PR/RT sequences.

Results: For PR/RT sequences at least one CAB/RPV LAI failure-related factor was observed in 16.27% naïve and 19.53% non-naïve patients, while combination of at least two factors (RPV RAM(s) or A1/A6 subtype) was observed in <1% sequences (Table 1).

Parameter	Naïve	Non-naïve
None of the two factors	3042/3633 (83.73%)	515/640 (80.47%)
Any factor:	591/3633(16.27%)	125/640 (19.53%)
RPV RAM(s) non A1/A6	197/3633 (5.42%)	84/640 (13.12%)
A1/A6 non RPV RAM(s)	375/3633 (10.32%)	38/640 (5.94%)
RPV RAM(s) A1/A6	19/3633 (0.53%)	3/640 (0.47%)

Table 1.

Parameter	Naïve	Non-naïve
None of the three factors	734/935 (78.50%)	183/272 (67.28%)
Any one of the three following factors:	201/935 (21.50%)	89/272 (32.72%)
RPV RAM(s) non A1/A6 non CAB RAM(s)	48/935 (5.13%)	30/272 (11.03%)
A1/A6 non RPV RAM(s) non CAB RAM(s)	135/935 (14.44%)	19/272 (6.99%)
CAB RAM(s) non A1/A6 non RPV RAM(s)	7/935 (0.75%)	28/272 (10.29%)
Any two of the three following factors:	11/935 (1.18%)	11/272 (4.04%)
RPV RAM(s) A1/A6	9/935 (0.96%)	0/272 (0%)
CAB RAM(s) A1/A6	1/935 (0.11%)	1/272 (0.37%)
RPV RAM(s) CAB RAM(s)	1/935 (0.11%)	10/272 (3.67%)
All three factors	0/935 (0%)	1/272 (0.37%)

Table 2.

For cases with INT/PR/RT data available 21.50% naïve and 32.72% non-naïve sequences had at least one factor associated with CAB/RPV failure with the combination of factors noted in 1.18% and 4.04% treatment naïve and experienced patients, respectively (Table 2).

The most common mutation associated with RPV resistance was E138A/G/K/Q (5.42% vs 6.41%, respectively). The most common mutation associated with CAB resistance among naïve sequences was R263K (0.64%), and N155H (7.35%) in non-naïve.

Conclusions: Despite common presence of factors associated with CAB/RPV failure they rarely occurred in combination. Defining subtype and screening for INSTI and NNRTI mutations should be performed prior to LAI treatment implementation.

EPB244

Drug resistance in children with HIV in the Democratic Republic of Congo, Equatorial Guinea and Panama

J. Ventosa Cubillo[1], A. Rodríguez Galet[1], M. Rubio Garrido[1], A. Valadés Alcaraz[1], G. Reina[2], A. Ndarabu[3], R. Pinzón[4], D. Estripeaut[4], M.L. Navarro[5], V. Bendomo[6], J. Nzang[7], P. Ncogo[8], A. Benito[9], Á. Holguín[1]
[1]*Ramón y Cajal Health Institute (IRYCIS), Microbiology and Parasitology, Madrid, Spain,* [2]*Navarra Institute for Health Research, Microbiology, Pamplona, Spain,* [3]*Monkole Hospital, Kinshasa, Congo, Democratic Republic of the,* [4]*Hospital del Niño Doctor José Renán Esquivel, PLANTAIDS-CYTED, Panama City, Panama,* [5]*Hospital Gregorio Marañón, CoRISpe-PLANTAIDS-CYTED -CIBERINF, Madrid, Spain,* [6]*Hospital Regional de Bata, Unidad de Referencia de Enfermedades Infecciosas (UREI), Bata, Equatorial Guinea,* [7]*Centro de Referencia para el Control de Endemias (CRCE), Malabo, Equatorial Guinea,* [8]*Fundación Estatal, Salud, Infancia y Bienestar Social (FCSAI), Madrid, Spain,* [9]*Institute of Health Carlos III, National Centre of Tropical Medicine, Madrid, Spain*

Background: An inadequate HIV viraemia and resistance monitoring in resource-limited countries leads to uncontrolled circulation of HIV strains with drug resistance mutations (DRM), compromising antiretroviral therapy (ART) success. We described the DRM prevalence and its therapeutic impact in HIV-infected paediatric patients from the Democratic Republic of Congo (DRC), Equatorial Guinea (EQ) and Panama (PA).

Methods: Dried blood (DBS) or plasma samples were collected from 198 children/adolescents under ART, in Kinshasa, DRC (n=71, 2016-2018), Bata, EQ (n=56, 2019-2020), and PA (n=71, 2018-2019), with clinical suspicion of therapeutic failure. HIV-1 infection was confirmed in Madrid by confirmatory serological/molecular tests. After viral load (VL) quantification, pol coding region (PR, RT, IN) was sequenced, analyzing HIV-1 DRM and predicting ARV-susceptibility (Stanfordv9.0).

Results: Despite ART use, 86%/88%/100% (DRC/EQ/PA) children showed virological failure (VL>1000c/ml in DRC/EQ, >50c/ml in PA) at sampling. HIV pol sequences were recovered in at least one region in 160 (81%) children (55 DRC/43 EQ/62 PA), with 14-10-12 years median age. All children with pol sequence and available data had received nucleos(t)ide analogs (NRTI), 100%/100%/45% non-NRTI (NNRTI), 9%/16%/95% protease inhibitors (PI) and only 14 patients (1 DRC/2 EQ/11 PA) integrase inhibitors (INI).

We identified more children harboring viruses with major-DRM to at least one drug family in DRC (67%) than in EQ (63%) or PA (55%), carrying major-DRM to one (13%/16%/40%), two (47%/42%/10%), or three (6%/5%/5%) ARV families. Most of the patients were susceptible to INI and PI. M184V (45%/50%/54%) and K103N (43%/35%/32%) predominated as DRM in RT.

Considering ARV families, most had DRM to NNRTI (74%/68%/39%) or NRTI (61%/55%/59%), major-DRM to PI (8%/3%/5%), minor-DRM to INI (15%/3%/8%), and major-DRM to INI (0%/0%/6%). NRTI+NNRTI resistance happened in 45%/52%/12%. Among the HIV-infected children under ART failure, 33%/37%/45% did not have DRM, suggesting lack of adherence to ART.

Conclusions: We provide the first comparison on acquired resistance in HIV-infected treated children in DRC, EQ and PA. The lack of viraemia control after ART and the high rate of DRM could compromise the HIV control in the three countries. Periodic VL and resistance monitoring is urgent to reduce the spread of resistant variants.

EPB245

High drug resistance levels compromise the control of HIV infection in paediatric and adult populations in Bata, Equatorial Guinea

A. Rodriguez Galet[1], V. Bendomo[2], M. Eyene[2], T. Mikue-Owono[3], J. Nzang[4], P. Ncogo[5], B. García[6], A. Benito[7], Á. Holguín[1]

[1]Ramón y Cajal Health Research Institute (IRYCIS), Microbiology, Madrid, Spain, [2]General Hospital of Bata, Infectious Diseases Reference Unit (UREI), Bata, Equatorial Guinea, [3]General Hospital of Bata, Clinical Analysis Laboratory, Bata, Equatorial Guinea, [4]State Foundation, Health, Childhood and Social Welfare (FCSAI), Bata, Equatorial Guinea, [5]State Foundation, Health, Childhood and Social Welfare (FCSAI), Malabo, Equatorial Guinea, [6]State Foundation, Health, Childhood and Social Welfare (FCSAI), Madrid, Spain, [7]National Center of Tropical Medicine, Madrid, Spain

Background: The lack of HIV viral load (VL) and resistance monitoring in sub-Saharan Africa leads to uncontrolled circulation of HIV-strains with drug resistance mutations (DRM) and compromises antiretroviral therapy (ART). This study describes, for the first time, the DRM-prevalence and its therapeutic impact in HIV-infected children and adults in Equatorial Guinea (EQ).

Methods: From 2019-2021, dried blood was collected in EQ from 178 adults (114 treated/64 naive) and 56 treated children with clinical suspicion of therapeutic failure. The HIV-1 infection was confirmed in Madrid by serological/molecular confirmatory tests.

After VL quantification, HIV-1 *pol* region was sequenced, identifying transmitted (TDR, naïve, WHO-TDR-list2009) or acquired (treated) DRM resistance and the predicted ARV-susceptibility (Stanfordv9.0).

Results: Despite ART use, 87.5%/61% of 170 treated-children/adults showed virological failure (VL>1000c/ml) at sampling. *Pol* sequences were recovered from 134 (75%) of 178 patients: 91 adults (33 treated/58 naïve) and 43 treated-children. ART information was available in 64 of 76 treated subjects, all with nucleoside (NRTI) and non-NRTI (NNRTI) retrotranscriptase inhibitors experience, 20% to protease inhibitors (IP) and 11% to integrase inhibitors (INI). They had received one (28%/39%), two (38%/28%), three (19%/21%) or four (14%/9%) different ART-regimens.

Among the 76 treated adults/children with available PR, RT or IN sequence, 64%/63% carried viruses with major-DRM, affecting one (39% /16%) or two (18%42%) ARV-families. Triple resistance appeared only in children (3%). Most harboured DRM to NNRTI (66%/68%) and NRTI (41%55%), mainly affecting nevirapine, efavirenz, emtricitabine and lamivudine. Minor-DRM to INI appeared in adults/children (19%/3%). Major-DRM to PI only in children (3%). NRTI+NNRTI resistance in 33%/52%.

Most participants were susceptible to INI and PI. 15% of treated patients with VL>1000c/ml did not carry DRM, suggesting adherence failure. TDR prevalence in 58 naïve-adults was 6.8%.

Conclusions: We provide the first pediatric resistance data in EQ, updating DRM in adults. The observed high rate of ART-failure and DRM could compromise the 95-95-95-UNAIDS targets in EQ.

Routine VL and resistance monitoring implementation is urgently required for early detection of ART-failures and optimal rescue therapy election in those carrying resistant viruses in EQ. ART regimens based on PI and INI instead of RTI can improve HIV control in that country.

High-level of cross-resistance to 2nd generation non-nucleoside reverse transcriptase inhibitors among patients failing antiretroviral therapy in Cameroon: implications for future ART-regimens in Africa

D.H. Gouissi Anguechia[1,2], J. Fokam[2,3], D. Takou[2], E. Ngoufack Jagni Semengue[4], G. Beloumou[5], S. Djupsa[5], B. Dambaya[2], V. Colizzi[4], C.-F. Perno[6], A. Ndjolo[2,1]

[1]Faculty of Medicine and Biomedical Sciences, University of Yaounde I, Yaounde I, Cameroon, [2]Chantal Biya International Reference Centre for Research on HIV/AIDS Prevention and Management (CIRCB), Yaounde, Cameroon, [3]University of Buea, Faculty of Health Sciences, Buea, Cameroon, [4]University of Rome ,Tor Vergata', Department of Experimental Medicine, Rome, Italy, [5]Chantal Biya International Reference Centre for Research on HIV/AIDS Prevention and Management (CIRCB), Yaoundé, Cameroon, [6]Bambino Gesu Hospital, Rome, Italy

Background: Etravirine (ETR), rilpivirine (RPV) and doravirine (DOR) are second generation (2Gen) non-nucleoside reverse transcriptase inhibitors (NNRTI) approved for the treatment of HIV-1 infection. In Africa, there are limited data on the resistance profile of 2Gen-NNRTI.

This study aimed to evaluate 2Gen-NNRTI resistance and their susceptibility in patients failing antiretroviral treatment (ART) in Cameroon.

Methods: A cross-sectional study was conducted from 2019-2020 among 340 patients failing ART, received at the Chantal Biya International Reference Centre, Yaoundé-Cameroon. Treatment history and immuno-virological data were obtained from patients' files.

Genotypic resistance testing was interpreted using Stanford HIVdb v8.7. The following variants were considered as resistance mutations to 2Gen-NNRTI: Y181CIV, Y188LC, V106AMI, M230L, K101EP, L234I, G190ASEQ, L100I.

The penalty scores of drug resistance were ≥60 (high-resistance); 30–59 (intermediate-resistance); <30 (susceptible). Acceptable threshold for potential drug-efficacy was set at >50% at population-level.

Results: A total of 340 patients were enrolled, of which 230 were failing first-line (1Gen-NNRTI based) and 110 second-line (protease-inhibitors) regimens. Median [IQR] CD4 and viremia were respectively 184 [60–332] cells/µl and 82,374 [21,817–289,907] copies/ml; ART-duration was 18 [10–27] months.

Overall rate of resistance to 2Gen-NNRTI was 79.70% [71.30–87.02], similar between first- vs second-lines. Prevailing mutations were: Y181C (23.52%), G190A (17.64%) and P225H (13.53%). Drug susceptibility rate was 52.05% (ETR); 43.23% (RPV), 36.17% (DOR).

Following susceptibility profile, patients failing on EFV-based regimens were more susceptible to 2Gen-NNRTI (OR=0.42; 95%CI:[0.24–0.74]; p=0.003), while those failing after receiving EFV and NVP were less susceptible to 2Gen-NNRTI (OR=4.4; 95%CI:[1.16–14.81]; p=0.02). Low viremia (≤4$\log_{10}$)was associated with susceptibility to 2Gen-NNRTI (OR=0.22; 95%CI:[0.12–0.41]; p<0.0001). CRF02_AG was the prevailing subtype (58.53%), followed by A1 (11.47%), G (7.35%); without any significant effect on 2Gen-NNRTI susceptibility (CRF02_AG vs non-AG; p=0.8).

Conclusions: After ART-failure in Cameroon, there is a high-level of cross-resistance to 2Gen-NNRTI. However, etravirine retains residual efficacy in half of the population. Thus, after ART-failure in African patients, the use of etravirine as 2Gen-NNRTI is possible, pending genotypic profiling.

EPB247

Evaluation of HIV drug resistance in virally suppressed patients in Cameroon

R.A. Nayang Mundo[1], J. Fokam[1,2], C. Chenwi[1,2], D. Takou[1], M.-S. Sosso[1], W.L. Pabo Togna[3], A. Ka'e[4], G.O. Beloumou[1], S.C. Djupsa[1], A. Abba[1], C.-F. Perno[1,5]

[1]Centre International de Référence CHANTAL BIYA pour la Recherche sur la Prévention et la Prise en Charge du VIH/SIDA, Virology, Yaoundé, Cameroon, [2]Faculté de Médecine et des Sciences Biomédicales du Cameroun, Microbiology, Yaoundé, Cameroon, [3]Faculty of Science, University of Buea, Buea, Cameroon, [4]University of Rome 'Tor Vergata', Rome, Italy, [5]University of Milan, Milan, Italy

Background: Viral suppression (Viral load < 1000copies/ml) is considered a therapeutic success in resource limited settings. However, several studies have shown the presence of resistance mutations at residual viral loads, which could compromise long-term therapeutic response.

We sought to assess the effectiveness of sequencing and determine the HIV drug resistance genotypic profile in virally suppressed patients (VSP) in Cameroon.

Methods: A cross-sectional and analytical study was conducted at the Chantal BIYA International Reference Centre from January 2020 to August 2021 among VSP. Sequencing was performed in the reverse-transcriptase and protease regions.

Sequences were analysed using the Stanford HIVDBv9.0 algorithm, and molecular phylogeny done using MEGAX. Sequencing success rate and occurrence of drug resistance mutations were assessed by viremia, with P<0.05 considered statistically significant.

Results: In total, 132 participants were retained; median age [IQR]: 43[33-51] years; 69% female. The median duration on antiretroviral therapy (ART) was 19 [12-34.4] months. The amplification rate was 39 (CI95%, 21.93-38.11) %, and the sequencing success rate 28.8% (38/132), thus 97.4% of amplicons.

Genotyping was more effective for patients with viremia ≥ 200 copies/ml, 47.2% (25/53) versus 16.5% (13/79) for viremia ≤ 200 copies/ml, p<0.001. Of the 38 sequences generated, the overall resistance rate was 89.74%, with 79.9% NRTI resistance, 79.4% NNRTI resistance and 15.3% PI/r resistance. This resistance rate was higher in patients with viremia ≥ 200 copies/ml, 32.0% versus viremia ≤ 200 copies/ml (7.7%),

OR 5.65; p=0.13. Seven viral clades were identified with predominance of CRF02_AG (64%). M184V (74.3%) and K103N (45.7%) were the most frequent mutations in reverse transcriptase and M46I 14.2% in protease.
The viral susceptibility profile revealed 41.1% (14/38) of participants on suboptimal therapies despite virological suppression.
Conclusions: In the Cameroonian context with broad HIV genetic diversity, sequencing appears to be effective in half of the virally suppressed patients with a viremia of at least 200 copies/ml.
Moreover, the emergence of major resistance mutations in these patients would be more considerable with a viral load ≥ 200 copies/ml. In these virally suppressed patients, nearly 4 out of 10 would need to optimise their therapy for long-term therapeutic success.

EPB248
High levels of non-nucleoside reverse transcriptase inhibitor (NNRTI) pre-treatment HIV drug resistance (PDR) in Zambia: results from the national survey

S. Sivile[1,2,3], L. Chirwa[1,2], M. Siwingwa[1,2], P. Funsani[3], S. Fwoloshi[1,2,3], J. Mutukwa[3], C. Sianyinda[3], M. Mwitumwa[1,2], A. Mweemba[4], N. Mbewe[1,2], K. Sikakena[1,2], O. Makayi[1,2], D. Chanda[1,2], D. Kampamba[1,3], A. Makupe[3], P. Zulu[1,2], T. Tembo[5], I. Sikazwe[5], C. Gondwe[1,2], K. Malama[3], R. Nsakanya[3], L. Chitembo[6], H. Phiri[3], R. Warrier[5], L. Mulenga[1,2,3,7,8]
[1]University Teaching Hospital, Adult Infectious Diseases Center, Lusaka, Zambia, [2]University of Zambia, School of Medicine, Internal Medicine, Division of Infectious Diseases, Lusaka, Zambia, [3]Ministry of Health, Directorate of Clinical Care and Diagnostics, Lusaka, Zambia,, Zambia, [4]Levy Mwanawasa University Teaching Hospital, Internal Medicine, Lusaka, Zambia, [5]Center For Infectious Diseases Research In Zambia, Lusaka, Zambia, [6]World Health Organisation, Lusaka, Zambia, [7]Vanderbilt University Medical Center (VUMC), Department of Medicine, Division of Infectious Diseases, Nashville, United States, [8]Vanderbilt Institute of Global Health (VIGH), Nashville, United States

Background: HIV drug resistance (HIVDR) negatively impacts the effectiveness of antiretroviral drugs leading to new HIV infections, increased HIV-related mortality, and antiretroviral therapy (ART) programme costs thereby reducing the gains obtained towards HIV epidemic control. The World Health Organization recommends that HIV treatment scale-up should include surveillance of HIVDR. We thus assessed the prevalence of HIVDR among HIV-positive Zambian adults initiating ART.
Methods: We conducted a country-wide cross-sectional survey among newly diagnosed pre-treatment HIV-1 positive individuals. Lack of prior ARV exposure data was not confirmed with ARV metabolites. Probability proportional to proxy size sampling method was used to select the clinics proportional to the total number of patients on ART in each clinic. Pretreatment drug resistance (PDR) testing was performed for adults newly diagnosed with HIV-1 using in-house sequencing assays in the *pol* gene and sequenced on an ABI 3130XL analyzer. HIVDR prediction was done using the Stanford University HIVdb tool. Weighted statistical analysis was performed using STATA 15.1 (StataCorp, College Station, TX, USA) following the WHO recommendations and the weighting considered the number of samples successfully sequenced.
Results: A total of 35 ART sites were selected and 208 ART initiators were enrolled in the survey. Majority (57.8%) of participants were female (95% CI: 47.8-67.2%) and 76.9% (95% CI: 69.2-83.2%) were >25 years old. HIV-1 subtype C was most frequently observed (98.8%, 95% CI: 94.4-99.8%). Adult PDR to non-nucleoside reverse transcriptase Inhibitors (NNRTIs) Efavirenz (EFV) or Nevirapine (NVP) was 16.2% (95% CI: 10.2-24.8) while adult PDR to nucleoside reverse transcriptase inhibitors (NRTIs) was 8.3% (95% CI: 3.8-16.9). No PDR to protease inhibitors (PIs) or integrase strand transfer inhibitors (INSTIs) were found. No significant difference was observed on the level of PDR to EFV or NVP between male and female (OR: 1.24, 95%CI: 0.34-4.48, p=0.737).
Conclusions: High rates of pretreatment HIVDR to EFV or NVP at 16.2% was observed in Zambia. This is above the 10% recommendation by WHO for the transitioning of ARVs from NNRTI. We recommend ARV transitioning away from NNRTI-based regimens coupled with periodic HIVDR surveillance for newer INSTIs.

EPB249
Combined effects of the K156N integrase polymorphism and 3'PPT resistance mutations against integrase inhibitors

R. Mahmud[1], R. Overmars[1], R. Gruters[1], J. van Kampen[1], D. van de Vijver[1], T. Mesplede[1]
[1]Erasmus University Medical Center, Viroscience, Rotterdam, Netherlands, the

Background: Most antiretroviral drug regimens recommended for treatment initiation are anchored with dolutegravir or bictegravir. These two integrase strand transfer inhibitors are safe and effective, and they have a high barrier against the development of drug resistance mutations in integrase. It is suspected that resistance against dolutegravir and bictegravir may occur outside the integrase coding sequence. We were first to show this to be the case in a patient treated with dolutegravir monotherapy.
Here we further explored this alternative resistance pathway and characterized K156N, a natural integrase polymorphism found *in vivo* in combination with 3'PPT resistance mutations.
Methods: We created recombinant pNL4.3 proviral clones with the K156N natural polymorphism and clinically relevant 3'PPT mutations alone and in combination.

We produced the corresponding viruses and characterized their infectivity, replicative capacity, and drug susceptibility. We used structural modeling to understand the effects of K156N.

Results: By itself, K156N was innocuous to HIV-1 infectivity and replicative capacity. It did not confer significant levels of resistance against integrase inhibitors. The 3'PPT mutations reduced viral infectivity and replication and conferred low levels of resistance against integrase inhibitors. Viruses that combine K156N with 3'PPT mutations had improved infectivity and replicative capacity but displayed only minor changes in resistance. K156N induced structural changes in integrase that altered its binding to HIV DNA. Specifically, DNA binding was shifted by one nucleotide, potentially allowing higher mobility of HIV DNA ends within the catalytic site.

Conclusions: K156N is a new natural polymorphism of interest that can be found in association with 3'PPT resistance mutations against integrase inhibitors. The structural changes imparted by K156N to integrase structure may facilitate the development of resistance. Further investigation is needed to evaluate the clinical significance of our work.

Profiling integrase mutations after raltegravir salvage therapy failure in Brazil

R. Diaz[1], I.B. Nassar[1], J. Hunter[1], E. Nunes[1], E. Cruz[1], M. Schechter[1]
[1]*Unifesp - University of São Paulo, Infectology, São Paulo, Brazil*

Background: Due to the widespread, long-term use of antiretrovirals in Brazil, many patients were exposed to sequential monotherapy and unboosted Protease Inhibitors (PIs). Until January 2017, the only Integrase Strand Transfer Inhibitor (INSTI) available in Brazil was Raltegravir, which was reserved for salvage therapy when resistance to PIs was detected.

Methods: We analyzed the mutational profile of genetic fragments of HIV-1 reverse transcriptase, protease, and integrase from 701 patients with virological failure to raltegravir and current or previous virological failure to nucleoside reverse transcriptase inhibitors (NRTIs), non-nucleoside reverse transcriptase inhibitors NNRTIs, and PIs from January 2017 to December 2018 in Brazil. Statistical analyzes were performed using the R program.

Results: All individuals were using boosted PIs and NRTIs. Some patients were also using etravirine, and/or maraviroc and/or enfuvirtide. From 701 patients, 182 (26%) resistance-associated mutations (RAMs) to INSTI, 145 (20.7%) to PIs, 339 (48.4%) to NRTIs, and 327 (46.7%) to NNRTIs. In general, 148HR pathway was found in 45 (24,72%), N155HS in 40 (21,97%), and Y143CHR in 33 (18,13%). As a proxy of early virologic failure, we analyzed the prevalence of mutations among individuals harboring only one INST RAM. We found the N155H/S pathway in 22 (12,08%) followed by Y143R/C in 7 (3,84%) (no 148 pathway detected). Among individuals with more than 1 INSTI RAM, we detected 148 pathway in 45 (24,72%), followed by 155 in 18 (9,89%), and 143 in 26 (14,28%). The longer the time of exposure to salvage therapy schemes containing raltegravir, the higher the prevalence of the 148 pathway. Viral load was lower among patients harboring wild-type INSTI strains than 1 and 2 INSTI RAMs ($p=0.023$ and $p=0.020$, respectively). There was a positive relationship between the number of previous use of cART and the number of INSTI RAM ($p = 0.0007$). There was a distinct RAM profile according to the HIV-1 clade (Table). Strains predicted as R5 present more 155 RAM ($p=0.003$), whereas non-CCR5 users present more 148 RAMs ($p=0.0002$).

Conclusions: Here, the prevalence of INSTI RAMs was low, revealing either a relatively higher genetic barrier to resistance or low adherence.

Virological failure and acquired drug resistance among ART-experienced people living with HIV in Nepal: a nationally representative surveillance study

K. Deuba[1], R.M. Rajbhandari[2], D. Changsom[3], S. Saeng-aroon[3], M.K. Shrestha[4], R.S.N. Kunwar[1], U. Shrestha[1], B.B. Rawal[4], G. Pant[5], S.K. Mishra[6], M. Sharma[6], T.N. Pokhrel[7], HIVDR study group
[1]*Save the Children Stationed at National Centre for AIDS & STD Control, Kathmandu, Nepal,* [2]*Intrepid Nepal (INPL), Kathmandu, Nepal,* [3]*Ministry of Public Health, Hazardous Pathogen Laboratory, National Institute of Health, Department of Medical Sciences, Nonthaburi, Thailand,* [4]*National Centre for AIDS & STD Control, Ministry of Health and Population, Kathmandu, Nepal,* [5]*Save the Children, Kathmandu, Nepal,* [6]*National Public Health Laboratory, Kathmandu, Nepal,* [7]*Ministry of Health and Population, Kathmandu, Nepal*

Background: The implementation of test and treat—antiretroviral treatment (ART) irrespective of CD4 count— has significantly improved the number of people living with HIV on ART also in Nepal, where ART coverage improved from 22% in 2013 to 72% in 2021.The coverage of viral load testing is low in Nepal. In limited resource health systems, such as the Nepalese, the emergence of drug-resistant HIV is a potential public health threat, undermining long-term effectiveness of first-line ART regimens.

This is the first nationally representative study to estimate population viral load suppression and acquired HIV drug resistance (ADR) among people living with HIV in Nepal.

Methods: In this cross-sectional study, 1418 patients (N=713 males, 701 females, 4 transgender) from 20 ART centres in Nepal were recruited using two-stage cluster design, probability proportional to proxy size sampling from May to August 2019. Eligible participants were HIV -positive individuals on ART for 9-15 months or at least 48

months. Plasma specimens were collected and tested for HIV-1 RNA level and presence of drug resistance mutations when viral load (VL) ≥1000 copies/ml. HIV-1 genotypes have been uploaded to GenBank (MZ538450-MZ538499).
The outcome variables were the prevalence of viral load suppression (VL<1000 copies/mL) and detectable HIV drug resistance in samples with VL≥1000 copies/mL). The Stanford HIV database algorithm was used to classify drug resistance and sequences classified as low-, intermediate- or high-level resistance were aggregated as any HIV drug resistance.
Results: The prevalence of viral load suppression among those on ART 9-15 months was 95.91% (95% CI: 92.29–97.88), and 97.48% (95% CI: 95.49–98.60) on ART at least 48 months group. The prevalence of acquired HIV drug resistance with viral load ≥1000 copies/ml was 75.33% (49.79–90.39) among those on ART for 9-15 months and 89.94% (63.09–97.90) among those on ART for at least 48 months group.
Conclusions: This study suggest that improved accessibility to viral load monitoring and timely assessment of drug resistance in routine HIV programme is very important in Nepal to ascertain HIV treatment access for all in need.

EPB252

Impact of Dolutegravir (DTG) on viral load suppression and HIV Drug Resistance (HIVDR) among Zambian children on ART: Results from the pediatric Acquired HIVDR (pADR) national survey

S. Miti[1], G. Munthali[2], L. Chitembo[3], M. Mubiana-Mbewe[4], M. Mwiya[5], K. Zyambo[5,2], M. Matthew[6], L. Chirwa[5], M. Siwingwa[5,7], P. Funsani[2], T. Tembo[4], S. Sivile[5,7,2], P. [1]Arthur Davison Children's Hospital, Ndola, Zambia, [2]Ministry of Health, Lusaka, Zambia, [3]World Health Organisation (WHO), Lusaka, Zambia, [4]Centre for Infectious Diseases Research in Zambia (CIDRZ), Lusaka, Zambia, [5]University Teaching Hospital, Adult Infectious Diseases Center, Lusaka, Zambia, [6]University Teaching Hospital, Children's Hospital, Lusaka, Zambia, [7]University of Zambia, Department of Medicine, Division of Infectious Diseases, Lusaka, Zambia, [8]University Teaching Hospital, Department of Pathology, Lusaka, Zambia, [9]Vanderbilt University Medical Center (VUMC), Division of Infectious Diseases, Nashville, United States, [10]Vanderbilt Institute for Global Health (VIGH), Nashville, United States

Background: Children living with HIV (CLHIV) continue to lag behind in access to more potent and better ARV regimens leading to sub-optimal viral load suppression (VLS) and consequent HIV drug resistance (HIVDR). There has, however, been limited monitoring of HIVDR in this population, especially in the sub-saharan region. We thus assessed VLS and HIVDR among HIV-1 positive Zambian CLHIV on ART for 12 and 36 months.
Methods: We conducted nationally representative HIV Acquired Drug Resistance (ADR) cross-sectional surveys among CLHIV (<15 years old) on ART for 12 ±3 months (ADR12) and 36 ±3 months (ADR36).Systematic sampling of clinics was performed to generate probability proportional to proxy size samples. We defined VLS as HIV-1 RNA <1,000 copies/mL. HIVDR was assessed for reverse transcriptase, protease and integrase Sanger sequences using theStanford University HIVdb algorithm.Proportions for each outcome at linearized standard error 95% confidence interval (CI) and summary estimates were determined. Results were weighted according to the study design.
Results: We enrolled 333 CLHIV in the ADR12. Majority (52%), were female and overall VLS was 69.4% (95% CI: 59.8–77.5%). Among children with VL ≥1000 copies/mL, HIVDR to non-nucleoside reverse transcriptase inhibitors (NNRTIs) was 71.0% (95% CI: 56.4–82.3%) and 66.7% (95% CI: 55.3–76.4%) to NRTIs. HIVDR to NNRTIs was 88.6% (95% CI: 67.2–96.7%) among children on NNRTIs and with VL ≥1000 copies/mL versus 3.2% (95% CI: 0.5–17.9%) for those on protease inhibitors (PIs).
We further enrolled 828 children in the ADR36 with 45.1% being female. Similarly, VLS was 68.3%, (95% CI:59.1–76.3%) but VLS was significantly higher among those on a dolutegravir (DTG)-based regimen (OR: 6.91, 95% CI: 2.48–19.29, p=0.001). Among those with VL ≥1000 copies/mL, prevalence of HIVDR to NNRTI was 81.4% (95% CI: 75.3–86.3%), 74.7% (95% CI: 67.7–80.7%) to NRTIs, 3.1% (95% CI: 1.5–6.1%) to PIs and no HIVDR to integrase strand transfer inhibitors (INSTIs).
Conclusions: To improve VLS and overall outcomes in CLHIV on ART, there is an urgent need to accelerate the transition to DTG-based ARV regimens. Programmatic gaps in the treatment cascade including routine HIVDR monitoring need to be strengthened.

[1]*Ministry of Health, Lusaka, Zambia,* [2]*University Teaching Hospital, Adult Infectious Diseases Center, Lusaka, Zambia,* [3]*University of Zambia, Department of Medicine, Division of Infectious Diseases, Lusaka, Zambia,* [4]*Vanderbilt University Medical Center (VUMC), Division of Infectious Diseases, Nashville, United States,* [5]*Vanderbilt Institute for Global Health (VIGH), Nashville, United States,* [6]*Levy Mwanawasa Medical University, Internal Medicine, Lusaka, Zambia,* [7]*Levy Mwanawasa Medical University, Infectious Diseases, Lusaka, Zambia,* [8]*Centre for Infectious Diseases Research in Zambia (CIDRZ), Lusaka, Zambia,* [9]*University Teaching Hospital, Department of Pathology, Lusaka, Zambia,* [10]*World Health Organisation (WHO), Lusaka, Zambia*

Background: HIV drug resistance (HIVDR) testing following treatment failure assists in selection of subsequent antiretroviral therapy (ART) but is not widely available in resource-constrained settings. The World Health Organization recommends periodic national HIVDR surveillance. We therefore assessed the prevalence of acquired HIVDR (ADR) among Zambian adults on ART.

Methods: We conducted a cross sectional surveys among HIV-1 infected adults at 12 ± 3 months (ADR12) and > 48 months (ADR48) of ART. Sampling of clinics was performed using systematic sampling to generate probability proportional to proxy size samples.

We defined viral load suppression (VLS) as HIV-1 RNA <1,000 copies/mL. ADR was assessed using in-house sequencing assays in the *pol*gene and sequenced on an ABI 3130XL analyzer while prediction was done usingthe Stanford HIVdb tool.Proportions for each outcome at linearized standard error 95% confidence interval (CI) and summary estimates were determined.

Results: We enrolled 1,226 participants (ADR12: 462 and ADR48: 764). VLS was high at 89.9% (84.5%-93.5%, CI 95%) inADR12and 92.2% (87.1%-95.4%, CI 95%) in ADR48.

Majority, (60.7%) [95% CI: 55.7–65.5%] in ADR12 and 58.8% (95% CI: 49.9–67.2%) in ADR48, were receiving non-nucleoside reverse transcriptase inhibitors (NNRTI)-based ART. 38.1% (95% CI: 33.4–43.0%) in ADR12 and 34.6% (95% CI: 27.4–42.5%) in ADR48 were receiving Dolutegravir (DTG)-based ART.

Theprevalence of ADR to NNRTIs was81.1% (95% CI: 65.0–90.8%) in ADR12 and 74.5% (95% CI: 60.7–84.6%) in ADR48. ADR to nucleoside reverse transcriptase inhibitor (NRTI) was prevalent in 70.3% (95% CI: 53.8–82.8%) in ADR12 and70.2% (95% CI: 55.3–81.87%) in ADR48. Resistance to protease inhibitors (PIs) was low (ADR48: 2.1%, 95% CI: 0.3–15.3%) and no resistance to both PIs and Integrase Strand Transfer Inhibitors (INSTIs) in ADR12 was observed.

Among adults on NNRTI + tenofovir-based regimens, ADR to Tenofovir was 53.8% (95% CI: 33.7–72.8%) in ADR12 and 50.0% (95% CI: 31.9–68.1%) in ADR48.

Conclusions: High ADR to NNRTI and NRTI at early and late time points of ART was observed in Zambia.We recommend prompt switching to effective ART in those without VLS and continuous HIVDR surveillance for newer INSTI ARVs.

Impact of COVID-19 on HIV care

EPB254

Secondary impacts of the COVID-19 pandemic on Young People Living with HIV in Kenya

M. Singh[1], W. Nyandiko[2,3], A. DeLong[4], C. Ashimosi[3], D. Munyoro[2], J. Lidweye[2], J. Nyagaya[2], W. Beigon[5], J. Aluoch[2], A. Chory[5,6], E. Sang[2], E. Gillette[5], E. Jepkemboi[2], M. Orido[2], V. Novitsky[1], J. Hogan[4], R. Vreeman[5,6], R. Kantor[1]

[1]*Warren Alpert Medical School of Brown University, Providence, United States,* [2]*Moi Teaching and Referral Hospital, Eldoret, Kenya,* [3]*Academic Model Providing Access to Healthcare (AMPATH), Eldoret, Kenya,* [4]*Brown University, Center for Statistical Sciences, Providence, United States,* [5]*Icahn School of Medicine at Mount Sinai, New York City, United States,* [6]*Arnhold Institute for Global Health, New York City, United States*

Background: The impact of COVID-19 associated restrictions to contain SARS-CoV-2 on young people living with HIV (YPLWH), who are already at risk of disengagement from care and poor clinical outcomes, is unknown, particularly in resource-limited settings. We hypothesized that the COVID-19 pandemic impacted the psychological, physical, and socioeconomic wellness of YPLWH, leading to reduced antiretroviral therapy (ART) adherence and poor clinical outcomes.

Methods: Perinatally-infected YPLWH receiving care at four HIV clinics at the Academic Model Providing Access to Healthcare (AMPATH) in and around Eldoret, Kenya were enrolled between February-December/2021. In-person or phone surveys were conducted to generate three wellness measures: psychological (depression and anxiety; score 0-12), physical (illnesses and hospitalizations; score 0-5), and socioeconomic (education, employment, food, and housing; score 0-6); and ART adherence (self-reported; score 0-6). HIV viral load (VL) was determined (VL>1,000 copies/mL defined as ART failure).

The hypotheses were examined by:

1. Describing temporal patterns of wellness composite scores based on enrollment date using general additive models,

2. Investigating overall associations between wellness and adherence scores using linear regression, and;
3. Evaluating associations between adherence and treatment failure using logistic regression.
Models were adjusted for age, gender and clinic.

Results: Among 430 participants (mean age 16.5 years, range 8-24; 49% female), psychological wellness remained stable throughout the study period with 48% affected (i.e. reporting unwell); physical wellness was lowest between February-March/2021, highest between April-July/2021, and lower thereafter (66% affected); socioeconomic wellness was highest between February-May/2021, lower between June-July/2021, higher between August-September/2021, and lowest thereafter (62% affected); and self-reported adherence remained stable (75% affected). In regression analysis, higher psychological (coeff = 0.21, 95% CI: 0.12-0.30, p<0.001), physical (coeff = 0.29, 95% CI: 0.15-0.43, p<0.001), and socioeconomic (coeff = 0.17, 95% CI: 0.06-0.29, p=0.004) wellness were associated with good adherence. HIV treatment failure was associated with poor adherence Odds Ratio 1.32 per one-unit worse adherence, 95% CI: 1.00-1.73, p=0.045).

Conclusions: Societal changes imposed by the COVID-19 pandemic may have impacted psychological, physical, and socioeconomic wellness among Kenyan YPLWH, potentially resulting in lower ART adherence and higher ART failure. Findings highlight intervention opportunities to support this vulnerable population in the current and future pandemics.

EPB255

Seroprevalence of SARS-CoV-2 infection and evolution of humoral response in PLWHIV

B. Abdi[1], A. Laetitia Ndoadoumgue[2], S. Djebara[3], K. Zafilza[1], R. Palich[3], S. Marot[1], M. Wirden[1], Y. Dudoit[3], E. Teyssou[1], R. Tubiana[3], C. Soulie[1], M.-A. Valantin[3], C. Katlama[3], V. Calvez[1], L. Assoumou[2], A.-G. Marcelin[1], V. Pourcher[3]

[1]Sorbonne Université, INSERM, Institut Pierre Louis d'Epidémiologie et de Santé Publique (IPLESP UMRS 1136), AP-HP, Hôpital Pitié Salpêtrière, Laboratoire de Virologie, Paris, Paris, France, [2]Sorbonne Université, INSERM, Institut Pierre Louis d'Epidémiologie et de Santé Publique (IPLESP UMRS 1136), Paris, France, [3]Sorbonne Université, INSERM, Institut Pierre Louis d'Epidémiologie et de Santé Publique (IPLESP UMRS 1136), AP-HP, Hôpital Pitié Salpêtrière, Service des Maladies Infectieuses et Tropicales, Paris, France

Background: Data on SARS-CoV-2 seroprevalence in PLWHIV are still poor. We sought to shed further light on this issue, studying the humoral immune response evolution and identifying the associated risk factors during the initial disease outbreak in patients living in the Ile-de-France area (IDF).

Methods: For this longitudinal prospective cohort study, we included all PLWHIV followed in the department of infectious diseases of the Pitié-Salpétrière hospital between April and September 2020. Patients with positive anti-SARS-CoV-2 antibodies at D0 have been evaluated at 6 and 12 months (M). Semi-qualitative detection of IgG against nucleoprotein (N) and quantitative detection of IgG against spike (S) protein were measured using a chemiluminescent microparticle immunoassay. Serum IgA against the S1 domain of the S protein were measured using enzyme-linked immunosorbent assay (anti-SARS-CoV-2 ELISA, EuroImmun). Factors associated with positive serum IgG anti-N were identified using a logistic regression model. Analyses were performed using SAS software.

Results: A total of 1901 PLWHIV were included: 64.4% of patients were male, median age: 53 years (IQR 44-60), ART duration: 13.9 years (IQR 7.5-22.2), CD4:588 cells/mm^3 (IQR 429 - 772) and 26.6% were active smokers. At inclusion, 254 (13.4%) had positive IgG anti-N and among them, 88.2% and 64.1% had serum IgG anti-S and IgA anti-S respectively. Longitudinal analysis of SARS-CoV-2 antibodies reveals the persistence of IgG anti-N, IgG anti-S and IgA anti-S in 51.9%, 87.3% and 75.4% patients respectively at M6 and 35.2%, 87.6%, and 81.2% patients respectively at M12.
Over the one year study period, levels of IgG anti-N and anti-S decreased significantly (p<0.0001 and p= 0.017 respectively), while serum IgA anti-S level increased significantly (p<0.0001). At baseline, Sub-Saharan African patients were more likely to have positive IgG anti-N in comparison with patients originated from France and other countries (OR: 4.78 (95% CI 3.39, 6.73), p<0.0001), while active smoking was a protective factor (OR: 0.57 (95% CI 0.36, 0.90), p=0.0176).

Conclusions: Our findings demonstrate a higher seroprevalence of SARS-CoV-2 in PLWHIV compared to general population in IDF (5.7%) at the same period. A higher seroprevalence was observed in African sub-saharan patients and a lower seroprevalence was observed in smokers compared to non-smokers.

EPB256

Impact of COVID-19 pandemic on HIV treatment services in 12 PEPFAR-supported sites in 8 provinces, Thailand, 2021

R. Luengwattanapong[1], D. Rosa[2], W. Manosuthi[3], S. Pongprapass[4], P. Thamrongwonglert[5], S. Watcharasuwanseree[6], R. Bansong[7], P. Tharee[8], P. Leethong[9], P. Mootsikapun[10], W. Munsakul[11], P. Tangchitmeti[12], W. Nasomsong[13], P. Potidang[14], T. Tasaneeyapan[1], W. Kiatchanon[1], N. Jongchotchatchawal[1], S. Northbrook[1], R. Lolekha[1]

[1]Division of Global HIV and Tuberculosis, U.S. Centers for Disease Control and Prevention (CDC), Nonthaburi, Thailand, [2]Division of AIDS and STIs, Department of Disease Control, Thailand Ministry of Public Health, Nonthaburi, Thailand, [3]Bamrasnaradura Infectious Diseases Institute, Ministry of Public Health, Nonthaburi, Thailand, [4]Chiangrai Prachanukroh Hospital, Chiang Rai, Thailand, [5]Khon Kaen Hospital, Khon Kaen, Thailand, [6]Udon Thani Hospital, Udon Thani, Thailand, [7]Sunpasitthiprasong Hospital, Ubon Ratchathani, Thailand, [8]Lerdsin Hospital, Bangkok, Thailand, [9]Samut Prakan Hospital, Samut Prakan, Thailand, [10]Srinagarind Hospital, Faculty of Medicine, Khon Kaen University, Khon Kaen, Thailand, [11]Faculty of Medicine Vajira Hospital, Navamindradhiraj University, Bangkok, Thailand, [12]Pathum Thani Hospital, Pathum Thani, Thailand, [13]Phramongkutklao College of Medicine, Bangkok, Thailand, [14]Lat Krabang Hospital, Bangkok, Thailand

Background: Thailand saw a surge of new COVID-19 infections from <10 cases/day in October 2020 to >3,000 cases/day in June 2021, peaking at >20,000 cases/day in August 2021. This surge resulted in movement restriction measures and supply chain disruptions, potentially impacting HIV treatment services among people living with HIV (PLHIV). We assessed the impact of COVID-19 on HIV treatment services in PEPFAR-supported sites.

Methods: Cross-sectional data from routinely collected indicators on HIV services from 12 PEPFAR-supported hospitals in 8 provinces in Thailand were analyzed by comparing indicators collected during Q1 (Oct-Dec 2020) to indicators during the COVID-19 infection surge in Q4 (Jul-Sep 2021).

We analyzed the number of PLHIV receiving antiretroviral treatment (ART), percent of ART coverage, number of new HIV-positive cases, median baseline CD4 of newly diagnosed PLHIV, median time between HIV diagnosis and ART initiation among PLHIV without opportunistic infection (OI), percent of multi-month dispensing (MMD), number & percent of interruption in treatment (IIT), viral load coverage (VLC), and viral load suppression (VLS).

Results: ART coverage among PEPFAR-supported sites increased from 80.8% in Q1 to 84.6% in Q4 (Table). New HIV-positive tests remained at about 450 cases with median baseline CD4 around 230 cells/mm³ at Q1 & Q4. The median time between HIV diagnosis and ART initiation among PLHIV without OI decreased from 11 days in Q1 to 6 days in Q4, while the percent of multi-month dispensing ≥3 months in Q1-4 was more than 50%. IIT increased from 4.3% to 5.0%, VLC decreased from 88.6% to 83.2%, and VLS remained constant around 98% throughout Q1-4.

	Q1 2021 (Oct-Dec 2020)	Q2 2021 (Jan-Mar 2021)	Q3 2021 (Apr-Jun 2021)	Q4 2021 (Jul-Sep 2021)
# of PLHIV Registered at the Sites	39,056	41,815	41,688	40,481
# of PLHIV on ART (% ART Coverage)	31,569 (80.8%)	34,497 (82.5%)	33,980 (81.5%)	34,230 (84.6%)
# of New HIV-Positive Tests	463	422	339	442
Median CD4 of Newly Dx PLHIV (cells/mm³)	238.5	195.0	201.0	232.5
Median Days Between HIV Diagnosis and ART Initiation among PLHIV without OI	11 (n=422)	7 (n=319)	7 (n=247)	6 (n=214)
# of OverallInterruption in Treatment (% of Overall Interruption in Treatment)	1362 (4.3%)	1091 (3.2%)	1991 (5.9%)	1716 (5.0%)
% of Viral Load Coverage	88.6%	89.1%	86.5%	83.2%
% of Viral Load Suppression	98.2%	97.6%	98.1%	98.3%
% 3-5 MMD/% ≥6 MMD/% Overall ≥3 MMD	12.9% / 38.5% / 51.4%	26.6% / 30.5% / 57.1%	21.1% / 33.8% / 54.9%	16.6% / 35.7% / 52.3%

Table. Treatment Indicators.

Conclusions: Our findings showed gaps in IIT and VLC, highlighting the need for ongoing data analysis to recognize challenges and introduce new interventions to provide treatment service continuity during the COVID-19 pandemic.

EPB257

Profile of patients hospitalized with COVID-19 with HIV and AIDS in Mozambique

A. Couto[1], M.d.P. Nhavane[2], R. Langa[2], O. Tiberi[1], I. Gaspar[1]

[1]Ministry of Health - Mozambique, STI, HIV and AIDS Program, Maputo, Mozambique, [2]Ministry of Health - Mozambique, Medical Assistance Directorate, Maputo, Mozambique

Background: The first case of COVID-19 occurred in March 2020 and immediately the Government of Mozambique declared a state of emergency to help slow the spread. This approach was effective, and the country only breached 1000 cases per day in January 2021. Until January 2022, the country had experienced 4 waves of COVID-19, resulting in 220,241 positive cases of COVD-19 and 8,300 hospitalizations.

Description: The analyses was based on evaluation of routine data from March 2020 till January 2022 (January 19th). The data were analyzed to explore the profile of hospitalized patients in terms of gender, proportion of HIV patients among those hospitalized, if they were on HIV treatment, severity of case and final outcome of the hospitalization (if they were discharged alive or dead).

Lessons learned: Out of 8,300 patients hospitalized with COVID-19, it was possible to observe that 12% (971) had HIV, of which 53% were male and 47% female. From those

88 % (853) were on anti-retroviral therapy at the time of hospitalization (HAART), 4% had abandoned treatment and 8% of the cases were newly diagnosed with HIV during COVID-19 hospitalization. In terms of severity cases for HIV positive patients: 32% of the cases was moderate (no need of oxygen), 56% severe condition (in need of oxygen therapy) and 12 % was in critical condition (need of mechanical ventilation).

Overall, for patients with the comorbidity of HIV, 55% of the patients were discharged from the hospital and 31% died of COVID-19 with the remaining 14% without a final outcome assessed. The percent of registered COVID-19 deaths for the general population, however, was only 25% during the same period.

Conclusions/Next steps: Based on the data reviewed is possible to concluded that People Living with HIV has a great risk to have severe condition and death from COVID 19.

EPB258

Analysis of the impact of COVID-19 pandemic on PrEP uptake in Toronto: a retrospective 18-month single-site chart review

A.K. Bachari[1], J. McCully[2], N. Tsergas[3], M. Loutfy[4], M. Shokoohi[5], K. Woodward[6], P. El-Helou[7]

[1]Royal College of Surgeons in Ireland, Faculty of Medicine and Health Sciences, Dublin, Ireland, [2]Maple Leaf Research, Toronto, Canada, [3]Ontario HIV Treatment network, Toronto, Canada, [4]University of Toronto, Faculty of Medicine, Toronto, Canada, [5]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, [6]McMaster University, School of Medicine, Hamilton, Canada, [7]Maple Leaf Medical Clinic, Toronto, Canada

Background: The primary objective of this study was to determine the impact of the COVID-19 pandemic on PrEP uptake, comparing three time periods – 6 months prior to (T1), first 6 months of (T2), and second 6 months of the pandemic (T3), from September 2019-March 2021.

Methods: This 18-month chart review quantified PrEP uptake, STI testing, and follow-up appointment rates in Toronto based on data from Maple Leaf PrEP Clinic in three 6-month time periods. Descriptive statistics and a generalised estimating equation were used to analyse differences in PrEP uptake between time periods and associations with age, gender, ethnicity, duration in care, living in Toronto vs. not, and medication coverage status. Friedman and Wilcoxon Signed Rank Tests were used to determine changes in STI testing and clinic visit habits.

Results: Overall, 1737 patients were included in the chart review. The included patients were mostly men (99.0%) with 8.1% identifying as Black. Controlling for all examined covariates, individuals had 3.43 [2.74; 4.28] higher odds of discontinuing PrEP during T2 than T1 with no significant difference between T3 and T1. None of the covariates examined were associated with a significant increase in odds of discontinuation. For patients continuing PrEP throughout the 18 months (n=255), T2 ($p<0.001$) and T3 ($p<0.001$) visit counts were shifted lower than T1 visit counts with no difference between T2 and T3 visit counts ($p=0.394$). Similarly, T2 ($p<0.001$) and T3 ($p<0.001$) STI test counts were shifted lower than T1 STI test counts. The evidence also suggests that T3 STI test counts were shifted from T2 STI test counts ($p<0.001$) with the negative change in median difference indicating a rebound increase in T3. A significant majority of patients discontinuing PrEP cited their perceived lack of HIV risk (63.1% vs 35.4%; $p<0.001$) as their primary reason for discontinuation in post- vs pre-pandemic times.

Conclusions: The study findings indicate a significant decrease in uptake of one of the most successful HIV prevention tools. The importance of sexual health services in times of a pandemic are highlighted. Future studies should consider the health and economic consequences of decreased uptake of HIV prevention efforts.

EPB259

Depression in People Living with Human Immunodeficiency Virus During the Coronavirus Disease 2019 Pandemic in 4 African Countries

P.C. Adjei[1], N. Dear[2,3], A. Esber[1,3], H. Kibuuka[4], J. Maswai[1,5], J. Owuoth[6,7], V. Singoei[7,6], E. Bahemana[2,8], M. Iroezindu[2,9], T.A. Crowell[1,3], C.S. Polyak[2,3], J.A. Ake[1]

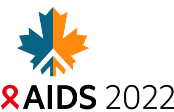
[1]Walter Reed Army Institute of Research, Military HIV Research Program, Forest Glen, United States, [2]Walter Reed Army Institute of Research, U.S. Military HIV Research Program, Forest Glen, United States, [3]Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc., Bethesda, United States, [4]Makerere University Walter Reed Project, Kampala, Uganda, [5]U.S. Army Medical Research Directorate, Kericho, Kenya, [6]U.S. Army Medical Research Directorate, Kisumu, Kenya, [7]HJF Medical Research International, Kisumu, Kenya, [8]HJF Medical Research International, Mbeya, Tanzania, The United Republic of, [9]HJF Medical Research International, Abuja, Nigeria

Background: We previously demonstrated transient reductions in HIV clinic attendance and food security during the COVID-19 pandemic for people living with HIV (PLWH) in the African Cohort Study (AFRICOS).

We compared the odds of depression during the pandemic compared with the pre-pandemic period in PLWH. We hypothesized that the pandemic conferred higher odds of depression on PLWH.

Methods: AFRICOS is an ongoing prospective cohort that enrolls PLWH at 12 clinics in Kenya, Uganda, Tanzania, and Nigeria. Longitudinal evaluations include the CES-D questionnaire every 6 months, with depression defined by a score ≥16.

We compared the odds of depression during the pre-COVID-19 period (1 January 2019 to 19 March 2020) and four equal divisions of the COVID-19 period (7 May 2020 to 1 September 2021).Logistic regression with generalized



estimating equations was used to estimate odds ratios (ORs) and 95% confidence intervals (95% CIs) comparing depression before and during the pandemic. Models were *a priori* adjusted for sex, age, and site.

Results: As of 1 September 2021, 2467 PLWH were considered actively engaged. Among 1992 participants with visits before and during the COVID-19 period, the median age at first visit included was 43 (interquartile range 36-51) years and 1159 (58.2%) were female. At first visit included, 62 (3.1%) had a CES-D score suggestive of depression.

Compared with the pre-pandemic period, PLWH had higher odds of reporting symptoms consistent with depression in the second and third parts of the pandemic period with ORs 1.60 (95% CI 1.07-2.41) and 1.76 (95% CI 1.21-2.56) respectively *(Figure).*

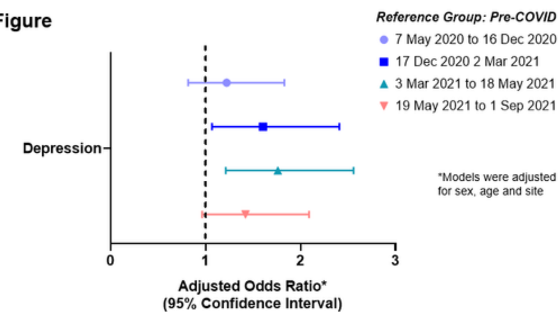


Figure. Compared with the pre-pandemic period, PLWH had higher odds of reporting symptoms consistent with depression in the second and third parts of the pandemic period.

Conclusions: Transient depressive symptoms associated with the evolving COVID-19 pandemic may have contributed to worsened HIV outcomes among PLWH. Addressing mental health issues as part of the public health response to outbreaks may improve engagement and clinical outcomes.

EPB260

Impact of the COVID-19 pandemic on pain prevalence and management among people living with HIV in Ontario

A. Zhabokritsky[1,2], S. Walmsley[1,3], L. Szadkowski[4,3], D. Kreutzwiser[5], L. Murphy[6], K. O'Brien[7], K. Vader[8], C. Price[9], A. Tseng[10,2]

[1]University of Toronto, Department of Medicine, Toronto, Canada, [2]University Health Network, Toronto, Canada, [3]Toronto General Hospital Research Institute, Toronto, Canada, [4]University Health Network, Biostatistics Research Unit, Toronto, Canada, [5]St. Joseph's Health Care London, London, Canada, [6]University Health Network, Department of Pharmacy, Toronto, Canada, [7]University of Toronto, Department of Physical Therapy, Toronto, Canada, [8]Queen's University, School of Rehabilitation Therapy, Kingston, Canada, [9]Ontario HIV Treatment Network Cohort Study, Project Community Advisory Committee, Toronto, Canada, [10]University of Toronto, Leslie Dan Faculty of Pharmacy, Toronto, Canada

Background: People living with HIV (PLWH) are disproportionately affected by high rates of pain with significant gaps in pain management. The COVID-19 pandemic has amplified these challenges through limited access to service providers, substance use treatment and harm reduction services, amid increased psychosocial stresses and financial burdens.

We set out to characterize the prevalence, severity, functional impact, and treatment of pain among PLWH in Ontario, Canada, prior to and during the first year of the COVID-19 pandemic.

Methods: The Ontario HIV Treatment Network Cohort Study (OCS) is an observational, open dynamic cohort of PLWH in Ontario, Canada. Interviews using a standardized questionnaire are administered on a yearly basis. Individuals who completed the OCS questionnaire in 2019 (pre-pandemic period) or 2020 (pandemic period) were included in the analysis. Pain prevalence and severity in the preceding 3 months, functional impact in the preceding week (measured as a mean of 7 interference items, each scored on a 0-10 scale) and treatment were evaluated in each study period.

Results: A total of 2874 participants with a median (interquartile range) age of 53 (43, 60) years (77% men) were included in the analysis. Prevalence of pain was 66% in 2019 and 74% in 2020, with a fifth of participants reporting severe pain.

Functional impact of pain was higher during the pandemic with 91% of those experiencing pain reporting some degree of interference with daily activities (vs 85% pre-pandemic) with a mean (standard deviation) interference score of 3.6 (1.6), compared to 3.0 (1.6) in 2019.

A total of 54% of individuals in 2019 and 62% in 2020 reported receiving formal treatment for pain. In the first year of the pandemic, utilization of prescription analgesics increased (33% vs 25% in 2019) along with use of over-

the-counter agents (55% vs 27% in 2019) and recreational substances (18% vs 10% in 2019), while use of non-pharmacological methods remained stable (21% during both periods).

Conclusions: Prevalence and functional impact of pain among PLWH in the OCS has increased during the COVID-19 pandemic with increased reliance on pharmacological and recreational substances. Addressing barriers to pain management among PLWH requires interdisciplinary, system-based strategies.

EPB261

Impact of COVID-19 on HIV care in Malawi and Uganda - a mixed methods study

J. Ben Farhat[1], R. Nesbitt[1], C. Hewison[2], C. Mambula[2], S. Balkan[2], E. Szumilin[2], P. Juul Bjertrup[3], H. Huerga[4]
[1]Epicentre, Paris, France, [2]MSF, Paris, France, [3]University of Copenhagen, Copenhagen, Denmark, [4]Epicentre, Brussels, Belgium

Background: The COVID-19 pandemic and the measures taken have severely disrupted health systems and medical care. PLHIV suffer from high levels of comorbidities and stigma, and often faced challenges in access to care.

The aim of this study was to explore the extent to which the pandemic and the public health measures have affected medical care for PLHIV. The study took place in two different contexts, in Arua (Uganda) and Chiradzulu (Malawi).

Methods: We conducted a multicentric mixed-methods study. The quantitative component explored patients' retention in care and viral suppression using data routinely collected from January 2018 to April 2021.

The qualitative study investigated patient perspectives and perceptions of the impact of Covid-19 on their lives and ability to manage their health, and on HIV care.

Results: From 2020 to 2021, we observed a 15% decrease in active cohort among adults on any regimen and a 17% decrease among children and adolescents in Arua. In Chiradzulu, the first- and second-line cohorts decreased in size (10% and 12% drop, respectively), while the third-line ART cohort remained stable.

We observed a reduction in ART initiations and clinical consultations at the start of pandemic (50% and 68% in Arua, 34% and 60% in Chiradzulu, respectively) and a gradual decrease in VL coverage.

In both contexts, patients and caregivers emphasized the impact of the pandemic and public health measures on livelihoods, education, access to food, food security and psychosocial wellbeing negatively, which affected their ability to manage HIV condition and to adhere. In Uganda, adolescents lost support, experienced increasing HIV stigma, and started to provide for themselves.

In Malawi, the fear of COVID at facilities and lack of communication about regarding day-to-day changes in activities was disturbing to patients and staff.

Conclusions: The COVID-19 epidemic had an important negative impact on HIV care in the health facilities and in the community. To ensure a conducive environment for patients' access to essential HIV care during future outbreaks requires continued collaboration with the authorities and advocacy for more less authoritarian ways of implementing restrictions. Innovative public health information campaigns about COVID-19, to dispel rumours and misinformation are recommended.

EPB262

Program adaptations in response to COVID-19 led to unprecedented program growth in Mozambique

S. Chilundo[1], A. Nguimfack[1], N. Guiloviça[2], I. Pathmanathan[1], I. Pereira[1], M.I. De Deus[1], L. Templin[1], I. Gaspar[3], A. Couto[3], J. Da Silva[4]
[1]Centers for Diseases Control and Prevention, Division of Global HIV & TB, Center for Global Health, Maputo, Mozambique, [2]United States Agency for International Development, Integrated Health Office, Maputo, Mozambique, [3]Ministry of Health, HIV Program, Maputo, Mozambique, [4]Centers for Diseases Control and Prevention, Division of Global HIV & TB, Center for Global Health, Atlanta, United States

Background: Mozambique has one of the largest numbers of people living with HIV (PLHIV) globally (n=2.1 million) and its national antiretroviral therapy (ART) program has historically struggled with client retention. In the first quarter (Q1) of fiscal year (FY) 2020, preceding the COVID-19 pandemic, 8.5% of patients interrupted treatment (defined as having no clinical contact or ART pickup more than 28 days since last expected clinical contact).

COVID-19-related mitigation measures and healthcare worker shortages disrupted care delivery and necessitated increasingly innovative strategies to connect patients with care options outside the health facility and assure treatment follow-up.

We describe ART program adaptations implemented in response to COVID-19 in Mozambique, and their impact on program growth and retention.

Description: Mozambique implemented several program adaptations to increase ART program and client resilience throughout the COVID-19 pandemic. Key measures included decongesting health facilities through expanded eligibility criteria for multi-month drug dispensing (MMD) to allow individuals to pick up ART every three or more months instead of monthly, alternative drug pick-up or distribution points in patient communities, use of remote options for adherence counseling and strengthened patient tracking, and acceleration of ART optimization.

Lessons learned: Through a combination of interventions, treatment interruption in Mozambique fell for men, women and children, from an overall 8.5% of PLHIV on treatment at the start of FY20 to 3.7% by the end of FY21,

despite COVID-19. There was an unprecedented 18.8% increase in the number of PLHIV currently on ART in Mozambique between FY20 to FY21, reaching 1.6 million PLHIV, with 254,000 new patients enrolled on ART in FY21 compared with 195,000 in FY20.

Conclusions/Next steps: In Mozambique, COVID-19 served as a catalyst for inclusion of improved service delivery models into national HIV policy, program adaptations that resulted in unprecedent program growth, and improvement in patient retention.

In addition to mitigating the impact of COVID-19 on PLHIV, many of these adaptations have also increased program and client resiliency in the face of other challenges, including new availability of expanded service delivery options for clients facing displacement and facility closures in the context of recent political instability in Northern Mozambique.

EPB263

Community responsive HIV/HCV care models for Rural and Indigenous communities and associated outcomes in Saskatchewan, Canada prior to and during the COVID-19 pandemic (2018-2021)

S. Skinner[1,2], S. Konrad[3], M. Pandey[4], C. Spence[5,6], I. Khan[3], D.T. Yalamanchili[2], B. Mason[2], M. Klein[6]

[1]University of Saskatchewan, Department of Medicine, Saskatoon, Canada, [2]Wellness Wheel Medical Clinic, Regina, Canada, [3]Indigenous Services Canada, Saskatchewan Region, Regina, Canada, [4]Saskatchewan Health Authority, Regina, Canada, [5]University of Saskatchewan, Saskatoon, Canada, [6]McGill University, Montreal, Canada

Background: Saskatchewan has the highest HIV and HCV rates in Canada. Rural Indigenous communities are disproportionately impacted by the epidemic with limited access to care and treatment. Two community-responsive care models were developed to address gaps in access. In an Indigenous community-led and nursing-led model, testing, care and treatment are provided directly in, and by community, and supported by an urban team. In an outreach, clinic-led model care was provided in a nearby town close to Indigenous communities by a visiting urban HIV/HCV care team. HIV outcomes and impacts of COVID-19 on both models were evaluated from 2018-2021.

Methods: Data for clients accessing care between 01/01/2018-12/31/2021 was extracted from an electronic medical records system. Demographics and clinical outcomes were described, including the proportion of active clients on treatment and virally suppressed (defined as at least one ART prescription in the calendar year and the last viral load within the calendar year <200 copies/mL, respectively) and the HCV cascade of care among clients who initiated treatment during this time period.

Results: COVID-19 restrictions, initiated in March 2020, included isolation and significantly reduced laboratory, mental health, and addiction services and on-site visits.

A virtual care approach supplemented and maintained care provision. Between 2018-2021, there were 156 HIV clients, of which 79% were HCV co-infected, and an additional 218 mono-infected HCV clients that accessed care between the two models. See table 1 and 2 for HIV and HCV cascade outcomes, respectively.

	In-community, nurse-led model of care				Outreach-based, clinic-led model of care			
	2018	2019	2020	2021	2018	2019	2020	2021
No. of active HIV clients	86	83	86	84	31	32	38	44
% of HIV clients on ART	87%	93%	92%	86%	65%	88%	84%	93%
Of those on ART, % virally suppressed	87%	82%	78%	72%	55%	64%	66%	88%
	2018-2019		2020-2021		2018-2019		2020-2021	
No. who initiated HCV treatment	44		34		50		10	
Of those who initiated HCV treatment, % who completed treatment	95%		82%		96%		90%	
Of those who completed HCV treatment, % cured	76%		61%		75%		67%	

Table 1. HIV and HCV Cascade of Care Outcomes

Conclusions: Superior outcomes in both models highlight the success of accessible community-responsive care models, emphasizing programs should be developed and adapted to local needs, strengths and resources.

Increased virtual care compensated for significant service slowdown during COVID-19, providing successful patient HIV/HCV care. Re-allocation of community HIV resources or reduced lab services may relate to reduction in viral suppression for in-community programs.

EPB264

The impact of COVID-19 pandemic on access to HIV services at urban context-based health facilities supported by CUAMM in collaboration with UNICEF

C. Di Chiara[1], N. Ronzoni[2], E. Barbieri[3], A. Agazzi[3], A. Zin[3], A. Merolle[4], F. Chenene[4], V. Cinturao[4], C. Liberati[3], E. Occa[4], D. Donà[3], G. Putoto[2], C. Giaquinto[3]

[1]University of Padua, Department for Women's and Children's Health, Padova, Italy, [2]Doctors with Africa CUAMM, Padova, Italy, [3]University of Padua, Padova, Italy, [4]Doctors with Africa CUAMM, Beira, Mozambique

Background: Since 2014, Doctors with Africa–CUAMM, is implementing in Beira, Mozambique, health projects focused on: healthcare workers training, data collecting, health commodities supply, and technical support to SAAJs (***S**erviço **A**migo do **A**dolescente e **J**ovem*), a network of primary healthcare centers promoting prevention and providing diagnosis, treatment, and retention in care of HIV patients. Starting from March-2020, the global spread of COVID-19 has been severely affecting public-health systems and economies worldwide. We describe the impact that COVID-19 had on the public-health projects supporting SAAJs in Beira.

Methods: A multi-center, retrospective observational study including HIV patients aged 10-24 years old attending SAAJs in Beira. Enrolled and lost to follow-up (LTFU) patients per month and HIV-viral load were considered indicators of CUAMM's implementing strategies.

Data were described with numbers and percentages. Mann-Kendall test was used to assess the monthly trend, and a linear regression model was applied.

Results: Data of eight SAAJs were analyzed from June-2019 to December-2021. The longitudinal evaluation of enrolled and follow-up subjects showed a significant increasing trend, with 35 new subjects per month treated with antiretroviral (ARV) in all SAAJs.

The overall monthly number of patients on ARV therapy in December-2021 was five-fold higher than in June-2019 (1603 vs 328), with no decline or arrest after the four pandemic waves that affected Mozambique. The number of LTFU patients showed a decline of 3‰ each month across the analyzed period (Figure). To support these findings, coherent viral suppression was achieved in most HIV-treated patients from March-2021 to December-2021.

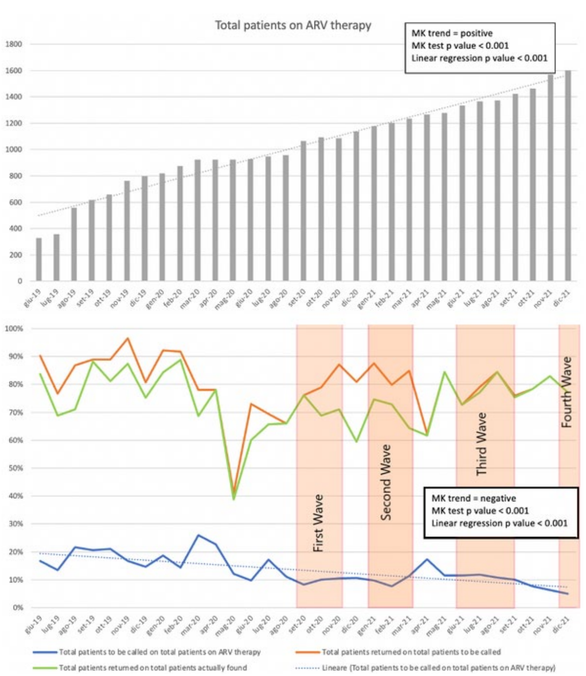

Figure.

Conclusions: All health centers supported by CUAMM projects, treating youths living with HIV in Beira, presented with a higher number of treated patients at every time point of the follow-up. The ongoing pandemic seems not to have impacted health systems implementation programs in this country. Other studies are needed to support this encouraging hypothesis.

EPB265

The in-hospital tuberculosis diagnostic cascade and early clinical outcomes among people living with HIV before and during the COVID-19 pandemic – a prospective multisite cohort study from Ghana

J. Åhsberg[1], S. Bjerrum[2], V.J. Ganu[3], J. Commey[4], A. Kwashie[5], Y. Adusi-Poku[6], P. Puplampu[7], Å. Bengård Andersen[8], E. Kenu[9], M. Lartey[7], I. Somuncu Johansen[1]

Background: To describe the routine in-hospital tuberculosis (TB) diagnostic cascade among people living with HIV (PLHIV) in Ghana, with specific focus on timing of diagnosis and treatment initiation before and during the COVID-19 pandemic.

Methods: In this prospective study we recruited adult PLHIV on admission at three major hospitals in Ghana between October 2019 and July 2021, if ≥1 TB symptoms, severe illness, or advanced HIV. Data on signs and symptoms, HIV and TB status, timing and results from TB diagnostics at baseline and 8 weeks follow-up were collected. Descriptive statistics were used for analysis.

Results: We recruited 248 patients (142 before and 106 during the COVID-19 pandemic) with a median age of 41.5 (IQR34-48) years and 178/248(71.8%) being female. Pre-pandemic, 81/142(57%) were not on antiretroviral treatment at time of enrolment vs. 75/106(70.8%) during the pandemic, p=0.027. Median CD4-count (*cells*/mm^3) pre-pandemic was 62.5 (IQR22-173) vs. 94.5 (IQR31-235) during the pandemic, p=0.029.

In both periods, the far majority of patients reported≥1 WHO TB symptom, but fewer patients reported cough during the pandemic (115/142(81.0%) vs. 63/106(59.4%), p<0.001). Pre-pandemic, 72/142(50.7%) were referred to sputum Xpert MTB/Rif (Xpert) after a median 0 (IQR0-2) days on admission vs. 65/106(61.3) after a median 1 (IQR0-3) day during the pandemic (p=0.044 for the time difference). Xpert results were available for 60/142(42.3%) patients pre-pandemic and 45/106(42.5%) during the

pandemic, p>0.05. Among participants followed up, 40/246(16.3%) were referred to start TB treatment and 34/246(13.8%) initiated treatment after a median 6 (IQR4-9) days, without difference between periods. Overall 8 weeks mortality was high at 63/246(25.6%) with no difference between periods.

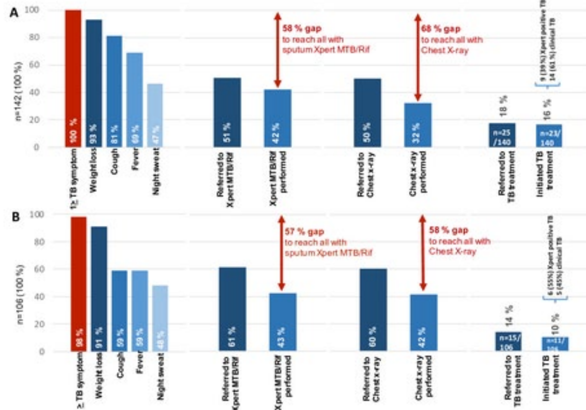

Figure 1.
A. Self-reported WHO TB symptoms and the routine TB diagnostic cascade among 142 PLHIV on admission at three Ghanaian hospitals before the COVID-19 pandemic.
B. Self-reported WHO TB symptoms and the routine TB diagnostic cascade among 106 PLHIV on admission at two Ghanaian hospitals during the COVID-19 pandemic.

Conclusions: In this cohort with severely immunosuppressed PLHIV almost all had at least one WHO TB symptom but only half were referred for routine TB investigations regardless of the pandemic. Missed or delayed TB diagnosis may be critical in this population with high mortality.

EPB266
The impact of COVID-19 pandemic on HIV service provision in Ukraine

K. Dumchev[1], O. Zeziulin[1], O. Nesterova[2], O. Neduzhko[1], L. Hetman[2]
[1]Ukrainian Institute on Public Health Policy, Kyiv, Ukraine, [2]Public Health Center of the Ministry of Health of Ukraine, Kyiv, Ukraine

Background: The COVID-19 pandemic and public health response continue to have an unprecedented impact across the globe. Lives of people living with HIV (PLWH) may be particularly affected due to socioeconomic disparities, co-morbidities that increase severity of the COVID-19 disease, and disruption in receiving vital health services.

Methods: A mixed methods study assessed the trends in provision of HIV services in HIV care facilities in Ukraine to verify the impact of COVID-19 and identify service gaps. Data on key indicators were extracted from official HIV program reports by the Ministry of Health and matched with the COVID-19 epidemiologic data. Three periods (01/2019-03/2020 [pre-COVID], 04-12/2020 [early-COVID], 01-12/2021 [late-COVID]) were compared using descriptive statistics.

Results: The graphic trends in key indicators and COVID-19 epidemic are presented in Figure. The average monthly number of HIV tests in health care facilities was 206,935 in pre-COVID period, decreasing to 154,009 in early- and 160,289 in late-COVID (23% decrease). The proportion of positive tests increased from 0.9% to 1.1% and then decreased to 1%. The average monthly number of new patients on ART also decreased from 1,716 to 1456 to 1373 (20% decrease) in three periods, respectively. The average monthly number of viral load tests increased from 26,862 to 27,963 to 31,211 (16% increase). The percent of viral suppression (<1000cp/ml) increased slightly from 94.5% to 94.8% to 95.4%.

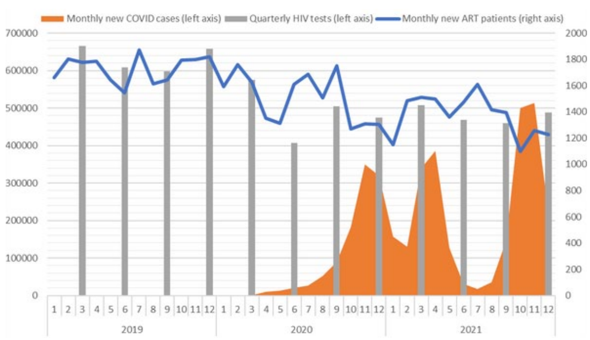

Figure. Trends in HIV testing and ART in Ukraine.

Conclusions: The pandemic had a substantial impact on the capacity of HIV clinics in Ukraine, leading to decreased number of tests and new patients on ART. The decrease did not correlate with the waves of COVID-19 transmission and was not reversed in late-COVID period. The number of PLWH who are not on ART in Ukraine remains significant (110,000 of the estimated 240,000 PLWH), therefore urgent measures should be taken to mitigate the impact of COVID-19 and restore HIV testing and treatment services.

Background: In countries with limited resources, people living with HIV (PLWH) may differently present lung infections hindering the differential diagnosis and the choice of treatment during coronavirus disease 2019 (COVID-19). This study aims to investigate the association between radiological changes and poor COVID-19 outcome PLWH from Central and Eastern Europe.

Methods: Since November 2020 ECEE Network Group have started collecting data on HIV/COVID-19 co-infection. In total data was submitted from 16 countries (eCRF) on 557 HIV+ patients. Analysis included patients with radiological examination performed. Logistic regression models were used to identify factors associated with death, ICU admission or partial recovery (poor COVID-19 outcome). Factors significant in univariate models (p<0.1) were included in multivariate model.

Results: Radiological data were available for 224 (40.2%) patients, 108 (48.2%) had computed tomography and 116 (51.8%) chest X-ray. Of these 211 (94.2%) were diagnosed with RT-PCR, 212 (94.6%) were symptomatic, 123 (55.6%) were hospitalized, 37 (16.6%) required oxygen therapy and 28 (13.1%) either died, was admitted to ICU or only partially recovered. By radiologist's description 138 (61.6%) patients had typical, 18 (8.0%) atypical and 68 (30.4%) no radiological changes.

In univariate models, CD4 count (OR=0.86 [95% CI: 0.76-0.98]), having a comorbidity (2.33 [1.43-3.80]), co-infection with HCV and/or HBV (3.17 [1.32-7.60]), being currently employed (0.31 [0.13-0.70]), being on antiretroviral therapy (0.22 [0.08-0.63]) and having typical (3.90 [1.12-13.65]) or atypical (10.8 [2.23-52.5]) radiological changes were significantly associated with poor COVID-19 outcome.

In the multivariate model being on antiretroviral therapy (OR=0.20 [95% CI:0.05-0.80]) decreased the odds of poor COVID-19 outcome. Having a comorbidity (2.12 [1.20-3.72]), as well as both typical (4.23 [1.05-17.0]) and atypical (6.39 [1.03-39.7]) radiological changes (vs. no changes) increased the odds of poor COVID-19 outcome.

Conclusions: Among HIV patients diagnosed with symptomatic SARS-CoV-2 infection presence of both typical and atypical radiological COVID-19 changes independently predicted poorer outcome.

Vaccination impact on COVID-19 related hospitalizations among PLWHIV in Argentina

J. Ballivian[1], M.F. Rombini[1], D. Cecchini[1,2], L. Calanni[3], F. Morales[4,5], E. Obieta[6], L. Morganti[2], C. Migazzi[7,1], M.M. Greco[8], M.L. M.L. Yantorno[8], R.L. Cuini[9], D. Pinto[1], Y. El Kozah[1,6], R. Perez[3], I. Cassetti[1]

[1]Helios Salud, Buenos Aires, Argentina, [2]Hospital General de Agudos Cosme Argerich, Buenos Aires, Argentina, [3]CEIN Unidad Infectológica Neuquén, Neuquén, Argentina, [4]Sanatorio Anchorena, Buenos Aires, Argentina, [5]Sanatorio Trinidad, Buenos Aires, Argentina, [6]Hospital Municipal Ciudad de Boulogne, Boulogne, Argentina, [7]Hospital General de Agudos Presidente Perón de Avellaneda, Avellaneda, Argentina, [8]Hospital Español de La Plata, La Plata, Argentina, [9]Hospital General de Agudos Dr. T. Álvarez, Buenos Aires, Argentina

Background: COVID-19 vaccines effectively prevent severe outcomes such as hospitalization and death in the general population. People living with HIV (PLWHIV) are a prioritized population for the vaccination rollout in Argentina since they are at higher risk of developing severe complications from COVID-19. This study evaluates the association of COVID-19 vaccination with hospital admissions in a cohort of PLWHIV co-infected with COVID-19 in Argentina.

Methods: Adult PLWHIV with confirmed SARS-CoV-2 infection were enrolled in a prospective observational multicentric cohort study (COVIDARE) which evaluated hospitalizations due to COVID-19 since September 2020. Participating centers included nationwide HIV clinics and general hospitals from Argentina.

This sub-analysis includes participants enrolled in the study after the vaccination rollout started in Argentina whose vaccination status was known at the time of a SARS-CoV-2 infection diagnosis. A multivariable logistic regression model was performed to assess the impact of vaccination on hospitalization due to COVID-19.

Results: Of 508 PLWHIV that met inclusion criteria for this analysis, 13.97% required hospital admission due to COVID-19. A comparative analysis of characteristics of PLWHIV with and without hospitalization is shown in table 1.

Variables		Total N=508	Admission not required N=437	Admission required N=71	p-value
Age categories	Age<60	286 (56.3%)	258 (59.0%)	28 (39.4%)	0.002
	Age>=60	222 (43.7%)	179 (41.0%)	43 (60.6%)	
Sex	Male	335 (65.9%)	286 (65.4%)	49 (69.0%)	0.56
	Female	173 (34.1%)	151 (34.6%)	22 (31.0%)	
Viral load	<20 copies/ml	404 (79.5%)	352 (80.5%)	52 (73.2%)	0.16
	>=20copies/ml	104 (20.5%)	85 (19.5%)	19 (26.8%)	
CD4+ categories	CD4<200	27 (5.3%)	18 (4.1%)	9 (12.7%)	0.002
	CD4 200-449	147 (28.9%)	121 (27.7%)	26 (36.6%)	
	CD4 >=500	334 (65.7%)	298 (68.2%)	36 (50.7%)	
Other comorbidities	No	307 (60.4%)	273 (62.5%)	34 (47.9%)	0.020
	Yes	201 (39.6%)	164 (37.5%)	37 (52.1%)	
ART	No	15 (3%)	10 (2.3%)	5 (7.0%)	0.028
	Yes	493 (97%)	427 (97.7%)	66 (93.0%)	
Vaccinated	No	331 (65.2%)	273 (62.5%)	58 (81.7%)	0.007
	At least 1 dose	105 (20.7%)	98 (22.4%)	7 (9.9%)	
	Fully vaccinated	72 (14.2%)	66 (15.1%)	6 (8.5%)	

Table 1. Characteristics of PLWHIV that required hospitalization due to COVID-19

In a multivariable logistic regression model, the presence of other comorbidities was associated with admission (aOR: 1.70; 95%CI: 1.01- 2.87 p=0.046). Conversely, CD4+ T-cell count >=500 cells/ml (aOR: 0.25; 95% CI: 0.09-0.66; p=0.005) and vaccination (aOR: 0.47; 95% CI 0.24-0.94, p=0.039) were inversely associated with hospital admission. Sex, age, antiretroviral therapy (ART) and detectable viral load had no significant association with hospitalization in this model.

Conclusions: This is the first analysis of the COVIDARE cohort which assessed the impact of vaccination on COVID-19 related hospitalizations.

In this study, the presence of comorbidities was the only variable associated with higher odds of admission. Vaccination and high CD4+ T-cell count provide a significant reduction in the odds of hospital admission among PLWHIV.

EPB269

Humoral immune response to COVID-19 vaccination in HIV infected adults with and without prior COVID: comparison with HIV uninfected controls

P. Charpentier[1,2], M. Silva[2], S. Solari[3], G. Allendes[2], G. Estadella[2], L. Cortés[4], P. Vial[4], M. Wolff[2,1]

[1]Universidad de Chile, School of Medicine, Santiago, Chile, [2]Fundación Arriarán, Hospital Clínico San Borja Arriarán, Infectious Diseases, Santiago, Chile, [3]Pontificia Universidad Católica de Chile, UC-Christus Laboratory, Santiago, Chile, [4]Universidad del Desarrollo, Santiago, Chile

Background: Anti SARS-CoV-2 vaccines differ in protective effectiveness according to type of vaccine, viral variant and immune status of receptor. HIV infection (HIV+) is a major risk factor for immune compromise.

The objective of this study was to evaluate immune response to vaccination in HIV+ adults according to level of CD4+ lymphocytes (LCD4+), presence of prior SARS-CoV-2 infection and vaccine used, compared with HIV uninfected controls.

Methods: Neutralizing antibodies (NAb) against protein S RBD using a vesicular stomatitis-based pseudo virus (1/ID50) and commercial anti protein S antibodies (Elecsys, Roche®, U/mL) were measured in 165 HIV+ cases and 27 controls from Fundación Arriaran HIV care center in Santiago, Chile.

Results: Cases were 87% male; median age in years,42 and median vaccine-sampling interval in days,154; for controls it was 37%, 36 years and 188 days, respectively. Mean (median) Elecsys titers in U/mL were 311 (42) in HIV + cases; 230 (34) in those receiving CoronaVac and 784 (581) in BNT162b2 receptors, and 462 (80) in controls; 123 (41) in CoronaVac vaccinees and 1044(826) in BNT162b2 vaccinees, respectively; of those studied only 42% of all cases had NAb (27% in CoronaVac vaccinees and94% in BNT162b2 vaccinees, but were present in 25% and 100% of controls, respectively.

All cases and controls with prior COVID-19 had NAb. There was a significant trend to lower antibodies in HIV+ cases with LCD4 below 500 cells/mL; 87% of all NAb positive cas-

es had > 100 U/Ml titers by Elecsys test, and 6% of those without NAb had >100 U/mL, Kappa Coefficient 0.798 (95% CI 0.685-0.910).

Conclusions: BNT162b2 induces much higher levels of anti SARS-CoV-2 antibodies and higher percentage of NAb than CoronaVac in HIV+ persons and uninfected controls. High percentage of HIV+ persons and uninfected adults lack NAbs after 5-6 months of two-dose CoronaVac vaccination. Prior COVID induces strong immune response in both groups. Elecsys test is an useful qualitative surrogate marker for NAb detection.

EPB270

Body composition and SARS-CoV-2 antibody levels among underserved populations in Miami, Florida: a rapid acceleration of diagnostics-underserved populations (RADxUP) study

J.A. Bastida Rodriguez[1], L. Acuna[1], Y. Huang[1], J. Tamargo[1], H. Martin[1], M. Barbieri[1], A. Marty[1], E. Roldan[1], Y. Hernandez Suarez[1], D. Brown[1], N. Garba[1], M. Jo Trepka[1], C. Palacios[1], A. Campa[1], S. Sales Martinez[1], M. Baum[1]

[1]*Florida International University, Miami, United States*

Background: Obesity is associated with a risk of morbidity and mortality from SARS-CoV-2 infection. However, there have been conflicting results regarding obesity and antibody levels.

The objective of this study was to determine if body composition was associated with SARS-CoV-2 neutralizing and nucleocapsid titers in people living with HIV (PLWH) and HIV seronegative individuals who self-reported SARS-CoV-2infection. Neutralizing antibodies are key to recovery and protection against viral disease and are related to vaccination. Nucleocapsid antibodies indicate prior infection unrelated to vaccination.

Methods: Demographics, anthropometrics, and serum were collected in an ongoing NIH RADx-UP STUDY. Participants self-reported date of infection, severity of symptoms (mild, moderate, or severe), and date of occurrence. Medical records were used to determine vaccination status and days elapsed since last vaccination in overweight (BMI≥25 kg/m^2) or lean (BMI<25 kg/m^2) groups.

ELISA kits (Epitope Diagnostics, San Diego, CA) were used for SARS-CoV-2 neutralizing and nucleocapsid quantification. Participants were selected if they reported a date of infection and had neutralizing and nucleocapsid antibody results.

Results: The mean age of the 84 post-infection participants was 56.3±11.8 years, 45.2% male, 53.8% Black, 75% overweight, 28.6% PLWH, and 64.3% were fully vaccinated. The average number of days between vaccination and serum collection was 91±51 days, and 273.3±146.8 days since reported infection; both did not differ between the overweight and lean groups (P>.05).

The overweight group had lower neutralizing (P=0.001), but higher nucleocapsid antibodies (P=0.003) compared to the lean group. Nucleocapsid antibody levels were positively correlated with severity of reported symptoms (r_s=0.242, P=0.032). The overweight group trended towards having more cases of severe symptoms or needing hospitalization (28.6%), compared to the lean group (13.3%), (P>0.05). HIV serostatus, age, and sex were not correlated with antibody titers or body composition(P>0.05). Overweight was inversely associated with neutralizing antibodies adjusting for full vaccinated status, days since last vaccination, and days since reporting positivity for SARS-CoV-2 (β=-23.21 SE=6.72; P=0.001).

Conclusions: Overweight was associated with more severe symptoms of SARS-CoV-2 infection, higher levels of nucleocapsid, and lower levels of neutralizing antibodies. HIV serostatus was not indicative of differences in SARS-COV-2 antibody titers. Additional studies are needed.

EPB271

Decay pattern of anti–SARS-CoV-2 antibodies in people with HIV

J. Milic[1], S. Renzetti[2], F. Motta[1], M. Meschiari[3], R. Fogliani[4], F. Ferrari[4], B. Meccugni[4], A. Calcagno[5], E. Foca'[2], S. Mimmi[4], S. Borsari[4], S. Calza[2], A. Cossarizza[1], C. Mussini[1], G. Guaraldi[1]

[1]*University of Modena and Reggio Emilia, Modena, Italy,* [2]*University of Brescia, Brescia, Italy,* [3]*Azienda Ospedaliero-Universitaria Policlinico of Modena, Department of Infectious Diseases, Modena, Italy,* [4]*Azienda Ospedaliero-Universitaria Policlinico of Modena, Modena, Italy,* [5]*University of Torino, Torino, Italy*

Background: We explored decay pattern of anti–SARS-CoV-2 antibodies titers after COVID-19 vaccination in people living with HIV (PLWH).

Methods: This observational study of PLWH attending Modena HIV Clinic (Italy) compared younger (<65 years) with older (>65 years) adults included in the GEPPO cohort. PLWH with two doses of vaccine with at least one available serology two weeks after vaccination were included. PLWH with SARS-CoV-2 prior or after vaccination or who did not complete vaccination were excluded.

Anti–SARS-CoV-2 titers were expressed in BAU/ml and their decay was analyzed in relation to interaction between age (> or <65 years), sex, and day-post vaccination. HIV variables and vaccine type were added as covariates in the linear mix-effect regression model estimated through bootstrap.

Results: A total 563 PLWH, 68.7% males, median age 56, 15.5% aged >65, were analyzed. Median duration since HIV diagnosis was 18.9 years, current CD4= 681.1 µL, 94% had HIV RNA undetectable. BNT162b2, mRNA-1273, %), ChAdOx1 were used in 528 (93.8%), 22 (3.9%) and 13 (2.3%) PLWH, respectively. Median follow-up was 10.8 weeks.

Mean time from 2nd dose of vaccine and 1st available antibody titer (baseline) was 12±7 weeks. At baseline, a significant difference was observed in antibody titer in men and women (804 vs. 1334.5, p<0.001) and in geriatric vs

younger adults (678.6 vs 934.2, p=0.011). Baseline antibody titer differed by vaccine type: BNT162b2=894 (Q1-Q3:307-1838), mRNA-1273=2080 (Q1-Q3:1445-2080), ChAdOx1=325 (Q1-Q3:179-840) BAU/mL (p<0.001).

Figure shows antibody decay according to sex and age interaction with time after correction for HIV variables and vaccine type. Weekly antibody decay differed by vaccine type.

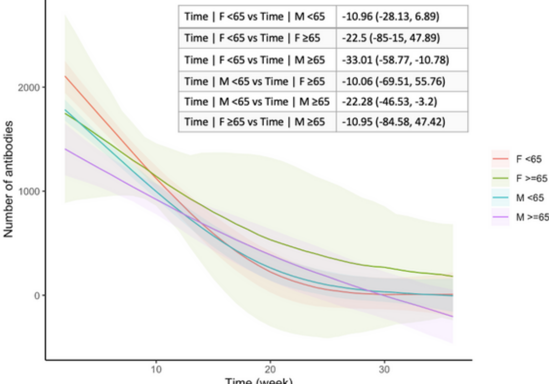

Figure.

Conclusions: PLWH aged >65 years showed lower baseline antibody titer. Men >65years displayed a lower decay over time compared to young PLWH. Further studies are needed to understand humoral and cellular response to SARS-CoV-2 vaccines in relation to age and sex in PLWH.

The forgotten face of Advanced HIV disease in India – programmatic experience and outcomes of patients admitted to a Medecins Sans Frontieres supported facility in Bihar, India

R. Mahajan[1], S. Murali[2], V. Kumar[1], A. Harshana[1], L.M. Planas[3], B. Alonso[3], S. Burza[1]

[1]Médecins Sans Frontières, New Delhi, India, [2]Médecins Sans Frontières, Patna, India, [3]Médecins Sans Frontières, Barcelona, Spain

Background: Patients with advanced HIV disease (AHD, defined by WHO as CD4 cell count <200cells/mm3 or WHO clinical stage 3 or 4 event or children less than 5 years of age) is associated with very high mortality of up to 60%. The global recommendations for the management of AHD include timely screening and treatment of opportunistic infections, linkage to and retention in HIV care. The Indian national program does not yet have AHD guidelines, and access to critical diagnostic tools for these patients are extremely limited.

We present clinical characteristics and risk factors for mortality of a cohort of patients admitted with AHD in a Medecins Sans Frontiers (MSF) health facility in Bihar, India.

Methods: A retrospective cohort analysis was conducted using routine program data of all admitted patients with AHD from February 2019 to March 2021. Continuous variables were compared across groups using t-test and categorical variables were compared using Chi-square or Fisher's exact test. P <.05 was used to establish significance.

Results: A total of 879 AHD patients were included in the final analysis. 649 (73.8 %) were males. Median age was 38 years (IQR 32, 45). 4.9% were under 15 years of age. 19.6% were ART Naïve at presentation. Median (IQR) CD4 count was 88 (37, 167) cells/mm^3. Overall inpatient case fatality rate was 19.3% (n=170). The most common opportunistic infection associated with AHD was tuberculosis (n=590, 67%). The other common comorbidity includes Pneumocystis Pneumonia (n=115, 13%), Cryptococcal Meningitis (n=81, 12.5%) and Visceral Leishmaniasis (n=58, 6.6%). Significant risk factors associated with mortality was tuberculosis (Relative risk (RR)=1.6, 95% CI:1.1-2.1), cryptococcal antigenemia (RR=1.6, 95% CI : 1.1-2.3), and CD4 count<50 cells/mm^3 (RR=1.5, 95%CI 1.1-2.1).

Conclusions: MSF, in collaboration with the state, has implemented a program positioned within a government facility that provides treatment to critically unwell people with AHD. Our findings suggest the need for a greater focus on AHD in India, with an urgent need to improve the availability and access of diagnostics and drugs to manage the complex medical needs of these vulnerable and heavily stigmatized patients. In doing so, ultimately fatal outcomes can be effectively reduced significantly.

EPC002

Assessment of cardiovascular health using the "Life's Simple 7" among the Canadian HIV and Aging Cohort study participants: a cross-sectional observational study

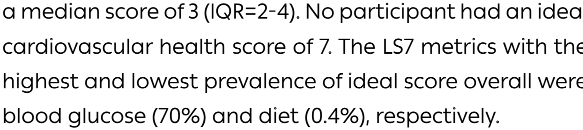
K. Giguère[1], D. Talbot[2], M. Messier-Peet[1], D. Temblay-Sher[1], S. Matte[1], A. Chamberland[1], A. Charest[3], S. Harrison[3], J.-G. Baril[4], B. Conway[5], C. Fortin[1], M. Harris[6], P. MacPherson[7], M. C.M. Murray[8], N. Pick[8], R. Thomas[9], B. Trottier[4], S. Trottier[10], S. Walmsley[11], A. Wong[12], C. Tremblay[1], B. Lamarche[3], M. Durand[1]

[1]Centre de Recherche du CHU de Montréal, Pavillon S, Montréal, Canada, [2]Université Laval, Québec, Canada, [3]Centre Nutrition, Santé et Société (NUTRISS), Institut sur la Nutrition et les Aliments Fonctionnels (INAF), Université Laval, Québec, Canada, [4]Clinique de Medecine Urbaine du Quartier Latin, Montréal, Canada, [5]Vancouver ID Research & Care Centre Society, Vancouver, Canada, [6]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [7]Ottawa Hospital Research Institute, Ottawa, Canada, [8]B.C. Women's Hospital, Vancouver, Canada, [9]Clinique Médicale l'Actuel, Montréal, Canada, [10]Centre Hospitalier de l'Université Laval, Québec, Canada, [11]University Health Network, University of Toronto, Toronto, Canada, [12]Regina Qu'Appelle Regional Health Authority, Saskatoon, Canada

Background: There is growing evidence that cardiovascular diseases (CVD) disproportionately affect people living with HIV (PLHIV). However, little is known about overall cardiovascular health among PLHIV.

Methods: We assessed the American Heart Association (AHA)'s "Life's Simple 7" (LS7) metrics (smoking, body mass index, diet, physical activity, total cholesterol, blood pressure, blood glucose) among Canadian HIV and Aging Cohort Study, CTN 272 (CHACS) participants who completed a validated web-based food-frequency questionnaire (web-FFQ). LS7 metrics were dichotomized using a set of "ideal" cutoffs recommended by the AHA to yield an overall LS7 score ranging from 0 to 7 points. Robust Poisson regressions were used to assess the associations between HIV status and the LS7 metrics, and between HIV status and LS7 diet submetrics (fruits/vegetables, fish, fiber-rich whole grain, sugar-sweetened beverages). Analyses were adjusted for age, sex, ethnic background, education, and annual income. Effect modification by sex was also assessed.

Results: A total of 279 CHACS participants (73% PLHIV) completed the web-FFQ at a median of 55 months (interquartile range [IQR]=40-64) of follow-up. Median age was 59 years (IQR=55-66), and most participants were male (82%) and White (87%). The distribution of the LS7 score was similar between PLHIV and HIV-negative groups with



a median score of 3 (IQR=2-4). No participant had an ideal cardiovascular health score of 7. The LS7 metrics with the highest and lowest prevalence of ideal score overall were blood glucose (70%) and diet (0.4%), respectively.
Female PLHIV were over 6 times more likely to not smoke tobacco compared to HIV-negative female participants (adjusted proportions ratio [aPR]=6.54, 95% confidence interval [95%CI]: 1.66-25.76) and less likely to have ideal blood glucose concentration (aPR=0.75, 95%CI: 0.57-0.99).
Among males, PLHIV were less likely to have an ideal total cholesterol concentration compared to HIV-negative participants (aPR=0.66, 95%CI: 0.48-0.91).
No statistically significant difference was observed between PLHIV and HIV-negative participants in the proportions of ideal scores for diet submetrics.
Conclusions: Our study highlights overall poor cardiovascular health among PLHIV and HIV-negative CHACS participants alike. Further public health efforts among adults aged ≥40 years are urgently needed and should focus on behavioural risk factors for CVD.

EPC003
Survival and determinants of mortality among HIV infected persons in rural Malawi: a historical cohort study of before test and treat strategy

M. Aron[1], E. Conolly[2], C. Kachimanga[2], F. Munyaneza[1], L. Thengo[1], J.C.D. Suffrin[2], R. Calderon-Margalit[3]
[1]Partners In Health / Abwenzi Pa Za Umoyo, Monitoring and Evaluation, Neno, Malawi, [2]Partners In Health / Abwenzi Pa Za Umoyo, Clinical Services, Neno, Malawi, [3]Hebrew University of Jerusalem, Braun School of Public Health and Community Medicine, Public Health and Community Medicine, Jerusalem, Israel

Background: Malawi has one of the highest HIV prevalence in the world estimated at 10.4%. Although there is substantial research on HIV in Malawi, most have been done in urban or peri urban areas. We aimed to describe survival patterns and identify clinical determinants of mortality among HIV infected persons in rural Malawi.
Methods: We conducted a historical cohort study of 937 children aged 0-14 years and 9, 041 adults aged 15+ years HIV persons who initiated antiretroviral drugs before test and treat strategy between 2007 and 2015 in Neno district. We utilized descriptive statistics and Kaplan Meier to describe mortality rates and survival patterns and Logistic regression and cox proportional hazard models to identify predictors of mortality.
Results: We found crude mortality rates of 33 per 1000 person years and 35.5 per 1000 person years for children and adults respectively. The cumulative survival probabilities for children were 92% and 82% at 1 and 9 years follow up whereas for adults were 93% and 81% respectively.
Among children, factors associated with low mortality included age group 6 – 14 years (OR = 0.31, 95%CI: 0.18 – 0.53) and CD4 count >=300cell/mm^3(aOR = 0.36, 95%CI: 0.17 – 0.73). Increased risk of mortality was found for children not enrolled in pre-anti-retroviral (ART) care (aOR = 2.69 95%CI: 1.47 – 4.96) and presenting with diarrhea at initiation (aOR = 3.76, 95%CI: 1.13 −12.53).
Among adults, age group 46-70 years (OR = 2.19, 95%CI: 1.73 – 2.78), WHO stage 3 and 4 (aOR = 2.58, 95%CI: 2.06 – 3.24), Kaposi Sarcoma (aOR =2.44, 95%CI: 137 – 4.35) and being underweight at ART initiation (aOR = 5.11, 95%CI: 4.38 – 5.95) were associated with mortality.
Among women of child bearing age, underweight at ART initiation (aHR = 6.03, 95%CI: 4.80 – 7.56) and not enrolled in pre-ART care (aHR = 2.25, 95%CI: 1.56 – 3.25) were significant predictors of mortality.
Conclusions: Our analysis demonstrates that good survival rates are possible in rural settings in sub-Saharan Africa such as Neno district, Malawi.
Increased mortality associated with WHO staging, being underweight and Kaposi Sarcoma associated validate the requirement of a robust national test and treat strategy with expected improved mortality.

EPC004
Geographic variation in 5-year mortality following HIV diagnosis: implications for clinical interventions

I.V. Bassett[1,2,3,4], J. Yan[5], J. Giddy[6], L.M. Bogart[7], A. Stuckwisch[2], D. Zionts[2], R. Naidoo[8], R.A. Parker[3,4,5]
[1]Massachusetts General Hospital, Division of Infectious Diseases, Boston, United States, [2]Massachusetts General Hospital, Medical Practice Evaluation Center, Boston, United States, [3]Harvard University, Center for AIDS Research, Boston, United States, [4]Harvard Medical School, Boston, United States, [5]Massachusetts General Hospital, Biostatistics Center, Boston, United States, [6]McCord Hospital, Durban, South Africa, [7]RAND Corporation, Santa Monica, United States, [8]Statistics South Africa, KwaZulu-Natal Province Office, Durban, South Africa

Background: Wide spatial variation in HIV prevalence has been observed across South Africa, but there is limited knowledge on spatial distribution of HIV outcomes. Providing policymakers with information on areas at increased risk for adverse outcomes is vital for appropriately targeting interventions.
We used spatial statistical analysis to identify geographic clusters and underlying factors associated with mortality in an urban South African setting.
Methods: We used data from the Sizanani trial (NCT01188941) where adults (≥ 18y) were enrolled at four Durban outpatient sites from August 2010-January 2013. We ascertained vital status via the South African National Population Register; median follow-up time was 5.8y (IQR 5.0-6.4).
We assigned geocoded residential addresses to census small area layers (SALs) with characteristics defined by 2011 South African Census data. Kulldorff's spatial scan

statistic (Bernoulli model) was used to identify mortality clusters among assigned SAL centroids. We then compared population-weighted averages of selected socioeconomic factors for SALs within and outside of mortality clusters.

Results: 1,143 participants living with HIV were assigned to 677 SAL centroids. One lower mortality cluster (n=90, RR=0.23, p=0.022) was identified. SALs within the cluster were on average younger (24y vs 25y, p<0.001), had fewer beds per household (3 vs 4, p<0.001), had higher proportions of females (52% vs 51%, p=0.013) and residents with no schooling past age 20 (4% vs 3%, p<0.001) or no schooling at all (4% vs 3%, p<0.001), and had lower proportions of residents with income >3,200 ZAR (5% vs 9%, p<0.001). SALs within the cluster also tended towards piped water that was further away from dwellings (p<0.001), less rubbish disposal (p<0.001), and lower quality toilets (p<0.001).

Conclusions: A lower mortality cluster occurred in a semi-rural area near Durban despite traditional geographic risk factors including lower education, income, access to water, rubbish disposal, and toilets. The cluster was in the catchment area of a district hospital that has conducted extensive community outreach.

Targeted expansion of support interventions such as adherence clubs or strengthened community health worker networks may improve mortality outcomes in areas with similar underlying characteristics.

EPC005

Most common causes of death among persons living with HIV — Zambia, February 2020-January 2022

P. Kapombe[1], M. Cheelo[1], K. Kamalonga[2], L. Tally[2], E. Stoops[2], C. Mwango[3], B. Munkombwe[4], J. Hines[2], S. Agolory[2]

[1]Ministry of Health, Lusaka, Zambia, [2]Centers for Disease Control and Prevention, Lusaka, Zambia, [3]Bloomberg Data 4 Health, Lusaka, Zambia, [4]Centers for Disease Control and Prevention, Atlanta, United States

Background: With significant improvement in life expectancy among populations of countries with high HIV burden, causes of death among persons living with HIV (PLHIV) may have changed. Zambia has achieved high antiretroviral therapy (ART) coverage for PLHIV yet recent estimates of the most common causes of death are not widely available. We utilized mortality surveillance data to report on common causes of mortality among PLHIV who died in the community setting in Zambia.

Methods: The Zambian Ministry of Health conducts routine mortality surveillance of community deaths in 44 hospitals in 32 (of 117) districts. Surveillance officers at these hospitals conduct verbal autopsies (VA) with relatives or close associates of deceased persons using a standardized World Health Organization tool, which solicits information about the circumstances proximal to death. HIV status is ascertained during the VA. A probable cause of death is assigned by a validated computer algorithm (InterVA). We analyzed the top causes of death by HIV status in R.

Results: VAs were conducted for 29,593 community deaths between February 2020 and January 2022, of whom 5,220 (17.6%) were HIV positive. The median age at death was 44 years among PLHIV and 52 years for persons with no HIV infection (p<0.01).

The most common causes of death among PLHIV identified via VA were HIV/AIDS-related causes (50.7%), cardiovascular disease (12.7%), tuberculosis (7.1%), stroke (3.6%), and acute respiratory infections (3.5%). Cardiovascular disease (23.8%), stroke (9.6%), and acute respiratory infections (8.0%) were the most common causes of death among persons without HIV infection.

Conclusions: Both infectious and noncommunicable diseases are common causes of death among PLHIV in Zambia during the universal ART era. Maintaining high ART coverage and viral suppression among PLHIV are critical to controlling the HIV epidemic and reducing HIV/AIDS-related deaths in Zambia.

Additionally, introducing interventions to strengthen integrated management of noncommunicable diseases into ART clinics might help to reduce mortality from these conditions by making noncommunicable disease care more accessible and standardized. Noncommunicable diseases are also a major mortality cause among persons without HIV infection. Mortality surveillance among persons dying in the community provides important information about major public health problems in Zambia.

EPC006

Causes of death for persons with HIV in an integrated healthcare system in Northern California, 2013-2017

K. Mohr[1], T. Levine-Hall[2], A. Trickey[3], J. Gill[4], J. Berenguer[5], L. Goodman[1], L. Pitts[6], M. Luu[1], J. Skarbinski[1,2], D. Satre[7,2], M. Silverberg[2]

[1]Oakland Medical Center, Kaiser Permanente Northern California, Oakland, United States, [2]Kaiser Permanente Northern California, Division of Research, Oakland, United States, [3]University of Bristol, Population Health Sciences, Bistrol, United Kingdom, [4]University of Calgary, Southern Alberta HIV Clinic, Department of Medicine, Calgary, Canada, [5]Hospital General Universitario Gregorio Marañón, Madrid, Spain, [6]Avenue 360 Health & Wellness, Houston, United States, [7]University of California, San Francisco, Department of Psychiatry and Behavioral Sciences, San Francisco, United States

Background: Causes of death (COD) in persons with HIV (PWH) have shifted from a high prevalence of AIDS-related deaths to non-AIDS-related causes, including cancer and cardiovascular disease. However, death certificates inaccurately label PWH as AIDS-related when due to these

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

other causes. The aim of this study was to evaluate the COD in PWH using the Coding Causes of Death (CoDe) methodology in HIV.

Methods: We identified adult PWH who died between July 2013 and December 2017 while members of Kaiser Permanente Northern California (KPNC). Using abstracted data from electronic health records, we employed CoDe methodology for COD, with adjudication by two KPNC clinicians and with review of conflicting reports by an external clinician panel.

We classified deaths into 12 major groups, describing distributions of COD overall, and by sex, race (Black, White, Hispanic), and HIV transmission risk (heterosexual, injection drug use [IDU], men who have sex with men [MSM]).

Results: The study sample included 302 PWH with a confirmed cause of death by the State of California. Of the 302 deaths (see table), 57 (18.9%) were AIDS-related, 56 (18.5%) were cardiovascular-related, and 58 (19.2%) were cancer-related. Further analyses of COD are differentiated by sex, race, HIV transmission risk as detailed in the table.

		Sex		Race			Risk Status		
Cause of Death, n (%)	Total	Male	Female	White	Black	Hispanic	MSM	Hetero.	IDU
AIDS	57 (19%)	52 (19%)	5 (19%)	34 (18%)	13 (22%)	6 (21%)	30 (16%)	15 (33%)	3 (8%)
Cardiac	56 (19%)	51 (19%)	5 (19%)	36 (19%)	11 (19%)	6 (21%)	39 (21%)	6 (13%)	5 (14%)
Cancer	58 (19%)	54 (20%)	4 (15%)	36 (19%)	10 (17%)	7 (24%)	38 (20%)	7 (16%)	7 (19%)
Infection	36 (12%)	31 (11%)	5 (19%)	23 (12%)	9 (16%)	4 (14%)	22 (12%)	7 (16%)	4 (11%)
Other	29 (10%)	28 (10%)	1 (4%)	20 (10%)	4 (7%)	3 (10%)	23 (12%)	4 (9%)	2 (6%)
Organ/Muscle Failure	17 (6%)	16 (6%)	1 (4%)	10 (5%)	3 (5%)	1 (3%)	10 (5%)	3 (7%)	- (-)
Substance Abuse	14 (5%)	13 (5%)	1 (4%)	10 (5%)	2 (3%)	- (-)	6 (3%)	- (-)	7 (19%)
Lung Disease	11 (4%)	9 (3%)	2 (7%)	8 (4%)	2 (3%)	- (-)	7 (4%)	- (-)	3 (8%)
Hepatitis	10 (3%)	8 (3%)	2 (7%)	5 (3%)	3 (5%)	1 (3%)	3 (2%)	- (-)	5 (14%)
Behavioral Health	6 (2%)	5 (2%)	1 (4%)	5 (3%)	1 (2%)	- (-)	4 (2%)	1 (2%)	- (-)
Diabetes	5 (2%)	5 (2%)	- (-)	2 (1%)	- (-)	1 (3%)	3 (2%)	2 (4%)	- (-)
Neurological Disease	3 (1%)	3 (1%)	- (-)	3 (2%)	- (-)	- (-)	1 (1%)	- (-)	- (-)
Grand Total	302 (100%)	275 (100%)	27 (100%)	192 (100%)	58 (100%)	29 (100%)	186 (100%)	45 (100%)	36 (100%)

Table 1. Distribution of causes of death among PWH by sex, race, and risk status.

Conclusions: After adjudicating deaths, we determined that AIDS, cardiovascular disease, and cancer were the most common COD for PWH in care. We also found different proportions in COD based on sex, race, and risk status groups. Utility of such information can promote focused preventive measures including early screening, detection, and targeted reduction in comorbidities.

Epidemiology of HIV in the general population

New challenges to reduce HIV mortality in Mexico: epidemiological trends have changed

E. Bravo-Garcia[1], H. Ortiz-Perez[2], J.S. Bravo-Garcia[1], C. Magis-Rodriguez[3]

[1]Spectrum: Educación, Salud y Sociedad, AC, Mexico, Mexico, [2]Universidad Autónoma Metropolitana - Xochimilco, Departamento de Atención a la Salud, Mexico, Mexico, [3]Universidad Nacional Autónoma de Mexico, Departamento de Salud Pública, Mexico, Mexico

Background: Mortality is the best indicator for evaluating the impact of government actions to control the HIV/AIDS epidemic. From 2008 to 2017 the HIV mortality in Mexico declined 22%. However, the recent data indicates a growing increase on mortality rates. The aim is to analyze the trend of HIV mortality in the last three decades in Mexico.

Methods: We computed Age Standardized Death Rates (ASDRs) per 100,000 population by sex, age, & social security status, using official mortality records (INEGI) and population estimates (CONAPO). To analyze trends in HIV mortality, JoinPoint regression analysis software was used.

Results: The most recent trend shows an increase in HIV mortality in the general population (**Annual Percent Change, APC=4.58**), as well as in men (APC=4.27) and **people with social security (APC=7.01)**. In contrast, in women and people without social security, HIV mortality decreased (fig 1).

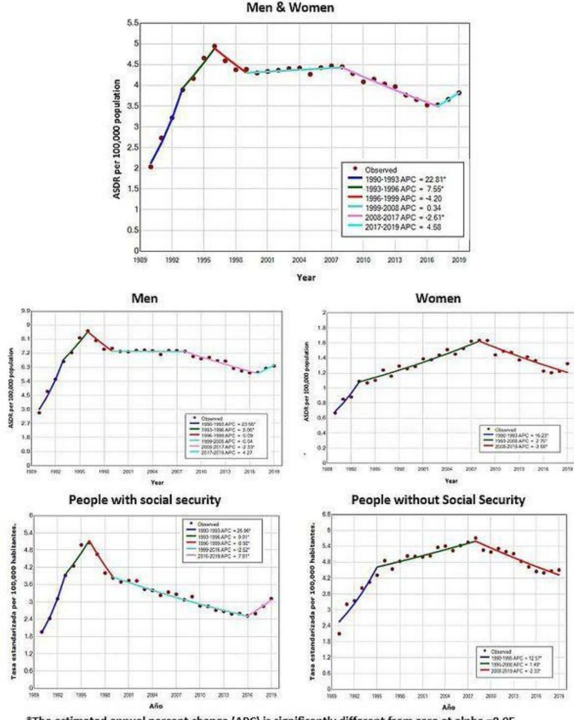

Figure 1. HIV/AIDS mortality by sex and social security status, Mexico, 1990-2019

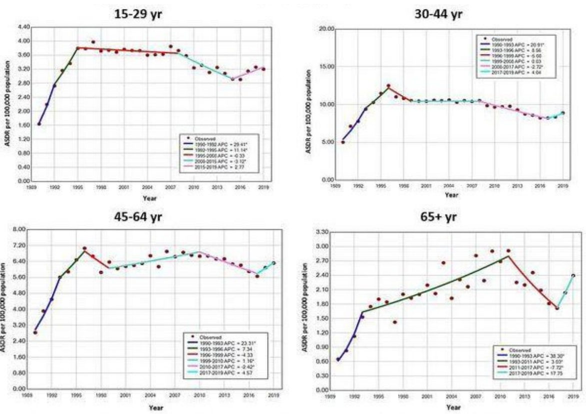
By age, HIV mortality increased in all groups: 15-19 yr (APC=2.77); 30-44 yr (APC=4.04); 45-64 yr (APC=4.57); and 65+ yr (APC=17.71) (fig 2). Although not all increases are statistically significant, there are an upward trend (fig 2).



*The estimated annual percent change (APC) is significantly different from zero at alpha =0.05

Figure 2. HIV/AIDS mortality by age groups, Mexico, 1990-2019

Conclusions: The declining of HIV/ AIDS mortality in Mexico has been reversed in last years. The huge gaps in the timely detection of HIV in key populations, coupled with a significant shortage of antiretroviral drugs and patient monitoring, have led to an increase mortality in several groups. For a country with free and universal access to HAART, it is unacceptable. It is urgent to change course and return to the best practices that had worked.

EPC009

Change in body weight after substituting efavirenz for dolutegravir in adults living with HIV in Johannesburg, South Africa

A.T. Brennan[1,2,3], C. Nattey[3], S. Rosen[1,3], M. Maskew[3], M.P. Fox[1,3,2], A. Stokes[1], W.D. Venter[4]

[1]Boston University School of Public Health, Department of Global Health, Boston, United States, [2]Boston University School of Public Health, Department of Epidemiology, Boston, United States, [3]Health Economics & Epidemiology Research Office, Johannesburg, South Africa, [4]University of the Witwatersrand, Ezintsha, Johannesburg, South Africa

Background: With the introduction of the integrase strand transfer inhibitor dolutegravir (DTG) into antiretroviral therapy (ART), persons living with HIV (PLWH) in South Africa (SA) have an effective new treatment option. Previous research, comparing DTG-based ART regimens to efavirenz (EFV)-based ones, showed DTG was safe and effective, but flagged weight gain as a concern. Weight gain after starting ART in PLWH is common, but substantial weight gain may increase the risk of non-communicable chronic diseases and reduce life expectancy. We evaluated weight change in patients who substituted EFV for DTG in first-line ART regimens.

Methods: A matched cohort study in virally suppressed, adults living with HIV initiated onto tenofovir + lamivudine or emtricitabine + efavirenz between January 2010-December 2020 at Themba Lethu Clinic in Johannesburg, SA. Patients were propensity score matched 1:1 (those who stayed on EFV-containing regimen (unexposed): and those who substituted EFV for DTG (exposed)). To create the propensity scores, we predicted risk of substituting EFV for DTG using logistic regression. Predictor variables included gender, age, months on ART, first ART regimen and CD4 count. We used linear regression to assess the effect of substituting EFV for DTG on absolute and percent weight change 6-months after DTG substitution.

Results: 276 unexposed patients were matched to 276 exposed patients. Patients that remained on EFV maintained their exact weight (median 69.8kg; (IQR): 61.0-80.3kg), while those on DTG increased from a median of 68.9kg (IQR: 59.3-83.7kg) to 72.0kg (IQR: 61.6-85.5kg) by 6-months post substitution of EFV for DTG. Linear regression results show a mean change in weight of 2.7kg (95%CI: 2.0-3.4kg) and a 4.0% (95%CI: 2.5-5.5%) mean increase in weight when comparing patients substituting EFV for DTG to those who remained on EFV. We also found that females, younger patients, those with lower CD4 counts and those on ART for longer had a higher mean absolute and percent weight change.

Conclusions: PLWH on ART gained more weight after substituting EFV for DTG than did those remaining on EFV. Future studies with longer-term follow-up are needed to confirm these findings in larger cohorts and investigate the effects of cardiometabolic disease risk factors.

Liberia adherence and loss-to-follow-up in HIV and AIDS care and treatment

K.L. Gray[1,2], M. Kiazolu[1], J. Jones[1], A. Konstantinova[3], J. Zawolo[2], W.-m. Harmon-Gray[2], N. Walker[4], M. Odo[5], J. Garbo[1], S. Caldwell[1], N. Bhadelia[6], J. DeMarco[7], L. Skrip[2]

[1]Ministry of Health, National AIDS and STI Control Program, Monrovia, Liberia, [2]University of Liberia, School of Public Health, Monrovia, Liberia, [3]Evidence Action, Washington DC, United States, [4]Liverpool School of Tropical Medicine, Clinical Sciences, Liverpool, United Kingdom, [5]FHI 360, Monrovia, Liberia, [6]Boston University, Center for Emerging Infectious Diseases Policy and Research, Boston, United States, [7]University of North Carolina, Charlotte, United States

Background: Retaining patients on antiretroviral therapy (ART) has been a major challenge for many national HIV programs in resource-limited settings. We estimate the retention rates of patients along the HIV care cascade in Liberia and identify factors associated with loss-to-follow-up (LTFU), death, and suboptimal treatment adherence.

Methods: We conducted a nationwide retrospective cohort study utilizing facility- and patient-level records. Patients aged ≥15 years, first registered in HIV care from January 2016 – December 2017 at 28 facilities were includ-

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

ed. We used Cox proportional hazard models to explore associations between demographic and clinical factors and the outcomes of LTFU and death, and a multinomial logistic regression model to investigate factors associated with suboptimal treatment adherence.

Results: Among the 4185 records assessed, 27.4% (n=1145) were males and the median age of the cohort was 37 (IQR: 30-45) years. At 24 months of follow-up, 41.8% (n=1751) of patients were LTFU, 6.6% (n=278) died, 0.5% (n=21) stopped treatment, 3% (n=127) transferred to another facility and 47.9% (n=2008) were retained in care and treatment.

The incidence of LTFU was 46.0 (95% CI: 40.8 – 51.6) per 100 person-years. Relative to patients at WHO clinical stage I at first treatment visit, patients at WHO clinical stage III [adjusted hazard ratio (aHR) 1.59, 95%CI: 1.21 – 2.09] or IV (aHR 2.41, 95%CI: 1.51 – 3.84) had increased risk of LTFU; whereas at registration, age category 35 – 44 years (aHR 0.65, 95%CI: 0.44 – 0.98) and ≥45 years (aHR 0.60, 95%CI: 0.39 – 0.93) had a decreased risk.

For death, patients assessed with WHO clinical stage II (aHR 2.35, 95%CI: 1.53 – 3.61), III (aHR 2.55, 95%CI: 1.75 – 3.71), and IV (aHR 4.21, 95%CI: 2.57 – 6.89) had an increased risk, while non-pregnant females (aHR 0.68, 95%CI: 0.51 – 0.92) and pregnant females (aHR 0.42, 95%CI: 0.20 – 0.90) had a decreased risk when compared to males. Suboptimal adherence was strongly associated with the experience of drug side effects – poor adherence (aOR 1.75, 95%CI: 1.11– 2.76).

Conclusions: Loss-to-follow-up and poor adherence remain major challenges to achieving viral suppression targets in Liberia. Active support and close monitoring of patients who have signs of clinical progression and/or drug side effects could improve patient outcomes.

EPC011

Geographic and population distributions of HIV-1 and HIV-2 subtypes: a systematic literature review and meta-analysis (2010-2021)

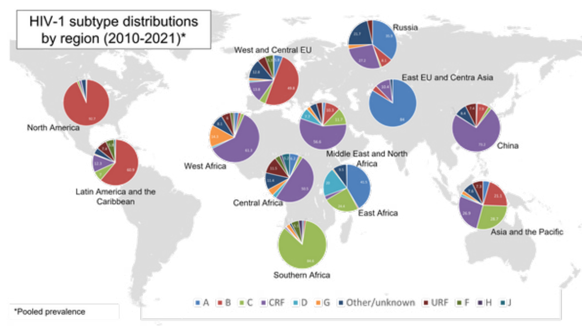
A. Williams[1], S. Menon[1], N. Bbosa[2], M. Crowe[1], N. Agarwal[1], J. Biccler[1], F. Adungo[3], D. Ssemwanga[2], C. Moecklinghoff[3], M. Macartney[3], V. Oriol-Mathieu[3]

[1]P95 Epidemiology & Pharmacovigilance, Leuven, Belgium, [2]Medical Research Council (MRC)/Uganda Virus Research Institute (UVRI) and London School of Hygiene and Tropical Medicine (LSHTM) Uganda Research Unit, Entebbe, Uganda, [3]Janssen Vaccines & Prevention B.V, Leiden, Netherlands, the

Background: Two types of HIV (1 and 2) are in circulation, with HIV-1 by far responsible for most infections. One major barrier to developing a safe and effective vaccine is the genetic diversity of HIV-1 subtypes within populations and across regions. This limits the coverage of both humoral and cellular immune responses to HIV-1 strains selected in vaccine candidates. Prophylactic vaccine development requires up-to-date knowledge of subtype diversity within populations and geographically. This review synthesized recent literature on the distribution of HIV-1 and HIV-2 subtypes.

Methods: We searched PubMed, EMBASE, and CABI Global Healthfor peer-reviewed publications reporting HIV-1 or HIV-2 subtype prevalence data between January 2010 and June 2021. We included publications in any language across all regions and in any population, irrespective of age, gender, ethnicity, CD4 count, viral load, ARV treatment regimen, or coinfections. Only data collected from 2010 onwards was included. HIV subtype data were grouped at regional and country levels, and across risk groups over time. We assessed risk of bias using an adapted Newcastle-Ottawa scale for cross-sectional studies.

Results: A total of 454 studies across 91 countries were included. Circulating recombinant forms (CRFs) accounted for 32.4% (29.0 - 35.7) of all circulating HIV-1, followed by subtype B (22.8% [19.5 - 26.2]), then C (13.1% [9.9 - 16.6). Most papers reporting risk group subtype breakdowns (n=171) focused on MSM (41%), followed by people who inject drugs (PWIDs) (29%). Among MSM and PWIDs, 52.8%(46.3 - 58.8)and 28.9% (18.2 - 39.7) of HIV infections were CRFs, respectively.



Conclusions: The HIV subtype distribution from this review generally follows those seen in previous reviews, with a high prevalence of CRFs. We found that reporting of HIV-2 data is often scarce. Other than MSM, PWIDs, and sex workers, there is little subtype reporting on other risk groups.

EPC012

Gender differentials in syphilis incidence by HIV status in a prospective rural and urban cohort study in Uganda

R. Bulamba Malyabe[1], G. Nakigozi[2], A. Miller[3], A. Mia Ekström[4], F. Nalugoda[5], E. Kyasanku[6], S. Mugamba[7,8], G. Nalwoga Kigozi[9], J.a. Katarina[4], Z. Leo[4], C. Fredrik Sjoland[4], J. Nkale[2], S. Watya[2], G. Kigozi[2], J. Wagman[10]

Background: Information on burden and incidence of syphilis in sub-Saharan Africa in the era ofantiretroviral therapy forHIV treatment and scale up of pre-exposure prophylaxis for HIV prevention is generally lacking.
We analyzed the prevalence and incidence of syphilis by gender and HIV status, in a prospective rural and urban cohort study in Uganda and explore associations between syphilis and HIV status.
Methods: We analyzed longitudinal data from 4,519 people in the AMBSO Population Health Surveillance Cohort Study, for the period 2018 to 2020 in Wakiso and Hoima districts, Uganda. We collected Socio-demographic data and established HIV and syphilis status for consenting participants aged 13-80 years. Syphilis testing was done using Treponema pallidum test. Incident syphilis was stratified by HIV status, key demographics.
A generalized linear regression model was performed to determine the association between syphilis, HIV and other covariates.
Results: A total of 4,519(2,034 (45%) male, 2,485 (55%) female); was analyzed mean age 30.4 years (SD=13.8)). At baseline, HIV and syphilis prevalence was 7.5% and 7%, respectively. Syphilis prevalence among People living with HIV (PLWH) was three times higher compared to HIV negatives (18% vs 6%, p<0.001).
The incidence rate of syphilis at follow-up (26/1,000 persons, overall) was significantly higher among PLWH (69/1,000, 95% CI=12.9-21.6) compared to those without HIV (17/ 1,000, 95% CI=16.4-25.7).
This was consistent among both males and female (male PLWH: male PLWH, (81/1,000 persons, 95% CI=36.4-180.3) vs male HIV-(18 per 1,000 persons, 95% CI=12.3-25.6); Female HIV+ (64 per 1,000 persons, 95% CI=37.4-110.8) vs female HIV- (29 per 1,000 persons).
After controlling for age, sex and location, persons living with HIV were 3 times more likely to be syphilis positive (95% CI=1.9-3.6) than HIV- persons.
Conclusions: In this large population-based cohort, the prevalence and incidence of syphilis was consistently higher among PLWH, underscoring the importance of integrating routine syphilis screening, prevention education and treatment into HIV care and antenatal care services for HIV+ to prevent congenital transmission. Partner testing, notification and treatment for syphilis should also be prioritized to prevent reinfection.

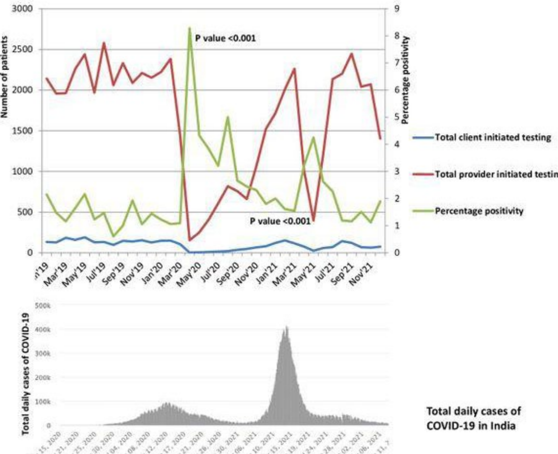
EPC013

Profile of attendees at integrated counselling and testing centre for HIV testing at a tertiary care hospital in India during the COVID-19 pandemic

P. Srivastava[1], A. Bhargava[1], S. Muralidhar[1], N. Khunger[1]
[1]Vardhman Mahavir Medical College and Safdarjung Hospital, Department of Dermatology & STD, New Delhi, India

Background: The ongoing COVID-19 pandemic has severely impacted health care delivery to non-COVID-19 diseases. This study was undertaken to gauge the impact of COVID-19 pandemic on HIV-ICTC clinic attendees at a tertiary care hospital.
Methods: Retrospective observational study was carried out at HIV-ICTC centre at Safdarjung Hospital, India, wherein data of all the cases undergoing HIV testing and counselling from January-2019 to December-2021 was reviewed. The data was statistically analysed for changing trends and profile of HIV testing during the COVID-19 pandemic.
Results: During the study period, 62,809 people underwent testing for HIV, of which 5.5% were client-initiated while 94.5% were provider-initiated. Positivity was 1.69%. There was a statistically significant drop in total testing during both waves of COVID-19 along with corresponding appreciable increase in HIV positivity.
More older people underwent provider-initiated testing ($p<0.001, \chi^2=360.9$, df-1) whereas transgender experienced significantly more client-initiated testing ($p<0.001, \chi^2=163.3$, df-1).
The most common route of transmission was heterosexual exposure. Sero-concordance was 47.4% among partners of HIV-positive patients.

		Total tested	HIV Positive	p-Value
Referral	Client initiated	3477	94(2.70%)	P<0.001,x²-20.95,df-1
	Provider initiated	59332	970(1.63%)	
Sex	Male	33144	798(2.40%)	P<0.001,x²-163.3,df-1
	Female	29641	266(0.89%)	
	Transgender	24	10(41.66%)	
Age group	</= 24yrs	19516	190(0.30%)	P<0.001,x²-360.0,df-1
	25-34yrs	18452	393(2.12%)	
	35-49yrs	14177	353(2.48%)	
	>/=50yrs	10667	123(1.15%)	



Conclusions: The shift of resources towards COVID-19 and implementation of social confinement measures, limited the testing for HIV. The provider initiated testing played a pivotal role during that time as seen by spikes in positivity rates.

The key to control HIV in a population lies in prevention and early testing. Success of information, education and communication (IEC) activities is reflected in more client initiated testing in young people and high risk groups like transgender. This study reinforces the importance of IEC strengthening HIV prevention and control programme.

EPC014

HIV incidence among non-migrating persons following a household migration event: a population-based, longitudinal study in Rakai, Uganda

R. Young[1], J. Ssekasanvu[1], F. Nalugoda[2], J. Kagaayi[2], R. Ssekubugu[2], G. Kigozi[2], S.J. Reynolds[3], L. Nelson[4], M.J. Wawer[1], B.A.S. Nonyane[1], L.W. Chang[5], C. Kennedy[1], L. Paina[1], P.A. Anglewicz[1], D. Serwadda[6], M.K. Grabowski[5]

[1]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [2]Rakai Health Sciences Program, Kalisizo, Uganda, [3]National Institute for Allergy and Infectious Diseases, Bethesda, United States, [4]Centers for Disease Control and Prevention, Kampala, Uganda, [5]Johns Hopkins School of Medicine, Baltimore, United States, [6]Makerere University School of Public Health, Kampala, Uganda

Background: How migration impacts HIV incidence among non-migrating household members is poorly understood. Here, we measure HIV incidence among non-migrants living in households with and without migration in Rakai, Uganda.

Methods: We used four survey rounds of data collected during July 2011–May 2018 from non-migrant participants 15–49 years in the Rakai Community Cohort Study, an open, population-based cohort. Non-migrants were defined as those with no evidence of migration between surveys or at the prior survey.

The primary exposure was a household migration event occurring assessed from census data among all household members irrespective of age. Migrant households were those with ≥1 member moving into or out of the household from another community between surveys (~18 months) with the intention to stay. Incident HIV cases tested positive following a negative result at the preceding visit.

Incidence rate ratios with 95% confidence intervals were estimated using multivariate Poisson regressions with generalized estimating equations and robust standard errors.

We stratified analyses by gender, migration into or out of the household, and the relationship between non-migrants and migrants (i.e., spouse, child).

Results: In total, 11,318 non-migrants (5,674 women) were followed for 37,359 person-years. 28% (6,059/21,370) of non-migrant study visits reported migration into or out of the household, and 240 HIV incident cases were identified. Overall, non-migrants in migrant households were not at greater risk of acquiring HIV (Table 1).

However, in stratified analyses, HIV incidence among men was significantly higher where the spouse had recently migrated in (adjIRR:2.12; 95%CI:1.05-4.27) or out (adjIRR:4.01; 95%CI:2.16-7.44) compared to men with no spouse migration. Women with in- and out-migrant spouses also had non-statistically significant higher HIV incidence.

[c]Compared to spouses with non-migrating spouses
[d]Adjusted for age category, education, study round, fishing or inland community and marital status for non-spouse regressions.

Table 1: HIV incidence rate ratios for men and women

Conclusions: HIV incidence was higher among non-migrating persons with migrant spouses, especially men. Targeted HIV prevention interventions should be directed towards individuals with a spouse who recently moved into or out of the household.

Epidemiology of HIV in women

EPC015
HIV and syphilis sentinel surveillance for pregnant women attending antenatal clinics in Tanzania: a national survey based on data from routine PMTCT HIV services

J. Mushi[1], P. Faustine[1], B. Mutayoba[1], V. Sambu[1], W. Maokola[1], M. Mizinduko[2], B. Sunguya[2], E. Mboya[2], M. Nyamuhagata[3], D. Kajoka[3]
[1]MOH, HIV/AIDS Control Program, Dodoma, Tanzania, The United Republic of, [2]MUHAS, Epidemiology, Dar es Salaam, Tanzania, The United Republic of, [3]MOH, PMTCT, Dodoma, Tanzania, The United Republic of

Background: Despite the prevalence of HIV declining, women are still disproportionately affected than men with prevalence of 6.2% vs. 3.2%. Syphilis also still poses a dire threat especially during pregnancy. Tracking the HIV epidemic in terms is paramount in efforts to eliminate the infection by 2030. The WHO guidelines advocate for conducting HIV surveillances using routinely collected PMTCT programme data in surveillances.
However, there have been gaps in reporting these results. Thus, we aimed to establish the HIV and syphilis prevalence among antenatal clinic attendees and measure reliability of routine PMTCT data to be used as an alternative data-source for national estimates.

Methods: We conducted a cross sectional survey to women >=15 years attending ANC for the first time in their current pregnancy between September and December 2020. The survey involved 159 sites that provides PMTCT services from all 26 regions. HIV and syphilis testing was done using an HIV-Syphilis Duo Kit. Dried blood spots were prepared from all who happened to be HIV positive or with indeterminate results; and from 5% of those with HIV negative results. The DBS were tested using ELISA. Retrospective data quality assessment was conducted to assess quality of routine PMTCT program data.
Results: Of the 39,516 eligible women 98.1% consented to participate and had their HIV and syphilis results. The overall prevalence was 6.3% for HIV and 1.5% for syphilis. A total of 173 (0.4%) participants had HIV and syphilis co-infection. Nearly two third (73.6%) of HIV positive mothers knew their HIV positive status and 93% of the known HIV infected pregnant women were on ART.
Agreement between positives results was at 93.7% and 82.1% (k = 0.66) for negative results. Data quality assessment revealed low completeness (76.3%) in some varibles. Overall validity of data was 89%.
Conclusions: HIV prevalence is still high among pregnant women indicating the disproportion impact of the infection when compared with men. The prevalence of syphilis is at alarming levels and needs an urgent intervention. Quality of HIV testing in ANC facilities needs closer monitoring. Data quality at ANC facilities needs improvement.

EPC016
Low birth weight among infants born to women living with HIV and HIV-uninfected women at CA-IeDEA sites in Rwanda

N. Zotova[1], A. Munyaneza[2], D. Watnick[3], G. Murenzi[2], G. Kubwimana[2], A. Adedimeji[4], K. Anastos[1], M. Yotebieng[1]
[1]Albert Einstein College of Medicine, Division of General Internal Medicine, New York, United States, [2]Rwanda Military Hospital and Research for Development (RD Rwanda), Kigali, Rwanda, [3]Albert Einstein College of Medicine, Pediatrics, New York, United States, [4]Albert Einstein College of Medicine, Department of Epidemiology & Population Health, New York, United States

Background: In utero exposure to HIV or to HIV and triple antiretroviral therapy (ART) are associated with preterm births and low birthweight babies (LBW). Yet, in this era of universal ART for pregnant women living with HIV (WLWH), data on pregnancy outcomes among WLWH remain limited. In this study, we describe pregnancy outcomes and assess predictors of LBW among WLWH and HIV-uninfected women.
Methods: Data from antenatal care, delivery and PMTCT registries from women, who gave birth between 2012 and 2020 at the International Epidemiology Database to Evaluate AIDS (IeDEA) sites in Rwanda, were retrospectively extracted and linked.

Oral abstracts

Poster exhibition

E-posters

The sample was restricted to women tested for HIV at admission to maternity clinics with documented pregnancy outcomes: stillbirth, preterm birth (gestational age <37 weeks), and LBW (<2500g).

For our primary outcome (LBW), we restricted our sample to singleton term births and used logistic regression models to compare LBW among WLHW and HIV-uninfected women, adjusting for significantly associated predictors, to estimate odds ratios (aOR) and 95% confidence intervals (CI).

Results: Among 11,312 women, 9.5% (n=1,079) were WLWH, 0.8% (n=90) had a stillbirth and 0.5% (n=46) had multiple births. Of 10,529 single live births, 0.7% (n=70) were preterm. Of 10,459 term births, 3.2% (n=332) were LBW including 4% (n=40) among WLWH and 3.1% (n=292) among HIV-uninfected women. In a multivariable model that included mother's age, weight, marital status, primigravida status, andHIV status, positive HIV status was associated with higher odds of LBW (aOR 1.45, 95% CI 0.83, 2.52) as was primigravidae (aOR 2.17, 95% CI 1.47, 3.21). Women's greater weight was associated with lower odds of LBW ([60-64 kg vs. <60 kg: aOR 0.5, 95% CI 0.32, 0.76] and [65+ kg vs. <60 kg: aOR 0.48, 95% CI 0.32, 0.71]).

Conclusions: Even in this era of universal ART during pregnancy, WLWH remain more likely to have LBW term babies. Lower maternal weight was also independently associated with LBW, suggesting supplementary nutrition to pregnant WLWH might help reduce LBW risk especially among primigravidae women.

Acknowledgements: This work was supported by NIAID, NICHD, NCI, and NIDA, as part of Central Africa IeDEA (U01AI096299).

EPC017

Mental health impacted antiretroviral therapy adherence among Brazilian cisgender and transgender women during the COVID-19 pandemic

E. Mesquita Peixoto[1,2,3], T. S. Torres[2], E. M. Jalil[2], R. Khalili Friedman[2], C. B Cunha[2], M. Ramos[2], V.M. de Azevedo Oliveira Knupp[4], C. Moreira Jalil[2], L. Machado de Mello Andrade[1], C.R. Vinissius de Castro[1,2], R. de Mattos Russo Rafael[5], V. G. Veloso[2], L. de Souza Velasque[1], B. Gilda Jegerhorn Grinsztejn[2]

[1]Federal University of the State of Rio de Janeiro, Rio de Janeiro, Brazil, [2]Oswaldo Cruz Foundation, INI/LAPCLIN-AIDS, Rio de Janeiro, Brazil, [3]OMS/OPAS, Rio de Janeiro, Brazil, [4]Federal Fluminense University, Rio de Janeiro, Brazil, [5]University of the State of Rio de Janeiro, Department of Public Health, Rio de Janeiro, Brazil

Background: Brazil was the country most affected by the COVID-19 pandemic in Latin America. Social distancing recommendations increased loneliness and mental health issues, including increased substance use, which could have impacted antiretroviral therapy (ART) adherence among people living with HIV. We aimed to evaluate self-reported ART non-adherence and its predictors among cisgender and transgender women living with HIV in Rio de Janeiro, Brazil, during social distancing period.

Methods: Cross-sectional study nested to an open, clinic-based cohort of women living with HIV (WLWH), aged 18+ years who started ART before the COVID-19 pandemic onset. Trained interviewers used structured questionnaires to collected data through telephone calls between May-July/2020. We used the Brazilian Portuguese version of UCLA Loneliness Scale (20-items, range: 0-60) to measure one's subjective feelings of loneliness and social isolation; participants with scores >36 had severe loneliness. Self-reported ART non-adherence was defined as missing at least one dose since social distancing initiation (March/2020). We used multivariate logistic regression models to evaluate predictors of self-reported ART non-adherence. Covariables were age, gender, race, monthly *per capita* income, severe loneliness, increased alcohol use during social distancing, social distancing level, current sex work and physical violence. Initial multivariate models included variables with p<0.1 in bivariate analyses and only variables with p<0.05 were retained in final multivariate model.

Results: Among 620 women enrolled (538 [86.8%] cisgender; 82 [13.2%] transgender), median age was 48 years (interquartile range:40-55), 406 (65.9%) were Black or *Pardo*/Mixed, 478 (77.0%) had an income <U$200.00, 171 (27.6%) reported complete adherence to social distancing recommendations, 24 (3.9%) were currently sex-works, and 119 (19.2%) reported physically violence during social distancing. Severe loneliness was present in 52 (8.6%); 26 participants (4.2%) reported increased alcohol use.

Only 19 (3.1%) women reported ART non-adherence between March-July/2020. Increased alcohol use (aOR=4.8 [95%CI=1.02-16.57) and severe loneliness (aOR=5.27 [95%CI=1.76-14.21]) were associated with increased odds of ART non-adherence.

Conclusions: Social distancing recommendations interfered in loneliness experience and alcohol use among Brazilian WLWH in a short-term period. Strategies tailored to WLWH with higher scores of loneliness and increased alcohol use could support ART adherence. There is an urgent need to identify long-term impacts of the COVID-19 epidemic on the care cascade continuum of WLWH in resource-constrained settings.

EPC018

Cross-generational sexual relationships as a potential predictor of HIV infection in Zambia 2018 – a cross sectional study

J. Zulu[1], N. Sinyange[1], Z. Jessy[2], M. Charles[2]
[1]*Zambia National Public Health Institute, Work Force Development, Lusaka, Zambia,* [2]*University of Zambia, Public Health, Lusaka, Zambia*

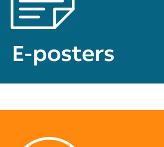
Background: The number of new HIV infections amongst adolescent girls and young women (AGYW) in sub- Saharan Africa (SSA) remains high. In the 2013–2014 Zambia Demographic and Health Survey (ZDHS), 7.2% of sexually active adolescent girls reported having sexual intercourse with men 10 or more years older than them, a 60% increase from the 2007 ZDHS.
We sought to describe cross-generational sexual relationships as a potential predictor of HIV infection in adolescent girls and young women in Zambia.
Methods: We employed a cross-sectional quantitative approach using the 2018 ZDHS data. AGYW aged 15 to 24 years that responded to questions on cross-generational sexual relationships were sampled. Frequencies of the selected variables were calculated, followed by univariate logistic regression. Significant variables, at P-value of 0.05 and 95% confidence interval, together with priori variables were fitted into a multivariable logistic regression. STATA software, version 14.0 SE was used for analysis.
Results: A total of 737 AGYW aged 15- 24 years were sampled for this study. The median age was 21 years (IQR=18-23). Most resided in urban areas (75.8%) and had no or primary education (61.9%). Crude odds ratios showed AGYW who had attained secondary and tertiary education had 20% reduced odds of engaging in cross-generational sex compared to those with primary or no education.
Key Predictors of cross-generation sex included having ever been tested for HIV [AOR=0.6; 95% CI 0.36-0.89; P=0.013], age at sexual debut [AOR=3.6; 95% CI 1.04-12.18; P=0.043] and total number of sexual partners [AOR=0.6; 95% CI 0.45- 0.91; P=0.014].
Conclusions: These findings call for improved packaging of messages on HIV testing, counselling and prevention services. There's need to promote equity and access to education for AGYW in order to empower them with information on safe sex practices. Inclusion of some biomedical interventions such as pre-exposure prophylaxis (PrEP) among AGYW is also needed.

EPC019

PrEP roll out to pregnant women attending MCH clinics in Northern, Luapula & Muchinga provinces in Zambia

T.M.M. Jere-Nonde[1]
[1]*Right to Care Zambia, Technical, Kasama, Zambia*

Background: HIV incidence is high in pregnant and breastfeeding women (PBFW), particularly in low-resourced sub-Saharan Africa. Oral pre-exposure prophylaxis (PrEP) can effectively reduce HIV acquisition in women during these periods and to mitigate this challenge, Right To Care Zambia (RTCZ) supports activities to eliminate Mother To Child Transmission of HIV in PBFW in Northern Zambia.
The objective for this abstract is to strengthen eMTCT, reduce mother to child transmission by following up during pregnancy and throughout the breastfeeding period.
Description: Sensitization is given during the Maternal Child Health clinics. Pregnant women are tested for HIV, if negative, they are offered PrEP and initiated if they accept. Initiated clients are followed up throughout pregnancy and breastfeeding period. The collection of this data started in FY20 Oct 2020 .Data was collected between OCT FY20 to March FY21. Pregnancy is the main inclusion criteria and the women needs to weigh ≥ 35kg to qualify for Truvada the drug used in PrEP. This programme is in rural Zambia. Women not empowered by education have difficulties in being assertive and make health decisions on their own.
Lessons learned: 830 PBFW were offered PrEP and 766 (92%) were eligible and 611 (80%) were initiated on PrEP during the reporting period. The programme started with 28 PBFW being initiated on PrEP in October 2020.
Data has shown that PBFW are more adherent to PrEP as a preventive method to their unborn child. There is strengthened integration of MCH and ART department resulting in accessibility of prevention services.
Pregnancy is an opportunity for some women to visit the health centre and opportunity to be offered PrEP. Women readily accept PrEP to protect their infant during pregnancy and breastfeeding.
Conclusions/Next steps: PrEP uptake in PBFW has improved in the Northern, Muchinga, and Luapula provinces of Zambia. MCH departments continued to function whilst adhering to Covid19 preventive measures. In April and May FY21 we saw 44% when compared to February 2021 a drop due to the rising numbers of COVID 19 cases, as observed in other indicators. It is recommended that screening for PrEP be extended to breastfeeding women as they attend Family Planning and Under-five clinics.



Epidemiology of HIV in infants and children

EPC020
The Mother-To-Child Transmission of HIV-1 and profile of viral reservoirs in pediatric population: a meta-analysis of the Cameroonian data

A.C. Ka'e[1,2], A.D. Nka[1,2], B. Yagai[1,2], I. Domkam Kammogne[3], E. Ngoufack Jagni Semengue[1,1], C. Nkenfou[1], M.C. Tommo Tchouaket[1], D. Takou[1], S.M. Sosso[1], N. Fainguem[1], A. Abba[1], W. Pabo[1], N. Kamgaing[1], F. Ceccherini-Silberstein[2], M. Mercedes Santoro[2], J. Fokam[1,4]
[1]*Chantal Biya International Reference Centre for Research on HIV/AIDS Prevention and Management (CIRCB), Virology, Yaounde, Cameroon,* [2]*University of Rome "Tor Vergata", Microbiology, Immunology, Infectious Diseases and Organ Transplantation, Rome, Italy,* [3]*Concern Worldwide, Niamey, Niger, the,* [4]*Faculty of Health Science, Virology, Buea, Cameroon*

Background: The mother-to-child transmission of HIV-1 (MTCT) remains on the major route of HIV-transmission among pediatric populations in Africa. Though a prevention of MTCT (PMTCT) high-priority country, data on the MTCT burdens in Cameroon remains fragmented. Our objective was to assess the pooled MTCT rate, its risk-factors, and to characterize viral reservoirs of infected-children in Cameroon.
Methods: All relevant observational cohort and cross-sectional studies conducted in Cameroon were searched from PubMed, African Journals Online, Google scholar, ScienceDirect and academic medical education databases. Heterogeneity and publication bias were respectively assessed by the I^2 statistic and the Egger/funnel plot test. Meta-analysis was performed using the random effects model. MTCT rate >5% was considered as "high". This review was registered in the Prospero database, CRD42021224497.
Results: We included a total of 29 studies and analyzed 46 684 children born from HIV-positive mothers. The overall rate of MTCT was 7.00% (95% CI = 6.07-8.51). According to regions, the highest burden was in Adamaoua-region (17.51% [95% CI:14.21-21.07]) with only one study found. PMTCT option-B+ resulted in about 25% reduction of MTCT (8.97% [95% CI: 8.71-9.24] without option-B+ versus 2.88% [95% CI: 5.03-9.34] with option-B+). Regarding risk-factors, MTCT was significantly associated with the absence of PMTCT-interventions both in children (OR:5.40 [95% CI: 2.58-11.27]) and mothers (OR: 3.59 [95% CI: 2.15-5.99]). Regarding viral reservoirs, a pro-viral DNA mean of 3.34±1.05 log_{10}/mL was observed among 5/57 children and archived HIV drug resistance mutations were identified in pro-viral DNA marker among 21/79 infected-children.
Conclusions: In spite of the dropdown in MTCT following option-B+ implementation, MTCT remains high in Cameroon, with substantial disparities across regions. Thus, in this era of option-B+, achieving MTCT elimination requires interventions in northern-Cameroon. Of note, MTCT was mostly driven by the sub-optimal PMTCT intervention among both mothers and child in the Cameroonian context. The variation in pro-viral load in infected-children underlines the relevance of characterizing viral reservoirs for possible infection control in tropical settings.

EPC021
Trends in pediatric HIV treatment continuity and the impact of COVID-19: a multi-country review of PEPFAR supported programs

A. Perez[1], R. Gunnala[1], I. Faturiyele[1], N. Buono[1], J. Thuku[1]
[1]*United States Agency for International Development (USAID), Global Health Bureau, Office of HIV/AIDS, Washington DC, United States*

Background: Globally, 1.7 million children currently live with HIV (CLHIV), and AIDS-related deaths are the highest cause of mortality. The COVID-19 pandemic has disrupted HIV services and impacted continuity of treatment (CoT). It is critical to characterize the COVID-19 pandemic's impact on CoT for CLHIV.
Methods: We analyzed routinely collected programmatic data for CLHIV on antiretroviral therapy (ART) from 25 USAID-supported PEPFAR countries.
We compared quarterly results across two 6-month periods before (October 2019 - March 2020; Fiscal Year 2020 [FY20] Q1 - Q2) and during (October 2020 - March 2021; FY21 Q1 - Q2) the COVID-19 pandemic for the following indicators: number/percentage of overall interruptions in treatment (IIT), number/percentage of IIT by time on ART, and number/percentage of overall returns to treatment (RTT).
Results were analyzed for all children <15 years old (y/o) and by fine age bands (1-4, 5-9, 10-14 y/o). Analyses were conducted in Microsoft Excel.
Results: The proportion of children who experienced IIT in both quarters during COVID-19 was higher than in comparable quarters pre-COVID-19.
Children on ART <3 months reported less IIT in quarters during COVID-19 relative to pre-COVID-19 quarters.
Children on ART for >3 months reported more IIT in quarters during COVID-19 compared to pre-COVID-19.
Children 1-4 y/o experienced higher frequency of IIT both before and during COVID-19 compared to 5-9 y/o and 10-14 y/o, despite increases in IIT for the older groups during COVID-19. See Table 1 below for a full description of results.
Conclusions: CoT for CLHIV on ART in 25 USAID/PEPFAR countries was negatively impacted during COVID-19. IIT remains the highest among CLHIV newly initiated on treatment. CLHIV aged 1-4 are the most vulnerable to IIT relative to older children. CoT is crucial for preventing morbidity/mortality in CLHIV and interventions targeting younger children who are newly initiated are of critical importance, particularly adaptations during the COVID-19 pandemic.

		IIT % (n)						RTT % (n)
		All Children <15 y/o	All Children <15 y/o on ART <3 months	All Children <15 y/o on ART >3 months	All Children 1-4 y/o	All Children 5-9 y/o	All Children 10-14 y/o	All Children <15 y/o
Pre-COVID-19	FY20Q1	3.0% (8,047)	15.24% (1,592)	2.52% (6,455)	6.1% (2,739)	2.5% (2,283)	2.1% (2,531)	2.88% (7,185)
	FY20Q2	2.57% (6,671)	8.08% (772)	2.37% (5,899)	4.02% (1,744)	2.53% (2,215)	2.04% (2,486)	3.35% (8,729)
During COVID-19	FY21Q1	3.55% (9,272)	7.42% (565)	3.43% (8,707)	4.79% (2,122)	3.48% (3,070)	3.11% (3,286)	3.04% (7,455)
	FY21Q2	2.85% (7,219)	7.74% (595)	2.70% (6,624)	3.94% (1,706)	2.81% (2,400)	2.45% (2,917)	3.25% (8,053)

Table 1. Comparison of IIT and RTT for CLHIV Pre and During the COVID-19 Pandemic

EPC022

Temporal trends of pediatric HIV infection due to mother-to-child transmission in the state of São Paulo - Brazil, 1987-2020

C.S.B. Domingues[1,2], Â. Tayra[1], M.C. Polon[1], A.L.C. Monteiro[1], S.M.Y. Takita[1], M.C. Gianna[1], A. Gonçalves[1], M.V. Tancredi[1]
[1]Health Secretariat of the State of São Paulo, STD/AIDS Reference and Training Center, São Paulo, Brazil, [2]University of São Paulo, Faculty of Public Health, São Paulo, Brazil

Background: In the State of São Paulo (SSP) the first cases of mother-to-child transmission of HIV (MTCT-HIV) occurred in 1987. The elimination of MTCT-HIV is close to achieve in the SSP since the implementation of ACTG-076 protocol and the others preventive measures. The aim of this study is to analyze trends in pediatric HIV infection due to MTCT-HIV in the SSP.

Methods: Trend study by polynomial regression, in three periods (1987-1997; 1998-2009; 2010-2020), using moving average (MA) of the incidence rate pediatric HIV infections due to MTCT (IR-MTCT-HIV). The dependent variable (Y) was the MA-IR-MTCT-HIV and the independent variable (X) was the time (year of birth). In order to avoid autocorrelation between the points, the time variable was centered through the midpoint of the historical series. The goodness-of-fit via r^2, analysis of residues and $p<0.05$ were used to determine which models and data were most appropriate. The IR-MTCT-HIV was estimated using the number of cases as the numerator, the population of live births (LB) as the denominator, and the ratio was multiplied by 100,000. The MA-IR-MTCT-HIV was calculated by adding the IR-MTCT-HIV of the three year and dividing by the total number of periods.

Results: There were 6,131 cases of pediatric HIV infections due to MTCT (1987-2020). In the first period, the IR-MTCT-HIV increased 3.9 times, from 15.92/100,000LB(1987) to 62.40/100,000LB(1997); in the second period it declined by 72.2%, from 52.28/100,000LB(1998) to 14.53/100,000LB(2009); in the third period the decline was 78.5%, from 10.14/100,000LB(2010) to 2.18/100,000LB(2020). For the period 1987-1997, an increasing trend in the MA-IR-MTCT-HIV was observed with first-order modeling [$Y=50.74+6.26X$; $r^2=0.98$;$p<0.001$]; however, for the second period (1998-2009) the trend was downward until 2005, stability until 2009 and a second-order modeling [$Y=18.20-3.63X+0.66$; $r^2=0.99$;$p<0.001$]. The third period (2010-2020) maintained a downward trend with first-order modeling [$Y=6.76-0.73X$; $r^2=0.91$;$p<0.001$].

Conclusions: The temporal trends of pediatric HIV infection showed the success of the Brazilian public policies. Interventions at different levels of maternal-child health care and at different moments in the life cycle, such as access to reproductive health care, antenatal care and delivery, diagnosis and treatment/prophylaxis are important to eliminate MTCT-HIV and to avoid AIDS development in children.

Epidemiology of HIV in adolescents

EPC023

Long-term virological treatment outcomes in adolescents and young adults living with HIV with perinatally and behaviourally acquired infection in the Netherlands

A. Weijsenfeld[1,2,1], C. Smit[3], F. Wit[3], T. Mudrikova[4], J. Nellen[2], M. van der Valk[3,5], D. Pajkrt[1]
[1]Amsterdam University Medical Centers, location AMC, Department of Paediatric Infectious Diseases, Emma Children's Hospital, Amsterdam, Netherlands, the, [2]Amsterdam University Medical Centers, location AMC, Department of Internal Medicine, Amsterdam, Netherlands, the, [3]Stichting HIV Monitoring, Amsterdam, Netherlands, the, [4]University Medical Centre Utrecht, Department of Internal Medicine, Utrecht, Netherlands, the, [5]Amsterdam University Medical Centers, University of Amsterdam, Department of Internal Medicine, Division of Infectious Diseases, Institute for Infection and Immunity, Amsterdam, Netherlands, the

Background: Long-term viral suppression on combination antiretroviral therapy (cART) is not established among all individuals living with HIV. Young adults (YA, aged 18-24 years) are recognised as a group vulnerable for suboptimal virological treatment outcomes.

The aim of this study is to evaluate longitudinal virological treatment outcomes and to identify risk factors for virological failure (VF) among YA with behaviourally (BPLWH) and perinatally (PPLWH) acquired HIV in the Netherlands.

Methods: We included adolescents and YA registered in the national ATHENA observational cohort from 2000 until 2020 who had entered care before the age of 25 years, who had received cART for at least six months with at least two available HIV RNA measurements between the age of 18 and 24 years.

To compare VF (two successive HIV RNA measurements >200 copies/ml) between age groups 12-17, 18-24 and 25-30, follow-up time was between the age of 12 and 30 years.

A multivariable generalized linear mixed model was used to evaluate risk factors for VF. Analyses were stratified by HIV acquisition mode.

Results: In total 1331 individuals were included (1174 BPLWH and 157 PPLWH, table 1). VF rates for the year 2020 were 7% in BPLWH YA and 19% in PPLWH YA. The adjusted risk of VF was significantly higher in the YA age group compared to the 25-30 age group for both BPLWH (OR: 1.27, 95% CI 1.07-1.50) as PPLWH (OR: 2.34, 95% CI 1.48-3.71)(table 2). Since the beginning of the follow-up, we observed a decrease in the risk of VF. In PPLWH, pre-treatment with mono-or dual therapy was associated with a higher risk of VF.

		BPLWH = individuals who acquired HIV behaviourally N = 1174 male gender: 762	PPLWH = individuals who acquired HIV perinatally N = 157 male gender: 80
Country or region of birth	Netherlands Sub-Saharan Africa Latin America/Caribbean Other	479 (40.8) 337 (28.7) 197(16.8) 161 (13.7)	79 (50.3) 56 (35.7) 11 (7.0) 11 (7.0)
HIV acquisition mode	MSM (men who have sex with men) Heterosexual MTCT (mother to child transmission) Other	579 (49.3) 505 (43.0) - 90 (7.7)	- - 157 (100) -
Age at diagnoses Age at cART initiation Nadir CD4+ T-cell count (cells/µl) VF ever (n/%) Cumulative time HIV RNA >200 (years)		20.8 (19.1-22.2) 21.6 (20.0-22.8) 300 (179-440) 495 (42.2) 0.9(0-12)	2.5 (0.6-6.4) 5.7 (2.3-10.00) 260 (74-415) 86 (54.8) 1.7(0-11)

EPC023 Table 1: Demographic and clinical characteristics of HIV-infected adolescents and young adults in the Netherlands (2000-2020)

Conclusions: Young adulthood is a vulnerable period, with increased risk for VF for both BPLWH and PPLWH. The risk of VF decreased over time and with aging. Interventions to support adherence in YA should take into account the possible specific developmental and psychosocial problems which drive non-adherence, as those might differ between risk groups.

EPC024
The NANI-Mental Health Project

I. Owolabi[1]

[1]*The Nigerian Business Coalition Against AIDS (NiBUCAA), Chief Executive Officer, Ijora Causeway, Nigeria*

Background: The overall disruption caused by COVID-19 has had a far-reaching impact on vulnerable people (women, young people, people living with HIV). It is in this light, that the NANI-Mental Health project was conceived. The project integrated mental health education and awareness into the existing Sexual Reproductive Health (SRH) and HIV/AIDS program for Adolescent and Young People (AYP) which leveraged trained and certified young graduates as Community Peer Educator Trainers (C-PETS) to reach out to AYP in community and schools.

The objectives of the project were:

- To strengthen the capacity of 12 Master Trainers as Mental Health mentors
- To improve the capacity of 300NANI Ambassadors on mental health and the New Normal

- To increase the knowledge of3,000 community-based Peer Educators on mental health-related topics

Description:

1. High-level advocacy to the leadership of the National Youth Service Corps (NYSC), Ministries of Health and Education to get their buy-in, collaboration and support.

2. Content Development for training manual

3. Capacity building for 12 Master Trainers on Mental Health

4. Sensitization & Capacity Building for NANI Ambassadors was conducted at 6 NYSC camps to inform corps members of the project and get their willingness to participate. During the sensitization, we directly reached 8,785 corps members with information on mental health, HIV/AIDS and Sexual Reproductive Health and trained 447 volunteer corps members as NANI - Mental Health Ambassadors.

5. Training of Peer Educators: NANI Ambassadors reached 3,266 in-school adolescents and young people within the ages of 13 – 17 years students across 17 schools in 6 Project States with information on HIV/AIDS, Sexual Reproductive Health and mental health topics such as Bullying in Schools, Peer Pressure, Learning to Identify and Understand Emotions and Self Compassion

6. Monitoring, evaluation and reporting of the project

Lessons learned:

- Insufficient knowledge on Guidance and Counselling (G&C) department in Secondary Schools on mental health
- Lack of mental health subjects in secondary school curriculum
- Limited research on mental health in Nigeria

Conclusions/Next steps:

1. Increase in mental health awareness which will spur conversations on mental health policy development and implementation

2. The need for investment in mental health and HIV research in Nigeria

EPC025

Adherence to antiretroviral therapy bymedication possession ratio and virological suppression among adolescents and young adults living with HIV on in Dar es Salaam, Tanzania: a retrospective cohort study

M. Amour[1], R. Sangeda[1], E. Balandya[1], L. Machumi[2], A. Rugarabamu[2], E. Aris[2], H. Ndumwa[1], E. Lyamuya[1], B. Kidenya[3], B. Mmbaga[4,5], B. Njiro[1], B. Sunguya[1]

[1]Muhimbili University of Health and Allied Sciences, Community Health, Dar es Salaam, Tanzania, The United Republic of, [2]Management and Development for Health, Dar es Salaam, Tanzania, The United Republic of, [3]Catholic University of Health and Allied Sciences, Mwanza, Tanzania, The United Republic of, [4]Kilimanjaro Christian Medical University College, Moshi, Tanzania, The United Republic of, [5]Kilimanjaro Clinical Research Institute, Moshi, Tanzania, The United Republic of

Background: Adherence to antiretroviral therapy (ART) is a strong determinant of virological suppression. We aimed to determine the magnitude of adherence as measured by medication possession ratio (MPR) as well as virological suppression, and its predictors among adolescents and young adults living with HIV on ART in Tanzania.

Methods: This retrospective cohort study was conducted using archived data from HIV care and treatment centers in Dar es Salaam, Tanzania between 2015 and 2019. Descriptive analyses were conducted to determine magnitude of adherence to ART and viral suppression. The logistic regression model assessed predictors for adherence and virological suppression.

Results: Data of 5,750 adolescents and young adults living with HIV was analysed. Of these, 1,697 (29.5%) were adolescents (aged 10-19) and 4,053 (70.5%) were young adults (aged 20-24). The majority were females; 4748 (82.6%). About 63% of adolescents and young adults on ART had good adherence with medication possession ratio of at least 85% at one year post ART initiation.Independent predictors ofART adherence were male sex, (aOR=1.3, 95% CI 1.1–1.5), CD4 >500 cells/mm^3; (aOR=0.7, 95% CI: 0.6-0.9); WHO stage III (aOR=1.6, 95% CI 1.3–1.9), and enrollment in 2019 (aOR=1.5, 95% CI 1.2–1.9). Predictors of virological suppression were MPR≥85% (aOR=2.0, 95% CI 1.6–2.4); CD4 >500 cells/mm^3 (aOR=2.4, 95% CI 1.7–3.4) and once-daily dosing (aOR=2.0, 95% CI 1.3–2.5).

Conclusions: Adherence to ART among adolescents and young adults living with HIV is suboptimal. Gender and immunological status at ART initiation are important predictors of adherence to ART and virological suppression.

HIV testing services (HTS) among clients 13-14 years old in recent infection surveillance, Malawi 2019-2020

A. Zheng[1,2], Z. Tessema[1,2], J. Theu[3], F.F. Bangara[3], A. Ernst[4], G. O'Malley[5], C. Blair[5], T. Dobbs[1], V. Shanmugam[1], A. Kabaghe[6], N. Wadonda-Kabondo[6], G. Bello[3,7], S. Hrapcak[1], H. Dale[1], A. Auld[6], E. Yufenyuy[1], E. Kim[6], D. Payne[6], M.M. Arons[1]

[1]*Centers for Disease Control and Prevention, Division of Global HIV and Tuberculosis, Center for Global Health, Atlanta, United States,* [2]*Public Health Institute/Centers for Disease Control, Global Health Fellowship Program, Oakland, United States,* [3]*International Training and Education Center for Health (I-TECH), Department of Global Health, University of Washington, Lilongwe, Malawi,* [4]*Global Strategic Information, Institute for Global Health Sciences, University of California, San Francisco, United States,* [5]*International Training and Education Center for Health (I-TECH), Department of Global Health, University of Washington, Seattle, United States,* [6]*Centers for Disease Control and Prevention, Division of Global HIV and Tuberculosis, Center for Global Health, Lilongwe, Malawi,* [7]*Ministry of Health, Lilongwe, Malawi*

Background: Rapid tests for recent infection (RTRIs) and viral load (VL) testing comprise a recent infection testing algorithm (RITA) to characterize newly diagnosed HIV-1 infections as recent (≤12 months) or long-term. RTRI recent with VL≥1,000 copies/mL indicates RITA recent. Recent infection surveillance guidance recommends testing clients aged 15+. In Malawi, clients≥13 years can access HTS independently and are included in recent infection surveillance.

We reviewed Malawi's recent infection data to describe newly HIV diagnosed 13-14 year-olds and their impact on recent HIV surveillance, detection, and response.

Methods: Recent infection data was pooled from 155 facilities in 11 districts implementing from April 2019-April 2020. Clients reporting ART usage, previous HIV diagnosis, or had a VL<1,000 copies/mL were excluded.

Among 13-14 year-olds, we calculated proportions of RITA recent infections compared to those aged 15+, described their demographics, HTS modality, and previous testing history.

Results: Of 15,032 newly diagnosed clients, 78 (0.5%) were 13-14 year-olds, of which one (1.3%, 95% Wilson Score CI: 0.2%, 6.9%) was RITA recent, accounting for 0.2% of all 519 RITA recent infections. Comparatively, among clients≥15 years, 3.5% (518/14,954) were RITA recent.

Among 13-14 year-olds, 49 (62.8%) were female, 3 (6.1%) were pregnant, and one (2.0%) was breastfeeding at time of diagnosis. Fifty-eight (74.4%) reported no previous testing history; 20 (25.6%) reported previous negative results, of whom 18 (90.0%) reported their negative result >1 year ago. Fifty-two (66.7%) accessed HTS at voluntary counseling and testing, 12 (15.4%) at outpatient departments, 4 (5.1%) at youth clinics, and 10 (12.8%) via other modalities. Forty-two (53.8%) were diagnosed in rural settings and 49 (62.8%) at primary facilities.

Conclusions: Results suggest the proportion of clients aged 13-14 with recent HIV infection is unlikely to meaningfully contribute to recent HIV surveillance, detection, and response. Per self-report, clients were unlikely to access HTS prior to diagnosis and were primarily accessing testing and being diagnosed at primary care facilities. Age of sexual debut and testing consent may be considered when deciding to include younger ages in recency surveillance. Younger adolescents with recent infections, particularly those pregnant and breastfeeding, may face additional vulnerabilities and should be linked to psychosocial support.

Background: Adolescent men who have sex with men (aMSM) and transgender women (aTGW) are disproportionally affected by the HIV epidemic mainly due to structural and behavioral factors, and face barriers to accessing HIV prevention and care services.

We aimed to analyze factors associated with incident HIV infection among aMSM and aTGW enrolled in PrEP.

Methods: PrEP1519 is a single-arm, demonstration cohort study of daily TDF/FTC as PrEP among aMSM and aTGW aged 15-19 years old (yo). It is ongoing in three Brazilian capital cities. Eligible are those HIV uninfected at baseline, at high risk of HIV, and no risk of kidney and liver damage.

We included those enrolled in PrEP, who had at least one PrEP dispensation and two visits at PrEP clinics, from February/2019-October/2021. Study visits occurred at baseline, weeks 4, 12, and then quarterly. Demographic

and sociobehavioural data were collected by a questionnaire. Cox regression model was used to model the time to seroconversion of a PrEP user and to estimate adjusted hazard ratios (aHR) by medication possession ratio. Participants who had PrEP pills and an HIV-negative test were right-censored at the maximum follow-up date at 96 weeks.

Results: During the follow-up, 1,043 adolescents were enrolled in PrEP. Most MSM (91.9%), 18-19 yo (80.8%), self-identified as black/brown (69.7%). HIV incidence rate was 1.7 (95%CI: 0.8-2.6) per 100 person-years. Self-reported sexually transmitted infections (aHR: 3.02; 95%CI: 1.06–8.56), PrEP initiation during thequarantine measures of the COVID-19 pandemic (aHR: 3.89; 95%CI:1.13–13.4), commercial sex in the last 3 months (aHR: 3.47; 95%CI:1.14–10.58), and fewer years of schooling (aHR: 2.22; 95%CI:0.75–6.55) were predictors of the HIV incidence.

The estimated incidence for TGW was lower than for aMSM (aHR:0.32; 95%CI:0.04–2.51), but 95%CI was wide and imprecise.Indicators of sexual practices were not associated with the incidence.

Conclusions: The estimated HIV incidence was lower when compared to adult MSM and TGW non-PrEP users in other Brazilian studies but higher compared to the rates in adults PrEP studies, which indicates more attention to adolescents in PrEP programs is needed.

EPC029
Maternal education as a driver of HIV infection in adolescents and young adults in sub-Saharan Africa: a multinational analysis of population-based survey data

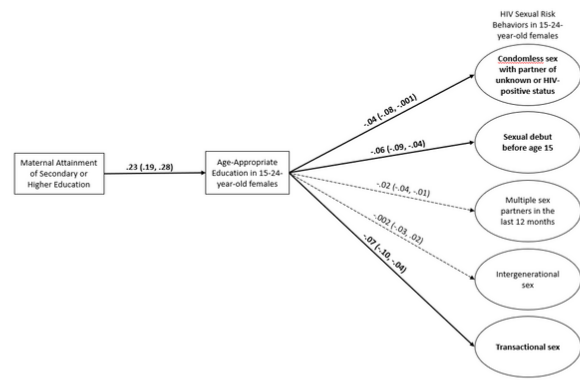
G. Chung[1], R. Mathu[2], J. Mantell[3], S. Hoffman[2], A. Low[2]
[1]*University of Michigan School of Public Health, Ann Arbor, United States,* [2]*ICAP at Columbia University, New York, United States,* [3]*Columbia University Irving Medical Center, Department of Psychiatry, New York, United States*

Background: Adolescent and young adults (AYA) aged 15 to 24, particularly women, remain at high risk of HIV infection. Effective HIV prevention efforts require an understanding of the mechanism by which parental factors such as education impact the HIV status of AYA.

Using data from the Population-based HIV Impact Assessment (PHIA) surveys, this analysis examined the multigenerational effect of education on HIV risk in AYA.

Methods: We pooled data from 13 PHIA surveys conducted between 2015-2019. AYA were linked to their cohabitating parents using the household roster. We examined whether maternal education was associated with AYA HIV status using logistic regression. Structural equation modeling (SEM) was used to test the mediating effect of age-appropriate educational level (being in at least secondary school for 15-17-year-olds and having completed secondary school for 18-24-year-olds) on the association between maternal attainment of secondary or higher education and AYA HIV sexual risk behaviors. Analyses were stratified by gender and by high (>10%) vs. low (≤10%) HIV prevalence countries. AYA age, marital status, urban/rural residence and country as a fixed effect were included as covariates.

Results: Data from 43,123 sons and 54,970 daughters were included. In high prevalence countries, maternal education was significantly associated with lower odds of HIV infection in girls (OR = 0.66; 95% CI = 0.47, 0.92), but not in boys. In sexually active girls, age-appropriate education significantly mediated the protective effect of higher maternal education on condomless sex with partner of unknown or HIV-positive status (β = -0.04; 95% CI = -0.08, -0.0007), sexual debut before age 15 (β = -0.06; 95% CI = -0.09, -0.04), and transactional sex (β = -0.07; 95% CI = -0.10, -0.04).



Conclusions: Our study highlights the multigenerational benefit of education for women. Governments should continue to support educational efforts, especially for adolescent girls who face difficulties staying in school.

EPC030
Artificial-Intelligence-based Predictions of HIV Prevalence in Nigeria through Testing among Adolescents and Young Adults

C.H. Nwokoye[1]
[1]*Nigerian Correctional Service, Awka, Nigeria*

Background: Adolescents and young adults (AYA) are more likely to contract HIV, and testing is essential for people who have HIV and those who don't, because the latter are more likely to adopt/encourage precautionary practices. Nigeria has a huge population of above 200 million people, but only 38% know their status. Therefore, this study is aimed at applying an artificial-intelligence based approach (i.e. the long-short-term memory recurrent neural networks (LSTM RNN) for the prediction of the nation's HIV prevalence rates using testing information and subsequently checking the accuracy using evaluation metrics such as mean squared error (MSE), root mean square error (RMSE), and mean absolute error (MAE).

Methods: The testing information/rates used in this study were gleaned from a 2016–2017 survey conducted across 37,440 households in 37 states in Nigeria. 52,690 participants took the survey but the focus is on AYAs aged 15–24

years, who constitute 18,494 participants. The data contains states, ever tested for HIV, recently tested for HIV (last year) and HIV prevalence rates. The LSTM RNN model design included the Vanilla/Stacked versions, with an 80:20 train/test split.

Results: First, the histogram, sample, correlation were generated (Figure 1). Below this figure are the variation of model hyper-parameters to get the numerous predictions of the real data (Figure 2).

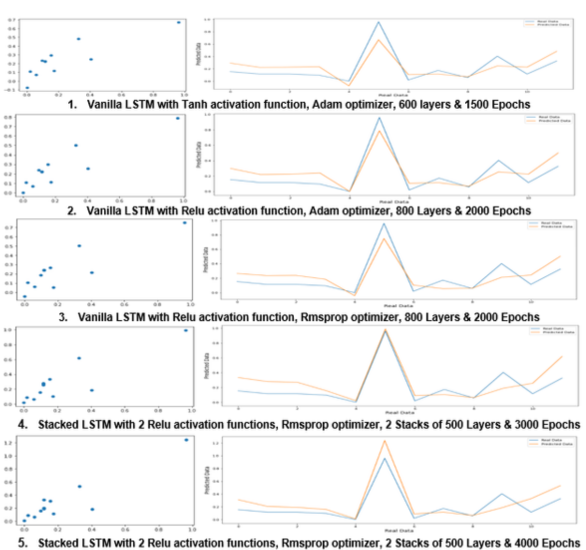


Figure 1.

	States	Ever tested for HIV	Recently tested for HIV	HIV prevalence rate
0	FCT Abuja	47.3	28.8	1.6
1	Abia	19.6	10.3	2.1
2	Adamawa	25.8	19.5	1.2
3	Akwa Ibom	41.3	25.5	5.5
4	Anambra	29.3	11.4	2.4

Sample Data

	Ever tested for HIV	Recently tested for HIV	HIV prevalence rate
Ever tested for HIV	1.000000	0.934605	0.754345
Recently tested for HIV	0.934605	1.000000	0.787005
HIV prevalence rate	0.754345	0.787005	1.000000

Correlation

LSTM/Layers/Epochs	Activation function/ Optimizer	MSE	RMSE	MAE
Vanilla/600/1500	Tanh/Adam	0.0222	0.1490	0.0988
Vanilla/800/2000	Relu/Adam	0.0229	0.1513	0.0982
Vanilla/800/2000	Relu/Rmsprop	0.0205	0.1431	0.0938
Vanilla/1000/3000	Relu/Rmsprop	0.0205	0.1431	0.0947
Stacked/2(500)/3000	2 Relu/Rmsprop	0.0151	0.1229	0.0653
Stacked/2(512)/5000	2 Relu/Rmsprop	0.0043	0.0656	0.0387
Stacked/2(512)/4000	2 Relu/Rmsprop	0.0014	0.0374	0.0262

Evaluation Metrics for the Training and Testing Experiments

Figure 2.

Conclusions: The experiments show that the 4th experiment in Figure 2 shows the best predicted values. The assumption is that HIV researchers can use LSTM models to predict prevalence data if they know how many people have been tested.

Epidemiology of HIV in key populations (e.g., gay men and other men who have sex with men, sex workers, transgender people, people who inject rugs and prisoners and other incarcerated people)

EPC031

Sexual behavior, condom use and rates of HIV and other sexually transmitted infections among male and female non-Thai sex workers in Chiang Mai, Northern Thailand

A. Tangmunkongvorakul[1], M. Kelly[2], C. Banwell[3], K. Srithanaviboonchai[4]

[1]Chiang Mai University, Research Institute for Health Sciences, Chiang Mai, Thailand, [2]Australian National University, Department of Global Health, Research School of Population Health, Canberra, Australia, [3]Australian National University, National Centre for Epidemiology & Population Health, Canberra, Australia, [4]Chiang Mai University, Faculty of Medicine, Chiang Mai, Thailand

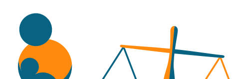
Background: About three quarters of sex workers in Thailand's northern capital of Chiang Mai are non-Thai but they are not tracked in Thai national annual sentinel surveillance systems. This study investigates sexual behavior and rates of HIV and sexually transmitted infections (STIs) in this ignored group.

Methods: This descriptive cross-sectional study was conducted among non-Thai sex workers who worked in urban and rural Chiang Mai between March-October 2019. Recruitment was via NGO staff and/or health personnel coordinating with owners/managers of sex work venues. All respondents were interviewed face-to-face by gender-matched trained interviewers. At survey sites, all participants had a blood test for HIV and Syphilis.

A subgroup of female participants had cervical secretion screening for *Chlamydia trachomatis* (CT) and *Neisseria gonorrhea* (NG). Median and interquartile range (IQR) were calculated for continuous variables. Number and proportion were computed for categorical variables, and compared by sex using Fisher's exact test.

Results: In total, 396 non-Thai sex workers (198 males and 198 females) from 23 sex work venues were interviewed. Respondents were aged 18-49 years (median 25, IQR 22-30). Male respondents were significantly younger than females (p=0.003). Most were from Myanmar (92.9%), and 63.4% had been in sex work within two years.

Three quarters had sex with up to 100 different people (median 50, IQR 15-99), with 11.6% having had more than 200 sexual partners. Their clients were mainly Thai (64.5%) and the rest were Asian foreigners. In the preceding month, 17.0% consistently used condoms with regular sex partners, 53.7% with casual sex partners (non-clients), and 87.9% with clients. Female sex workers were more likely to consistently use condoms with clients (p=0.001). Prevalence of HIV infection was 2.3% (2.5% males, 2.0% females). Syph-



ilis was found in 3.0% (4.0% males, 2.0% females). Among 100 female participants, 22% tested positive for CT and 7% for NG.

Conclusions: Among non-Thai sex workers, consistent condom use was very low with regular partners, and inconsistent with clients. Rates of HIV, Syphilis, CT and NG were higher compared to reported Thai population. Findings highlight the need for non-Thai sex works to be included in national policies for HIV and STI prevention.

EPC032

90-90-90 targets for engagement in HIV care have been met for trans women in San Francisco, yet challenges remain

I. Chiu[1,2], M. Leathers[1,2], D. Cano[1,2], C.M. Turner[2,3], D. Trujillo[2], S. Sicro[2], S. Arayasirikul[2,3], K.D. Taylor[3], E.C. Wilson[2,3], W. McFarland[2,3]
[1]University of California, Berkeley, Berkeley, United States, [2]Center for Public Health Research, Department of Public Health, San Francisco, United States, [3]University of California, San Francisco, Department of Epidemiology and Biostatistics, San Francisco, United States

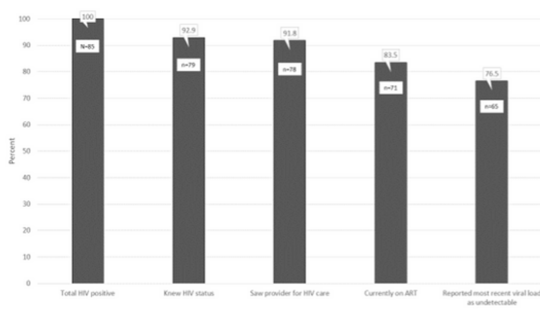
Background: Trans women have very high HIV prevalence and have lagged behind 90-90-90 targets for engagement in care. When engagement was last measured in San Francisco in 2017, 96% of trans women were aware of their status, 75% were on antiretroviral therapy (ART), and 88% had viral suppression. Since 2017, several initiatives have attempted to address these gaps, including peer navigators, free gender-affirming surgery, and affordable housing.

The current study updates HIV prevalence and engagement in care among trans women following the implementation of these initiatives in San Francisco.

Methods: We conducted a community-based, cross-sectional survey of trans women in San Francisco recruited through respondent-driven sampling (N=201, 2019-2020). Eligibility criteria were: self-identified women, trans women, or other gender and had been assigned male at birth; living in San Francisco; English or Spanish-speaking; and 18 years or older. Measures included HIV serostatus, risk factors for infection, and indicators of engagement with HIV care. Multivariable logistic regression analysis characterized associations with HIV seropositivity.

Results: Among 201 trans women enrolled, 85 (42.3%) had HIV (95%CI 35.4.-49.4). HIV was associated with having a sexual partner who injected drugs (AOR 3.30, 95%CI 1.58-6.90), ever injecting drugs (AOR 2.28, 95%CI 1.06-4.89), cost not being a barrier to healthcare (AOR 2.63, 95%CI 1.02-6.67), having emotional support from family (AOR 2.85, 95%CI 1.43-5.65), and Black race/ethnicity (AOR 2.59, 95%CI 1.16-5.69).

Of trans women living with HIV, 92.9% were previously diagnosed, 89.9% were on ART, and 91.5% reported viral suppression.



Conclusions: Trans women in San Francisco met 90-90-90 targets in 2020, at 93-90-92. Recent initiatives appear to have improved engagement in HIV care, gender-affirming care, and potentially family support. Uptake in PrEP among people who inject drugs and Black/African Americans may have a substantial impact on HIV transmission to trans women. Addressing systemic racism and intersecting stigmas may be needed to achieve 95-95-95 targets.

EPC033

Heterogeneity in HIV/STI risk and prevention among cisgender people with transgender and non-binary partners

D. Tordoff[1], S. Glick[2], L. Barbee[2], A. Duerr[3], The Seattle Trans and Non-binary Sexual Health (STARS) Advisory Board
[1]University of Washington, Epidemiology, Seattle, United States, [2]University of Washington, School of Medicine, Seattle, United States, [3]Fred Hutchinson Cancer Research Center, Seattle, United States

Background: Although transgender people have a high prevalence of HIV/STIs, less is known about the epidemiology of HIV/STIs and prevention utilization among the cisgender partners of transgender people.

Methods: We pooled data from five cross-sectional data sources in Washington State: the 2019, 2020, and 2021 annual Pride Surveys, 2017 National HIV Behavioral Surveillance among MSM, and data from the public health Sexual Health Clinic in Seattle from 2019-2020.

We estimated the proportion of cisgender participants who reported having a transgender partner in the last year, stratified by self-reported sexual minority status (e.g. gay, bisexual, queer, lesbian, or pansexual). We used Poisson regression to assess if HIV/STI prevalence, testing, or PrEP use was associated with having a transgender sex partner in the past year.

Results: Our sample included 2896 cisgender women and 7540 cisgender men. Overall, 9% of sexual minority cisgender men and 13% of sexual minority cisgender women reported having any transgender partners, most commonly non-binary partners.

Only 2% of heterosexual cisgender men reported having a transgender partner, mostly commonly transgender women. HIV/STI prevalence was highest among cisgender men who partner with non-binary people and transgen-

der men, although these men were also the most likely to engage in high levels of testing and PrEP use (Table). Cisgender men who partner with transgender women were significantly less likely to have ever used PrEP (aRR 0.34, 95%CI:0.22-0.53). HIV/STI testing and PrEP use was lowest among cisgender women (Table).

In all regression models, having a transgender partner was associated with a 2-fold higher likelihood of HIV testing but was not associated with higher HIV prevalence.

	Cis Men who Partner with Trans Women n (%)	Cis Men who Partner with Trans Men n (%)	Cis Men who Partner with Non-binary People n (%)	Cis Women who Partner with Trans Women n (%)	Cis Women who Partner with Trans Men n (%)	Cis Women who Partner with Non-binary People n (%)

Current PrEP Use	18 (15.8)	56 (35.0)	67 (28.9)	1 (2.0)	0 (0.0)	1 (0.6)

Table. HIV/STI Prevalence and Prevention among Cisgender People with Transgender Partners in Washington State, 2019-2021

Conclusions: Sexual minority cisgender people commonly reported having transgender partners (approximately 1 in 10). There was significant heterogeneity of HIV/STI prevention utilization for cisgender men and women with transgender partners. Notably, PrEP use was low among some subgroups with high HIV/STI prevalence.

EPC034

Prevalence of HIV and STIs in Peruvian men who have sex with men (MSM) and transgender women (TGW) and factors associated with new HIV diagnosis

J. Sánchez[1], M.F. Reyes[2], K. Konda[3], C. Benites[4], P. Alarcon[1], A.N. Soriano[2], R. Alfaro[1], P. Gonzales[1], C.V. Munayco[2]
[1]*Universidad Nacional Mayor de San Marcos, Centro de Investigaciones Tecnológicas, Biomédicas y Medioambientales, Lima, Peru,* [2]*Centro Nacional de Epidemiología, Prevención y Control de Enfermedades, Unidad de Análisis Epidemiológico y Modelamiento Matemático, Lima, Peru,* [3]*Universidad Peruana Cayetano Heredia, Centro de Investigación Interdisciplinaria en Sexualidad, SIDA y Sociedad, Lima, Peru,* [4]*Ministerio de Salud del Perú, Dirección de Prevención y Control de VIH-SIDA, Enfermedades de Transmisión Sexual y Hepatitis (DPVIH), Lima, Peru*

Background: HIV/STI surveillance is key to steering public health efforts to control HIV. We aimed to determine the prevalence of HIV and other STIs among MSM and TGW in Peru and the factors associated with new HIV diagnosis.

Methods: In 2019, time-space sampling was used to estimate HIV/STI prevalence in 7 cities (MSM) and 10 cities (TGW) in Peru. The survey collected socio-demographics, sexual risk behaviors, substance use, self-reported STI history, HIV testing history.

Weighted prevalence and 95% confidence intervals were calculated for HIV and syphilis. Multivariate logistic models were estimated using stepwise backward selection to determine the factors associated with new HIV diagnosis, defined as unknown prior infection, among MSM and TGW.

Results: Overall, 1768 MSM and 1198 TGW were enrolled. The weighted HIV prevalence was 10.0% (95%CI=8.0-12.4) among MSM and 31.8% (95%CI=28.4-35.4) among TGW; newly diagnosed HIV was 6.2% (95%CI=4.5-8.6) among MSM and 17.1%(95%CI=14.2-20.5) among TGW; while the prevalence of recent syphilis was 4.5% (95%CI=3.3-6.3) among MSM and 44.8% (95%CI=41.0–48.7) among TGW. Among both MSM and TGW, history of syphilis and active syphilis were associated with increased prevalence of newly diagnosed HIV infection (all p-values<0.05).

Among TGW, higher education and income were associated with decreased prevalence of newly diagnosed HIV; while being a sex worker was associated with increased prevalence of new HIV (all p-values<0.05). Sexual risk behaviors, including passive anal intercourse, were associated with increased prevalence of newly diagnosed HIV infection (all p-values<0.05).

Conclusions: Peruvian MSM and TGW continue to be vulnerable populations for HIV acquisition, as it is throughout the Americas. Prevention efforts should take into account the structural vulnerabilities of TGW and continue to improve sexual health services to address risk factors for new HIV diagnosis, including syphilis infection.

Life after U=U: condom and PrEP use patterns among HIV discordant couples

E. Morgan[1], J. Sherman[1], M. Berrigan[2], L. Christian[1], C. Kamp Dush[2], W. Manning[3]
[1]The Ohio State University, Columbus, United States, [2]University of Minnesota, Minneapolis, United States, [3]Bowling Green State University, Bowling Green, United States

Background: Undetectable=Untransmittable (U=U) is a broad messaging campaign explaining that people living with HIV who maintain an undetectable viral load through the use of daily antiretroviral therapies cannot sexually transmit HIV.
We aim to assess whether patterns of condom or pre-exposure prophylaxis (PrEP) use may be changing among serodiscordant couples in the new era of U=U messaging.

Methods: Data come from the National Couples' Health and Time (NCHAT) Study designed to assess health of cohabitating different- and same-gender couples aged 20-60 across the United States. We utilized survey weighted logistic regression analyses to assess the association between participant/partner HIV status and use of condoms and PrEP (either Truvada or Descovy). Models were adjusted for demographics (e.g., age, race/ethnicity, and sexual orientation) and known confounders including illicit drug use and detectable HIV viral load status.

Results: Among 3,441 NCHAT participants, 83 (2.4%) self-reported a diagnosis of HIV while 68 (2.0%) reported their current spouse or partner was diagnosed with HIV. 359 (10.4%) reported condom using during their last sexual encounter, 159 (4.6%) reported ever having used PrEP, and 72 (2.1%) reported current PrEP use. Adjusting for detectable viral load status, participants diagnosed with HIV were significantly less likely to report using a condom during their last sexual encounter (aOR = 0.04; 95% CI: 0.004 – 0.50) compared to those undiagnosed with HIV.
Similarly, adjusting for detectable status, those whose partners/spouses are diagnosed with HIV were significantly less likely to use a condom relative to those whose partners/spouses are undiagnosed with HIV (aOR = 0.16; 95% CI: 0.03 – 0.81).
Finally, those in discordant relationships, relative to those in concordant relationships, were significantly more likely to have ever used PrEP (aOR = 4.19; 95% CI: 1.29 – 13.62) and to currently be on PrEP (aOR = 124.80; 95% CI: 4.40 – 3544.60).

Conclusions: These results demonstrate reduced use of condoms and increased use of PrEP among participants in HIV discordant relationships.
Taken together, these data suggest that the U=U messaging campaign is working and providing confidence among participants in discordant relationships that HIV cannot be sexually transmitted, particularly in light of PrEP use among the HIV undiagnosed partners.

HIV prevalence among male clients and non-paying male sex partners of female sex workers in sub-Saharan Africa: a systematic review and meta-analysis

M. Xi[1,2,3], K.C. Yiu[4], V. Srivatsav[5], M. Alary[6], S. Schwartz[7], P. Vickerman[8], M.-C. Boily[9], C. Ziegler[4], S. Baral[7], S. Mishra[1,4,10]
[1]University of Toronto, Institute of Health Policy, Management, and Evaluation, Toronto, Canada, [2]University Health Network, KITE - Toronto Rehabilitation Institute, Toronto, Canada, [3]The Ottawa Hospital, Ottawa Hospital Research Institute, Ottawa, Canada, [4]St. Michael's Hospital, Li Ka Shing Knowledge Institute, Toronto, Canada, [5]McMaster University, Michael G. Degroote School of Medicine, Faculty of Health Sciences, Hamilton, Canada, [6]Laval University, Research Center of CHU, Quebec City, Canada, [7]Johns Hopkins University, Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [8]Bristol University, Bristol, United Kingdom, [9]Imperial College London, Faculty of Medicine, School of Public Health, London, United Kingdom, [10]University of Toronto, Division of Infectious Disease, Department of Medicine, Toronto, Canada

Background: Most HIV prevention programs focus predominantly on FSW, and little is known about the epidemiology of HIV among paying male sex partners (clients) and non-paying male sex partners of FSW. We undertook a systematic review and meta-analysis to estimate the HIV prevalence among male sex partners of FSW in sub-Saharan Africa.

Methods: We searched Medline, EMBASE, The Cochrane Database, Scopus, CINAHL, and various grey literature sources (e.g., Demographic and Health Survey reports) for articles reporting HIV prevalence of clients and non-

Oral abstracts

Late-breaker abstracts

Author Index

paying male partners of FSW published between January 2004 and October 2018. HIV prevalence estimates were pooled using a random effects model to obtain overall and regional HIV prevalence among clients in sub-Saharan Africa. Sources of between-study heterogeneity were identified using meta-regression analysis.

Results: The search identified 2045 unique citations, of which 53 studies met our inclusion criteria. Zero studies contained data on non-paying partners of FSW. Fifty-three studies, representing 12,322 clients of FSW across 31 countries in sub-Saharan Africa, were included in the pooled HIV prevalence estimate.

Overall, HIV prevalence among clients was 6.6% (95% CI: 4.9-8.5%). HIV prevalence among clients in West/Central Africa was 3.3% (2.0-4.9%, I^2=87.3%, n=27 studies); in East Africa was 8.4% (6.3-10.7%, I^2=78.3%, n=15); and in Southern Africa was 14.7% (10.6-19.3%, I^2=92.9%, n=11).

On meta-regression, region and how clients were defined were the main source of heterogeneity in HIV prevalence, with little variability attributable to year and study type in the fully adjusted model. Using West/Central Africa as the reference group, risk of HIV was higher in East (adjusted odds ratio (AOR): 2.92, 95% CI:1.68-5.08) and Southern Africa (AOR: 7.15, 95% CI: 4.25-12.03).

Conclusions: The high prevalence of HIV in clients of FSW in sub-Saharan Africa demonstrates similar patterns to overall HIV prevalence across regions. Future research on the epidemiology of HIV among non-paying male partners of FSW is also needed.

EPC038
HIV prevalence among international migrants: a systematic review and meta-analysis

D. Santoso[1], S.K.B.M. Asfia[1], M. Brito de Mello[2], R.C. Baggaley[2], C.C. Johnson[2], E.P.F. Chow[1], C.K. Fairley[1], J.J. Ong[1]
[1]Monash University, Central Clinical School, Carlton, Australia, [2]World Health Organization, Global HIV, Hepatitis and STI Programmes, Geneva, Switzerland

Background: Hundreds of millions of migrants cross international borders each year. International migrants may face health inequities that exposes them to a higher risk for HIV compared to native populations. Addressing these health inequities also serves to protect the health of the native populations by preventing potential spread of infections.

We aimed to conduct a systematic review to estimate the HIV prevalence in international migrants compared with native populations.

Methods: We searched five databases for publications between 2010 and March 2021. Two reviewers independently screened the studies, whilst a third reviewer resolved any discrepancies. Using a random-effects meta-analysis, we calculated the pooled HIV prevalence ratios comparing HIV prevalence of migrants with native-born populations. We estimated pooled prevalence ratios (PR) according to migrant type, region of origin, and country-income level.

Results: In total, 4,681 studies were screened and 37 included in the final analysis. Most studies (84%) were from high-income countries. Migrant populations were categorised as refugees (8%), asylum seekers (3%), undocumented people (3%) while the rest were other international migrants (86%). The pooled PR for international migrants was 1.72 (95% confidence intervals (CI) 1.10 – 2.66, I^2=99.7%), refugees was 2.37 (95% CI 0.33–16.99, I^2=99.5%), asylum seekers was 54.79 (95% CI 17.23–174.23, I^2=90.2%), whilst undocumented people was 3.98 (95% CI 0.11–143.01, I^2=94.6%). Geographically, pooled PR of migrants originating from African countries was the highest at 4.12 (95% CI 1.44 – 11.76, I^2=99.7%). Based on country-income level, the pooled PR of migrants residing in high-income countries was higher than those in low-income countries (2.25, 95% CI 1.27 – 3.98, I^2=99.8% vs 0.23, 95% CI 0.20 – 0.28, I^2=0%).

Conclusions: Overall, we found a higher prevalence of HIV among international migrants compared to native populations. To ensure that 'no one is left behind' in ongoing efforts achieve and maintain low HIV incidence, inclusive health policies and targeted strategies for delivering HIV testing, prevention and treatment services for migrant populations are urgently needed.

EPC039
HIV and risk behaviors trends among people who inject drugs in Iran, 2010 to 2020

M. Khezri[1], M. Shokoohi[2], A. Mirzazadeh[3], F. Tavakoli[1], N. Ghalekhani[1], G. Mousavian[1], S. Mehmandoost[1], P. Afsar Kazerooni[4], A.A. Haghdoost[1], M. Karamouzian[5], H. Sharifi[1]
[1]Kerman University of Medical Sciences, HIV/STI Surveillance Research Center, and WHO Collaborating Center for HIV Surveillance, Institute for Futures Studies in Health, Kerman, Iran, Islamic Republic of, [2]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, [3]University of California San Francisco, Department of Epidemiology and Biostatistics, San Francisco, United States, [4]Shiraz University of Medical Sciences, Shiraz HIV/AIDS Research Center, Shiraz, Iran, Islamic Republic of, [5]Brown University, Department of Epidemiology, School of Public Health, Providence, United States

Background: Injection drug use is one of the main routes of HIV transmission and acquisition in Iran. We assessed HIV prevalence, risk behaviors, and uptake of prevention services among people who inject drugs (PWID) in Iran between 2010 and 2020. We also examined the individual and environmental determinants of HIV seropositivity in 2020.

Methods: PWID were recruited from major cities across the country under three national biobehavioral surveillance surveys using convenience sampling method from

harm reduction facilities and through outreach efforts in both 2010 and 2014 surveys and using respondent-driven sampling in the 2020 survey. Participants were tested for HIV and interviewed using a behavioral questionnaire that included socio-demographics, behaviors, and harm reduction service usage.

The analytic sample included 2,349 participants in 2010, 2,307 in 2014, and 2,684 in 2020. We used multivariable logistic regression models to examine risk factors associated with HIV seropositivity.

Results: Participants in the 2010 survey were younger than those in the 2014 and 2020 surveys (mean age = 34.5, 36.8, and 40.2, respectively). Participants were predominantly male in all surveys (97.8%, 97.5%, and 96.7%). HIV prevalence decreased from 15.1% (95% confidence intervals (CI): 13.6, 16.6) in 2010 to 9.3% (95% CI: 8.1, 10.5) in 2014 to 3.5% (95% CI: 2.9, 4.3) in 2020.

The prevalence of receptive needle sharing (25.2%, 10.4%, and 3.9%) and unprotected sex (79.4%, 67.9%, and 65.2%) also decreased over time. Uptake of free needle/syringe increased (68.8%, 57.4%, and 87.9%), while uptake of free condom remained relatively stable across surveys (34.3%, 36.1%, and 32.6%).

Multivariable analysis for the 2020 survey showed that history of homelessness (adjusted odds ratio (AOR): 2.10; 95% CI: 1.11, 3.95), incarceration (AOR: 2.66, 95% CI: 1.33, 5.32), and longer injecting career (AOR: 3.27, 95% CI: 1.50, 7.14) significantly increased the odds of HIV seropositivity.

Conclusions: During the past decade, HIV prevalence decreased among PWID in parallel with a reduction in drug- and sexual-related risk behaviors. PWID with a history of homelessness or incarceration and those who inject drugs for a longer period continue to have a higher prevalence of HIV and need to be provided with targeted prevention and screening interventions.

EPC040

Concordance in sexual partnership HIV serostatus and transmission prevention coverage among gay, bisexual and other men who have sex with men (GBMSM) and transgender (TG) individuals in Nairobi, Kenya

E. Fearon[1], A. Bourne[2], P. Weatherburn[1], J. Kimani[3,4,5], A.D. Smith[6]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]La Trobe University, Melbourne, Australia, [3]University of Manitoba, Winnipeg, Canada, [4]Partners for Health and Development in Africa, Nairobi, Kenya, [5]University of Nairobi, Nairobi, Kenya, [6]University of Oxford, Oxford, United Kingdom

Background: Half of GBMSM and TG individuals living with HIV have an unsuppressed viral load in Nairobi and uptake of daily oral PrEP is low. This study examines partnership HIV-seroconcordance to understand whether HIV prevention and treatment practices correspond with partnership transmission risk.

Methods: A respondent driven sampling survey (May-December 2017) recruited 618 GBMSM and TG adults with current or birth-assigned male gender resident in Nairobi County. Participants tested for HIV and viral load, reported HIV testing, HIV prevention practices, access and demand, and four most recent sexual partners/partnerships, including partner HIV status if known.

Active partnerships were classified as HIV seroconcordant, serodiscordant, or unknown seroconcordance. We examined the association between gender, age, HIV, relationship type and seroconcordance using a multinomial regression model with random effects for participant. Here we show HIV prevention behaviours stratified by participant HIV status and seroconcordance.

Results: 600/618 participants gave complete data about 2058 partners; 863 (41.4%) were one-time and 807 (39.2%) sustained and active partnerships (81.4% male, 14.1% female and 4.5% transgender). 55.0% of active partners shared their HIV status, leading to 43.0% of partnerships classified as seroconcordant, 9.3% as discordant and 47.7% of unknown seroconcordance.

Adjusted for relationship type, age and gender, participant HIV status was associated with seroconcordance (p<0.001). Within HIV strata, there was little evidence that transmission prevention coverage/access/demand was targeted to seroconcordance (Table 1).

Recent testing (p=0.002) and access to PEP (p=0.009) was less prevalent amongst discordant and unknown seroconcordance partnerships among those HIV-negative.

HIV status of participant	HIV status reported of partner:	Positive, n (%)	Negative, n (%)	Unknown, n (%)	Total partnerships, n (%)	p-value for difference by seroconcordance, accounting for clustering by participant
Positive	Condoms used	27/38 (71.1%)	49/63 (77.8%)	115/176 (65.3%)	191/277 (69.0%)	0.193
	Viral load <50 copies/ml	26/38 (68.4%)	28/63 (44.4%)	92/176 (52.3%)	146/277 (52.7%)	0.138
	Total HIV-positive, across partner seroconcordance	**38/277 (13.7%)**	**63/277 (22.7%)**	**176/277 (63.5%)**	**277/807 (34.2%)**	
Negative	Condoms used	10/12 (83.3%)	208/309 (67.3%)	142/209 (67.9%)	360/530 (67.9%)	0.555
	HIV tested in previous 6 months	5/12 (41.7%)	188/309 (60.8%)	90/209 (43.1%)	283/530 (53.4%)	0.002
	Current Pre Exposure Prophylaxis (PrEP) use	0/12 (0%)	17/309 (5.5%)	14/209 (6.7%)	31/530 (5.9%)	0.808
	Likely/Very likely to use PrEP if available	9/12 (75%)	198/309 (64.1%)	121/209 (57.9%)	328/530 (61.9%)	0.318
	Aware of Post Exposure Prophylaxis (PEP) and where to access it	5/12 (41.7%)	197/309 (63.8%)	102/209 (48.8%)	304/530 (57.4%)	0.009
	Total HIV-negative, across partner seroconcordance	**12/530 (2.3%)**	**309/530 (58.3%)**	**209/530 (39.4%)**	**530/807 (65.7%)**	

Table 1: Transmission prevention coverage by HIV-seroconcordance, 807 active partnerships.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

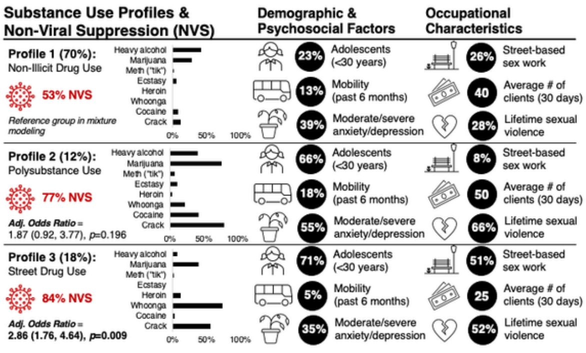
Author Index

Conclusions: Most ongoing GBMSM and TG partnerships are either HIV serodiscordant or of unknown concordance, and many partnerships at highest risk of transmission are not covered by prevention tools.
These findings suggest value in partnerships-focused HIV testing, status sharing and prevention approaches that are under-utilised for this population in Kenya.

EPC041
Polysubstance use profiles and unsuppressed viral load among female sex workers living with HIV in Durban, South Africa: a latent class analysis

J.G. Rosen[1], J. Knox[2], K. Rucinski[1], M. Mcingana[3], N. Mulumba[4], C.A. Comins[5], L. Shipp[5], S. Makama[4], W. Beckham[6], H. Hausler[3,7], S. Baral[5], S. Schwartz[5]
[1]Johns Hopkins Bloomberg School of Public Health, International Health, Baltimore, United States, [2]Columbia University, HIV Center for Clinical and Behavioral Studies, New York, United States, [3]TB HIV Care, Cape Town, South Africa, [4]TB HIV Care, Key Populations Programme, Durban, South Africa, [5]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [6]Johns Hopkins Bloomberg School of Public Health, Health, Behavior, and Society, Baltimore, United States, [7]University of Pretoria, Pretoria, South Africa

Background: Substance use can challenge HIV treatment adherence among people living with HIV. However, there has been limited study and ultimately limited services addressing substance use for female sex workers living with HIV (FSWLH) in South Africa.
In response, we used latent class analysis (LCA) to characterize the relationship between types of substance use and non-viral suppression (NVS) among FSWLH in Durban, South Africa.
Methods: FSWLH (N=1,371) completed a baseline questionnaire and viral load assessment from 2018 to 2020. We implemented LCA to partition FSWLH into discrete groups based on substances used in the past month: alcohol (heavy use: ≥5 drinks 2+ times weekly), marijuana, cocaine, crack, methamphetamines, ecstasy, whoonga, and heroin.
We calculated Wald tests to identify demographic, psychosocial, and occupational predictors of probabilistic class membership and implemented multivariable mixture modeling to describe associations of LCA-identified substance use patterns with NVS (≥50 copies/mL), adjusting for potential confounders.
Results: Substance use was common, with participants reporting use of heavy alcohol (35%), marijuana (35%), crack (27%), and whoonga (16%). Three substance use profiles emerged:
non-illicit drug use (marijuana/alcohol mostly, ~70% sample prevalence),
polysubstance use (~12% sample prevalence), and
street drug use (whoonga/crack predominantly, ~18% sample prevalence), each with distinct demographic, psychosocial, and occupational characteristics
(see Figure). Polysubstance use and street drug use were each associated with higher probabilities of NVS compared to non-illicit drug use (77% vs. 84% vs. 53%, χ^2 77.169, p<0.001). In multivariable analysis, polysubstance use (adj. Odds Ratio [aOR] 1.87, 95%CI: 0.92–3.77) and street drug use (aOR 2.86, 95%CI: 1.76–4.64) were associated with NVS relative to non-illicit drug use.



Figure

Conclusions: LCA and mixture modeling identified distinct substance use patterns and demonstrated their relative contributions to HIV viremia among FSWLH. Reducing vulnerabilities associated with polysubstance use is key to optimizing HIV treatment adherence and, subsequently, improving viral load outcomes for FSWLH.

EPC042
HIV transmission dynamics in internally-displaced people who inject drugs in Ukraine

T.I. Vasylyeva[1], G. Kovalenko[2], A. Yakovleva[3], L. Meredith[4]
[1]University of California, Medicine, San Diego, United States, [2]University of Cambridge, Pathology, Cambridge, United Kingdom, [3]University of Oxford, Medicine, Oxford, United Kingdom, [4]Amazon Diagnostic Laboratory, Manchester, United Kingdom

Background: Ukraine has a large number of people displaced from regions experiencing conflict, a high prevalence of injection drug use, and a high prevalence of HIV. Internally displaced people who inject drugs (IDPWID) might be at a higher risk for HIV if their linkage to HIV prevention and care has been affected by displacement. Intervention strategies might depend on patterns of mixing within the IDPWID community and between IDPWID and host population.
Methods: We used respondent-driven sampling to recruit IDPWID in Odessa, Ukraine, in July - September 2020. All participants were interviewed, tested for HIV with rapid tests, and asked to provide a blood sample for HIV genetic sequencing. HIV *pol* sequences were obtained through Nanopore sequencing and used to reconstruct phylogenetic trees together with publicly available HIV sequences from Odessa and IDPWID regions of origin.

Results: We recruited 164 IDPWID (19% women, median age 37), 64 (39%) of them received a positive rapid HIV test result, and 28 of them (44% of all HIV-positive) were newly diagnosed. Only 13 IDPWID (20% of all HIV-positive and 36% of those aware of their HIV-positive status) were receiving anti-retroviral treatment at the time of the survey; 8 of them (61%) were virally suppressed. 88 (54%) IDPWID moved to Odessa in 2014/2015 right after the conflict started; 36 IDPWID (22%) have not received an HIV test since relocation to Odessa.

We received 35 HIV *pol* sequences from the study participants' samples and aligned them to 251 and 107 sequences from Odessa and from IDPWID regions of origin, respectively (total N = 393). We found 6 transmission clusters that involved IDPWID: four included IDPWID sequences only (total N=9) and two included IDPWID and Odessa sequences (total N=7). All but one clusters included IDPWID from different regions of origin, suggesting transmission post-relocation to Odessa.

Conclusions: Linkage to HIV testing and treatment is low in IDPWID in Odessa. Analysis of HIV sequences showed frequent mixing of IDPWID from different regions of origin post-relocation, but limited mixing with the host population. Studying HIV transmission patterns within the IDPWID community and between IDPWID and local populations can help design targeted preventive interventions.

EPC043

Sexual risk behaviors among factory workers in Shenzhen, China: a cross-sectional study

D. Luo[1], K. Zhang[2], Y. Chen[2], D. Chen[3], X. Meng[4], W. Ke[5], T. Hu[2], B. Liang[1], L. Fu[1], G. Luo[1], X. Yang[6], B. Cao[7], Y. Cai[8], Z. Wang[6], H. Zou[1,9]

[1]*School of Public Health, Sun Yat-sen University, Shenzhen, China,* [2]*Longhua District Center for Disease Control and Prevention, Shenzhen, China,* [3]*Shenzhen Health Development Research Center, Shenzhen, China,* [4]*Wuxi Municipal Center for Disease Control and Prevention, Wuxi, China,* [5]*Dermatology Hospital, Southern Medical University, Guangzhou, China,* [6]*JC School of Public Health and Primary Care, Faculty of Medicine, Chinese University of Hong Kong, Hong Kong, China,* [7]*School of Media and Communication, Shenzhen University, Shenzhen, China,* [8]*School of Public Health, Shanghai Jiaotong University School of Medicine, Shanghai, China,* [9]*Campus of Sun Yat-sen University, Shenzhen, China*

Background: Factory workers make up the majority of Chinese internal migrants, with Shenzhen being a leading exporter of workers. Long-term separation from their companions and therefore having sex with casual partners make factory workers vulnerable to HIV infections. This study aims to evaluate HIV knowledge, sexual risk behaviors, and associated factors among factory workers in Shenzhen.

Methods: A cross-sectional study was conducted from November 2019 to April 2020 by multi-stage stratified cluster random sampling. Eligible participants were: full-time workers; ≥18 years old; working in factories with more than 50 employees. A self-administered questionnaire was used to collect information on demographic characteristics, HIV knowledge, sexual experience, sexual risk behaviors, and non-sexual behaviors. Univariate and multivariable logistic regression were applied to examine factors associated with sexual risk behaviors.

Results: A total of 2029 factory workers were included in the study. Of them, the mean age was 37.22 (±4.39) years; 48.5% were men; 89.3% had worked for more than 1 year in Shenzhen; 59.9% had a higher level of HIV/AIDS knowledge. Sexual risk behaviors were reported including unprotective sex last time (32.3%), having more than one sex partner (11.5%), and engaging in commercial sex (44.3%) in the past year. Factors associated with having unprotective sex last time were being married or cohabitated (adjusted odds ratio [AOR] 1.53, 95% confidence interval [CI] 1.11-2.12), higher educational levels (0.62, 0.46-0.85), and not using a condom at sex debut (0.17, 0.13-0.22).

Regarding being males (3.24, 2.10-4.99 and 2.27, 1.35-3.80), being married or cohabitated (0.48, 0.33-0.70 and 0.38, 0.24-0.60), having sexual debut older than 18 years (0.16, 0.09-0.28 and 0.34, 0.17-0.69), and using drugs before or during intercourse (4.20, 2.21-7.98 and 13.35, 6.89-25.87) were associated with both having more than one sex partner and engaging in commercial sex in last year.

Conclusions: Most respondents had basic HIV knowledge, but their sexual risk behaviors were prevalent. Our findings demonstrated that programs aimed at promotion of safer sex practices should target vulnerable migrant workers.

EPC044

Assessing the association of access to opioid substitution therapy and HIV incidence among people who inject drugs (PWID) in Kachin, Myanmar, 2008-2020

A. McNaughton[1], J. Stone[1], K.T. Oo[2], Z.Z. Let[2], M. Taw[2], M.T. Aung[2], A.M. Min[2], E. Wisse[3], P. Vickerman[1]

[1]*University of Bristol, Bristol, United Kingdom,* [2]*Médecins du Monde, Kachin, Myanmar,* [3]*Médecins du Monde, Paris, France*

Background: Kachin is a conflict-affected region in North Myanmar, with a large population of people who inject drugs (PWID). Recent surveys among PWID have estimated HIV prevalence in Kachin to be >40%. This study aimed to examine trends in and associations with HIV incidence among PWID attending three harm reduction drop-in centres (DICs) in Kachin using routine HIV testing data gathered from these DICs.

Methods: Demographic data and information relating to HIV testing and drug use behaviours was collected from threeMédecins du Monde (MdM) DICs offering HIV

testing in Hopin, Mogaung, and Myitkyina for 2008-2020. HIV prevalence was assessed using testing data from first-time DIC visits. HIV incidence was estimated by linking subsequent test records. Cox regression was used to examine associations with HIV incidence, including the impact of opioid substitution therapy (OST).

Results: First test results were available for 13,056 PWID. HIV prevalence was high in the population at 52.0% (95%CI 51.2-52.9%). HIV prevalence peaked in 2017 at 69.7% (95%CI 67.2-72.1%), declining over subsequent years to 39.5% (95%CI 36.9-42.2%) by 2020. Data on follow-up HIV testing was available for 2,343/6,268 (37.4%) PWID testing initially negative, totalling 5988.6 person-years (py), with 466 incident HIV infections between 2009-2020.

Overall HIV incidence among PWID in Kachin was 7.8 per 100py (95%CI 7.1-8.5) and decreased from 23.9 (95%CI 16.9-33.8) in 2008-11 to 5.5 per 100py (95%CI 4.9-6.3) in 2017-20. Incidence was highest in Myitkyina (12.6 per 100py; 95%CI 10.6-14.9). Hopin and Mogaung DICs provided OST from 2008, with 65.4% of their clients followed on OST for an average of 2.5yrs. For PWID at these two DICs, a history of starting OST during follow up was associated with reduced HIV incidence (aHR 0.45, 95%CI 0.36-0.58; p<0.001), adjusting for DIC location and year of testing. Recent (≤6weeks) needle sharing was associated with higher incidence (aHR 2.23, 95%CI 1.86-2.97; p<0.001).

Conclusions: Although HIV incidence is high among PWID in Kachin, data suggests it has decreased over recent years and is reduced after starting OST. It is possible that increases in needle and syringe provision and OST access among PWID may have contributed to the observed decrease in incidence.

EPC045

Estimating the population size of transgender people in South Africa using multiple methods

R. Chimatira[1], E.M. Sibanda[1], O. Mtapuri[1,2], D. Jebese-Mfenqe[1], J. Chikwanda[1], T. Thengwa[1], P. Ndagurwa[1,2], T. Nyengerai[1,2], B. Futshane[1], N. Tshuma[1,2]
[1]*Beyond Zero, East London, South Africa,* [2]*Best Health Solutions, Johannesburg, South Africa*

Background: National estimates of the sizes of key populations (KPs) are essential for HIV prevention intervention planning, resource allocation and for advocacy efforts. However, epidemiologic studies typically provide size estimates for only limited high priority geographic areas. Beyond Zero conducted the first study that used a range of data sources and employed multiple methods to estimate the number of adult transgender TG people in South Africa.

Methods: We implemented population size estimation (PSE) of TG people in South Africa in 2021 using several primary approaches (respondent-driven sampling, service multiplier, wisdom of the crowd) and secondary sources (administrative records, capture-recapture). Data were collected from a representative sample of 15/52 districts across all nine provinces. The estimates based on the wisdom of the crowd, service multiplier and respondent-driven sampling were loaded into the anchored multiplier calculator with their lower/upper bounds to generate the consensual estimate with their associated confidence intervals.

Results: The median of estimates was 179 327 TG people in South Africa (95% CI 174 609 to 184 059), which corresponds to 0.30% (95% CI 0.29 to 0.31) of the total population of the country. The median of the estimated population size for each province are: Eastern Cape - 21951 (95% CI 18598 to 25 489); Free State - 5967 (95% CI 3 962 to 8 518); Gauteng - 50916 (95% CI 43 823 to 53 434); KwaZulu-Natal (KZN) - 22388 (95% CI 16 524 to 25 124); and Limpopo - 18960 (95% CI 14 900 to 21 763).

Conclusions: Our estimates suggest that 0.30% (95% CI 0.29 to 0.31) of adults in South Africa might be TG people. Overall, the approaches used in this TG PSE study were robust and consistent with other estimates of adults of reproductive age who are transgender which are between 0.10% to 1.1% (UNAIDS, 2014) and 0.50%–0.90% (Poteat, 2014).

The results provide an important point for macro- and micro-level planning of HIV services at the national and local levels, and for allocating programme resources and assessing programme coverage and quality.

EPC046

In-country migration as a predictor of HIV infection among *travestis* and transgender women in Northeast Brazil

B. Oliveira Leite[1], L. Magno[2], F. Inácio Bastos[3], I. Dourado[1], The DIVAS-NE Study Group
[1]*Federal University of Bahia, Salvador, Brazil,* [2]*State University of Bahia, Salvador, Brazil,* [3]*Oswaldo Cruz Foundation, Rio de Janeiro, Brazil*

Background: *Travestis* and transgender women (TrTW) experience high mobility mainly due to social vulnerability that drives them to seek better living conditions in Brazil, which is a continental country. This mobility may expose them to a greater risk of HIV infection. Therefore, we aimed to investigate the association between in-country migration and HIV infection among TrTW.

Methods: A cross-sectional study of 864 TrTW recruited by the respondent-driven sampling method in capitals of three States in Northeast Brazil in 2017. The eligibility criteria were: 18 years old or older and to identify herself as a travesti (emic concept to describe a specific gender identity in Brazil) or trans woman. A socio-behavioral questionary and HIV rapid tests were applied.

In-country migration was defined as having a current residence place different from the birthplace. Weighted odds ratio (OR) with a 95% confidence interval (CI) estimated the association between in-country migration

and HIV, by age groups (18-34 years old/35 and older), and adjusted by socio-behavioral variables: skin color, income, years of schooling, participation in TrTW civil society organizations, gender-based discrimination, lifetime sex work, lifetime forced sex, illicit use of industrial liquid silicone and primary health care as a usual source of care. The analysis was conducted using the library for complex samples of STATA software.

Results: 36.5% (95%CI:32.1-41.3) of TrMT reported in-country migration; and only 8.2% international migration (95%CI:5.9-11.4). The prevalence of HIV was 24.5% (95%CI:20.5-28.9).

The main reason for in-country migration was to look for work and improve the quality of life (53.7%;95%CI:45.3-62.0). The rate of in-country migration was substantial and increased the odds of HIV infection among TrTW 18-34 years old (aOR:1.84; 95%CI:1.04-3.27); and especially among those 35 years and older (aOR:3.08;95%CI:1.18-8.04).

Conclusions: Studies on the association of migration and HIV infection are recent and scarce among TrTW. The findings suggest the risk of HIV may be higher among TrTW who migrated in-country, which increases, even more, the disproportionality of this infection among them. Therefore, it becomes necessary to develop strategies and health policies that reflect the intense mobility that exists in these populations.

EPC047

Predictors of HIV risk among MSM and transgender women who report online male sexual partners: findings from a cross-sectional two-city study in India

R. Nelson[1], V. Chakrapani[1], A. Sebastian[2], S. Rawat[3], D. Baruah[3]

[1]Centre for Sexuality and Health Research and Policy (C-SHaRP), Chennai, India, [2]National Institute of Advanced Sciences (NIAS), Bengaluru, India, [3]The Humsafar Trust, Mumbai, India

Background: In India, the increasing use of smartphones among MSM and transgender women (TGW) increases access to sexual partners through virtual spaces. Limited information is available on HIV risk behaviors of MSM and TGW who use virtual spaces to meet sexual partners.

We aimed to examine sociodemographics and related characteristics of MSM and TGW who report online sexual partners, and to identify predictors of condomless anal sex (CAS).

Methods: Between November 2020 and January 2021, we conducted interviewer-administered surveys with 500 MSM and 500 TGW (as part of an ongoing cohort study called 'S3') recruited through community-based organizations in Chennai and Mumbai in India.

Data were collected on the use of social media and dating apps, sociodemographics, condom use, and mental health (e.g., depression, anxiety, problematic alcohol use). Multivariable logistic regression analyses were conducted to identify factors that predict CAS among those with online sexual partners.

Results: Most MSM (59.2%) and TGW (50.4%) reported meeting male sexual partners online through generic platforms (e.g., Facebook, WhatsApp, Instagram), and/or gay apps (e.g., Grindr, Blued). CAS was not significantly different between those who had online sexual partners vs. those who did not (MSM: 31.1% vs. 40.4%; TGW: 29.9% vs. 34.5%).

Those who had completed college (MSM: aOR=1.95, p<.001; TGW: aOR=2.20, p<.01) and those in sex work (MSM: aOR=2.13, p<.001; TGW: aOR=2.50, p<.01) had higher odds of having online sexual partners. In adjusted multivariable models, having online sexual partners was not a significant predictor of CAS.

Among MSM with online sexual partners, internalized homonegativity and resilient coping were significant predictors of CAS; and among TGW with online sexual partners, internalized transprejudice and depression were significant predictors of CAS.

Conclusions: Condomless anal sex is highly prevalent among MSM and TGW who reported online sexual partners. Interventions, which can be delivered online or offline, that address internalized stigma (internalized homonegativity or transprejudice) and depression, and steps to improve resilience could decrease HIV risk among those with online sexual partners.

Given the mixing of offline and online sexual networks, online interventions need to be implemented to promote safer sex and mental health, complementing physical outreach.

EPC048

Feeling safe in a 'risk environment'? Correlates of injecting meth use among MSM who attend sexualized drug parties

M. Charoenyang[1], N. Samoh[1], Y. Kongjaroen[1], T.E. Guadamuz[1]

[1]Mahidol University Center of Excellence in Research on Gender, Sexuality and Health (MUGSH), Nakhon Pathom, Thailand

Background: The escalating rates of injecting methamphetamine (meth) use to enhance sexual pleasure are attributed to rising HIV infections. Moreover, Bangkok has become an epicenter for sexualized drug parties where injecting meth use has become common place. Using Tim Rhodes' 'risk environment' as a framework, we assessed correlates of injecting meth use among MSM who attended sexualized drug parties.

Methods: Between September and December 2021, 532 MSM who are at least18 years old and who have attended circuit or private parties, were recruited through various social media platforms related to sexualized drug parties (private LINE®chat groups, private Facebook groups,

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

and private Twitter groups). Participants completed self-administered survey, that included questions on demographics, sexual behaviors and substances use. Multivariable logistic regression was used to examine the correlates of injecting meth use.

Results: Of participants, 234 (44%) reported injecting meth usein the past six months. Significant correlates of injecting meth use included having an average monthly income of >$900, (AOR: 1.70, 95% CI: 1.02-2.86), self-reported HIV status (AOR: 2.59, 95% CI: 1.58-4.24), having more than 20 sex partners in the past six months (AOR: 2.84,95% CI: 1.17-6.92), having sex without condom at last sex intercourse (AOR: 3.65,95% CI: 2.19-6.92), having received things/opportunities in exchange for sex (AOR: 3.29, 95% CI: 2.15-5.05), never used alcohol during/before sex (AOR: 4.23, 95% CI: 2.15-5.05) and feeling safe living as gay/bi/MSM/non-hetero in Thailand (AOR:2.08, 95% CI:1.35-3.22).

Conclusions: Results suggest while injecting meth use, unsafe sex, and sex exchange are common in sexualized drug parties, alcohol use is not. Remarkably, participants who attended sexualized drug parties feel safe living in Thailand as a gay/bi/MSM/non-hetero.

This juxtaposition of feeling safe amidst very harsh drug laws may be an entry point for HIV prevention and harm reduction practitioners to promote enabling environments for high-risk MSM.

EPC049

Epidemiology and cause of increasing new infection of HIV among key population in Punjab, Pakistan

A. Ikram[1], M. Ahmed[2]

[1]*Sathi Foundation, Lahore, Pakistan,* [2]*Sathi Foundation, Faisalabad, Pakistan*

Background: Sathi Foundation is a transgender-based organization working to provide free HIV/AIDS testing and Sexually Transmitted Infections (STIs) diagnosis and treatment services among sexual minorities in Pakistan. It does through community outreach, Voluntary Confidential Counseling, and Testing. In a country like Pakistan, where keeping condoms along can get you arrested, sexual and gender minorities are living at the edge regarding their sexual lives and are forced to indulge in unprotected sexual activities due to the stigma attached to the preventions like condoms and lubricants.

Description: Under the Global Fund's project, Sathi Foundation registered 2975 individuals from Sexual and gender minorities including 1278 transgender persons and 1697 Male who sex with Male (MSM) during the tenure of July to December 2021. In total, 52 individuals tested positive for HIV (39 Transgender and 13 MSM) who reported low income, illiterate and are forced to involved in sex work to earn their bread and butter. Out of 39 PLHIVs, only individuals were able to connect to the treatment cascade reasoning the fear of status disclosure to their families of partners, poor health maintenance due to low income or no source of income, or/and lack of education and information about HIV/AIDS.

Lessons learned: Through the data conducted by Sathi Foundation and one on one interviews with the sexual and gender minority, one of the major issues highlighted by the community was an increase in the prevalence due to the increase in substance abuse specifically chemical drugs. Usage of Chemical drugs has become a common practice among young gay boys to enhance their sexual performance and it is also commonly used by the community members who are involved in sex work.

Sathi Foundation has recently started to educate the community regarding drug abuse issues and empower them through advocacy and awareness sessions to reduce drug consumption among the community.

Conclusions/Next steps: Sathi Foundation has represented its statistics to the Punjab Aids Control Program and Government to strategize the interventions and reduce drug trafficking and its consumption among the community. Sathi Foundation is conducting sessions with the community across the province (Punjab) to raise awareness about HIV/AIDS prevention.

EPC050

Exploring the descriptive epidemiology of demographics and tweet themes among gay, bisexual, and other men who have sex with men users from Twitter in the United States

Y. Liu[1], J. Mitchell[2], H. Lv[3], J. Luo[3]

[1]*University of Rochester Medical Center, Public Health Sciences, Rochester, United States,* [2]*Florida International University, Miami, United States,* [3]*University of Rochester, Department of Computer Science, Rochester, United States*

Background: Evidence suggests that an increasing number of gay, bisexual and other men who have sex with men (MSM) use open network social media (e.g., Twitter) to create and discuss topics/viewpoints related to HIV prevention and relevant lived experience related to health and social issues. However, no study has explored the demographic profiles or the tweet contents (e.g., theme) generated by MSM Twitter users in the United States (US).

We seek to use big data science and social media mining techniques to explore the descriptive epidemiology of demographics and tweet themes among this subgroup.

Methods: We used a python library (*Tweepy)* to continuously (2021.2-2022.1) collect eligible tweets (e.g., with the keyword/hashtag indication of gay and same-sex behaviors) and associated metadata (e.g., user profiles, # of followers, tweets' likes/retweets) from Twitter. We used an unsupervised machine learning model (e.g., *Latent Dirichlet Allocation) to c*haracterize themes from the collected tweets. Various artificial intelligence-based, computational inference techniques (e.g., Face++,*16-layer VGG CNN* architecture, M3-inference model) were used to infer user

demographics (e.g., location, race, age, and sexual orientation). Descriptive analyses were performed to enumerate top themes and the distribution of user demographic profiles.

Results: A total of 1,063,642 tweets from 21,015 verified, unique MSM users on Twitter were identified. Computationally inferred statistics showed that the mean age of these MSM users was 33 years, with most being White (47%), followed by Black (28%), Hispanic/Latino (19%), and other races (6%).

Overall, 73%, 12%, and 15% of the tweets were generated by users in urban, suburban, and rural areas, respectively, with most users from Los Angeles, Houston/Dallas, New York City, Chicago, and Miami metropolitan areas.

The most discussed and liked/retweeted themes included the experience of gay/HIV-related discrimination/stigma, gay pride/empowerment, sexual orientation disclosure, demands for social support, and experience of HIV prevention uptake (e.g., HIV testing,pre-exposure prophylaxis).

Conclusions: Our research highlights the feasibility of mining tweets to understand the trending topics and related user demographic profiles of MSM in the US.

These findings may yield insight into "who is talking what" and provide implications for designing targeted social media messaging to address various health-related concerns that resonate among social media-using MSM.

EPC051

Global incidence of hepatitis C virus (HCV) and HIV infection among people who inject drugs: a systematic review and meta-analysis

A. Artenie[1], J. Stone[1], H. Fraser[1], C. Arum[1], A.G. Lim[1], A. McNaughton[1], A. Trickey[1], Z. Ward[1], M. Alary[2,3], T. Azim[4], J. Bruneau[5,6], K. Debeck[7,8], K. Dumchev[9], J.R. Havens[10], K. Hayashi[11], J. Iversen[12], A. Judd[13], M. Kåberg[14,15], L. Maher[16], V. Mravčík[17], N.E. Palmateer[18,19], S.A. Strathdee[20], V. Sypsa[21], C.S. Todd[22], M. Hickman[1], P. Vickerman[1]

[1]University of Bristol, Population Health Sciences, Bristol, United Kingdom, [2]Centre de Recherche du CHU de Québec, Québec City, Canada, [3]Université Laval, Département de Médecine Sociale et Préventive, Québec City, Canada, [4]BRAC University, Dhaka, Bangladesh, [5]Université de Montréal, Département de Médecine Familiale et Médecine d'Urgence, Montréal, Canada, [6]Centre Hospitalier de l'Université de Montréal, Montréal, Canada, [7]Simon Fraser University, School of Public Health, Burnaby, Canada, [8]BC Centre on Substance Use, Vancouver, Canada, [9]Ukrainian Institute on Public Health Policy, Kyiv, Ukraine, [10]University of Kentucky College of Medicine, Department of Behavioral Science, Lexington, United States, [11]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [12]UNSW Sydney, Kirby Institute for Infection and Immunity, Sydney, Australia, [13]MRC Clinical Trials Unit at UCL, London, United Kingdom, [14]Stockholm Needle Exchange, Stockholm Centre for Dependency Disorders, Stockholm, Sweden, [15]Karolinska Institute, Karolinska University Hospital Huddinge, Department of Medicine Huddinge, Stockholm, Sweden, [16]Kirby Institute, UNSW Sydney, Kensington, Australia, [17]Society Podané ruce, Brno, Czechia, [18]Glasgow Caledonian University, School of Health & Life Sciences, Glasgow, United Kingdom, [19]Public Health Scotland, Glasgow, United Kingdom, [20]University of California, School of Medicine, San Diego, United States, [21]National and Kapodistrian University of Athens, Department of Hygiene, Epidemiology and Medical Statistics, Medical School, Athens, Greece, [22]PROMISE Zambia, Durham, United States

Background: Data on the incidence of hepatitis C virus (HCV) and HIV infection among people who inject drugs (PWID) are key to informing prevention strategies. We conducted a systematic review and meta-analysis to synthesize global data on primary HCV and HIV incidence among PWID.

Methods: We searched MEDLINE, Embase and PsycINFO for studies published between 01/01/2000 and 14/09/2020 that estimated HCV or HIV incidence among community-recruited PWID. We also contacted the authors of 35 studies to request updated or unpublished data.

We included studies that estimated incidence by longitudinally re-testing people at-risk or by using tests for recent infection. We used random-effects meta-analysis to pool HCV and HIV incidence rates and the relative risks

of HCV and HIV acquisition among women who inject drugs compared to men who inject drugs and young PWID (defined as <20 - ≤35) compared to PWID who were not young.

Results: We retrieved 58 and 51 estimates for HCV and HIV incidence, derived from 25 and 24 countries, respectively. Globally, the pooled HCV incidence was 14.4 per 100 person-years (100py; 95% confidence interval (CI): 12.1-17.0, I^2=96.2%) and the pooled HIV incidence was 1.6 per 100py (95%CI: 1.1-2.2, I^2=98.2%) [Figure].

Relative to men, women had a higher risk of HCV and HIV acquisition [pooled relative risks: 1.20 (95%CI: 1.07-1.34; 32 estimates) and 1.30 (95%CI: 1.09-1.55; 25 estimates), respectively]. Relative to PWID who were not young, PWID who were had a higher risk of HCV and HIV acquisition [pooled relative risks: 1.32 (95%CI: 1.11-1.57; 24 estimates) and 1.42 (95%CI: 1.17-1.73; 21 estimates), respectively].

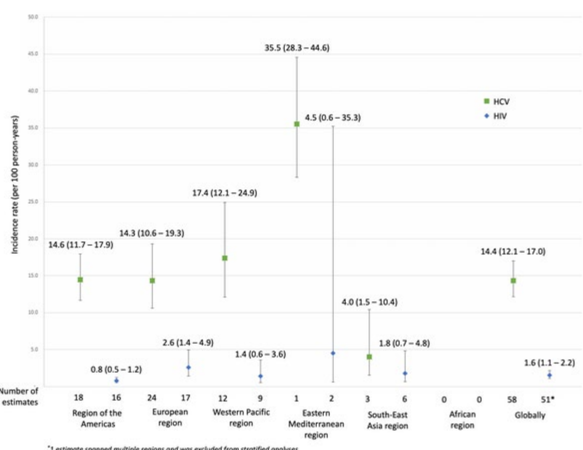


Figure. Incidence of HIV among people who inject drugs.

Conclusions: Findings indicate high HCV and HIV incidence among PWID, particularly among women and those who are young, emphasizing the importance of targeted prevention strategies. The limited data available in some regions indicate a pressing need to implement systems for monitoring HCV and HIV incidence in this population.

EPC052

HIV seroprevalence and sexual prevalence practices among men who have sex with men in southeast Nigeria

U. Amalu[1]

[1]*University of Port Harcourt, Port Harcourt, Nigeria*

Background: According to the Nigeria HIV/AIDS Indicator and Impact Survey, the prevalence of HIV/AIDS is 1.4% in Nigeria. Despite significant interventions to curb the spread and achieve epidemic control, men who have sex with men (MSM) are disproportionately affected by this epidemic.

Data on HIV and sexual behavior among MSM is scarce in Nigeria, therefore the prevalence of HIV among MSM in south east Nigeria.

Methods: Using a community-based cross-sectional study conducted between June 2021 and October 2021 in 54 MSM hotspots, data was collected on socio-demographics and sexual behavior of 1378 cisgender MSM by interviewer-administered questionnaires. We followed the national algorithm to perform HIV tests, and statistical analysis was done using SPSS.

Results: HIV prevalence was 13.1% among the participants of median age 24 (IQR = 21 – 30 years). Almost all respondents (97%) had adequate knowledge of HIV and transmission mechanisms, and the most common source of information was social media. However, misconceptions on prevention were found in 71.4% of respondents. 77% reported having multiple sex partners and inconsistent condom use (54.4%) in the last three months.

Conclusions: Our study demonstrated that despite high knowledge of HIV/AIDS among MSM, information on prevention is inadequate leading to unsafe sexual practices. This necessitates the need for attention to be shifted towards prevention messaging and scale up of prevention services if epidemic control is to be achieved by 2030.

Epidemiology of HIV and hepatitis C in people who inject drugs in Nepal

K. Deuba[1], R.M. Rajbhandari[2], M.K. Shrestha[3], L.R. Pandey[3], D. Dahal[3], N.R. Awasthi[3], R. Bhattarai[4], A. Bhattachan[3], L. Johnston[5], S. Devkota[3], IBBS Study Group

[1]*Save the Children Stationed at National Centre for AIDS & STD Control, Kathmandu, Nepal,* [2]*Intrepid, Kathmandu, Nepal,* [3]*National Centre for AIDS & STD Control, Ministry of Health and Population, Kathmandu, Nepal,* [4]*Save the Children, Kathmandu, Nepal,* [5]*UNAIDS Consultant, Kathmandu, Nepal*

Background: People who inject drugs (PWID) are at increased risk for HIV and hepatitis C virus (HCV) due to same injection risk behaviors, including multi-person use of needles and syringes. This first nationally representative survey aimed to measure the prevalence of HIV, HCV, HIV/HCV co-infection and associated risk behaviors among PWID in Nepal.

Methods: This cross-sectional study included 1690 male injecting drug users who were recruited using respondent driven sampling from March to October 2020 in all seven provinces of Nepal. Rapid tests for HIV and HCV, and face-to-face interviews were conducted to collect biological and behavioural information. Data for male injecting drug users for each of the seven Provinces were adjusted for network size and differential recruitment and analyzed using RDS Analyst. Gile's estimate was used to calculate network weight and proportion of population. Multiplier was used to calculate aggregate weight of particular province. National and subnational HIV and HCV estimates presented as prevalence with 95% confidence intervals (CI).

Results: Nationally, 31% (n=534; CI=27.6-33.5) of male injecting drug users were between 20-24 years and 56% (n=917; CI=52.5-58.9) were 25 years and above. HIV prevalence among male injecting drug users in Nepal is 2.8% (n=37; CI=1.9-4.16) whereas the highest prevalence is in Bagmati province, 4.6%. HCV prevalence is 13.3% (n=204; CI=11.2-15.6) and the highest being in Sudurpaschim province, 26.8%. Among those who are HIV seropositive (n=37), 72% are co-infected with HCV. Less than one fourth (19% [n=369; CI=16.7-21.9]) of male injecting drug users ever shared the same needle/syringe with another person, among which 43% (n=176; CI=36.9-50.1) shared a needle/syringe with another person the last time they injected drugs.

Conclusions: More male injecting drug users have burden of HCV than HIV infection, and response to HCV is non-existent among PWID in Nepal. These findings support the need for urgent implementation of interventions to minimise the risk of HCV acquisition, including developing integrated responses for HIV and HCV among PWID in Nepal.

Risk factors for acquisition, infectivity and transmission of HIV

EPC054

Determinants of HIV infection among Out of School Youths: lessons from Northwest Nigeria

A. Adeyemi[1], O. Fakunle[2], I. Fakunle[3], C. Odonye[4]

[1]*Center for Infectious Diseases Research and Evaluation, Lafia, Nigeria,* [2]*Health and Human Service Secretariat, Public Health, Abuja, Nigeria,* [3]*UNICEF, Bauchi, Nigeria,* [4]*Dalhatu Araf Specialist Hospital, Lafia, Nigeria*

Background: Northwest Nigeria has a demographic profile made up of largely young population with high proportion of out of school youths (OOSY). Due to sociocultural, economic and biological factors, OOSY are at risk of sexual and reproductive health issues including HIV/AIDS.

Moreover, OOSY are marginalized due to inability to assess structured and well-organized school-based HIV education and prevention programs. This study assessed HIV prevalence and its determinants among OOSY in Northwest Nigeria.

Methods: We used a cross-sectional study design. A multi-stage sampling technique that included stratification by rural and urban was undertaken. A total of 3,900 OOSY aged 15-24years was reached. Data collection including HIV testing was undertaken between June and October 2021 in five Northwest Nigeria states. Multiple logistic regression was used to assess the determinants of HIV infection.

Results: The mean age was 15.1±3.4years, 58.2% were male and 42.6% were urban dwellers. Mean age at sexual debut was 13.6±2.9years; mean age of first alcohol intake was 15.1±4.4years; and mean age at first cigarette smoking was 14.9±2.8years. About 60.5% engaged in daily intake of alcoholic drinks; 27.9% were current smokers; 70.2% had sex in the last 12 months and 33.4% had sex in the last 3 months. HIV prevalence was 2.8%.

About 34.0% used tramadol as a stimulant, 19.8% used marijuana and 7.6% injected drugs. About 18.2% were involved in transactional sex and 12.2% had symptoms of previous sexually transmitted infections.

Also, 42.8% had comprehensive knowledge of HIV/AIDS, 20.4% were involved in multiple partnership, inconsistent condom use was 29.7% and 32.0% had sex with partners older than 10years.

Determinants of HIV infection were tramadol use OR=2.5 95%CI 1.4-4.7, inconsistent condom use OR=3.9 95%CI 2.0-6.7, comprehensive knowledge of HIV/AIDS OR=0.7 95%CI 0.4-0.9 and sex with older male partners OR=3.4 95%CI 1.3-5.1.

Conclusions: Tramadol use, inconsistent condom use and intergenerational sex were determinants of HIV infection among OOSY. There is a need to design targeted HIV prevention programs with comprehensive knowledge, and education against substance abuse for them.

Additionally, OOSY programming needs to be prioritized in Northwest Nigeria due to their higher HIV prevalence compared to the national youth prevalence.

EPC055

Prevalence and incidence of sexually transmitted infections in a cohort of female sex workers in San Pedro, Côte d'Ivoire (ANRS 12381 PRINCESSE)

N.M. Nouaman[1,2], P.A. Coffie[1,3], M. Plazy[4], V. Becquet[5,6], A. Agoua[7], C. Zébago[7], H. Dao[7], J. Larmarange[6], S. Eholie[8], the ANRS 12381 PRINCESSE Study Group

[1]*Programme PAC-CI, site ANRS Côte d'Ivoire, Abidjan, Cote D'Ivoire,* [2]*Université Félix Houphouet-Boigny, Département de Santé Publique et d'Odontologie légale,UFR d'Odonto-Stomatologie, Abidjan, Cote D'Ivoire,* [3]*Université Félix Houphouet Boigny, Département de Dermatologie et Infectiologie, UFR des Sciences Médicales, Abidjan, Cote D'Ivoire,* [4]*Bordeaux Population Health Research Center, Université de Bordeaux, Inserm, IRD, Bordeaux, France,* [5]*Ined, Aubervilliers, Paris, France,* [6]*Ceped, IRD, Université de Paris, Inserm, Paris,France, Paris, France,* [7]*ONG Aprosam, San Pedro, Côte d'Ivoire, San Pedro, Cote D'Ivoire,* [8]*Université Félix Houphouet-Boigny, Département de Dermatologie et Infectiologie, UFR des Sciences Médicales, Abidjan, Cote D'Ivoire*

Background: The ANRS 12381 PRINCESSE study is an interventional single-arm cohort. Participants recruitment started in November 2019.

The study aimed to evaluate a comprehensive and community-based care offer among FSWs aged ≥ 18 years in the San Pedro area.

Methods: Care services included quarterly syndromic screening for STIs, as well as vaginal and anal swabs for the screening of *chlamydia trachomatis* (CT) and *neisseria gonorrhoea* (NG) by polymerase chain reaction (PCR) at M0, M12 and M24. At the same visits, identification of dysplasias and precancerous lesions of the cervix was performed by visual inspection after applying acetic acid and Lugol's iodine. STIs were managed according to the national algorithm. We describe:

i. The characteristics of cervical lesions as well as the prevalence of STIs (syndromic and PCR) and associated symptoms and;

ii. The incidence of syndromic STIs during follow-up.

Results: In November 2021, 372 FSWs were included. The median age was 29 years, 34% had never been to school, 56% were Ivorian, and the median duration of sex work was 2 years. At inclusion, 4.7% [95% confidence interval: 2.8-7.5] had cervical lesions with 3.5% leukoplakia and 2.2% haemorrhagic cervical junction zone.

The prevalence of syndromic STIs was 17.2% [13.0-22.6]; associated clinical signs were vaginal discharge (13.7%), vaginal ulceration (2.1%), lower abdominal pain (4.3%) and cervical inflammation (2.6%). The prevalence of anovaginal CT and NG were 8.7% [6.2- 12.1] and 10.4% [7.6- 13.9], respectively; clinical signs were found in 2.4% of CT-positive and 12.2% of NG-positive FSWs. Most FSWs with syndromic STIs did not have CT or NG infection.

During the follow-up, 82 cases of syndromic STIs were observed per 209 person-years, i.e. an incidence of 39.1% [31.1-49.0]. PCR data at M12 and M24 are being consolidated and will allow estimating the incidence of CT and NG.

Conclusions: A high prevalence and incidence of syndromic STIs were observed among FSWs, highlighting the importance and the interest of a regular follow-up. The results also showed the predominantly asymptomatic nature of STIs discovered by PCR in this at-risk population and, therefore, the importance of coupling syndromic screening and PCR analyses.

EPC056

Co-occurring substance use and mental health conditions and syndemics of HIV and HCV among people with opioid use disorders in a Fast-Track City in the United States

P. Marotta[1], D. Humphries[2], T. Kaser[1], L. Marks[3], H. Reno[4], L. Filiatreau[4], P. Cavazos-Rehg[4], G. Gross[1], E. Sacham[5], K. Stringer[6], V. McKay[1], V. Wang[2], T. Brown[7], R. Heimer[2], D. Spiegelman[2]

[1]Washington University in St. Louis, Brown School, Saint Louis, United States, [2]Yale University, School of Public Health, New Haven, United States, [3]Washington University in St. Louis, Infectious Disease Clinic, School of Medicine, Saint Louis, United States, [4]Washington University in St. Louis, School of Medicine, St. Louis, United States, [5]St. Louis University, St. Louis, United States, [6]Middle Tennessee State University, Murfreesboro, United States, [7]Vivent Health, St. Louis, United States

Background: The rising opioid use crisis in the United States has resulted in heightened risk of HIV and HCV transmission among people with opioid use disorders (OUD). Research is lacking that investigates the association between co-occurring substance use and mental health disorders and risk of HIV and HCV infection among people with OUD.

Methods: This cross-sectional study examined electronic health records from inpatient, emergency department, and ambulatory patient encounters and lab test results at a large metropolitan hospital network of 7832 people with OUD from 2018-2021 in St. Louis, Missouri.

Multinomial regression analyses with generalized linear modeling was used to identify significant relationships between mental health substance use disorders, and relative risk of HIV, HCV infection and co-infection after adjusting for race, age, sex, and recent STI.

Results: Results: The prevalence of HIV infection was 2.3% (n=181) and HCV infection was 15.6% (n=1225). HCV co-infection among those with HIV and OUD was 44.8% (n=81). Stimulant use disorder was associated with being diagnosed with HIV (RR=1.9, 95%CI=1.2, 3.2, p=.007), HCV (RR=2.0, 95%CI=1.7, 2.3, p<.001), and HIV-HCV co-infection (RR=1.9, 95%CI=1.1, 3.1, p=.017).

Depressive disorders were associated with HIV (RR=2.4, 95%CI=1.6, 3.7, p<.001), HCV (RR=1.5, 95%CI = 1.2, 2.0, p<.001) and HIV-HCV co-infection (RR=4.7, 95%CI=2.7, 8.3, p<.001).

African American people were at significantly greater risk of being infected with HIV (RR=3.6, 95%CI=2.3, 5.6, p<.001) and co-infected with HIV-HCV (RR=3.2, 95%CI=2.0, 5.6, p<.001) compared to white people. Injection drug use was associated with HCV (RR=6.2, 95%CI=5.1, 7.6, p<.001) and HIV-HCV co-infection (RR=9.1, 95%CI=5.3, 15.6, p<.001).

Having an STI in the past year was associated with HIV (RR=3.1, 95%CI=1.8, 5.6, p<.001), HCV (RR=1.6, 95%CI=1.2, 2.1, p=.002) and HIV-HCV coinfection (RR=4.7, 95%CI=2.7, .8.3, p<.001). Comparing people who were co-infected with HIV and HCV to those infected only with HIV, those co-infected

were more likely to have a diagnosis of depression (RR=2.0, 1.05, 3.7, p=0.035, engage in injection drug use (RR=13.6, 95%CI=3.9 47.4 p<.001).

Conclusions: Findings from this study underscore the importance of addressing co-occurring substance use and mental health disorders to redress syndemics of HIV-HCV infection among people with opioid use disorders.

EPC057
Sustained HIV viral suppression among people living with HIV in Trinidad and Tobago

M. Coudray[1], L.O. Lavia[2], E. Cyrus[1], N. Lyons[2], G. Boyce[2], R.J. Edwards[2]
[1]University of Central Florida, Population Health Sciences, Orlando, United States, [2]Medical Research Foundation of Trinidad and Tobago, Port of Spain, Trinidad and Tobago

Background: Suppression of the human immunodeficiency virus (HIV) (<200 copies/mL) among people living with HIV (PLHIV) is essential to prevent HIV transmission. However, HIV viral suppression is typically assessed using a single viral load test rather than examining sustained viral suppression. Extant literature shows that sustained viral suppression significantly reduces the risk of HIV transmission, thus this study aims to identify sociodemographic factors associated with sustained viral suppression.

Methods: We conducted a retrospective analysis of secondary data from 586 PLHIV who attended the Medical Research Foundation of Trinidad and Tobago (MRFTT), which is a treatment and care site that serves PLHIV 18 years and older, between 2017 and 2021. Sustained viral suppression was defined as having a HIV viral load <200 copies/ml in all viral load tests between 2017-2021.

Descriptive analysis performed for all variables, followed by a regression model of the statistically significant variables (p ≤ 0.05), and sustained viral suppression. Of the 586 PLHIV 22 passed away during the reporting period leaving the surviving cohort at 564.

Results: The average age was 45 years (SD = 11.25), and each patient had an average number of 98 visits (SD = 38.81) to the clinic over the study period. 172 (30.5%) of patients achieved sustained viral suppression. Patients with a sustained viral suppression had an average age of 46 years (SD = 11.84), and an average number of 101 visits (SD =33.26). Patients who were on anti-retroviral therapy for more than 5 years (OR=1.655; 95% CI= 1.029 - 2.662), and were enrolled at the clinic for more than 5 years (OR=2.396; 95% CI= 1.221-4.701) were more likely to achieve sustained viral suppression.

Conclusions: Despite access to free HIV treatment and care, significant disparities exist in sustained viral suppression among PLIV in T&T. Addressing these disparities may improve the ability of PLIV to sustain viral suppression and substantially reduce their risk of transmission.

EPC058
Spatio-temporal estimates of risk group proportions for adolescent girls and young women across 13 priority countries in sub-Saharan Africa

A. Howes[1], K.A. Risher[2], V.K. Nguyen[3], O. Stevens[3], K.M. Jia[4], T.M. Wolock[1], L. Zembe[5], I. Wanyeki[5], M. Mahy[5], C. Benedikt[5], S.R. Flaxman[6], J.W. Eaton[3]
[1]Imperial College London, Department of Mathematics, London, United Kingdom, [2]Northwestern University, Department of Medical Social Sciences, Feinberg School of Medicine, Evanston, United States, [3]Imperial College London, MRC Centre for Global Infectious Disease Analysis, School of Public Health, London, United Kingdom, [4]Havard University, Harvard T. H. Chan School of Public Health, Boston, United States, [5]Joint United Nations Programme on HIV/AIDS, Geneva, Switzerland, [6]University of Oxford, Department of Computer Science, Oxford, United Kingdom

Background: The UNAIDS Global AIDS Strategy 2021-2026 sets forth adolescent girls and young women (AGYW) as a priority population for HIV prevention and recommends differentiating intervention portfolios geographically based on local HIV incidence and individual risk behaviours.

We developed district-level estimates for proportions of young women in each risk category across thirteen Global Fund AGYW priority countries in southern and eastern Africa.

Methods: We analysed forty national household surveys conducted between 1999-2018 in thirteen priority countries. The proportion of AGYW in three sexual risk categories (not sexually active, cohabiting with a single partner, and non-regular partners) was modelled using a spatio-temporal small-area estimation model.

We considered variation resulting from age, space, time, and space-time interaction effects. Our model utilised the multinomial-Poisson transformation, facilitating inference with R-INLA.

Results: Data consisted of 498,248 female survey respondents aged 15-29. There was substantial variation in the risk group proportions across countries and between districts within each country (Figure 1, bottom). 26.1% (95% CrI: [8.38, 57.8]) of 15-29 year-olds were in the highest risk category.

Among 20-29 year-olds, we found a geographic delineation, north of which in the east of the continent, cohabiting (61.3%) is more common than non-regular partners (23.1%), and south of which, non-regular partners (56.8%) are more common than cohabiting (26.7%) (Figure 1, top).

Overall 57.4% of 15-19 year-old adolescent girls were not sexually active, but in Mozambique early sexual debut is common, with 37.9% already cohabiting.

Conclusions: The proportion of AGYW in each risk category varied substantially between age groups and within and between countries, but did not change substantially over

time. Our estimates provide data for HIV programmes to implement a stratified HIV prevention approach, and set targets as proposed in the Global AIDS Strategy.

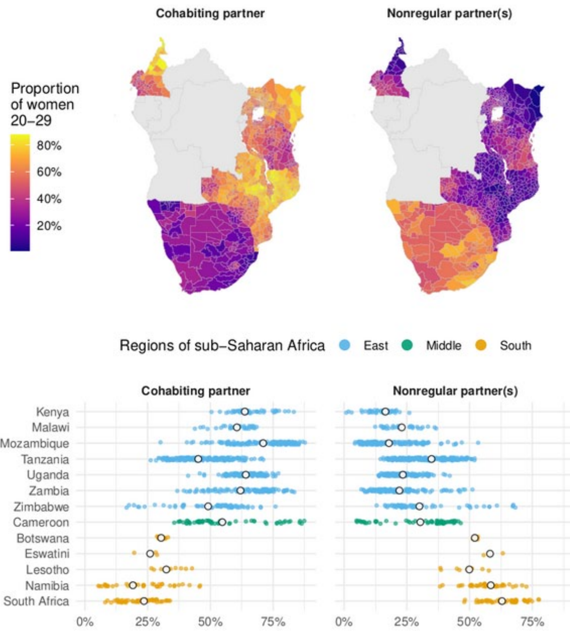

Figure 1.

Female genital schistosomiasis and STI prevalence among at-risk women for HIV in Zambia

S. Mwangelwa[1], C. Kabengele[2], W. Kilembe[2], C. Himukumbwa[1], V. Musale[2], E. Rogers[3], K. Mumba[1], C. Chanda[2], R. Parker[3], A. Tichacek[3], M. Inambao[1], B. Vwalika[4], S. Allen[3], K.M. Wall[3]

[1]Center for Family Health Research in Zambia, Ndola, Zambia, [2]Center for Family Health Research in Zambia, Lusaka, Zambia, [3]Emory University, Atlanta, United States, [4]University of Zambia School of Medicine, Obstetrics and Gynaelcology, Lusaka, Zambia

Background: Young women remain disproportionately affected by HIV in sub-Saharan Africa with prevalence as much as eight times higher than men of matching age groups. In a cohort of HIV- young women at increased risk of HIV at Center for Family Health Research in Zambia (CFHRZ), the HIV incidence of 3/100 PY. Female genital schistosomiasis (FGS) and STIs are associated with risk of HIV infection among women. We conducted a cross-sectional survey to ascertain the prevalence of FGS and its risk factors and STIs among women.

Methods: From March 2020-December 2021, we surveyed women in the cohorts at CFHRZ in Lusaka and Ndola, Zambia, and assessed FGS risk factors and positivity using colposcopy. We also collected genital samples and tested them for Chlamydia, Gonorrhea, and Human Papilloma Virus (HPV) using Gene Xpert. We evaluated factors associated with FGS positivity using logistic regression.

Results: Among 536 women, overall FGS prevalence was high at 23.5%. The most common FGS indicators on colposcopy were abnormal blood vessels and homogenous yellow sandy patches.

From the survey, factors associated ($p<0.1$) with FGS positivity included: living in a village or rural area prior to the age of 16, younger age at first intercourse, menstruating less than once per month, not using disposable sanitary pads or reusable cloths/towel during menstruation, and use of the hormonal contraceptive implant.

On physical examination, associated factors included: presence of bilateral inguinal adenopathy, cervicitis, non-bloody discharge from cervix, and cervical nodules. FGS co-infection with a high-risk HPV type was common (36%), with Chlamydia (9%) and with Gonorrhea (5%) but the difference in prevalence of these infections compared to women without FGS was not statistically significant. These genital abnormalities were mostly asymptomatic.

Conclusions: This is one of the first studies to report that the prevalence of FGS in young HIV- women living in urban areas in Zambia is concerningly high. Further, it is not uncommon for women with FGS to have other genital pathology and this exacerbates their risk of HIV acquisition. This study underscores the need for focused interventions to address genital abnormalities among young women in sub-Saharan Africa to mitigate the risks of HIV acquisition.

Epidemiology of AIDS events (e.g., AIDS-related opportunistic infections and cancers)

EPC060

Prevalence and determinants of reduced glomerular filtration rate in HIV-infected patients on antiretroviral therapy at Bafoussam Regional Hospital in Cameroon

P. Nyibio Ntsekendio[1,2], G. Tayong Enih Fosah[3], C. Epie Bekolo[1], C. Kouanfack[1,4]

[1]University of Dschang, Public Health, Dschang, Cameroon, [2]Regional Technical Group for HIV/AIDS Control for the North West Region, Monitoring and Evaluation, Bamenda, Cameroon, [3]National AIDS Control Committee, Regional Technical Group for HIV/AIDS Control, Bamenda, Cameroon, [4]Central Hospital-Cameroon, Day Hospital, Yaounde, Cameroon

Background: Chronic kidney disease (CKD) one of the major problem in patients on Antiretroviral Therapy (ART), and can lead to loss of kidney function, leading to complications and end-stage kidney disease requiring kidney replacement therapy. The purpose of this study was to determine the prevalence and determinants of reduced glomerular filtration rate in HIV-infected patients on ART at the Bafoussam Regional Hospital (BRH).

Methods: This was a cross-sectional study conducted from January to April, 2021, targeting HIV-infected patients on ART at the Treatment Centre of BRH by consecutive sampling. Data on socio-demographic and clinical factors were collected using a semi-structured questionnaire administered face to face.

Statistical analysis was performed by estimating the prevalence using the CKD-EPI (Chronic Kidney Disease Epidemiology collaboration) equation and logistic regression models to identify potential factors associated with glomerular filtration rate reduction.

Results: Of the 1268 participants targeted, 846 (92.66%) consented to participate in the study. The female gender represented about 430 (50.83%). A total of 105 (12.41%) participants had an eGFR <60 ml/min/1.73 and 80(16.91%) were on TDF-based regimen.

The factors found to be significantly associated with reduced glomerular filtration rate were: male gender (aOR=1.76, 95%CI: 1.01-3.08, P=0.045), HBV coinfection (aOR=2.27, 95%CI: 1.30-3.97, P=0.001), HCV coinfection (aOR=3.24, 95%CI: 2.01-5.97, P=0.001), diabetes (aOR=3.79, 95%CI: 2.15-2.15, P=0.001), hypertension (aOR=3.41, 95%CI: 1.95-5.98, P=0.001), WHO stage [stage III (aOR= 3.15, 95%CI: 1.35-7.33, P=0.01) and stage IV (aOR= 23.4, 95%CI: 10.6-51.8, P=0.001)], ART regimen [AZT+3TC+LPV/r (aOR=6.2, 95%CI: 1.53-25.16, P=0.01) and TDF/3TC/DTG (aOR=4.10, 95%CI: 1.02-16.43, P=0.04)].

Conclusions: High prevalence of reduced eGFR was observed among patients with HIV-infected patients at BRH. This GFR reduction was associated with history of diabetes, hypertension, HBV/ HCV coinfections, WHO stage III/IV, and patients on AZT+3TC+LPV/r and TDF/3TC/DTG. Thus, decision makers should regulate routine monitoring, screening and management of eGFR in HIV-infected patients especially those with these clues.

EPC061

Cancer treatment and survival among cervical cancer patients living with or without HIV in South Africa

Y. Turdo[1], Y. Ruffieux[1], T.M.G. Boshomane[2], H. Mouton[3], K. Taghavi[1], A.D. Haas[1], G. Maartens[3,4], E. Rohner[1]

[1]University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland, [2]University of Pretoria & Steve Biko Academic Hospital, Department of Nuclear Medicine, Pretoria, South Africa, [3]University of Cape Town, Department of Medicin, Division of Clinical Pharmacology, Cape Town, South Africa, [4]University of Cape Town, Institute of Infectious Disease and Molecular Medicine, Wellcome Centre for Infectious Diseases Research in Africa, Cape Town, South Africa

Background: Cervical cancer is the most common cause of cancer-related deaths among women in South Africa and women living with HIV are disproportionally affected.

We compared cancer treatment and all-cause mortality between HIV-positive and HIV-negative cervical cancer patients in South Africa.

Methods: We used reimbursement claims data from a private open medical aid scheme in South Africa from 01/2011–07/2020. We included women with ≤2 ICD-10 codes for cervical cancer (C53) on separate days, who had received cancer treatment within 180 days of diagnosis. We assessed treatment provision using logistic regression and factors associated with all-cause mortality using Cox regression. We assigned missing values for histology and ethnicity using multiple imputation.

Results: Among 483 women with cervical cancer, 136 (28%) were HIV-positive at cancer diagnosis (median age: 46 years) and 347 (72%) were HIV-negative (median age: 54 years). Most HIV-positive patients were Black (96%), compared to 61% among HIV-negative patients, although 79 patients had missing information on ethnicity. Among 285 patients with available ICD-O-3 morphology claims codes, the proportion with adenocarcinoma was substantially lower in HIV-positive (4%) than in HIV-negative patients (26%). Most HIV-positive patients (71%) were on antiretroviral therapy at cancer diagnosis. HIV-positive patients were more likely to receive radiotherapy (adjusted odds ratio [aOR] 2.28, 95% confidence interval [CI] 1.29-4.02) or chemotherapy (aOR 2.39, 95%CI 1.13-5.06) and less likely to receive surgery (aOR 0.48, 95%CI 0.28-0.82) than HIV-negative patients. HIV-positive cervical cancer patients were at higher risk of death than HIV-negative patients (adjusted hazard ratio [aHR] 1.50, 95%CI 1.04-2.16). Other factors associated with higher all-cause mortality included older age (>60 vs <40 years, aHR 2.26, 95%CI 1.45-3.54) and cancer stage at diagnosis. Patients with metastasised cancer had a 4-fold higher risk of death than those with localised cancer during the ≤9 months after cancer diagnosis (aHR 3.95, 95%CI 2.47-6.31); whereas >9 months after cancer diagnosis the risk of dying became similar (aHR 1.38, 95%CI 0.73-2.60).

Conclusions: HIV-positive cervical cancer patients were at increased risk of death compared with HIV-negative patients. The higher all-cause mortality in HIV-positive cervical cancer patients may be explained by differences in tumour progression, clinical care, and HIV-specific mortality.

EPC062

Knowledge of Kaposi sarcoma among oncology and HIV providers in Kenya

S. Prasad[1,2], D. McMahon[1], H. Byakwaga[3], M. Laker-Oketta[3], A. Semeere[3], L. Chemtai[4], R. Ali[1,5], S. Collier[6], T. Maurer[7], I. Bassett[1], J. Martin[8], N. Busakhala[4,9], E. Freeman[1,10]

[1]Massachusetts General Hospital, Boston, United States, [2]Icahn School of Medicine, The Mount Sinai Hospital, New York, United States, [3]Infectious Diseases Institute, Kampala, Uganda, [4]Academic Model Providing Access to Healthcare, Eldoret, Kenya, [5]The George Washington University School of Medicine, Washington D.C., United States, [6]University of Washington, Seattle, United States, [7]Indiana University, Indianapolis, United States, [8]University of California San Francisco, San Francisco, United States, [9]Moi University, College of Health Sciences, School of Medicine, Pharmacology and Toxicology, Eldoret, Kenya, [10]Medical Practice Evaluation Center, Mongan Institute, Massachusetts General Hospital, Boston, United States

Background: In sub-Saharan Africa (SSA), the burden of HIV-associated malignancies such as Kaposi Sarcoma (KS) remains high, despite widespread access to antiretroviral therapy. KS diagnoses are often made in late stages of disease, when interventions are less effective with poor prognoses. Delayed diagnoses and poor outcomes in cancer have been linked to low provider knowledge, though little is known about provider knowledge regarding KS in SSA. We aimed to assess clinical knowledge of KS among providers who treat KS in Kenya.

Methods: We approached all healthcare providers working in either oncology referral clinics or selected HIV primary care clinics in the AMPATH network in Kenya from August 2019-January 2020. KS knowledge was assessed using a self-administered structured questionnaire adapted from prior experience in East Africa, which included 38 questions regarding KS classification, morphology, symptomatology, diagnosis and management (example question: true/false, each of the following can be used to effectively treat KS (ART/amputation/chemotherapy/antibiotics/radiation/dexamethasone).

Results: Of 196 healthcare workers enrolled (76% HIV providers, 24% oncology providers), the median age was 37 (IQR 31,42) years, 62% were male and most had a university (37%) or tertiary/vocational degree (50%). Range of provider cadres included medical/clinical officers (MO/CO) (26%), nurses (20%), peer mentors (13%), social workers (7.7%) and pharmacists/pharmacy technicians (7.2%).

On average, oncology providers had an overall score of 65.8% correctly answered questions, while HIV providers had a mean score of 60.2%. MO/COs had high overall mean knowledge scores, with 79.2% questions answered correctly *(Table 1)*; these were 86.0% for oncologists and 76.9% for HIV MO/COs. Across most healthcare provider groups, respondents scored lowest on the section assessing knowledge of KS treatment/management (range: 42.5-71.9%).

	All (n = 196)	MO/CO* (n = 51)	Nurse† (n = 38)	Pharmacist§ (n = 14)	Counsellor (n = 16)	Peer Mentor (n = 25)	Social Worker (n = 15)	Health Info Officer (n = 12)	Other Staff (n = 23)
Total Score[a]	61.4 (17.9)	79.2 (12.7)	65.5 (14.7)	56.2 (8.5)	51.2 (14.1)	48.8 (14.7)	51.1 (9.7)	50.7 (13.8)	52.6 (16.1)

*Medical or clinical officer titles; †nurse or nurse manager; § pharmacy tech or pharmacist

Table 1. Knowledge regarding KS amogst health care professionals in Kenya by provider type. Values refer to mean % answered correctly (SD) per group, with 100% being maximum score per topic.

Conclusions: Assessing gaps in KS-specific knowledge among diverse cadres of health professionals may be especially important in resource-limited areas, where burden is high and lower-level cadres are often providing front-line HIV and cancer care.

EPC063

Causes of outpatients before diagnosis of HIV infection in people living with HIV (PLHIV) based on the real-world data

Z. Li[1], Q. Zhao[1], P. Shen[2], H. Lin[3], N. He[1]

[1]Fudan University, Department of Epidemiology, Key Laboratory of Public Health Safety of Ministry of Education, School of Public Health, Shanghai, China, [2]Yinzhou District Center for Disease Control and Prevention, Ningbo, China, [3]Yinzhou District Health Bureau, Ningbo, China

Background: Late diagnosis of HIV infection is associated with poor responses to antiretroviral treatment and higher prevalence of comorbidities in people living with HIV (PLHIV). Herein, we describe the distribution of diseases in outpatient setting within 5 years before diagnosis of HIV infection in PLHIV.

Methods: A retrospective cohort study was conducted in Yinzhou District, Ningbo City of China during 2009-2020. Based on the diagnoses of outpatients, we estimated the number of clinic visits per 100 person-years of diseases by gender and age and assessed its association with late diagnosis using time-dependent Cox regression mode

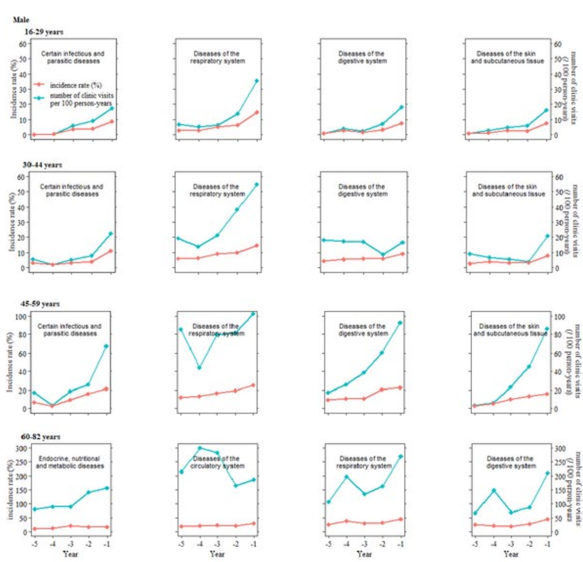

Figure 1. Distribution of diseases within 5 years before diagnosis of HIV infection in males

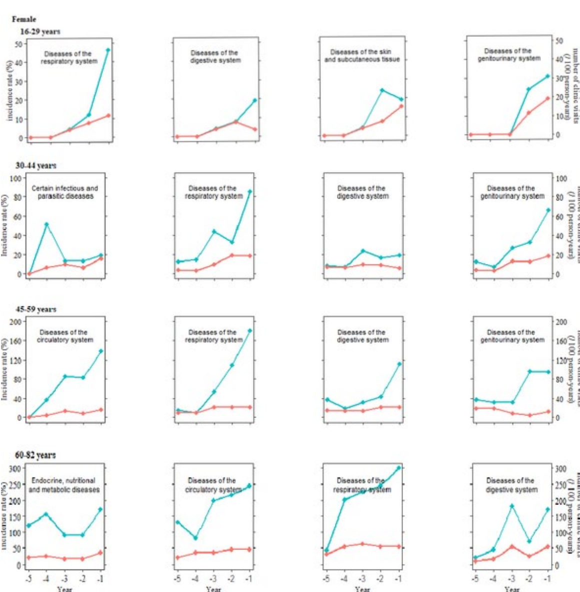

Figure 2 Distribution of diseases within 5 years before diagnosis of HIV infection in females.

Results: Among the 789 PLHIV, almost are males with 696 males vs, 93 females. Large percentage of PLHIV had late diagnosis of HIV infection, especially in the age groups 45-59 (84.46%) and 60-82 (83.37%). These diseases increased rapidly before diagnosis in HIV-infected males of all ages, including diseases of the respiratory system, certain infectious and parasitic diseases, diseases of the digestive system, and diseases of the skin and subcutaneous tissue.

Conclusions: We found HIV cases went to outpatients for some certain diseases before diagnosis of HIV infection considerably. These diseases may be helpful for early diagnosis of HIV infection.

EPC064

Cervical cancer screen and treat program in women living with HIV, Chiengi and Nchelenge districts, Luapula Province, Zambia, January to September 2021

L. Tembo[1], M. Malasa[1], N. Sinyange[1], P. Bwalya[2], D. Katongo[2]

[1]*Zambia Field Epidemiology Training Program, Zambia Field Epidemiology Training Program, Lusaka, Zambia,* [2]*Ministry of Health, Ministry of Health, Mansa, Zambia*

Background: Zambia has the third-highest age-standardized incidence of cervical cancer at 22.9 per 1,000 women in Sub-Saharan Africa. Cervical cancer contributes 25% of the cancer burden in Zambia. Women living with Human Immunodeficiency Virus (WLHIV) have a five-fold risk of cervical cancer. We investigated the positivity of cervical intraepithelial neoplasia (CIN) and suspected invasive cervical carcinoma (ICC) and its associated factors in Chiengi and Nchelenge Districts.

Methods: This was a cross-sectional study of WLHIV screened for cervical cancer using visual inspection with acetic acid (VIA) in Chiengi and Nchelenge Districts, January to September 2021. CIN are treatable pre-malignant lesions. CIN1 has <70% lesions, and CIN2+ has >70% lesions. ICC is deep tissue malignant lesions. Data collected from VIA sites included the outcome (tested positive [CIN and suspected ICC] or negative), age, and geographical location. Backward stepwise logistic regression was used to identify the best predictors. Analysis was performed in R, and the odds ratio was the measure of association.

Results: Nchelenge and Chiengi Districts have a total of 7793 and 3202 WLHIV, with cervical cancer screening coverage of 12% and 36%. Data for 1622 clients were analyzed. The median age was 36 (interquartile range [IQR]: 27-44) years. 25% (407) tested positive, of the positives; 14% (57) had CIN1, 84% (343) had CIN2+ and 2% (7) had suspected ICC. Chiengi's positivity was 36% (365) and Nchelenge, was 12% (42). Both districts had one VIA site. Chiengi offered treatment for CIN1. Nchelenge offered treatment for CIN1 and CIN2+.

All suspected ICC are referred. WLHIV of Chiengi had increased odds of CIN and suspected ICC compared to WLHIV of Nchelenge (AOR=7.4,95% CI: 5.3-10.5). Compared to WLHIV above 45, WLHIV in age-groups 16-30 and 31-45 years had higher odds of CIN and suspected ICC (AOR=1.7, 95%CI: 1.2-2.5, AOR=1.5, 95%CI: 1.1-2.2, respectively).

Conclusions: CIN positivity was high, and the screening coverage was low. Scaling up cervical cancer screen and treat services, conducting targeted screen and treatment in areas with high positivity, training adequate staff to screen and treat CIN, and messaging on the importance of cervical cancer screening to reduce cervical cancer-related morbidity and mortality in WLHIV.

EPC065

Socio-economic inequalities in the coverage of cervical cancer screening among women living with HIV in Low- and Middle-Income Countries between 2010 and 2019

D.B. Abila[1], S.B. Wasukira[2], P. Ainembabazi[3], H. Wabinga[4]

[1]*Makerere University, Kampala, Uganda,* [2]*Makerere University, School of Public Health, Kampala, Uganda,* [3]*Infectious Disease Institue, Kampala, Uganda,* [4]*Makerere University, Department of Pathology, Kampala, Uganda*

Background: Women living with HIV (WLWHIV) are at a higher risk of developing cervical cancer and the World Health Organisation recommends that they are screened from the age of 25 years. There is a need to describe inequalities in access to screening. We described the coverage of and socioeconomic inequalities in cervical cancer screening among WLWHIV in LMICs.

Methods: We conducted a weighted multi-country secondary data analysis of the 2010 – 2019 cross-sectional Demographic and Health Surveys (DHS) completed in Cameroon, Ivory Coast, Lesotho, Namibia, and Zimbabwe. These countries tested women for HIV and had questions on cervical cancer screening. Our analysis included WLWHIV aged 25 to 49 years.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Absolute and relative socioeconomic inequalities were calculated using the Slope Index of Inequality (SII) and Concentration Index (CIX) respectively by wealth quintile..

Results: A total of 2,950 WLWHIV from five countries were included in this study. The proportion of women who had heard about cervical cancer ranged from 41.0% to 86.9%. The proportion of women who had ever screened for cervical cancer was highest in Namibia (35.7%) and lowest in Ivory Coast (1.8%.) The pooled estimate of the coverage of cervical cancer screening in the five countries was 16.5% [95% Confidence interval (CI): 6.1 – 27.0].

In all the countries, higher proportions in the richest wealth quintile were screened compared to those in the poorest wealth quintile. In all the countries, higher proportions of WLWHIV in the urban areas were screened compared to those in the rural areas. In all the countries except Cameroon, the coverage of screening showed pro-rich inequalities.

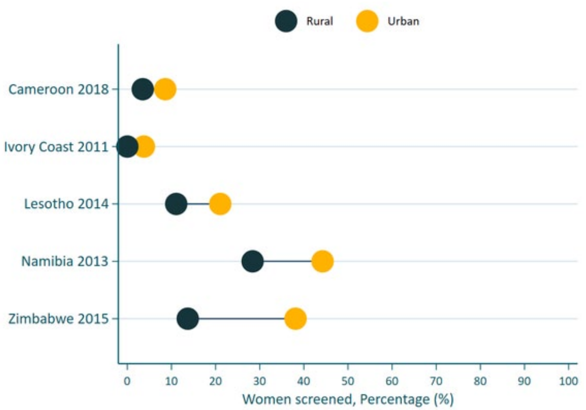

Figure. Coverage by type of place of residence.

Conclusions: There exist inequalities in the utilization of cervical cancer screening by the wealth index and type of place of residence. Cervical cancer screening programs in LMICs need to reduce these inequalities among WLWHIV.

Epidemiology of non-AIDS infections and communicable diseases (e.g., viral hepatitis, STIs, TB, COVID-19)

Depressive symptoms and health services utilization in the HIV-Hepatitis C co-infected population in Canada

G. Marathe[1,2], E.E. Moodie[1], M.-J. Brouillette[2,3], C. Laniece Delaunay[1,2], C. Cooper[4], M. Hull[5], V. Martel-Laferrière[6], S. Walmsley[7], J. Cox[1,2], M.B. Klein[1,2,8], Canadian Co-Infection Cohort

[1]McGill University, Department of Epidemiology, Biostatistics and Occupational Health, Montreal, Canada, [2]McGill University Health Center-Research Institute, Centre for Outcomes Research and Evaluation, Montreal, Canada, [3]McGill University, Department of Psychiatry, Montreal, Canada, [4]University of Ottawa, Department of Medicine, Ottawa, Canada, [5]St. Paul's Hospital, Centre for Excellence in HIV/AIDS, Vancouver, Canada, [6]Centre de Recherche du Centre Hospitalier de l'Université de Montréal, Department of Microbiology, Infectious Diseases and Immunology, Montreal, Canada, [7]University of Toronto, Department of Medicine, Toronto, Canada, [8]CIHR Canadian HIV Trials Network (CTN), Vancouver, Canada

Background: Depression is highly prevalent among people living with Hepatitis C (HCV) and HIV, which can contribute to high health services utilization (HSU). HCV cure have benefits in preventing liver disease and beyond, which could have an impact on HSU.

Thus, we examined the relationship between depressive symptoms and HSU in the HIV-HCV co-infected population in Canada and how it was affected by sustained virologic response (SVR).

Methods: We used data from the Canadian Co-infection Cohort, a multicentre prospective cohort, and its associated food security sub-study. We predicted Centre for Epidemiologic Studies Depression Scale-10 classes for depressive symptoms using a random forest classifier and corrected for misclassification.

The HSU outcomes were number of self-reported inpatient visits (hospital stays, emergency room)and outpatient visits (general practitioner, HIV clinic, specialist, walk-ins) in the past 6 months. We restricted the analysis to the 2ndgeneration direct acting antiviral (DAA) era (post-November 2013).

All HCV-RNA+ participants were followed until death, withdrawal or end of study period (July 2020). Participants achieved SVR if they had undetectable HCV-RNA at least 12-weeks after end of treatment. We used an adjusted zero-inflated negative binomial model accounting for overdispersion and excess zeroes.

Results: We included 1,153 participants, of which 530 were treated for HCV and 504 (95%) achieved SVR. The median number of inpatient visits was 0 (IQR:0-1) and outpatient visits was 3 (IQR:1-6).

Among those who had not achieved SVR, inpatient visits were 17% higher among those with depressive symptoms than those without; outpatient visits were 5% higher. Among those who achieved SVR, there was no evidence of an association between depressive symptoms and HSU. SVR was associated with 24% lower inpatient visits, however outpatient visits remained the same post-SVR.

Outcomes Outcomes	SVR		Depressive symptoms - Among those who achieved SVR		Depressive symptoms - Among those who did not achieve SVR	
	Incidence Rate Ratio (IRR)	95% Confidence Interval (CI)	IRR	95% CI	IRR	95% CI
Inpatient visits	0.76	0.70-0.84	1.03	0.89-1.19	1.17	1.06-1.29
Outpatient visits	1.00	0.97-1.02	1.01	0.97-1.05	1.05	1.02-1.08

Table 1: Effect of depressive symptoms and SVR on HSU

Conclusions: Depressive symptoms were associated with an increase in HSU, indicating depression contributes to poor health outcomes in the co-infected population. SVR was associated with a reduction in inpatient visits but not outpatient visits. SVR appears to attenuate the effect of depressive symptoms on HSU.

EPC067

Risk factors and outcomes for syphilis coinfection among men and women living with HIV in KwaZulu-Natal, South Africa

V. Le[1], C. Moe[2], M. Krows[3], S. Govere[4], M.Y.S. Moosa[5], C. Celum[3,1], P. Drain[1,2,3]
[1]University of Washington, Department of Medicine, Seattle, United States, [2]University of Washington, Department of Epidemiology, Seattle, United States, [3]University of Washington, Department of Global Health, Seattle, United States, [4]AIDS Healthcare Foundation, Durban, South Africa, [5]University of KwaZulu-Natal, Department of Infectious Diseases, Durban, South Africa

Background: The prevalence of syphilis co-infection among people living with HIV (PLHIV) in South Africa was reported to be ~1.6% among adults. Syphilis co-infection may accelerate clinical progression and lead to worse health outcomes. We sought to compare the risk factors for syphilis co-infection for PLHIV, and to determine if syphilis co-infection altered health outcomes among men and women in KwaZulu-Natal, South Africa.
Methods: We conducted a prospective cohort study of adult PLHIV participants at the iThembalabantu Clinic in Umlazi Township, South Africa from September 2013 to April 2017.At initial HIV diagnosis and 12 months later, we collected information on demographics, clinical data, as well as biological specimens like the rapid plasma reagin (RPR) test for syphilis. In the analysis, we used Fisher's exact and t-tests for independent samples were used to examine associations between cohort demographic characteristics and outcomes.
Results: Among 2,580 adult PLHIV, 123 (4.7%) were concurrently positive for treponema pallidum by RPR titers. PLHIV with a syphilis co-infection were younger (31.2 years vs. 33.4 years, p<0.01) than PLHIV without syphilis.
There was no difference in co-infection prevalence across genders. The prevalence of tobacco usage (p<.03) and having a partner who had also tested positive for HIV (p<.03) were both higher in PLHIV with syphilis.
Once identified at 0 months, participants with syphilis were treated with a penicillin regimen. At 12 months after initial HIV/syphilis diagnosis, there were no significant differences in mean CD4 count, rates of hospitalizations, deaths, other opportunistic infections, or HIV-related cancers.
Conclusions: In our cohort, syphilis co-infection was higher than reported in population surveys, and may have been related to younger age, an HIV-positive partner, or tobacco use. Identifying these age and risk-taking behavior differences may help diagnose those with both HIV and syphilis earlier, which is crucial in regions with healthcare access barriers within South Africa. As all syphilis co-infected participants were promptly treated, the efficacy of syphilis treatment was valuable in preventing differences in disease progression, mortality, or health outcomes.

EPC068

The impact of travel distance to rifampicin-resistant tuberculosis treatment sites on outcomes of all-oral RR-TB treatment regimens in South Africa

K.C. McNabb[1], A. Bergman[1], N. Mthimkhulu[1], K. Lowensen[1], A. Patil[1], C. Budhathoki[1], J.E. Farley[1,2]
[1]Johns Hopkins School of Nursing, Center for Infectious Disease and Nursing Innovation, Baltimore, United States, [2]Johns Hopkins University School of Medicine, Center for AIDS Research, Baltimore, United States

Background: People living with HIV (PLWH) are disproportionately affected by South Africa's high rates of rifampicin-resistant tuberculosis (RR-TB). Older RR-TB research linked increased distance from home to treatment site with increased risk for death; however, regimens were much longer in duration. Newer, all-oral RR-TB treatment regimens decrease treatment duration and lessen the frequency of healthcare visits.
Here, we examine the relationship between distance traveled and treatment outcomes with new treatment regimens.
Methods: We retrospectively analyzed 271 RR-TB patients treated with all-oral regimens at nine South African public RR-TB hospitals between 2015 and 2019. We linked patients to their residential ward using location data reported to the National Health Laboratory Service. Travel distance was calculated from each patient's ward centroid to their RR-TB treatment site using the *georoute* command in Stata. Binary logistic regression was used to model the relationship between RR-TB treatment outcome and travel

distance with unsuccessful outcomes (i.e., death, treatment failure, and loss to follow-up) compared to successful outcomes (i.e., cure, treatment complete).

Results: Out of 271 participants, there were 187 PLWH (69.00%), and 80 (29.52%) unsuccessful outcomes. The median age was 40 (IQR:31-51) years, 59.04% male, 59.77% unemployed, and 79.25% had not completed secondary school. The median travel distance was slightly longer for PLWH (32.01km, IQR:11.34-58.29) compared to those who were not (29.27km, IQR:9.96-54.74).

In the final model, travel distance was not significantly related to RR-TB treatment outcomes (OR: 0.997, 95% CI [0.988, 1.006]) when adjusting for other relevant covariates, including HIV status, age, gender, education level, employment status, number of children, government assistance, informal housing, rural residence, and rural treatment site.

Conclusions: These null findings may indicate that all-oral RR-TB regimens lessen the burden of increased distance from a treatment site, but more research is necessary. Geospatial analyses in South Africa present several challenges, including changing municipal and ward borders and the use of multiple address formats.

For future analyses of distance to treatment, we recommend using GPS coordinates to record the location of a patient's residence. When GPS data collection is not feasible, we recommend recording the patient's address, ward, and the nearest school.

EPC069

Epidemiology of Human Papillomavirus genotypes and prevalence of cervical precancerous lesions among women living with HIV: results from a pilot cervical cancer screening program in Uganda

M. Lubega[1], C. Okiira[2], A. Nabaggala[2], C. Achola[2], Y. Kamuntu[1], A. Musoke[1], A. Abala[1], S. Ndidde[2]

[1]*Clinton Health Access Initiative, Kampala, Uganda,* [2]*Uganda National Health Laboratory Services, Kampala, Uganda*

Background: There is lack of data on distribution of human papillomavirus (HPV) genotypes among women living with HIV (WLHIV) in Uganda. Yet, WLHIV are more likely to be infected with human papillomavirus (HPV) and to have persistent HPV progressing to cervical pre-cancer and/or invasive cervical cancer compared to HIV negative women. Information on epidemiology of high-risk HPV (hrHPV) infections and prevalence of specific HPV genotypes is very vital in mounting an effective response to the growing challenge of cervical cancer in Uganda.

Methods: A pilot cervical cancer screening program was conducted between September and April 2021. HPV testing using self-collected vaginal samples was offered to WLHIV aged 25-49 attending antiretroviral clinics in 10 high-volume hospitals. Samples were processed using GeneXpert and Hologic Panther devices. HPV+ women were referred for Visual Inspection with Acetic acid (VIA) triage, and those having precancerous or cancerous lesions were treated with cryotherapy, thermocoagulation, LEEP or referred for further management. Data was collected from hospital registers to determine the distribution of HPV genotypes and prevalence of cervical precancerous lesions among HPV positive WLHIV.

Results: Across the 10 pilot sites, 6,611 WLHIV were offered screening and 6,012 (91%) had a valid result. HPV positivity rate was 30% (1,817). Of the HPV+ women, 214 (12%) were HPV16 positive, 187 (20%) were HPV 18/45 and 1,203 (66%) had other hrHPV genotypes as a pooled result including HPV 31, 33, 35, 39, 51, 52, 56, 58, 59, 66 and 68. 213 (12%) of the women had multiple infections with hrHPV genotypes.

823 (45%) of the HPV+ women were effectively linked to care and triaged with VIA and 173 (21%) were found with precancerous lesions, of whom 137 (79%) were treated as appropriate. Fourteen women were found to be suspicious of cancer and referred for further management.

Conclusions: HrHPV infections are common among WLHIV, including HPV16 and HPV18 that cause majority of cervical cancer. A significant proportion of women have infections that progress to cervical pre-cancer. HPV+ WLHIV found to have no lesions need to be proactively followed-up to ensure that non-regressive infections are appropriately managed. Cervical cancer efforts need to intensify screening among WLHIV.

EPC070

Self-reported TB testing according to HIV status and TB symptoms in urban communities in Blantyre, Malawi

R.H. Nzawa-Soko[1,2], R.M. Burke[1,2], H.R.A. Feasey[1,2], M. Khundi[1,2], M. Nliwasa[1,1], A.T. Choko[1], P. MacPherson[1,2,3], E.L. Corbett[2,1]

[1]*Malawi Liverpool Wellcome Trust Reseach Programme, Data, Blantyre, Malawi,* [2]*London School of Hygiene and Tropical Medicine, London, United Kingdom,* [3]*Liverpool School of Tropical Medicine, Liverpool, United Kingdom*

Background: Identifying the "missing millions" with undiagnosed TB is critical to meeting TB elimination goals. Intensified TB testing efforts are focused on symptomatic individuals and high-risk groups including people living with HIV (PLHIV), but uptake can be suboptimal.

Methods: Between May 2019 and March 2020, we conducted a TB-HIV prevalence survey among adults in urban residential Blantyre, Malawi, including questions about TB testing (chest X-ray or sputum). Using log-binomial regression, we investigated factors associated with recent (past 12 months) and lifetime (ever-tested) self-reported TB testing. We investigated associations with HIV (negative, positive-on-ART, positive-no-ART), age group, sex, and additionally for recent TB testing, current TB symptoms (cough, fever, night sweats, weight loss).

Results: Extended questionnaires were completed by 2,043 randomly selected prevalence survey participants, of whom 310 (15.2%) had tested for TB at least once (ever-

tested) including 145 (46.8% of ever-tested) recent testers. PLHIV on ART were more likely to have ever-tested for TB than HIV-negative people (aRR 2.01, 95% CI:1.62-2.47). There was no association with sex, but older people were more likely to have ever-tested. For recent testing, associations were similar to ever testing for HIV status, sex, and age. Current TB symptoms, reported by 307/2043 (15.0%), were associated with increased testing in the past 12 months compared to asymptomatic participants (aRR 1.98, 95% CI:1.41,2.7). Uptake appeared suboptimal, with only 14% of those symptomatic recently tested.

	Number in group	Number TB tested (%)	Univariate RR (95% CI)	Multivariable aRR (95% CI)
Lifetime TB testing				
HIV negative	1,761	206 (12%)	Ref	Ref
HIV positive on ART	249	95 (38%)	3.26 (2.65-3.98)	2.01 (1.62-2.47)
HIV positive not on ART	33	9 (27%)	2.33 (1.20-3.82)	1.71 (0.89-2.7)
Recent TB testing				
HIV negative	1,761	97 (5.5%)	Ref	Ref
HIV positive on ART	249	44 (18%)	3.21 (2.28-4.43)	2.05 (1.43-2.90)
HIV positive not on ART	33	4 (12%)	2.20 (0.70-4.85)	1.70 (0.55-3.68)
Current TB symptoms	307	42 (14%)	2.31 (1.63-3.20)	1.98 (1.41-2.74)

Table 1: Ever-tested for TB and Recent TB testing: univariate and multivariate risk ratios
**Multivariable aRR also adjusted for age group and sex*

Conclusions: Few PLHIV in Blantyre recalled ever testing for TB, although lifetime reporting of having tested was substantially higher for PLHIV on ART than for HIV-negative people, possibly reflecting screening at ART visits. Tracking trends in lifetime and recent TB testing reported by PLHIV could provide a valuable indicator of the intensity of case-finding efforts.

EPC071
Impact of COVID-19 lockdown on testing for and diagnoses of sexually transmitted infections in Bangkok, Thailand

N. Pungpapong[1], K. Termvanich[2], S. Suriwong[2], N. Teeratakulpisan[2], O. Surisarn[2], T. Amatsombat[2], A. Chancham[2], K. Rurkoukos[2], P. Mingkwanrungruang[2], M. Bucha[2], T. Phattanathawornkool[2], R. Trichavaroj[2], M. Avery[3], S. Mills[3], P. Phanuphak[2], N. Phanuphak[2], R.A. Ramautarsing[2]
[1]Winchester College, Winchester, United Kingdom, [2]Institute of HIV Research and Innovation, Bangkok, Thailand, [3]FHI 360, Bangkok, Thailand

Background: Thailand's third and largest COVID-19 wave started in April 2021 and resulted in a complete lockdown in July, with curfews and tight gathering and movement restrictions. We assessed the impact of these measures on sexually transmitted infection (STI) testing and diagnosis patterns at the Pribta-Tangerine clinic in Bangkok.

Methods: We analyzed data from clients visiting the gender-friendly and comprehensive sexual health clinic from January to September 2021, including those testing for syphilis serology and/or *Neisseria gonorrhoeae* and *Chlamydia trachomatis* by nucleic acid amplification.
Weekly changes in number of clients and STI tests, proportion of clients coming for STI testing, and percent positivity before and after lockdown were analyzed with interrupted time series analysis and further disaggregated by population and age.

Results: From January 1 to September 30, 2021, 3,658 clients visited Pribta-Tangerine; 1,840 (50.3%) had an STI test. Lockdown resulted in a 47.5% and 43.9% decrease in overall STI testing and diagnoses, respectively (Figure 1); the same was seen for each STI.
STI testing decreased among men who have sex with men (58.8%, incidence rate ratio [IRR] 0.412; 95% confidence interval [CI] 0.256-0.663) and transgender people (50.2%, IRR 0.498; 95%CI 0.299-0.831), but not the general population.
Among clients ≥30 years of age, STI testing (34.7%, IRR 0.653; 95%CI 0.472-0.904) and diagnoses (57.4%, IRR 0.426; 95%CI 0.301-0.603) decreased; among those <30 years, STI testing decreased (54.6%, IRR 0.454; 95%CI 0.285-0.725), but diagnoses remained unchanged. No significant changes were observed in proportion of clients coming for STI testing or proportion of positive STI tests.

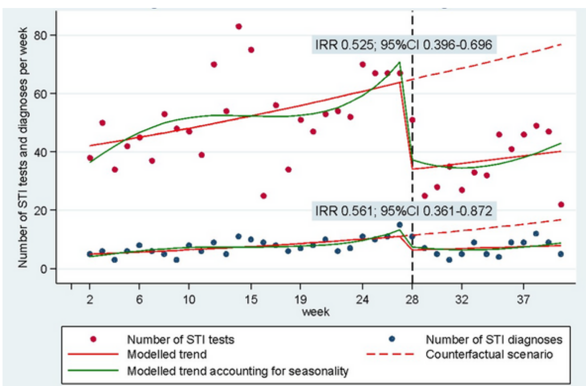

Figure 1. Number of STI tests and diagnoses.

Conclusions: The significant decrease in STI testing and diagnoses during COVID-19 lockdown in Bangkok is likely due to reduced clinical visits rather than a reduction in STIs. It is essential for sexual health services to continue under COVID-19-related measures, and that people are encouraged to get tested.

EPC072

Self-sampling strategies (with/without digital supports) for *Chlamydia trachomatis* and *Neisseria gonorrhoeae*: evidence from a meta-analyses

F. Vialard[1], A. Anand[1], C. Leung Soo[2], A. de Waal[1], M. McGuire[1], S. Carmona[3], M. Fernández-Suárez[3], A.A. Zwerling[4], N. Pant Pai[1,2]
[1]*Research Institute of the McGill University Health Centre, Centre for Outcome Research and Evaluation, Montreal, Canada,* [2]*McGill University, Department of Epidemiology, Biostatistics and Occupational Health, Montreal, Canada,* [3]*Foundation for Innovative New Diagnostics, Geneva, Switzerland,* [4]*University of Ottawa, School of Epidemiology and Public Health, Ottawa, Canada*

Background: The COVID-19 pandemic has majorly disrupted screening services for sexually transmitted infections (STIs) including common bacterial STIs such as *Chlamydia trachomatis* (CT) and *Neisseria gonorrhoeae* (GC), resulting in increased infections and ongoing transmission. Rapid, accurate, contact-free, self-sampling-based tests, with confirmatory Nucleic Acid Amplification tests (NAATs) either alone or combined with digital supports (websites, text messages, apps) provide a convenient contact free solution. Evidence on all outcomes is not synthesized, so we conducted a systematic review and meta-analyses to fill this gap.

Methods: For the period Jan 2000-Dec 2021, two reviewers searched three databases (Pubmed, Embase, LILACs) and assessed all outcomes (i.e., accuracy to impact). We performed a bivariate random-effects meta-analysis in R with accuracy data.

Results: Of 37 studies, 35 were observational (95%) while two were (6%) RCTs. Of 37, 9 (24%) used digital interventions. Populations studied were: women (n=11/37, 30%); men who have sex with men (n=5/37, 14%); HIV-positive (n=2/37, 5%); bisexual women (n=1/37, 3%); correctional-facility detainees (n=1/37, 3%). Outcomes studied included Accuracy (n=17/37, 46%); Acceptability/Preference; n=22/37, 59%); Feasibility (n=9/37, 24%); Impact (n=10/37, 27%).
Self-sampling reached 54-70 % of first-time testers, with a high acceptability (83-100%), variable preference (23-84%) and high linkage to care (89-100%) improved by digital supports.
Stratified bivariate meta-regression analysis (n=12 studies), revealed consistently high specificities (with 95%CI) for both CT (99% [99-100%]) and GC (99% [99-100%]). It also revealed a gradient in sensitivity (Sn) estimates (with 95%CI) by sampling sites. For CT, Sn by site were: 91% [82-96%] for rectal, 89% [82-93%] for vaginal and 87% [84-91%] for pharyngeal; while for GC, Sn were: 94% [87-97%] for pharyngeal, 91% [84-95%] for rectal and 90% [83-94%] for vaginal, respectively.

Conclusions: Self-sampling for CT and GC reached first-time testers, was accepted, preferred and reported high linkages to care with digital supports. Self-sampling followed by NAATs was highly accurate across all sampling sites. To plug screening gaps recently intensified by the COVID-19 pandemic, we recommend a greater use of self-sampling strategies for CT and GC together with digital supports, worldwide.

EPC073

Risk factors and outcomes of bloodstream infections among people with HIV: a longitudinal cohort study from 2000-2017

R. Lang[1,2], M.J. Gill[1,2], J. Viczko[3], C. Naugler[3,4], D. Church[1,3,5]
[1]*University of Calgary, Department of Medicine, Calgary, Canada,* [2]*Southern Alberta HIV Clinic, Alberta Health Services, Calgary, Canada,* [3]*University of Calgary, Department of Pathology & Laboratory Medicine, Calgary, Canada,* [4]*University of Calgary, Community Health Sciences, Cumming School of Medicine, Calgary, Canada,* [5]*Calgary Laboratory Services, Alberta Health Services, Calgary, Canada*

Background: People with HIV (PWH) experience higher rates of serious bacterial infections compared to the general population. Despite advances in HIV care, bloodstream infections (BSI) in PWH remain a significant and poorly studied source of morbidity and mortality.
We characterize the epidemiology, microbiology and clinical outcomes including reinfection, hospitalization, and mortality rates of both community-acquired and hospital-acquired BSI in PWH.

Methods: Linking data from laboratory and clinical databases, all BSI between 01/01/2000-31/12/2017 in PWH in care at Southern Alberta Clinic (SAC) were identified. Crude incidence rates (IR) per 1,000 person-years (PY) for BSI and death were calculated. Cox proportional hazards models estimated crude and adjusted hazard ratios (aHR) and 95% confidence intervals ([,]) to conduct a risk factor analysis of BSI in PWH.
Logistic regression models with generalized estimating equations to allow for multiple BSI episodes within one individual estimated crude and adjusted odds ratios (aOR) to identify characteristics associated with a 1-year mortality following BSI.
Adjusted models included age, sex, race/ethnicity, HIV acquisition risk, CD4 nadir and CD4 most recent to BSI, ART use, BSI category and source, polymicrobial BSI and Charlson comorbidity index (CCI).

Results: Among 2,895 PWH, 396 BSI episodes occurred among 228(7.8%) PWH. There were 278(71.8%) Gram-positive and 109(28.2%) Gram-negative BSI. The IRs of BSI decreased with time but remained higher among PWH than the reported IRs of the general population in our region. PWH with lower CD4 nadirs, higher CCI scores and Hepatitis C coinfection were at highest risk for BSI.
Long-term all-cause mortality was greater in those experiencing BSI (HR 5.25[4.21,6.55]). CD4 count <200cells/mm^3 measured closest to the time of BSI was associated with

1-year mortality following BSI (aOR-3.88[1.78,8.46]). Repeat episodes (42.2%) and polymicrobial BSI (18.6%) were common.

Conclusions: BSI continue to occur at a greater rate among PWH than the general population with high reoccurrence rates, and associated morbidity and mortality. To risk stratify and develop targeted interventions we identified PWH at greatest risk for BSI. PWH with low CD4 counts at the time of BSI are at highest risk of poor outcomes and should be followed closely to identify and manage complications.

EPC074

Hepatitis C virus (HCV) acquisition risk among people who inject drugs Montreal: high-risk neighbourhoods and implications for HIV monitoring and targeting of pre-exposure prophylaxis

N. Minoyan[1,2], S.B. Høj[2], M.-P. Sylvestre[1,2], A.A. Artenie[3], V. Martel-Laferrière[4,2], S. Larney[5,2], D. Jutras-Aswad[6,2], J. Bruneau[5,2]

[1]École de Santé Publique de l'Université de Montréal, Montréal, Canada, [2]Centre de Recherche du Centre Hospitalier de l'Université de Montréal (CHUM), Montréal, Canada, [3]Population Health Sciences, Bristol Medical School, University of Bristol, Bristol, United Kingdom, [4]Université de Montréal, Département de Microbiologie, Infectiologie et Immunologie, Montreal, Canada, [5]Université de Montréal, Département de Médicine Familiale et Médecine d'Urgence, Faculté de Médecine, Montréal, Canada, [6]Université de Montréal, Département de Psychiatrie et d'Addictologie, Montréal, Canada

Background: HCV incidence among people who inject drugs (PWID) in Montreal, Canada remains high despite longstanding presence of harm reduction in the city. Recent changes to the drug scene, notably, the increased use of prescription opioids, may have implications for HIV prevention. Harm may be concentrated in specific neighbourhoods; geographic targeting of these areas may improve cost-effectiveness of efforts such as PrEP.

We estimated the association between residence in social injection hotspots and HCV infection among PWID in Montreal.

Methods: Data were drawn from HEPCO, a prospective cohort study involving three-monthly HCV testing and interviews with active PWID in Montreal (2010-2017). At each visit, participants reporting injection with other PWID in the past month reported the location (postcode) of their latest social injection episode.

We first used these postcodes to identify areas exhibiting heightened clustering of social injection activity ("hotspots"). All cohort participants at risk of HCV were then categorized as residing (or not) in a social injection hotspot, based on where they had slept most often in the past month. Incident HCV infection was defined as a positive antibody/RNA test among those previously-negative.

The association of interest was estimated using inverse-probability weighted marginal structural models to adjust for time-dependent confounding and non-differential dropout by age, gender, housing and income stability, opioid agonist treatment, incarceration and prescription opioid injection.

Weights were estimated using pooled logistic regression; hazard ratios were obtained from a weighted Cox model. Follow-up was censored at three years from the first HCV-negative visit.

Results: Participants were mostly white (89.8%) and male (79.8%) with a median age of 40. Hotspots, which covered an area of 5.78 square kilometres, were located in downtown/Ville-Marie. At baseline, participants residing in hotspots were older and generally more vulnerable than those residing in outer areas. 99 infections were observed over 956.0 person-years (rate: 10.4/100py [95%CI: 8.5-1.3]). Weighted models estimated a two-fold risk of infection in hotspots vs. areas outside (95%CI: 1.20-3.44).

Conclusions: Risk of HCV was elevated in social injection hotspots, supporting prioritization of blood-borne virus prevention efforts, including PrEP, to select geographic areas. Prevention may further require modifying structural determinants of harm among PWID.

EPC075

Effect of the COVID-19 pandemic on rates of sexually transmitted infections among youth living with HIV in Washington, DC

S. Khan[1], C. Foltz-Davis[1], N.Y. Rakhmanina[2], K. Richards[2], J. Mareuil[2], T. Williams[2], W.L.A. Koay[2]

[1]George Washington School of Medicine, Washington DC, United States, [2]Children's National Hospital, Special Immunology Clinic, Washington DC, United States

Background: Sexually transmitted infection (STI) trends during the COVID-19 pandemic among youth in the United States (US) showed an initial overall decline, followed by a resurgence of gonorrhea and syphilis. Limited data exists on STI dynamics among youth living with HIV (YLHIV) during the pandemic.

We report and compare STI rates during the pandemic and pre-pandemic periods among YLHIV aged 13-24 years in care at Children's National Hospital (CNH).

Methods: Descriptive statistics were used to analyze demographics and positivity rates of syphilis, and genital (urine) and extragenital (oral, rectal) gonorrhea and chlamydia tests among YLHIV seen at CNH during the pandemic (03/2020-02/2021) and during an analogous pre-pandemic period (03/2019-02/2020).

Results: During the pre-pandemic period, 105 YLHIV (54.3% female, median age 19.4 years, 93.3% Black, 18.1% men who have sex with men (MSM), 23.8% horizontally-infected) had STI testing at 225 individual encounters. Ten YLHIV (50% female, 100% Black, 50% MSM, 70% horizontally-infected) tested positive.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

The positivity rate for syphilis was 3.5% (3/86). Positivity rates for gonorrhea were high from oral (10.8%, 4/37) and rectal (8.7%, 2/37) sites, and low from genital sites (0.9%, 2/221).
During the pandemic, 107 YLHIV (47.7% female, median age 20.4 years, 87.9% Black, 30.0% MSM, 38.3% horizontally-infected) had STI testing at 205 encounters. Twenty-six YLHIV (26.9% female, 100% Black, 69.2% MSM, 80.8% horizontally-infected) tested positive for STIs. The positivity rate for syphilis was 5.3% (6/114). Positivity rates for gonorrhea were high from oral (18.9%, 7/37) and rectal (12.9%, 4/31) sites compared to genital sites (3.5%, 6/171).
Overall, the positivity rate for any STI increased from 7.6% (pre-pandemic) to 13.7% (during the pandemic). The positivity rates of chlamydia pre-pandemic and during the pandemic were similar: genital (3.6% vs 3.5%), oral (2.7% vs 2.7%), and rectal (13.0% vs 12.9%).
Conclusions: Higher numbers of YLHIV in our care had STIs during the pandemic, driven by higher positivity rates for syphilis and gonorrhea during the pandemic compared to pre-pandemic period. During both periods, extragenital STI positivity rates were higher compared to genital sites.
Further research is needed to better understand the STI dynamics among YLHIV, particularly for MSM and youth with horizontally-acquired HIV.

EPC076
The influence of HIV pre-exposure prophylaxis (PrEP) on the changing epidemiology of Lymphogranuloma venereum (LGV): 2016-2021

A.K. Gupta[1,2], B. Lyons[2,1], B. Arnold[2], D. Chang[2], M. Gilbert[2,3], L. Hoang[2], S. Makaroff[2], S. Malleson[2], C. Montgomery[2], V. Ryan[2], A. Severini[4,5], R. Stimpson[2], V. Valdrez[2], J. Wong[2,3], T. Grennan[2,6]
[1]University of British Columbia, Faculty of Pharmaceutical Sciences, Vancouver, Canada, [2]BC Centre for Disease Control, Vancouver, Canada, [3]University of British Columbia, School of Population and Public Health, Vancouver, Canada, [4]Public Health Agency of Canada, National Microbiology Laboratory, Winnipeg, Canada, [5]University of Manitoba, Department of Medical Microbiology, Winnipeg, Canada, [6]University of British Columbia, Faculty of Medicine, Division of Infectious Diseases, Vancouver, Canada

Background: Lymphogranuloma venereum (LGV), caused by invasive subtypes of *Chlamydia trachomatis,* is a sexually transmitted infection (STI) increasingly being seen among men who have sex with men (MSM).
Initially, most cases were among symptomatic MSM living with HIV with more recent cases seemingly in asymptomatic, HIV-negative MSM, potentially owing to routine STI screening for people using HIV pre-exposure prophylaxis (PrEP). Given this apparent change in presentation, we assessed the epidemiology of LGV in the period pre- and post- widespread, publicly-funded PrEP in British Columbia (BC), Canada.

Methods: A retrospective chart review of all LGV cases in BC from 01/01/2016-31/12/2021 was performed. Since 07/2011, all chlamydia-positive rectal specimens were routinely tested for LGV. We collected information pertaining to risk-factors, PrEP use, LGV and sociodemographics. Binomial logistic regression was completed to compare the clinical presentation of LGV pre- and post- publicly-funded PrEP coverage (i.e. pre-PrEP, post-PrEP) in BC on 01/01/2018.
Results: Among the 321 LGV cases, 80 (24.9%) and 241 (75.1%) occurred pre-PrEP and post-PrEP, respectively. Among pre-PrEP cases, most cases were among individuals living with HIV (56.4%; 44/78) and were symptomatic (67.2%; 39/58).
A minority experienced co-infection with gonorrhea (22.7%; 17/75) or syphilis (10.7%; 8/75). In contrast, most post-PrEP cases were among HIV-negative individuals (65.2%; 154/236) who were taking PrEP (68.6%; 105/150) with a mean HIRI-MSM score of 24.6 (95% confidence interval [CI] 22.9, 26.4).
A minority experienced co-infection with gonorrhea (14.5%; 35/241) or syphilis (7.0%; 17/241) and were less frequently symptomatic in presentation (58.6%; 123/210). Infections were more likely in HIV-negative individuals post-PrEP compared to pre-PrEP (odds ratio [OR] 2.43; 95% confidence interval [CI] 1.44, 4.09). PrEP users were more likely to experience asymptomatic LGV infection relative to HIV-negative PrEP non-users (OR 2.33; 95% CI 1.15, 4.72). There was a trend towards asymptomatic presentation among HIV-positive individuals, post-PrEP relative to pre-PrEP (OR 1.60; 95% CI 0.61, 4.27).
Conclusions: Since the implementation of publicly-funded PrEP programs, coupled with frequent STI screening, LGV's increasingly asymptomatic presentation highlights the importance of frequent asymptomatic STI screening combined with reflex LGV testing for chlamydia-positive rectal specimens. Further work is needed to determine the cause of this increase in cases.

EPC077
Incidence of sexually transmitted infections among adolescent's men who have sex with men and transgender women enrolled in a PrEP cohort study in Brazil

L. Dezanet[1], L. Magno[1,2], F. Soares[1], V. de Jesus Salgado[3], C. Marcellus Pereira de Abreu Oliveira[3], L. Miranda Marques[3], G. Barreto Campos[3], I. Dourado[1]
[1]Federal University of Bahia, Collective Health Institute, Salvador, Brazil, [2]State University of Bahia, Department of Life Sciences, Salvador, Brazil, [3]Federal University of Bahia, Multidisciplinary Health Institute, Vitória da Conquista, Brazil

Background: Adolescent men who have sex with men (aMSM) and transgender women (aTGW) are disproportionately affected by HIV and other sexually transmitted infections (STI).

However, studies on the incidence of STI among adolescents enrolled in PrEP are still scarce. We aimed to estimate the incidence of *N. gonorrhoeae, C. trachomatis, M. genitalium, M. hominis, U. urealyticum* and *U. parvum* among adolescents PrEP users.

Methods: PrEP1519 is a single-arm demonstration cohort study of daily TDF/FTC as PrEP. It is ongoing in 3 Brazilian capital cities among aMSM and aTGW aged 15-19 years-old (yo), recruited from February 2019-September 2021, with the following eligibility criteria: HIV uninfected, high risk of HIV, and with no risk of kidney and liver damage. They completed a questionnaire, and swab samples from multiple sites (oropharyngeal, anal, and urethral) were provider-collected and tested for each STI by using qPCR, at PrEP initiation and weeks 4, 12, and then quarterly through week 96.

For this analysis, we included participants who had a minimum of 2 consecutive visits at the Salvador site and provided a swab sample at PrEP initiation and at least one more during follow-up. Case of STI was defined as positive-qPCR from any anatomical site. STI incidence rate per person-year (PY) of follow-up and 95% confidence intervals (95%CI) were estimated.

Results: At PrEP initiation, participants were mostly MSM (91%) and 18-19 yo (84%). Median age of sexual debut was 14 yo (IQR:12-16), and 56% of participants did not use or did not remember using a condom at first sexual intercourse. Incidence measures of bacterial STI after initiating PrEP in Salvador (Brazil) are presented below. The incidence of *U. urealyticum* was particularly high.

	Total N	Incident cases	Sum of PY	Incidence rate per 100 PY	(95% CI)
N. gonorrhoeae	132	19	219.2	8.7	(5.5-13.6)
C. trachomatis	132	22	246.5	8.9	(5.9-13.6)
M. genitalium	137	11	204.5	4.6	(2.5-8.3)
M. hominis	133	19	224.3	8.5	(5.4-13.3)
U. urealyticum	128	43	186.3	23.1	(17.1-31.1)
U. parvum	137	10	253.9	3.9	(2.1-7.3)

Conclusions: Important rates of STI among adolescents in PrEP1519 indicate that innovative approaches to decrease STI incidence are much needed. Point-of-care STI testing should be an essential component to help decrease STI incidence among aMSM and aTGW PrEP users followed by appropriate STI treatment.

EPC078

Prevalence of tuberculosis in transgender women and according to HIV status in Lima, Peru

J.E. Peinado Rodríguez[1], R. Errea[2],
N.G. Hernández Llicahua[2], E. Gonzales Monzo[2],
K. Ramos Carhuas[2], M.A. Tovar Huamani[3], L. Lecca[4]
[1]*Socios En Salud Sucursal Peru (Partners in Health - Peru), Program Management Direction, Lima, Peru,* [2]*Socios En Salud Sucursal Peru (Partners in Health - Peru), Community Health Program, Lima, Peru,* [3]*Socios En Salud Sucursal Peru (Partners in Health - Peru), Medical Direction, Lima, Peru,* [4]*Socios En Salud Sucursal Peru (Partners in Health - Peru), Executive Directorate, Lima, Peru*

Background: The high prevalence of HIV in transgender women (TW), their socioeconomic vulnerability, and their limited access to the health system, places them at risk of becoming infected with tuberculosis. A study in Brazil reported a high prevalence of tuberculosis in TW regardless of their HIV status. Although Peru is one of the countries with the highest burden of drug-resistant tuberculosis in the world, little is known about the prevalence of tuberculosis in TW.

This study aimed to determine the overall prevalence of tuberculosis in TW of Lima-Peru, and according to their HIV status.

Methods: A cross-sectional study was conducted between May and June 2021 in adult TW who participated in a previous study and in TW members of a non-profit civil association in Lima. Radiographic diagnosis and identification using GeneXpert were carried out to determine the frequency of tuberculosis.

The frequency of HIV infection was determined through HIV testing (rapid and confirmatory) and by verifying the HIV status among those who reported a previous positive diagnosis.

Results: A total of 277 TW were approached, 103 of which agreed to be tested for tuberculosis with a mean age of 32.7 (±9.9) years. Of the 103, 3 TW (2.9%) were diagnosed with tuberculosis. Of 35 TW living with HIV who were tested for tuberculosis, 2 were positive (5.7%). Of 49 TW without HIV who were tested for tuberculosis, 1 resulted positive (2%).

Conclusions: The study shows a high prevalence of tuberculosis (2.9%) in TW. Although the sample is small, the results suggest that the prevalence of tuberculosis is not only high in TW living with HIV (5.7%), but also in those without HIV (2%), compared to the prevalence in the general population (0.1%).

More studies with stronger designs are required to assess whether TW have a higher burden of tuberculosis that warrants prioritizing this community within tuberculosis control activities in Peru.

EPC079

Stopping syphilis transmission in Arctic communities through rapid diagnostic testing (STAR study): a field diagnostic accuracy study

C. Caya[1], A. Singh[2], B. Serhir[3], V. Morin[4], M. Libman[5], R. Corsini[1], D. Goldfarb[6], T. Wong[7], Y. Xia[8], M. Maheu-Giroux[8], C. Yansouni[5]

[1]Research Institute of the McGill University Health Centre, Montreal, Canada, [2]University of Alberta, Edmonton, Canada, [3]Institut National de Santé Publique du Québec, Sainte-Anne-de-Bellevue, Canada, [4]Nunavik Regional Board of Health and Social Services, Kuujjuaq, Canada, [5]McGill University Health Centre, Montreal, Canada, [6]University of British Columbia, Vancouver, Canada, [7]Public Health Agency of Canada, Ottawa, Canada, [8]McGill University, Montreal, Canada

Background: Intense transmission of syphilis has emerged in some Canadian Arctic communities despite prevention efforts. Remoteness and limited diagnostic infrastructure yield long delays between screening and treatment of cases, with an estimated 50% of infectious contacts occurring during this interval in the region.

We assessed the field diagnostic accuracy of a rapid dual diagnostic test (RDT) for syphilis, evaluating both whole blood and centrifuged serum specimens, as a means of eliminating the screening-treatment interval and breaking syphilis transmission chains in remote Arctic communities.

Methods: In this REB-approved prospective multisite field evaluation, sexually active individuals aged ≥14 years were tested at the point-of-care by non-laboratory trained registered nurses in Nunavik and Nunavut, from 1 Jan 2020 to 31 Dec 2021.

Whole blood and serum specimens were concurrently collected for rapid testing with an RDT containing both treponemal and non-treponemal components (*ChembioDPP® Syphilis Screen & Confirm*) and compared to laboratory-based reference testing.

Reference laboratories performed reverse sequence algorithm testing for syphilis with enzyme immunoassay (EIA) and rapid plasma reagin (RPR) testing.

Results: A total of 176 participants were recruited (median age 29 years (IQR 23-38) and 61% female), of which 46 (26%) were confirmed new syphilis cases.

Overall, treponemal-RDT sensitivity compared to EIA was similar for serum (74% (95%CI 59-86%)) and whole blood specimens (77% (95%CI 61-89%)). Sensitivity of both specimen types increased to ≥93% for patients with RPR≥1:8, a threshold consistent with infectious syphilis. Specificity for the treponemal-RDT was 99% (95%CI 95-100) for both specimen types.

Relative to RPR, the non-treponemal-RDT sensitivity for serum was 95% (95%CI 83-99%) and increased to 100% (95%CI 89-100%) for RPR ≥1:8. The non-treponemal-RDT sensitivity relative to RPR for whole blood was 80% (95%CI 63-92), and 93% (95%CI 76-99) for RPR≥1:8.

Conclusions: In remote Arctic communities, *Chembio DPP® Syyphilis Screen & Confirm* had acceptable sensitivity and excellent specificity when performed by unsupervised non-laboratorians. Whole blood and serum yielded similar performance, making implementation feasible in communities where no centrifuge or calibrated pipettes are available. If used in addition to standard reference testing, implementing this RDT could shorten time-to-treatment by up to 3 weeks, without missing any cases.

EPC080

Systematic review and meta-analyses of the interaction between HIV infection and COVID-19: two years' evidence summary

Y. Wang[1], Y. Xie[2,3], S. Hu[4], W. Ai[5], Y. Tao[3], H. Tang[1], F. Jing[3], W. Tang[6,3]

[1]University of Florida, Department of Pharmaceutical Outcomes and Policy, Gainesville, United States, [2]Duke University, Duke Global Health Institute, Durham, United States, [3]University of North Carolina at Chapel Hill Project-China, Guangzhou, China, [4]Southern Medical University, Dermatology Hospital of Southern Medical University, Guangzhou, China, [5]Nanjing Medical University, School of Public Health, Nanjing, China, [6]University of North Carolina at Chapel Hill, Institute for Global Health and Infectious Diseases, Chapel Hill, United States

Background: During the COVID-19 pandemic, people living with HIV (PLWH) were considered to be at risk of worse COVID-19 outcomes once infected. However, the existing evidence is insufficient and inconsistent. This systematic review and meta-analysis aimed to summarize the existing evidence on comparing the risk of SARS-CoV-2 infection, severe COVID-19 symptoms, and mortality among PLWH and patients without HIV.

Methods: The articles included studies published in PubMed, Medline, Embase, and Cochrane between December 1st, 2019, and December 1st, 2021. We used the combination of 1) "HIV", "human immunodeficiency virus*", "AIDS", "acquired immunodeficiency syndrome" and 2) "COVID-19", "SARS-CoV*", "2019-nCoV", "nCoV" and "novel-coronavirus" as search strings.

We included the original studies published in English focusing on observational studies assessing the risk of SARS-CoV-2 infection, severe COVID-19 symptoms, and mortality among PLWH. Two reviewers independently screened each article, and a third reviewer was consulted for reconciliation.

Data were extracted by two independent reviewers. STrengthening the Reporting of OBservational studies in Epidemiology-Modified (STROBE-M) checklist was used for quality assessment. For the results with heterogeneity I^2>75%, a random-effects model was employed. The outcomes were risk ratios of SARS-COV-2 infection, severe COVID-19 symptoms, and mortality between people with and without HIV.

Results: We included a total of 32 studies and 71,779,737 study samples, of whom 797,564 (1.11%) were PLWH. Compared with COVID-19 patients without HIV infection, PLWH had comparable risk of SARS-CoV-2 infection (adjusted Risk Ratio=1.07, 95% CI: 0.53-2.16, I^2=96%, number of studies k=6, sample size n=20,199,805) and risk of developing severe COVID-19 symptoms (aRR=1.06, 95% CI: 0.97-1.16, I^2=75%, k=10, n=2,243,370).

PLWH, if infected with SARS-CoV-2, were found to have an increased risk of mortality compared with people without HIV (aRR=1.30, 95% CI: 1.09-1.56, I^2=76%, k=16, n=71,032,659). This finding was consistent across different subgroup analyses. There was no significant publication bias identified.

Conclusions: PLWH are at increased risk of COVID-19 mortality once infected. The local health system should one hand strengthen COVID-19 prevention and clinical management among PLWH to avoid infection and on the other hand, sustain the HIV care continuum of PLWH for HIV management.

EPC081
Clinical and demographic characteristics of tuberculosis patients in health care facilities in Botswana: a retrospective analysis

B. Kgwaadira[1], H.O. Ramadhani[2], J. Mangope[1], R. Marima[1], N. Ndwapi[1]

[1]Botswana University of Maryland School of Medicine, Gaborone, Botswana, [2]University of Maryland School of Medicine, Institute of Human Virology, Baltimore, United States

Background: Tuberculosis (TB) disease is the most common opportunistic infection affecting people living with HIV (PLHIV). In Botswana, HIV is the main driver of TB disease, accounting for about half of all TB cases in 2019. The demographic and clinical characteristics of all TB patients in 53 PEPFAR-supported facilities were evaluated between October 2020 and September 2021.

Methods: A retrospective analysis of all TB patients documented in Manual TB registers in 53 Bummhi supported facilities was conducted for demographic and clinical characteristics. TB diagnoses were made through GeneXpert, chest X-ray, microscopy or culture. Data extracted included age, gender, type of TB test, HIV status, ART status and mortality. Statistical analyses were conducted using SAS version 9.3 (SAS Institute Inc., Cary, NC, USA).

Results: A total of 1,073 TB cases were identified, of which 676 (63.2%) were male. The median age was 40 years (interquartile range (IQR): 29 – 52 years). Overall, 557 (51.9%) patients were HIV-co infected and 46 (4.3%) had no documented HIV status at time of TB treatment initiation. Of those HIV-co infected, 136/557 (24.4%) were HIV newly diagnosed, of whom 116 (85.3%) were initiated on ART. Nearly 90% (378/421) of the known HIV positive prior to TB diagnosis were already on ART. Only 9/1,073 (1.2%) of the total TB patients were documented as dead, including 1 (11.1%) who died prior to ART initiation. TB cases were predominantly diagnosed through GeneXpert and proportions of patients and type of TB diagnostic test is shown in Figure 1.

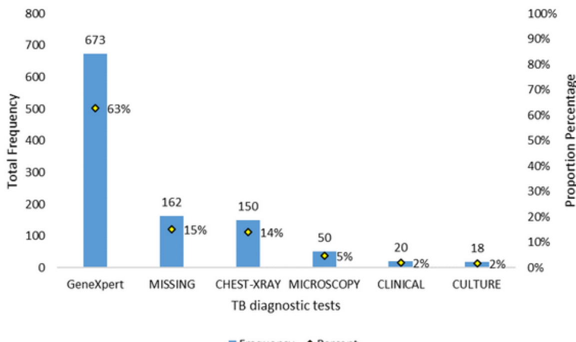

Figure 1.

Conclusions: A high proportion of TB patients were newly diagnosed HIV patients, implying that identification of PLHIV before acquiring a severe opportunistic infection needs to be improved to reach epidemic control. There is need to improve GeneXpert access for initial testing of presumptive TB cases.

EPC082
Declining trends of HIV and syphilis seroprevalence at integrated counselling and testing centre in a tertiary care hospital in North India: a six year study

K. Kapil[1], A. Bhargava[2], S. Muralidhar[2], N. Khunger[1]

[1]Vardhaman Mahavir Medical College, Dermatology, Venereology and Leprosy, New Delhi, India, [2]Vardhaman Mahavir Medical College, Apex Regional STD Centre, New Delhi, India

Background: Globally, 37.7 million people were living with HIV at the end of 2020. HIV and Syphilis are major public health issues in India. This study was undertaken to analyse the changing trends of HIV and Syphilis seroprevalence in Integrated Counselling and Testing Centre (ICTC) attendees over 6 years.

Methods: A retrospective study was conducted at ICTC centre, Safdarjung Hospital, New Delhi, India; wherein patients' records from January 2016 to December 2021 were analysed and trends in HIV and syphilis seroprevalence were recorded. Cases were classified according to HIV status, gender; referral from sexually transmitted infections(STI) clinic and non-STI attendees.

HIV tests and interpretation were done according to National AIDS Control Organisation(NACO) guidelines, and syphilis serological assays were done as per classical testing strategy.

Results: Of 131115 patients tested for HIV, 2.8% males while 1.08% females were positive($x2$=474.58,P<0.0001). HIV seroprevalence showed a declining trend from 2.68% in 2016 to 1.76% in 2021($x2$=39.676,P<0.0001).

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Similarly, syphilis sero-positivity decreased remarkably from 1.06% to 0.58%(x2=25.040,P<0.0001). Both HIV and syphilis showed a slight rise in the year 2020 (2.08% for HIV and 1.08% for syphilis) with remarkably less ICTC registrations due to Covid-19 pandemic.

The decrease in syphilis sero-positivity was minimal in people living with HIV/AIDS (PLHA), (1.62% to 1.43%, P=0.57), whereas significant in HIV negative attendees(1.04% to 0.57%, P<0.0001). Syphilis sero-positivity in PLHA was not notably higher than in HIV negative attendees (P=0.4168). Against this, syphilis prevalance in STI clinic attendees referred to ICTC was significantly higher than in non-STI clinic attendees (p < 0.0001).

Conclusions: Significant decline in HIV and syphilis sero-positivity points towards the successful implementation of HIV and STI prevention and control programmes in the region. The overall seroprevalence of HIV and syphilis in both groups increased abruptly in 2020, attributable to the COVID pandemic and lockdown that reduced the flow of low risk population attending hospitals and testing centres.

EPC083

Prevalence of non-communicable diseases among HIV-infected persons in sub-Saharan Africa: a systematic review

E.O. Ankrah[1], N.A. Acheampong[2]

[1]*Ghana AIDS Commission, Research, Monitoring and Evaluation, Accra, Ghana,* [2]*Ghana AIDS Commission, Accra, Ghana*

Background: Multimorbidity is a global public health concern, as non-communicable diseases (NCDs) are becoming an increasing burden for persons living with HIV as they live longer due to antiretroviral therapy. People living with HIV (PLHIV) have been found to have a higher risk of having non-communicable diseases. Non-communicable diseases (NCDs) are diseases that are not transmissible from person-to-person and include cardiovascular disease, diabetes, chronic respiratory disease, cancers, and mental health conditions.

To appropriately identify and treat non-communicable diseases (NCDs) among persons living with HIV (PLHIV) in low-and-middle-income countries (LMICs), it is imperative to understand the burden of NCDs among PLHIV in sub-Saharan and the current management of the diseases.

Methods: We examined peer-reviewed literature published between 1 January 2016 and 31 December 2020 to assess currently available evidence regarding HIV and three selected NCDs (cardiovascular disease, cervical cancer and diabetes) in sub-Saharan Africa. The inclusion criteria were: written in English; based in LMICs with a focus on sub-Saharan Africa, data on prevalence. The databases; PubMed/MEDLINE, and Scopus, were searched to identify relevant literature. Pooled estimates for prevalence were generated using random fixed-effects models.

Results: A total of 1,303 abstracts were reviewed. Out of this, 200 had potentially relevant prevalence data and 31 were selected for quantitative analysis. Pooled estimates for NCD prevalence among HIV-infected persons were hypertension 33.2%, invasive cervical cancer 3.9% and diabetes 18.3%. Gender (p = 0.002) was found to be significantly associated with the development of NCDs. Geographical location was a significant risk factor as those in urban areas were more likely to develop hypertension as compared to rural areas (p = 0.001).

Conclusions: Improved data collection and surveillance of NCDs among PLHIV in sub-Saharan Africa are necessary to inform integrated HIV/NCD care models.

Although efforts to integrate care exist, impactful research to better understand the complexities around developing, testing, and implementing appropriate approaches for effective diagnosis, prevention and integrated clinical care for HIV-associated non-communicable diseases is needed.

EPC084

High prevalence of anal high-risk human papillomavirus infectionin HIV-negative French men who have sex with men during 12 months of Pre-exposure prophylaxis uptake:potential efficacy of Gardasil-9® vaccination

H. Péré[1], R.-S. Mboumba Bouassa[2,1], L. Bélec[1], C. Gubavu[3], T. Weerasinghe[1], D. Veyer[1], A. Gravier[3], L. Hocqueloux[3], T. Prazuck[3]

[1]*Laboratoire de Virologie, Hôpital Européen Georges Pompidou, Université Paris Descartes, Paris, France,* [2]*Ecole Doctorale Régionale d'Infectiologie Tropicale de Franceville, Franceville, Gabon,* [3]*Service des Maladies Infectieuses et Tropicales, Centre Hospitalier Régional d'Orléans, Orléans, France*

Background: Despite the efficacy of Pre-exposure prophylaxis (PrEP), men having sex with men (MSM) taking PrEP become at risk for anal high-risk human Papillomavirus (HR-HPV) infection. We aim to assess the dynamic of anal HR-HPV infection in MSM during more than one year of PrEP uptake.

Methods: From 2017 to 2021, 164 MSM [mean age, 36.3 years (range: 18-68)] seeking for PrEP at the infectious diseases outpatient consultation service of the "*Centre Hospitalier Régionale d'Orléans*" in France, were prospectively recruited and screened by Anyplex™ II HPV 28 real-time PCR, for anal HPV.

Among them, 91 were followed-up during at least 12 months of PrEP uptake, and 40 received also the first and the second dose of Gardasil-9® HPV vaccine, and 24 received the 3rd dose.

Results: At the inclusion, anal HPV prevalence was 82.3%, including 67.1% of HR-HPV, 53.6% being caused by Gardasil-9® vaccine HR-HPV. HR-HPV33 (25.2%) and HPV16 (20.7%) were the predominant HR-HPV and HPV18 (10.4%) was less detected.

After 12 months of PrEP, anal HPV prevalence still very high (81.3%), including 61.5% of HR-HPV, 43.9% being caused by Gardasil-9® vaccine HR-HPV. HPV33 (9.9%), HPV18 (3.3%), HPV52 (8.8%), were strongly reduced, while HPV16 (20.8%) and the other HR-HPV remained as high as at the inclusion.

When comparing HR-HPV distribution in vaccinated MSM, at first dose and 3 months after the 3rd dose of G9, we observe a reduced prevalence of vaccine HPV16 (20% to 17.3%), HPV18 (from 12.5% to 0%), HPV33 (from 17.5% to 0%), HPV45 (from 7.5% to 4.3%), and HPV52 (from 12.5% to 4.3%), as well as the non-vaccine HPV35 (from 10% to 4.3%).

On the other hand, we observed an increase frequency of non-vaccine HPV39 (from 12.5% to 21.7%), HPV51 (from 10% to 13.04%), HPV56 (from 10% to 13.04%), HPV59 (from 5% to 8.7%), and HPV68 (from 12.5% to 13.04%), as well as vaccine HPV31 (from 7.5% to 8.7%) and HPV58 (from 7.5% to 8.7%).

Conclusions: HIV-negative MSM taking PrEP are at high risk of getting anal HR-HPV infection and introducing Gardasil-9® vaccination in the PrEP package would help preventing the acquisition of the most carcinogenic HPV genotypes.

EPC085

Scale-up of tuberculosis preventive therapy among people living with HIV in Uganda: initiation, completion, and TB disease notification rates, April 2017–September 2021

D. Lukoye[1], G. Gustavson[1], J. Ssempiira[1], P. Namuwenge[2], J. Kalamya[1], S. Dejene[3], E. Birabwa[4], E. Bill[1], E. Dirlikov[1], J. Calnan[3], L.A. Mills[1], S. Turuahabwe[2], L. Nelson[1]

[1]Centers for Disease Control and Prevention, Kampala, Uganda, [2]Uganda Ministry of Health, Kampala, Uganda, [3]United States Agency for International Development, Kampala, Uganda, [4]Walter Reed Army Institute of Research, Kampala, Uganda

Background: Tuberculosis (TB) is a leading cause of death globally, with 1.5 million deaths in 2020, including 214,000 among people living with HIV (PLHIV). TB preventive therapy (TPT) completion lowers incidence and mortality.

In 2016, Uganda, a WHO-designated TB high-burden country, began expanding TPT among PLHIV. We describe TPT scale-up between 2017-2021 to guide continued expansion.

Methods: We analyzed aggregated patient data from PEPFAR DATIM to describe quarterly and semiannual trends of reported TPT initiation and completion, and TB disease among PLHIV receiving PEPFAR-supported antiretroviral treatment (ART) during April 2017–September 2021. TPT initiation was defined as receiving prophylactic isoniazid (INH) with pyridoxine (semiannually), TPT completion rate as the proportion of those without ≥2 consecutive months of interruption among all who initiated TPT 6 months prior (semiannually), and TB disease notification rate as number of clinically and/or bacteriologically confirmed cases reported among PLHIV on ART (quarterly).

Using R version 4.1.2, we conducted descriptive analyses by age group, sex, and district. Temporal trends were described using time series plots.

Results: As of September 2021, a total of 1,266,588 PLHIV were on ART. TPT initiations increased from 18,394 during April–September 2017 to 122,969 in April–September 2021. TPT completion rates increased from 28.6% (5,264/18,394) during April–September 2017 to 92.1% (113,296/122,969) in April–September 2021.

On average across all semiannual periods, TPT completion rates were higher among PLHIV aged ≥15 years (median [interquartile range] = 86.1% [71.1–88.3%]) compared to those aged <15 years (median = 85.6% [63.9–86.7%]), and similar by sex (men = 86.5% [65.6–91.6%]; women = 86.2% [69.6–88.6%]).

The overall average district TPT completion rate was 75.5% (63.6–95.7%), with the highest rate in Lango region (82%) and lowest in the Teso region (66%). TB disease notification rates decreased from 59 per 100,000 persons during April–September 2017 to 47 per 100,000 persons during July–September 2021.

Conclusions: In 4 years, Uganda achieved high and increasing TPT completion rates among PLHIV; followed by a decline in TB notification rates. Ensuring all PLHIV complete TPT will likely require additional people-centered services, including scale-up of 3-month courses of TPT.

EPC086

HPV prevalence and risk factors in HIV-negative and HIV-positive South Africa adolescent girls: results from the HOPE study

D. Travill[1], D. Machalek[2,3], R. Munthali[1], T. Mogodiri[1], Z. Mbulawa[4,5], H. Rees[1], J. Kaldor[6], S. Delany-Moretlwe[1]

[1]Wits RHI, Research, Johannesburg, South Africa, [2]University of New South Wales, Kirby Institute for Infection and Immunity in Society, Sydney Kensington, Australia, [3]The Royal Women's Hospital, Centre for Women's Infectious Diseases, Melbourne, Australia, [4]Walter Sisulu University, Department of Laboratory Medicine and Pathology, Umtata, South Africa, [5]University of Cape Town, UCT-MRC Clinical Gynaecological Cancer Research Centre, Cape Town, South Africa, [6]University of New South Wales, Kirby Institute for Infection and Immunity in Society, Sydney, Australia

Background: Women living with HIV (WLH) experience high rates of Oncogenic (HR-HPV) infection, pre-cancerous lesions and cancer. Prevention strategies rely on HPV vaccination and cervical cancer screening.

Methods: From June to December 2019, we surveyed adolescent girls and young women (AGYW) aged 17-18 years at 18 sentinel clinics in four South African provinces (Gauteng, Mpumalanga, Free State, and Northwest) as part of an HPV vaccine impact study.

This age group were ineligible for the vaccination programme in 2014. Eligible participants completed a self-administered demographic and risk factor questionnaire,

underwent HIV counselling and rapid testing, and provided a self-collected vaginal swab for HPV testing using SeeGene Anyplex™ II HPV28 assay.

Results: Of 770 respondents, 636 had ever had vaginal sex. Of those, median age of sexual debut was 16 (IQR 16-17 years), 6% (25) reported sexual debut <15 years, 75% (480) reported 2+ lifetime sex partners. Of the 770, 30% were HIV positive.

Adolescent WLH were more likely to have had sex <=15 years (13% vs 4%), and less likely to be on contraception (72% vs 81%); 91% (217) were on anti-retroviral treatment (ART) (median duration ART 23.6 (6.3-83.5 months). HR-HPV was detected in 59% (376) of AGYW; with higher rates observed in adolescent WLH compared to their HIV negative peers (68% vs 56 % P=0.002).

Vaccine-specific type HPV 16/18 prevalence was two-fold higher in WLH (compared to HIV negative girls (53/171, 31% vs. 88/467, 19%; [1.90, 95% CI: 1.28-2.83). HR-HPV types associated with vaccine cross-protection including HPV 33 (8% vs 2% p=0.000), 35 (17% vs 11% p=0.021), 52 (20% vs 11%; p=0.001), and 58 (18% vs 8%; P=0.000) were also more common in WLH, except for HPV31 (11% vs 7% P=0.056)

Conclusions: HR-HPV infection is common in young WLH in South Africa. These data highlight the importance of high HPV vaccination coverage in populations with high HIV prevalence, as well the potential value of early and sustained ART initiation in ensuring clearance of infection and prevention of cervical cancer. The data also highlights the need for cervical cancer screening among WLH, particularly those that will have missed out vaccination programmes.

EPC087

High incidence of HIV and STIs in late pregnancy: compelling evidence for repeat etiological testing

V. Govender[1,2], D. Moodley[2,3], M. Naidoo[1], C. Connoly[4], S. Ngcapu[3,5], Q.A. Karim[3]

[1]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Women's Health and HIV Research Unit, Durban, South Africa, [2]University of Kwa Zulu Natal, Department of Obstetrics and Gynaecology, Durban, South Africa, [3]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa, [4]University of Kwa Zulu Natal, Department of Biostatistics, Durban, South Africa, [5]University of Kwa Zulu Natal, Department of Medical Microbiology, Durban, South Africa

Background: Adolescent girls and young women (AGWY) in South Africa (SA) are at especially high risk of acquiring sexually transmitted infections (STIs) including HIV-1 during late pregnancy. While repeat testing for syphilis and HIV-1 are routinely performed to prevent congenital syphilis and perinatal HIV infection, there is no evidence for need of repeat testing for other STIs in pregnancy. We determined the incidence of HIV-1 and STIs in pregnant AGYW through repeat testing for HIV, HSV-2, *T.vaginalis (TV), C.trachomatis (CT)* and *N.gonorrhea (NG)*in the 3rd trimester.

Methods: Pregnant women who tested negative for HIV-1 <28 weeks gestation at antenatal clinics in SA were enrolled in a cohort study during Feb 2017-Mar 2018.

At baseline (2nd trimester) a research nurse examined the participant for symptoms of STIs, collected vaginal swabs for BV and STI testing, and drew blood for HIV-1 and syphilis testing. Symptomatic women were treated syndromically. These procedures were repeated in the 3rd trimester. Vaginal swabs were stored for later testing for *CT, NG, MG*, HSV-2, and *TV*using PCR.

Results: Of 752 pregnant HIV-negative AGYW (180 adolescents 15-19 years), 39.3% tested positive for BV, 15.3% (*TV*), 5.7% (*NG*), 9.7% (*CT*), 3.5% (*MG*), 2.4% (HSV-2) and 0.5% (Syphilis) in the 2nd trimester. 460 (61.2%) women (106 adolescents) retested in the 3rd trimester, 18.4% tested positive for BV, 14.8% (*TV*), 13.0% (*NG*), 16.5% (*CT*), 4.8%(*MG*), 2.4% (HSV-2), 0.3% (syphilis) and 1.5% for HIV-1.

More than 85% were new cases; incidence rate of 41.7/100py for *TV*, 40.2/100py (*NG*), 50.3/100py (*CT*), 7.9/100py (HSV-2), 0.7/100py (Syphilis), 16.5/100py (BV) and 5/100py for HIV-1. Incidence rate for any STI in the 3rd trimester was 142.9/100py for adolescents and 137.9/100py for older women. 43.3% (95%CI 37.1-49.8) of women with any STI in the 2nd trimester and 20.7% (95%CI 15.2-27.1) in the 3rd trimester were symptomatic.

Conclusions: Repeat testing in the 3rd trimester of pregnancy revealed a high incidence of HIV-1 and other STIs, with 80% of women with a STI being asymptomatic.

We provide compelling evidence for the need for repeat aetiological testing of STIs in pregnant AGYW in a high HIV endemic setting.

Epidemiology of non-AIDS non-communicable diseases (e.g., non-AIDS cancers, CVD)

EPC088

Burden of chronic comorbidities among people living with and without HIV: disability-adjusted life years in British Columbia, Canada

N.G.A. Nanditha[1,2], J. Zhu[2], L. Wang[2], J. Kopec[3,4], R.S. Hogg[2,5], J.S.G. Montaner[2,1], V.D. Lima[2,1]
[1]University of British Columbia, Faculty of Medicine, Vancouver, Canada, [2]British Columbia Centre for Excellence in HIV/AIDS, Vancouver, Canada, [3]University of British Columbia, School of Population and Public Health, Vancouver, Canada, [4]Arthritis Research Canada, Richmond, Canada, [5]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada

Background: To describe the burden of chronic comorbidities among people living with and without HIV (PLWH vs. PnLWH) in British Columbia (BC), Canada, we estimated disability-adjusted life years (DALY) related to these comorbidities.

Methods: From a population-based cohort in BC, antiretroviral-treated adult PLWH were matched by age and sex to four PnLWH at baseline and followed for ≥1 year during 2001-2012. DALY combines years of life lost to premature mortality (YLL) and lived with disabilities (YLD).

YLL were yearly death counts multiplied by standard life expectancies at death, while YLD were yearly prevalent counts multiplied by severity-specific weights.

DALY associated with non-AIDS-defining cancers, diabetes, osteoarthritis, hypertension, non-HIV-related dementia, cardiovascular (CVD), chronic kidney, chronic liver and chronic obstructive pulmonary diseases (COPD) were measured for 2008-2012 cumulatively.

Non-parametric bootstrapping estimated the credible intervals (CI) of YLL; for YLD, probabilistic resampling was conducted considering literature-derived disease-specific severity distribution.

Results: At baseline, our matched cohort consisted of 82% males with a median age of 40 years (25th-75th percentiles: 34-47). At any point between 2008-2012, 7042 PLWH and 30,640 PnLWH were alive, leading to 5356.5 and 10,945.7 in estimated DALY, respectively (rate: 770.2 [95%CI: 710.2, 831.6] vs. 359.0 [336.0, 382.2] years/1000 people; Figure 1[C]).

Similar to trends observed in Canada, cancers and CVD predominantly contributed the DALY. Except for hypertension, osteoarthritis (both populations) and dementia (PLWH only), the burden of most comorbidities was driven by YLL rather than YLD (Figure 1[A-B]).

COPD and chronic liver contributed the third and fourth highest DALY among PLWH, as did diabetes and COPD among PnLWH.

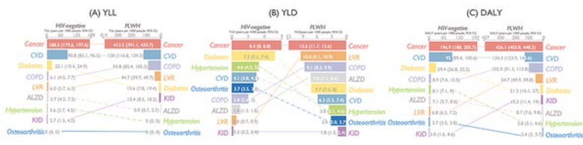

Figure 1. YLL, YLD and DALY associated with nine chronic comorbidities among people living with and without HIV in BC, Canada (2008-2012)

Conclusions: PLWH experience disproportionate burden of chronic comorbidities compared to PnLWH. The observed disparities may relate to socioeconomic and lifestyle differences, residual HIV-related inflammation, and ART-related toxicities. Our findings highlight the need to enhance prevention and management of comorbidities as part of HIV care.

EPC089

Incidence and predictors of clinical bone fractures among people with HIV on antiretroviral therapy

R. Hechter[1,2], H. Zhou[1], W. Leyden[3], Q. Yuan[1], K. Pak[1], H. Hu[4], J. Marcus[5], A. Adams[1], M. Horberg[4,2], M. Silverberg[3,2,6], J. Lo[3,7,8], W. Towner[1,8]
[1]Kaiser Permanente Southern California, Department of Research & Evaluation, Pasadena, United States, [2]Kaiser Permanente Bernard J. Tyson School of Medicine, Department of Health Systems Science, Pasadena, United States, [3]Kaiser Permanente Northern California, Division of Research, Oakland, United States, [4]Kaiser Permanente Mid-Atlantic States, Mid-Atlantic Permanente Research Institute, Rockville, United States, [5]Harvard Medical School and Harvard Pilgrim Health Care Institute, Department of Population Medicine, Boston, United States, [6]University of California, San Francisco, Department of Epidemiology and Biostatistics, San Francisco, United States, [7]The Permanente Medical Group, Department of Endocrinology, Oakland, United States, [8]Kaiser Permanente Bernard J. Tyson School of Medicine, Department of Clinical Science, Pasadena, United States

Background: People with HIV (PWH) have higher incidence rates of bone fracture compared with the general population. Use of antiretroviral therapy (ART) containing tenofovir disoproxil fumarate (TDF) is associated with lower bone mineral density (BMD) in PWH, but the relationship between use of TDF and incident bone fractures in PWH has not been well described.

Methods: We estimated the incidence rates (IR, per 1000 person-years) of clinical bone fractures in a cohort of PWH (age ≥40 years) who initiated ART between January 1, 2000 and September 1, 2015 at Kaiser Permanente in California and Mid-Atlantic States (D.C., Maryland, Virginia).

We extracted sociodemographic and clinical data from electronic health records. Patients with a history of dialysis, kidney transplant, metastatic cancer, or parathyroid abnormalities were excluded. The association of TDF use at baseline with the risk of incident fractures during

follow-up was estimated using Cox proportional hazards regression, adjusted for sociodemographic characteristics, history of substance use, clinical factors (nadir CD4 count, baseline HIV viral load, comorbidities), and study site.

Results: Among 6,508 PWH (5,689 male, 819 female) followed for 27,646 person-years (median: 3 person-years), we identified 232 incident fractures among those who used TDF (IR:14.0 per 1000 person-years, 95% CI: 12.2-15.8) and 128 fractures among those who did not use TDF (11.5 per 1000 person-years, 95% CI: 9.5-13.5). TDF use was not significantly associated with increased risk of clinical fractures (aHR 1.21, 95% CI: 0.93-1.57).

Significant risk factors for fractures included older age, chronic liver diseases, history of alcohol use disorder, history of drug use disorder and smoking (Figure 1).

Risk Factors	aHR (95% CI)
TDF use at baseline	1.21 (0.93-1.57)
Age	1.03 (1.01-1.04)
Gender	
Male	Reference
Female	1.32 (0.94-1.84)
Race/Ethnicity	
non-Hispanic White	Reference
non-Hispanic Black	0.61 (0.46- 0.83)
Hispanic	0.73 (0.54-0.98)
Asian	0.37 (0.15-0.89)
Other/Unknown	0.93 (0.61-1.43)
Chronic Liver Diseases	1.38 (1.01-1.89)
History of alcohol use disorder	1.61 (1.23-2.11)
History of drug use disorder	1.39 (1.06-1.81)
History of smoking	1.32 (1.05-1.65)

Adjusted Hazard Ratio

0 0.5 1 1.5 2 2.5

Figure 1. Predictors of clinical bone fractures among PWH on antiretroviral therapy

Conclusions: We did not observe a significantly increased risk of fractures associated with TDF use. To reduce the burden of bone fractures, healthcare providers and PWH should focus on key modifiable risk factors, including alcohol and drug use, chronic liver disease, and smoking.

EPC090

Gaps in the type 2 diabetes care-cascade and how HIV and/or TB disease impact movement through its stages: a national perspective using South Africa's National Health Laboratory Service(NHLS) database

A.T. Brennan[1,2,3], E. Lauren[4], J. Bor[1,2,3], N. Crowther[5], J. George[5], S. Khoza[5], K. Milsana[6], A. Dai[7], S. Rosen[1,3], A. Stokes[1], M.P. Fox[1,2,3]

[1]Boston University School of Public Health, Department of Global Health, Boston, United States, [2]Boston University School of Public Health, Department of Epidemiology, Boston, United States, [3]Health Economics & Epidemiology Research Office, Johannesburg, South Africa, [4]Boston University School of Public Health, Department of Biostatistics, Boston, United States, [5]University of Witwatersrand, Department of Chemical Pathology, Johannesburg, South Africa, [6]National Health Laboratory Services, School of Laboratory Medicine and Medical Science, University of KwaZulu-Natal, Department of Medical Microbiology, Durban, South Africa, [7]Boston University, Boston, United States

Background: Research out of South Africa(SA) suggests care for diabetes is poor. We evaluated the diabetes care cascade in SA using NHLS data and assessed how HIV and/or TB impact movement through its stages.

Methods: The NHLS cohort (n=373,909) included patients with a first hemoglobin A_{1c}(HbA$_{1c}$), plasma glucose(fasting(FPG) or random(RPG)) lab measured January 2012-March 2015.

Lab-diagnosed diabetes was defined as HbA$_{1c}$>6.5%, FPG ≥7.0mmol/l, or RPG ≥11.1mmol/l. Controlled diabetes was defined as HbA$_{1c}$<7.0% or FPG <8.0mmol/l or RPG <10.0mmol/l.

Cascade stages post diabetes diagnosis were linkage to care (having a diabetes lab within 12-months) and controlled diabetes at 12- and 24-months. We estimated gaps in the cascade nationally and by HIV and/or TB status.

Results: Nationally, 50% of patients screened for diabetes met lab-based criteria for the disease(Table). Of those with diabetes, 19% were linked to care, 5% were controlled at 12-months and <2% remained controlled at 24-months. We saw >70% loss in the transitions between stages.

Among those with diabetes, 19% linked to care (81% loss), among those 26% had their diabetes controlled within 12-months (74% loss), and among those 29% were controlled at 24-months (71% loss). The proportion of diabetes among PLWH was half that compared to HIV-uninfected, 29% and 54%, respectively.

Around 20% of patients, regardless of HIV and/or TB status linked to care within 12-months. A higher proportion of PLWH (vs. HIV-uninfected) had their diabetes under control at 12-months, while controlled diabetes at 24-months was comparable between groups.

		no. patients tested n (%)	lab-diagnosed diabetes n (%)	linkage to care within 12-mo. n (%)	cont. diabetes within 12-mo. n (%)	cont. diabetes within 24-mo. n (%)
sub-groups	HIV+/TB-	52,033 (100%)	15,190 (29.2%; 28.8-29.6%)	3,256 (21.4%; 20.8-22.1%)	992 (30.5%; 28.9-32.1%)	297 (30.0%; 27.1-32.9%)
	HIV+/TB+	4,702 (100%)	1,099 (23.4%; 22.2-24.6%)	203 (18.5%; 16.3-20.8%)	63 (31.0%; 25.0-37.7%)	21 (33.3%; 22.5-45.6%)
	HIV-/TB-	313,740 (100%)	168,439 (53.7%; 23.5-23.9%)	31,281 (18.6%; 18.4-18.8%)	7,904 (25.3%; 24.8-25.8%)	2,238 (28.3%; 27.3-29.3%)
	HIV-/TB+	3,434 (100%)	1,948 (56.7%; 55.1-58.4%)	444 (22.8%; 21.0-24.7%)	86 (19.4%; 15.9-23.2%)	20 (23.3%; 15.2-33.0%)
transition between stages		373,909 (100%)	186,676 (49.9%; 49.8-50.1%)	35,184 (18.8%; 18.7-19.0%)	9,045 (25.7%; 25.3-26.2%)	2,576 (28.5%; 27.6-29.4%)
overall care cascade		373,909 (100%)	186,676 (49.9%; 49.8-50.1%)	35,184 (18.8%; 18.7-19.0%)	9,045 (4.8%; 4.7-49.4%)	2,576 (1.4%; 1.3-1.4%)

Table. The transitions between the stages in the diabetes care cascade stratified by sub-group (n=373,909).

Conclusions: Diabetes care in our cohort of patients undergoing lab-based testing for the disease was poor, with >70% loss in the transitions between stages and <2% of those with diabetes achieving control within 24-months post diagnosis. PLWH had a lower proportion of diabetes compared to HIV-negative patients.

Although, still poor, PLWH had higher rates of completion of the cascade stages, possibly due to PLWH being integrated into HIV care.

EPC091

Prevalence of chronic kidney disease stratified by HIV, TB, and diabetes status: a national perspective using South Africa's National Health Laboratory Service (NHLS) database

A.T. Brennan[1,2,3], A. Dai[4], N. Crowther[5], J. Bor[1,2,3], M.P. Fox[1,2,3], S. Khoza[5], K. Milsana[6], S. Rosen[1,3], E. Lauren[7], J. George[5]

[1]Boston University School of Public Health, Department of Global Health, Boston, United States, [2]Boston University School of Public Health, Department of Epidemiology, Boston, United States, [3]Health Economics & Epidemiology Research Office, Johannesburg, South Africa, [4]Boston University, Boston, United States, [5]University of Witwatersrand, Department of Chemical Pathology, Johannesburg, South Africa, [6]National Health Laboratory Services, School of Laboratory Medicine and Medical Science, University of KwaZulu-Natal, Department of Medical Microbiology, Durban, South Africa, [7]Boston University School of Public Health, Department of Biostatistics, Boston, United States

Background: Complications like diabetes and chronic kidney disease (CKD) have replaced opportunistic infections as leading causes of mortality in people living with HIV (PLWH).

We evaluated the prevalence of lab-diagnosed CKD in South Africa (SA) using nationwide NHLS data and assessed how CKD risk is affected by HIV and diabetes.

Methods: The NHLS cohort (n=87,707; HIV-uninfected=74,607; PLWH=13,100) was limited to patients ≥30 years from government facilities with first creatinine measured between January 2012-December 2016. Diabetes was defined as hemoglobin A_{1c}≥6.5%, fasting plasma glucose≥7.0mmol/l, or random plasma glucose≥11.1mmol/l around date of first creatinine.

We used the CKD Epidemiology (CKD-EPI) equation to estimate glomerular filtration rate(eGFR) and defined CKD as 2 eGFR CKD-EPI measurements <60 ml/1.73/m^2 3- to 12-months apart. Log-binomial models were used to assess predictors of CKD, with interaction terms between diabetes/HIV and diabetes/TB.

Results: Prevalence of CKD was 20.7% (95%CI:20.4-21%) in HIV-uninfected and 23.9% (95%CI:23.2-24.7%) in PLWH. Prevalence increased with age. HIV-uninfected males had higher prevalence of CKD than HIV-uninfected females regardless of age group and diabetes status, while PLWH males had higher prevalence of CKD than PLWH females depending on age group but not diabetes status. Diabetics showed slightly higher prevalence of CKD than non-diabetics.

In adjusted analysis, PLWH had twice the risk of CKD. Older patients, males (vs. females) and diabetics (vs. non-diabetics) had an increased risk of CKD. Interaction terms had significant positive coefficients, suggesting that the effect of the combined action of diabetes/HIV and diabetes/TB is more than the sum of the individual effects.

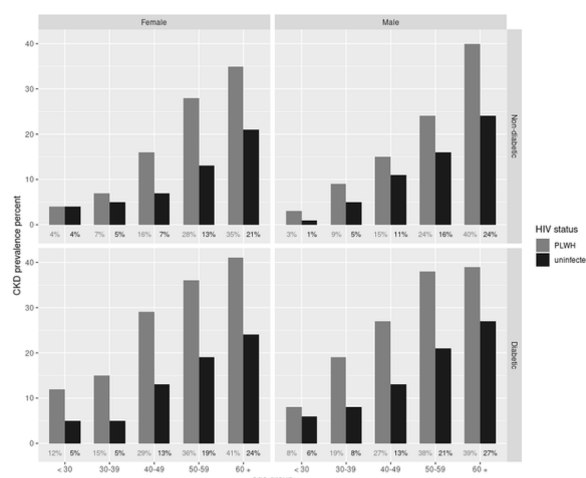

Figure. National prevalence of CKD stratified by HIV status, gender, age and diabetes status.

Conclusions: Prevalence of CKD was >20% in our cohort, with PLWH having higher rates than HIV-uninfected. SA has a high burden of HIV, TB and diabetes, all factors which drive CKD. As such, close monitoring of kidney function is warranted in all patients, even more so in those with diabetes, HIV and/or TB.

ing therapeutic tailored interventions to ensure healthy ageing. We aimed to identify whether people living with HIV (PLWH) experience accelerated or accentuated ageing by investigating differences in age of onset for various non-communicable diseases between people with and without HIV in the UK.

Methods: Between January 2000 and January 2020, all PLWH and people without HIV aged 18+ identified from the IQVIA Medical Research Database were eligible. Outcomes included cardiovascular disease (CVD), hypertension, diabetes and chronic kidney disease (CKD). All conditions were identified by Read codes and age at diagnosis was the date of the Read code assignment. For each outcome being investigated, people with and without HIV were excluded if they had the outcome of interest at baseline. PLWH and people without HIV were then matched based on propensity scores (1:1 ratio). For each outcome that occurred during prospective follow-up, linear regression was used to report unadjusted and adjusted p-values for any difference in age at diagnosis between people with and without HIV.

Results: 8880 PLWH were matched with 8880 people without HIV and were found to have an earlier onset of CVD (adjusted p-value 0.002). Similarly, PLWH had an earlier onset of hypertension (adjusted p-value 0.002). However, no difference between the age of onset was found for diabetes or CKD (adjusted p-values 0.368 and 0.483, respectively).

	Sample size; N	No. of events (%)	Mean age at diagnosis (SD)	Unadjusted models Coef.	P-value	95% CI	Adjusted models Coef.	P-value	95% CI

Chronic Kidney Disease									
People without HIV	9135	89 (1.0)	58.1 (11.9)	Ref.			Ref.		
People with HIV	9135	160 (1.8)	57.6 (12.2)	-0.550	0.730	-3.683, 2.584	-1.117	0.483	-4.245, 2.012

[a] Models are adjusted for the following baseline variables: sex, ethnicity, smoking status, body mass index, deprivation, study-entry date, substance use, lipid-lowering drug use and events for cardiovascular disease, hypertension, diabetes, chronic kidney disease, depression, anxiety and severe mental illness (the event being investigated was removed from the model)
[b] Cardiovascular disease comprises peripheral vascular disease, stroke, myocardial infarction, ischaemic heart disease and heart failure

Table 1. Unadjusted and adjusted differences in age at diagnosis for cardiovacular disease, hypertension, diabetes and chronic kidney disease.

Conclusions: The earlier development of CVD and hypertension in PLWH compared to people without HIV indicates accelerated ageing and is likely due to persistent immune response, chronic inflammation and/or ART exposure. These mechanisms may not have the same impact on organ decline.

EPC093

Risk factors linked to age-related comorbidities among people living with HIV aged over 40 years

[1]*Center for Epidemiological Studies on Sexually Transmitted Infections and AIDS in Catalonia, Badalona, Spain,* [2]*Hospital Germans Trias i Pujol, Badalona, Spain,* [3]*Hospital de la Vall d'Hebron, Barcelona, Spain,* [4]*Hospital de Bellvitge, Hospitalet del Llobregat, Spain,* [5]*Hospital Sant Pau, Barcelona, Spain,* [6]*Hospital del Mar, Barcelona, Spain,* [7]*Consorci Sanitari Integral, Hospitalet del Llobregat, Spain,* [8]*Hospital de Vic, Vic, Spain,* [9]*Hospital Clínic-Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain*

Background: Since the inception of the combined antiretroviral therapy, remarkable improvements have been witnessed regarding HIV outcomes, but this has led to a rise in chronic comorbidities usually associated with ageing. We described the factors associated with the most prevalent comorbidities in a cohort of people living with HIV (PLWH) aged over 40 years.

Methods: We conducted a retrospective cohort study using data from the Catalan PLWH cohort (PISCIS) between January 1, 2010, to December 31, 2019. Only patients who were aged 40 years as of the start of the study period were included in the analysis. Chronic conditions were coded according to the Swedish National study of Aging and Care in Kungsholmen (SNAC-K).

We used multivariable Cox regression models to assess factors associated with considered comorbidities (dyslipidemia, chronic liver diseases (CLD), hypertension, cardiovascular disease (CVD), solid neoplasms, and diabetes).

Results: The study included 6565 PLWH at baseline. By the end of the study period, 51.2% patients were without any of the selected comorbidities, while 47.0% had dyslipidemia, 33.6% CLD, 32.1% hypertension, 20.9% CVD, 16.9% solid neoplasms, and 12.4% diabetes.

Age was associated with an increased risk for all comorbidities except for solid neoplasms. Heterosexual men (HTX) and people who inject drugs (PWID) presented higher risk for CVD (HR=1.19 [CI=1.04-1.358], HR=1.99 [CI=1.72-2.30]) respectively; diabetes (HR=1.43 [CI=1.14-1.78], HR=1.69 [CI=1.32-2.15]), and solid neoplasms (HR=1.52 [CI=1.15-2.01], HR=9.08 [CI=7.20-11.47]).

We observed a lower risk of hypertension among PWID (HR=0.57 [CI=0.47-0.69]) compared to men who have sex with men (MSM). Moderate/severe economic deprivation was linked to a higher risk of CVD (HR=1.17 [CI=1.05-1.31]), hypertension (HR=1.21 [CI=1.06-1.38]), and CLD (HR=1.24 [CI=1.06-1.46]). Migrants had a lower risk of diabetes (HR=0.62 (0.49-0.79]) and hypertension (HR=0.74 (0.63-0.86]), while women had higher risk of CVD (HR=1.32 [CI=1.07-1.62]) and hypertension (HR=1.37 [CI=1.04-1.79]).

Conclusions: Apart from ageing, there are several sociodemographic factors associated to a higher risk of chronic comorbidities, such as female sex, lower socioeconomic status, being HTX, PWID or of Spanish origin. These factors are crucial in understanding the future health needs of an ageing PLWH population and could be vital in planning public health interventions.

EPC094

High-risk HPV infection in women living with HIV: experiences from a Zimbabwean HIV cohort

T. Kufa[1], A. Mandiriri[2], T. Shamu[3], S. Lowe[1], M. Pascoe[1]
[1]Newlands Clinic, Harare, Zimbabwe, [2]London School of Tropical Medicine and Hygiene, Public Health, London, United Kingdom, [3]University of Bern, Institute of Social and Preventive Medicine, Bern, Switzerland

Background: Cervical cancer (CC) is preventable yet remains the most common gynaecological cancer in Zimbabwe. Persistent infection with high-risk human papillomavirus (hrHPV) has been established as the necessary cause of CC. High prevalence rates of HPV have been described in women living with HIV (WLHIV) in sub-Saharan Africa, but there is limited data from Zimbabwe. The 2021 WHO guidelines for the screening of cervical pre-cancer and cancer recommend the detection of HPV DNA as the primary test. This study was conducted to describes the HPV prevalence and type distribution in an urban Zimbabwean cohort.

Methods: 2708 women were screened for hrHPV infection between January and December 2021. Data analysis of women with a positive hrHPV test included the type, associated risk factors and clinical diagnosis of cervical disease. The prevalence of hrHPV and type were calculated, and the chi square test was used to assess the relationship between type and clinical diagnosis. Predictors of HPV infection were analysed using logistic regression.

Results: The median age was 45 years (interquartile range [IQR] 37-52). 1433 (53%, 95% CI 51-55) were positive for HPV. The hrHPV types 58 (11.4%), 35 (10.3%) and 52 (10.1%) were most prevalent, followed by 16 (9.3%) and 18 (8.3%). The prevalence rates of other types (68, 56, 33, 51, 45) varied between 5 and 7%. 56 women had confirmed histological diagnosis of cervical precancer and 9 cancer. In women with precancer, type 52 was the most common, 15/56 (27%), and type 16 in women with CC, 7/9 (78%). In multivariable analysis, women with a detectable HIV viral load (>=1000copies/ml), were more likely to have hrHPV infection (aOR4.2, 95%CI 2.2-8) compared to those with an undetectable viral load(50copies/ml).

Conclusions: The high prevalence of hrHPV in this cohort highlights the necessity of CC screening in WLHIV. . Optimal HIV disease control is important in CC prevention, and . Pprimary prevention of HPV infection through vaccination programmes is highly recommended if the goal of elimination of CC in Zimbabwe is to be attained.

EPC095

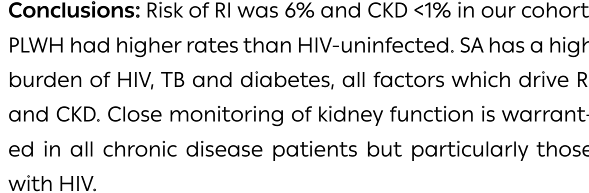
Predictors of incident renal insufficiency and chronic kidney disease in people living with HIV and diabetes using South Africa's National Health Laboratory Service (NHLS) database

A.T. Brennan[1,2,3], A. Dai[4], N. Crowther[5], J. Bor[1,2,3], M.P. Fox[1,2,3], S. Khoza[5], K. Milsana[6], S. Rosen[1,3], E. Lauren[7], J. George[5]
[1]Boston University School of Public Health, Department of Global Health, Boston, United States, [2]Boston University School of Public Health, Department of Epidemiology, Boston, United States, [3]Health Economics & Epidemiology Research Office, Johannesburg, South Africa, [4]Boston University, Boston, United States, [5]University of Witwatersrand, Department of Chemical Pathology, Johannesburg, South Africa, [6]National Health Laboratory Services, School of Laboratory Medicine and Medical Science, University of KwaZulu-Natal, Department of Medical Microbiology, Durban, South Africa, [7]Boston University School of Public Health, Department of Biostatistics, Boston, United States

Background: Non-communicable chronic diseases, like diabetes and chronic kidney disease (CKD), are leading causes of mortality in people living with HIV (PLWH).
We evaluated incidence of lab-diagnosed renal insufficiency (RI) and CKD in South Africa (SA) using national laboratory data and assessed how RI and CKD risk is affected by HIV and diabetes.

Methods: The National Health Laboratory Service cohort (n=13,104; HIV-uninfected n=8,669; PLWH n=4,435) included patients ≥30 years from government facilities whose first creatinine was measured between January 2012-2015 and was normal. Diabetes was defined as hemoglobin A_{1c}≥6.5%, fasting plasma glucose ≥7.0mmol/l, or random plasma glucose ≥11.1mmol/l around first creatinine.
We used the CKD Epidemiology (CKD-EPI) equation to estimate glomerular filtration rate and defined RI as 1 CKD-EPI<60 ml/1.73/m^2 and CKD as 2 CKD-EPI<60 ml/1.73/m^2 3-12 months apart. All patients had 24 months of potential follow-up. Mixed effects Poisson regression models were used to assess predictors of RI and CKD.

Results: 24-month risk of RI was 5.2% [95%CI:4.7%-5.7%] in HIV-uninfected and 6.5% [5.8%-7.3%] in PLWH, while CKD incidence was 0.6% [0.5%-0.8%] in HIV-uninfected and 1.0% [0.7%-1.3%] in PLWH.
Models for both outcomes found older patients (≥40 vs. 30-40) had an increased RI and CKD risk, with those ≥60 having the greatest risk (RI risk ratio (RR): 3.9 [95%CI:3.0-5.0]; CKD RR: 3.0 [1.7-5.2]). PLWH compared to HIV-uninfected had a 2.5-fold [2.1-3.2] and a 3-fold [1.7-5.2] increased risk of RI and CKD, respectively.
We found an increased risk of both outcomes in those with TB (RI RR: 1.8; [0.9-3.6]; CKD RR: 1.1; [0.8-1.5]). Male gender and diabetics had a small decreased risk of RI and slight increased risk of CKD. Both groups were less likely to have a follow-up lab measure, possibly suggesting a higher rate of loss in those groups.



Conclusions: Risk of RI was 6% and CKD <1% in our cohort. PLWH had higher rates than HIV-uninfected. SA has a high burden of HIV, TB and diabetes, all factors which drive RI and CKD. Close monitoring of kidney function is warranted in all chronic disease patients but particularly those with HIV.

EPC096

Improved access to cervical cancer screening and treatment for women living with HIV in Central Zambia

R. Makufele[1], B. Kafulubiti[2], S. Zulu[2], M. Sichamba[2], J. Chifwaila[2], T. Tulli[3]

[1]John Snow Inc, Strategic Information, Kabwe, Zambia, [2]John Snow Inc, Kabwe, Zambia, [3]John Snow Inc, Strategic Information, Lusaka, Zambia

Background: Cervical cancer is preventable and curable, as long as it is detected early and managed effectively, yet it is the fourth most common form of cancer among women aged 15-49 years old in Zambia. Women living with HIV (WLWH) are six times more likely than uninfected women to develop cervical cancer, and should be targeted for screening and treatment.

Description: The USAID SAFE program supports the Ministry of Health (MOH) in conducting cervical cancer screening and treatment services with specific focus on WLWH in selected project supported sites in the Central province. The USAID-SAFE increased cervical cancer screening and treatment through two main strategies;

1. Enhanced screening and treatment of precancerous lesions through outreach activities in hard to reach and hardly reached facilities.

2. Enhanced support for the same day treatment of precancerous lesions. USAID SAFE conducted trainings of MOH staff in VIA, LEEP and mentorship in cervical cancer in order to build local capacity for service providers.

Lessons learned: The initial focus on the provision of the cervical cancer screening and treatment only at static facilities led to the non-achievement of the set targets in the previous fiscal years due to reduced coverage of women accessing the services. Expanded service provision through outreach activities in rural and hard-to-reach areas increased coverage of eligible women accessing cervical cancer screening and treatment services. This led to an achievement of 94% screening against the set target of 23,836 in FY21. Further, this led to improved treatment rate from 62% in September, 2020 to 87% in September, 2021.

Conclusions/Next steps: Integration of cervical cancer into HIV services and promoting same day screening and treatment through static and outreach services improve access for women who are eligible. Instead of focusing only on static services, MOH and implementing partners should embark on identifying women in hard to reach areas to ensure increased access to cervical cancer screening and treatment services.

Describing the spread of HIV through molecular epidemiology

EPC097

HIV acquisition prior to entry into formal sex work: inference from viral next generation sequencing

F. Cholette[1,2], B. Neufeld[3], P. Sandstrom[2], H.K. Musyoki[4], H. Ma[5], S. Kaosa[4,6], J. Kioko[4,6], S. Isac[7], P. Bhattacharjee[3], E. Cheuk[3], M. Pickles[8,3], R. Mwatelah[1], R. Capina[2], C. Daniuk[2], L.R. McKinnon[1], J.F. Blanchard[3], S. Mishra[5,9,10,11], M. Becker[3]

[1]University of Manitoba, Department of Medical Microbiology and Infectious Diseases, Winnipeg, Canada, [2]Public Health Agency of Canada, National Microbiology Laboratory at the JC Wilt Infectious Diseases Research Centre, Winnipeg, Canada, [3]Institute for Global Public Health, University of Manitoba, Department of Community Health Sciences, Winnipeg, Canada, [4]National AIDS and STI Control Programme, Nairobi, Kenya, [5]Li Ka Shing Knowledge Institute, St. Michael's Hospital, MAP Centre for Urban Health Solutions, Toronto, Canada, [6]Partners for Health and Development in Africa, Nairobi, Kenya, [7]India Health Action, New Delhi, India, [8]Imperial College London, Medical Research Council Centre for Global Infectious Disease Analysis, London, United Kingdom, [9]University of Toronto, Department of Medicine, Toronto, Canada, [10]University of Toronto, Institute of Medical Sciences, Toronto, Canada, [11]University of Toronto, Institute of Health Policy, Management and Evaluation, Toronto, Canada

Background: HIV/STI programs tailored for self-identified sex workers reach women on average 2 years after formal engagement in sex work; and do not reach high-risk adolescent girls and young women (AGYW) who do not self-identify as sex workers. Yet epidemiological and programmatic data suggest that AGYW engaged in sex work, and/or other forms of transactional sex, experience vulnerabilities associated with HIV acquisition early in their sexual life course.

However, there are limited data on the timing of HIV acquisition among AGWY engaged in sex work or transactional sex. We estimated the time since infection in AGYW using molecular data and estimate the timing of HIV acquisition among AGWY engaged in sex work.

Methods: Dried blood spot (DBS) specimens were collected from AGYW living with HIV in Mombasa, Kenya (n=67) recruited from "hotspot" locations associated with sex work (as part of the 2015 *Transitions Study*).

A portion of the *pol*gene was sequenced from DBS using an in-house next generation sequencing HIV drug resistance mutation genotyping assay.

Estimated time since infection was inferred using a web-based tool as described by Puller et al. (2017) freely available at https://hiv.biozentrum.unibas.ch/ETI/.

Results: The majority of DBS samples (n=51, 76.1%) were successfully sequenced. Among the n=27 women engaged in sex work, the mean difference between estimated time since infection and first sex, first transactional sex, and

first self-identified as a sex worker was 0.5, -1.2, and -1.9 years, respectively, where negative values indicate that infection occurred before the corresponding event.

It was estimated that 74.1% (20/27) of AGYW who sell sex acquired HIV prior to entry into formal sex work. The median time since infection was similar between women who engaged in sex work (3.4 years, IQR: 1.7, 6.3), transactional sex only (3.6 years, IQR: 2.9, 8.2), and neither (4.8 years, IQR: 2.4, 7.0).

Conclusions: The majority of AGYW who self-identified as sex workers acquired HIV prior to entry into formal sex work. Current prevention programs tailored for sex workers may be missing out on key opportunities for HIV prevention. Our findings suggest the need to reach high risk AGYW earlier on in their sexual life course.

Surveillance of HIV in key populations

EPC098

Comprehensive clinical care disruption for criminally-justice involved people living with HIV following implementation of Shelter-in-Place and decarceration

A.A. Clemenzi-Allen[1,2], J. Hebert[3], M. Reid[2], H. Hammer[4], T. Mains[1], L. Pratt[1], P. Wesson[5]

[1]San Francisco Department of Public Health, Jail Health Services, San Francisco, United States, [2]University of California, San Francisco, Division of HIV, ID and Global Medicine, San Francisco, United States, [3]University of California, San Francisco, Department of Family and Community Medicine, San Francisco, United States, [4]San Francisco Department of Public Health, Ambulatory Care, San Francisco, United States, [5]University of California, San Francisco, Department of Epidemiology and Biostatistics, San Francisco, United States

Background: In March 2020, to protect against SARS-CoV-2 transmission in the county jail, the City and County of San Francisco (CCSF) implemented a decarceration policy, which reduced the jail census by 40%. However, decarceration policies could potentially exacerbate barriers to care for criminally-justice involved (CJI) PLWH during Shelter-in-Place (SIP) because incarcerations provide opportunities for improving health access and engagement.

We used an interrupted time series analysis to quantify disruptions in care received in and out of jail among CJI PLWH in the CCSF following decarceration and SIP.

Methods: Using county administrative data we constructed a retrospective cohort of adults with HIV booked at the CCSF jail with at least one clinic encounter (primary care, mental health, substance use or acute care) from January 2018 to December 2019. We estimated changes in clinic encounters following SIP (March 2020 to December 2020) using unadjusted and adjusted Generalized Estimating Equation (GEE) log-binomial and logistic regression models, controlling for race/ethnicity, gender, age, trimorbidity, and homelessness. Incarcerations greater than 6-days were coded as clinic encounters because clinical care in CCSF jail continued following SIP.

Results: We included 437 people: mean age was 43.1 years (standard-deviation 11); 88% were cisgender-male; 39% white; 59% were homeless; 65% had trimorbidity.

We observed reductions in HIV (aRR=0.77; 95% CI: 0.67, 0.90) and Substance Use (aRR=0.83; 95% CI: 0.70, 0.99) encounters immediately following SIP. Reductions continued in each subsequent month for HIV (aRR=0.96; 95% CI: 0.93,0.99), Substance Use (aRR=0.95; 95% CI: 0.91, 0.99), and Mental Health (aRR=0.97; 95% CI: 0.94, 1.00) encounters. We observed no changes in Acute Care encounters.

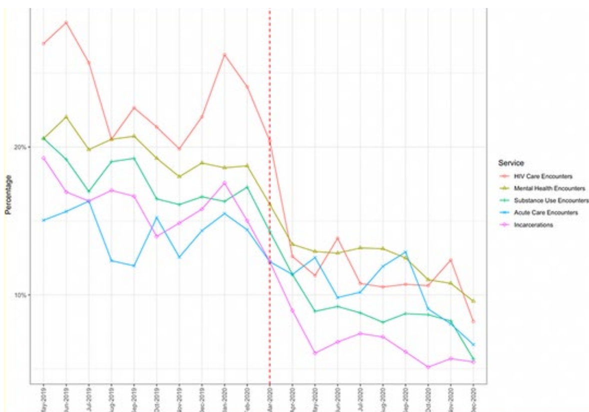


Figure. Time series of proportional engagement in clinic encounters among Criminal-Justice Involved People Living with HIV, San Francisco County.

Conclusions: Clinic encounters for CJI PWLH in CCSF significantly declined across multiple encounter domains and worsened during the COVID-19 pandemic. Efforts to End the HIV Epidemic during the COVID-19 pandemic must include strategies to (re)engage this key population outside of common institutional care settings.

EPC099

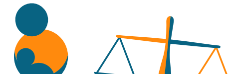
Estimation of the population size of gay, bisexual and other men who have sex with men in Canada, 2020

J. Sorge[1], S. Colyer[2], J. Cox[1], A. Kroch[2], N. Lachowsky[3], N. Popovic[1], Q. Yang[1]

[1]Public Health Agency of Canada, Infectious Diseases Programs Branch, Ottawa, Canada, [2]Ontario HIV Treatment Network, Toronto, Canada, [3]Community-Based Research Centre, Vancouver, Canada

Background: Gay, bisexual (GB) and other men who have sex with men (MSM), both an identity- and behaviourally-based community, account for over half of new HIV infections in Canada. Reliable population size estimates are necessary to allocate resources to meet prevention needs and for modelling the HIV epidemic. Previous Canadian estimates were solely identity-based, which did not ac-

count for GB-identified men not willing to reveal that on a government survey. A nuanced understanding of the epidemic among GBMSM has been limited by the challenges estimating this population size.
Our objective was to develop national behaviour- AND behaviour- and identity-based population size estimates of GBMSM.
Methods: Estimates for males aged ≥15 years were drawn from Statistics Canada's population size estimates, a 2020 national cross-sectional government population-based health survey, and a 2019/2020 national cross-sectional community-based survey of GBMSM. Estimated proportions of GB identity, those not likely to disclose GB identity, and MSM that do not identify as GB were applied to ≥15 male population estimates.
We then considered prior year anal sex history to specify estimates of those sexually active. Calculations were stratified by rural/non-rural geography, using a population cut-off at 1,000 residents. We present estimates with upper- and lower-bounds.
Results: We estimate that 3.5% of the ≥15 male population identified as GB, 13.5% of GB males would not disclose their sexual identity on a government survey, and 0.2% of non-GB identified males reported past year anal sex with a man. The national GBMSM population size in 2020 is estimated at 640,785 (617,263-664,307), 4.1% (3.9%-4.2%) of the Canadian male ≥15 population. A
mong these, an estimated 560,575 were in non-rural centres (4.2% of ≥15 males), and 80,210 were in rural areas (3.1% of ≥15 males). The estimate of GBMSM reporting past-year anal sex was 432,267 (361,984-502,549), representing 2.7% (2.3%-3.2%) of the male ≥15 population.
Conclusions: Combining data from multiple sources, these population size estimates included GBMSM previously unaccounted for in Canada.
These estimation methods may be scaled/adapted to other regions to derive robust and comparable estimates that capture previously-uncounted individuals.
Stratification of results by rural/non-rural environments provides additional information to guide health promotion and care services.



EPC100
HIV and syphilis surveillance survey and population size estimation among transgender women in Ulaanbaatar, Mongolia, 2021

S. Amarsanaa[1], T. Purevsuren[1], O. Bayandorj[1], J. Badrakh[1], D. Jagdagsuren[1], B. Chultemsuren[2], S. Zayasaikhan[2], L.G. Johnston[2]
[1]*National Center for Communicable Disease, AIDS/STI Surveillance and Research Department, Ulaanbaatar, Mongolia,* [2]*Youth for Health Center NGO, SKPA Program, Ulaanbaatar, Mongolia*

Background: Mongolia has little known about HIV prevalence, access to health care, including HIV testing, and sexual behaviors among transgender women (TGW). In the 2019 HIV biological behavioral surveys conducted among men who have sex with men (MSM), 11 participants (0.7%), reported as being TGW in Ulaanbaatar. In 2021, Mongolia had only two reported cases of TGW living with HIV. TGW in Mongolia is extremely hidden due to social stigma, discrimination, and frequent round-ups by police.
The objectives of these studies were to assess HIV and syphilis prevalence, HIV knowledge and testing, sexual risk behaviors, stigma, and discrimination among TGW in Ulaanbaatar, the capital of Mongolia.
Methods: We used respondent-driven sampling (RDS), an effective sampling method for recruiting and deriving population estimates of hidden populations. Beginning with 1 seed, the sample reached a total of 100 TGW.
Results: Most TGW had their sexual debut in their teens and just under half reported having anal penetrative sex with multiple male partners in the previous month. Seventy-one percent of TGW said they would be (71.3%) "very likely" to use PrEP if available. Almost all TGW reported ever having an HIV test (90.9%) and 96% have had an HIV test in the past 12 months and received their results.
Sixty-three percent of TGW have experienced verbal or physical abuse and 28% have been denied entry or ejected from a house and experienced sexual abuse and assault believed to be due to their TGW identity or presentation. One-third of TGW are ashamed to be TGW and 29% have attempted suicide because of their TGW identity. HIV prevalence was 5.4% and active syphilis prevalence was 12.8%. No TGW who were HIV antibody-positive were co-infected with active syphilis. There is an estimated 800 TGW living in Ulaanbaatar.
Conclusions: TGW practice risky sexual behaviors and face high amounts of stigma and discrimination because of their TGW identity. The scale-up evidence-based HIV prevention interventions targeting TGW, which include comprehensive mental health counseling and support, and allow access for those under the age of 18 years without parental consent is needed.

EPC101

Toward achieving the 95-95-95 targets among key populations in Eswatini: results from an integrated bio-behavioral surveillance survey

B. Sithole[1], L. Muzart[1], P. Dlamini[1], B. Phiri[1], M. Matsebula[1], N. Dlamini[1], C. Akolo[2], H. Mahler[2], A. Lambert[2], C. Casalini[2], V. Ranebennur[2], S. Matse[3], K. Lukhele[3]
[1]FHI 360, EpiC, Mbabane, Eswatini, [2]FHI 360, EpiC, Washington DC, United States, [3]Ministry of Health, Swaziland National AIDS Program, Mbabane, Eswatini

Background: In 2014, the Joint United Nations Programme on HIV/AIDS (UNAIDS) launched the 95-95-95 targets to be achieved by 2030. We conducted an integrated-biobehavioral-surveillance-survey (IBBSS) in Eswatini among key populations (KPs) to quantify HIV prevalence, knowledge of HIV status, treatment uptake, and viral load (VL) knowledge and status.

Methods: Between October 2020 and January 2021, FHI 360 LINKAGES project and Swaziland National AIDS Program conducted a cross-sectional-study among 416 men who have sex with men (MSM) and 676 female sex workers (FSWs) in Eswatini. Participants were recruited via respondent-driven sampling, a network-based peer-referral method designed for hard-to-reach populations.

We included FSWs who reported majority of their income in the past 12 months was from sex-work and MSM who reported having had anal sex with another man in the past 12 months. All participants were ≥18year, able to provide informed consent, and willing to undergo HIV testing and viral load (VL) testing if identified HIV positive. Participants completed a survey. The study was approved by Eswatini and FHI 360 ethics committees.

Results: Most KP individuals (99% FSWs, 98% MSM) were tested before. 60.7% FSWs tested HIV positive in the study and 86% already knew their status, while 27.1% MSM tested HIV positive and 58% already knew their status.

Antiretroviral therapy (ART) uptake was higher among FSWs, 97.7% (345/353), than MSM, 93.9% (63/66), while treatment-adherence was 99.7% (344/345) among FSWs and 99% (62/63) among MSM. Though 86.9% of FSWs and 87% of MSM reported previous VL testing, knowledge of VL status was low, with 33.6% of FSWs and 3.7% of MSM aware. Only 2.6% of FSWs and 1.8% of MSM reported VL suppression. However, VL testing from the study was 75% suppression for MSM and FSW but only 2.2% were aware they were suppressed.

Conclusions: Eswatini's KPs have not yet reached all 95-95-95 (80%, 97%, 94%, respectively) targets. MSM were lower in all outcomes except ART adherence, indicating a need for programs to focus on MSM outcomes.

Knowledge of VL status was very low and programs should look for innovative strategies to increase access to VL testing and improve KPs VL knowledge.

EPC102

Counting that counts: the success story of the Ghana Key Population Unique Identification System (GKPUIS)

D. Annang[1], P. Ayamah[2], S.A. Amoako[3]
[1]Ghana AIDS Commission, Research Monitoring and Evaluation, Accra, Ghana, [2]Ghana AIDS Commission, Technical Services, Accra, Ghana, [3]Ghana AIDS Commission, Finance and Administration, Accra, Ghana

Background: Ghana's National HIV Strategic Plan provides a framework for the implementation of a comprehensive package of services specifically to reach Key Populations (KP): Female Sex Workers (FSW), Men who have Sex with Men (MSM) and other vulnerable groups. In tracking the services provided to them, KP Program Managers are faced with how to determine which KP client has received which service and how to reduce double counting of KP clients to the barest minimum.

An effective unique identification system called the Ghana Key Population Unique Identification System (GKPUIS) was developed to address these challenges especially considering their mobility.

Description: The Ghana AIDS Commission (GAC) in collaboration with its partners developed the GKPUIS to improve the data management processes associated with KP programming in Ghana. The GKPUIS is a web-based system which uniquely identifies KPs with a system generated 16 alphanumeric code. The system was launched in April 2019 and is currently being used by 20 KP Implementing Organizations to capture and report KP programmatic data.

Lessons learned: From 1st October 2020 to 30th November 2021, 9,251 unique KP clients have been registered and approved in the GKPUIS. This is made up of 4,590 FSW and 4,661 MSM.

Data from the system also revealed that out of the registered KP clients 4,258 FSW and 3,526 MSM were offered any 4 out of the 6 minimum package of services (Prevention Information, education on HTS, STI SGBV, TB and Condom promotion and distribution) for a client to be classified as reached. In the case of FSW, 60.8% of those reached were tested with 11.9% positivity and 90.6% of those testing positive initiated on ART Treatment.

Also 94.9% of MSMs reached tested for HIV with a yield of 6.8% and and ART initiation of 96.8%.

Conclusions/Next steps: The rollout of the GKPUIS is providing real time data to support HIV prevention, treatment and care for KPs. There are currently ongoing modifications to the system to integrate features such as an offline mode for data capturing. Also the data from GKPUIS is being considered for the mapping and size estimation for KPs.

HIV prevention and care indicators for Saskatchewan First Nation communities before and during the COVID-19 pandemic, 2018-2020

I. Khan[1], S. Konrad[1], C. Cyr[1], G. Akinjobi[2], E. Dankwah[2], G.R. Janga[2], J. Blocka[3], B. Dow[1], S. Skinner[4], N. Ndubuka[2]
[1]Indigenous Services Canada, Saskatchewan Region, Regina, Canada, [2]Northern Inter-Tribal Health Authority, Prince Albert, Canada, [3]Indigenous Services Canada, Saskatchewan Region, Prince Albert, Canada, [4]University of Saskatchewan, Department of Medicine, Saskatoon, Canada

Background: The COVID-19 pandemic brought numerous restrictions and challenges, and has significantly impacted other public health priorities including HIV prevention and care. Saskatchewan, a Canadian prairie province, has had among the highest HIV rates in Canada for over a decade, with Indigenous people being overrepresented in the HIV epidemic.
This study aims to describe key indicators in HIV prevention and care among Saskatchewan First Nation communities before (2018-2019) and during (2020) the COVID-19 pandemic.
Methods: Data gathered for this analysis includes newly diagnosed HIV cases (captured in the Panorama public health surveillance system) and HIV testing in or near First Nation communities (captured via the provincial laboratory). The HIV cascade of care outcomes among individuals who resided in First Nation communities at the time of diagnoses (captured via the Annual HIV Public Health Review) include:
1. Linkage to care, defined as the time from diagnoses to the earliest HIV care bloodwork (HIV Viral Load (VL) or CD4 count);
2. On treatment, defined as at least one antiretroviral (ARV) dispensation in the calendar year; and,
3. Viral suppression, defined as the most recent VL in the year being less than 200 copies/mL.
Results: After a rising trend in HIV tests performed in and near First Nation communities, the testing rate decreased by 22% in 2020 compared to 2019.
The HIV diagnoses rates decreased accordingly in 2020 compared to 2018 and 2019. The proportion of persons living with diagnosed HIV who were on treatment remained stable in all three years, while the proportion who achieved viral suppression decreased by 7% in 2019 and a further 1% in 2020. See table 1.

	2018	2019	2020
HIV Tests Performed	10,025	10,915	8,538
HIV diagnoses rates (per 100,000)	32.1	31.7	27.7
Persons linked to care with 1 month of diagnosis (South Central First Nation communities only)	100%	78%	88%
Persons living with diagnosed HIV on treatment	79%	80%	79%
Of those on treatment, proportion virally suppressed (<200 copies/mL)	81%	74%	73%

Table 1. HIV Indicators for Saskatchewan First Nation Communities, 2018-2020

Conclusions: While the rates of testing and new diagnoses decreased in 2020, these high-level HIV cascade of care outcomes remained similar to pre-COVID-19 outcomes, highlighting the resiliency of HIV programs in Saskatchewan First Nation communities. However, further in-depth assessments are needed.

EPC104

A population level application of a novel method for estimating the timing of HIV acquisition among migrants to Australia

J. King[1], T. Dobbins[1], K. Petoumenos[1], R. Guy[1], R. Gray[1], B. Minas[2], S. Nigro[3], D. Si[4], S. McGregor[1]
[1]University of New South Wales, Kirby Institute, Sydney, Australia, [2]WA Department of Health, Communicable Disease Control Directorate, Perth, Australia, [3]NSW Health, Communicable Diseases Branch, Sydney, Australia, [4]Queensland Health, Communicable Diseases Branch, Prevention Division, Brisbane, Australia

Background: New HIV diagnoses have been declining in Australia, predominantly among Australian-born men who have sex with men, with no decline in the number of new diagnoses among people born-overseas (migrants). Accurate assessment of the timing of HIV acquisition relative to the date of migration will help inform the development of HIV testing and prevention programs.
A novel method for estimating the timing of HIV acquisition among migrants is presented, using surveillance data from the Australian National HIV Registry (NHR).
Methods: We developed a novel algorithm that incorporates a CD4+ T-cell decline back projection model, testing history, clinical status, as well as the clinician estimate for the place of acquisition. This algorithm was applied to all new cases of HIV diagnosed between 1 January 2016 and 31 December 2020, among migrants aged 15 years and older, with the objective of estimating whether HIV infection occurred before or after arrival in Australia.
Results: By augmenting the CD4+ T-cell decline back projection model with testing history and clinical status in the algorithm; the proportion of HIV diagnoses able to be estimated with a place of diagnosis increased from 56% to 60%.
By further augmenting the algorithm with the clinician estimate for the place of HIV acquisition, the proportion able to be estimated increased from 60% to 93%.
Of the 1,909 migrants newly diagnosed with HIV, 995 (52%) were estimated to have acquired HIV after migration to Australia, 772 (40%) before migration and another 142 (7%) were unable to be classified.
Conclusions: Two-fifths of migrants newly diagnosed with HIV likely acquired HIV before arrival to Australia, while more than half likely acquired HIV after arrival. Focused testing and prevention programs for migrant communities are needed to limit HIV transmission and achieve better health outcomes.

Our method offers increased objectivity and completeness for place of HIV acquisition estimates in surveillance data, allowing for a more representative picture of the local HIV epidemiology. The data fields used in our algorithm are used by many countries with similar HIV epidemic profiles, enabling adaptation of the algorithm for use elsewhere.

EPC105

Substantial improvement in HIV outcomes among men who have sex with men (MSM) in Baltimore, Maryland from 2008-2017

D. German[1], J. Glick[1], K. Yenokyan[2], A. Sawyer[1], M. Gribbin[3], C. Flynn[3]

[1]*Johns Hopkins Bloomberg School of Public Health, Health, Behavior and Society, Baltimore, United States,* [2]*Johns Hopkins Bloomberg School of Public Health, Baltimore, United States,* [3]*Maryland Department of Health, Baltimore, United States*

Background: Historically, Baltimore has reported exceedingly high HIV prevalence and persistent racial disparities in HIV outcomes among MSM. We examined trends in HIV testing, prevalence, and care by race over time among MSM in Baltimore to inform Ending the HIV Epidemic (EHE) efforts and identify residual disparities.

Methods: Using National HIV Behavioral Surveillance data from Baltimore: 2008, 2011, 2014, 2017, we examined prevalence of HIV testing, prevalence, new diagnoses, care, and anti-retroviral therapy (ART) use and potential socio-demographic disparities using unadjusted and adjusted logistic models calculated across time.

Separate analyses were also run for Black (BMSM) and White (WMSM) MSM and we compared marginal probabilities to evaluate time effects.

Results: In 2017, WMSM and bisexual or heterosexual MSM were less likely to report past year HIV testing, and test HIV-positive compared to BMSM and gay MSM. There were no demographic differences in new diagnoses, care, or ART use. Average predicted probability improved between 2008 and 2017 for each outcome and most shifts were statistically significant.

Among BMSM, recent testing and prevalence was lower among bisexual or heterosexual MSM (AOR: 0.33, 95% C.I. 0.16, 0.69 and AOR: 0.26, 0.14, 0.49). Among WMSM, recent testing was lower among those over 30 (AOR: 0.22, 95% CI 0.06, 0.80).

No other demographic differences were observed. Average predicted probability for each indicator improved over time among BMSM and WMSM, with most shifts attaining statistical significance.

Predicted probability of recent testing notably increased among BMSM (0.58, 95% C.I. 0.52, 0.66 to 0.76, 95% C.I. 0.39, 0.62) compared to WMSM (0.50, 95% C.I. 0.39, 0.62 to 0.58, 95% C.I. 0.45, 0.72). Disparities remain in predicted probability of HIV-positive test results (BMSM 0.42 95% C.I. 0.36, 0.49; WMSM 0.15, 95% C.I 0.08, 0.26) in 2017.

	2008	2011	2014	2017
Ever HIV test	0.91 (0.88, 0.94)	0.91 (0.88, 0.93)	0.94 (0.91, 0.96)	0.96 (0.94, 0.98)
HIV test past year	0.57 (0.52, 0.62)	0.48 (0.42, 0.53)	0.53 (0.48, 0.58)	0.73 (0.68, 0.78)
Positive test result	0.40 (0.34, 0.45)	0.42 (0.37, 0.46)	0.33 (0.28, 0.38)	0.35 (0.30, 0.39)
Unrecognized HIV	0.27 (0.22, 0.31)	0.27 (0.23, 0.32)	0.13 (0.10, 0.16)	0.07 (0.04, 0.10)
HIV care past year	0.85 (0.65, 0.94)	0.79 (0.54, 0.91)	0.88 (0.82, 0.95)	0.98 (0.92, 1.00)
Taking ARV	0.25 (0.12, 0.37)	0.72 (0.50, 0.86)	0.89 (0.79, 0.95)	0.86 (0.76, 0.96)

Table. Average Predicted Probability (95% CI)

Conclusions: HIV outcomes have improved substantially among MSM in Baltimore. There is a continued need to address racial disparities and support sustained HIV prevention and care.

EPC106

Review of the Mother-to-Child Transmission Indicators between 2010-2020

A. Aboushady[1], A. Nawwar[2], M. Othman[3]

[1]*Harvard University, Boston, United States,* [2]*Alexandria University, Faculty of Medicine, Alexandria, Egypt,* [3]*High Institute of Public Health, Alexandria, Egypt*

Background: Significant improvements in the prevention of mother-to-child transmission (PMTCT) of HIV have been achieved throughout the years. Yet, there remain many cases worldwide of mother-to-child transmission (MTCT) of HIV. According to UNICEF, there are four components for a comprehensive PMTCT program.

We focused on two components:

1. The prevention of transmission from a woman living with HIV (WLHIV) to her infant, and;
2. The provision of appropriate treatment, care, and support to WLHIV and their families.

Methods: We retrieved two different datasets from UNICEF with MTCT related indicators. The dataset included data from 147 countries, and we focused on the indicators, evaluating the two components mentioned above. The datasets were triangulated along with the World Bank's Gross National Income (GNI) dataset to integrate the income groups classification.

We analyzed the change in the MTCT rate and the percent of pregnant WLHIV receiving effective ARVs for PMTCT between 2010 and 2020.

Results: We visualized the geographic distribution of the two indicators in 2010 and 2020, in figure(1). For countries with the complete data, we found that in 11 out of 99 countries, the MTCT rate increased, of which 7 are from low and lower-middle-income countries.

While in the percent of pregnant WLHIV receiving effective ARVs for PMTCT, 11 out of 86 showed decreasing figures, of which 7 are from low and lower-middle-income countries. Meanwhile, 7 countries are deteriorating in both indicators. Four countries (Gambia, Niger, Sudan, and Yemen)

are from the low-income group, two (Algeria, Honduras) from the lower-middle-income group, and one (Georgia) from the upper-middle-income group.

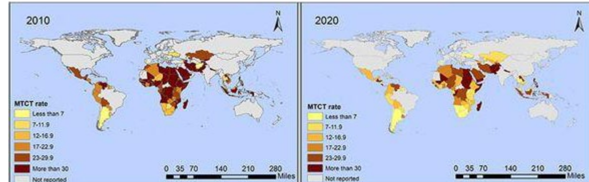

Figure. Estimated mother-to-child transmission (MTCT) rate

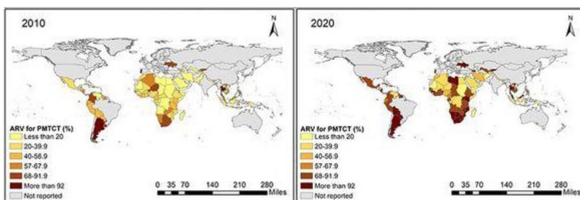

Figure. Percentage of pregnant women living with HIV receiving effective ARVs for PMTCT (excludes single-dose nevirapine)

Conclusions: In conclusion, inequality remains between different income groups. Some countries have alarming statistics, showing deteriorating figures in the transmission and prevention of MTCT. Such numbers require immediate action, given the expected deterioration with the ongoing burden on the health services, posed by the COVID-19 pandemic.

EPC107

Population shifts in detectable HIV viral load in rural Kwa-Zulu Natal

E. Okango[1], M. Inghels[2], F. Tanser[2,1]
[1]*Africa Health Research Institute, Durban, South Africa,*
[2]*University of Lincoln, Lincoln, United Kingdom*

Background: HIV viral load trends monitoring at populational level is crucial to assess current impact of HIV related health interventions and identify population groups for which efforts should be intensified. We aimed to investigate demographic shifts in detectable HIV viral load between 2011 and 2018 to determine the changing dynamics of HIV and new population sub-groups at risk in rural KwaZulu-Natal, South Africa, a region which has one of the highest HIV prevalence in the World.

Methods: The Africa Health Research Institute (AHRI) has been running a population- based cohort study among ~140,000 adults over 15 years in rural KwaZulu-Natal since 2004, which is currently the World's largest ongoing population-based HIV cohorts. Annual home-based HIV testing is offered to every resident of the study area (~4000 HIV positive individuals each year and approximately 33,000 samples in total).

The evolution of detectable viral load (>1500 copies/mL) obtained from dried blood spots collected between 2011-2018 was analysed by demographic characteristics (age-group, sex, gender, marital status).

Results: The overall population prevalence of detectable viral load declined on from 53.8% [95% CI 50.2%-54.6%] in 2011 to 33.5% [95% CI 28.9%-36.2%]. This prevalence declined more quickly among females compared to men (-22 pts vs -18 pts respectively, $p<0.05$). Age group 15-20 for both males and females continued to have the highest prevalence of detectable viral load over the study period (~68% in 2011, ~43% in 2018). The results also showed that males over 40y had were emerging as groups at risk.

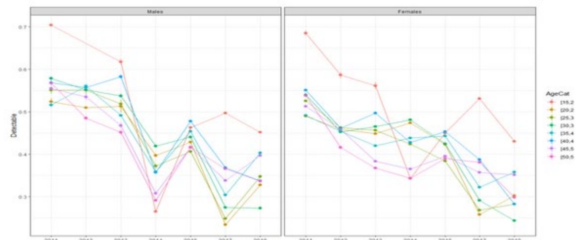

Figure 1. Age changes in detectable viral load.

Conclusions: Our findings have unraveled emerging groups at risk of viral non-suppression. This tracking is essential in detecting anomalies which will in turn help not only to inform novel intervention strategies for vulnerable groups but also determine what existing strategies are not working.

EPC108

Progress against the 2030 UNAIDS HIV elimination targets in Canadian Federal Correctional Institutions

M.-P. Gendron[1], S. Thompson[1], J. Smith[1]
[1]*Correctional Service Canada, Ottawa, Canada*

Background: Correctional Service Canada (CSC) is responsible for providing essential health care services for people incarcerated in federal institutions in Canada. This includes access to screening and treatment for human immunodeficiency virus (HIV). CSC is committed to the global HIV elimination targets set by UNAIDS. This study aims to measure CSC progress against these targets.

Methods: Data were extracted from the electronic medical records for the population incarcerated as of January 12th, 2022. The first target, awareness of HIV status, was defined as the proportion of the population who reported a previous HIV test or accepted an HIV test while incarcerated, the second, as the proportion of those living with HIV on treatment, and the third, as the proportion treated who achieved viral suppression (viral load below 250 copies/ml).

HIV cases were defined as those who received a positive serology result while incarcerated or self-reported receipt of a previous positive test result. Data were analyzed using SAS Enterprise Guide version 7.1.

Results: Overall, 91% of inmates had been tested for HIV, and the overall prevalence was 1.4% (n=165). Of those living with HIV 98% were receiving treatment and 94% of

those treated had achieved viral suppression. HIV prevalence was higher among indigenous people (1.9% vs 1.1%, p<0.05) who represented 46% of all cases and 94% had been tested for HIV. Among indigenous offenders living with HIV 100% were receiving treatment and 94% had achieved viral suppression. HIV prevalence was significantly higher among women compared to men (3.7% vs 1.2%, p<0.0001). Awareness of HIV status was higher among women compared to men (96% vs 91%). Among women living with HIV 100% were receiving a treatment and 100% had achieved viral suppression.

Conclusions: This analysis demonstrates continued progress towards global HIV eradication goals and the significant public health contribution made by CSC. While HIV disproportionately affects vulnerable groups including indigenous and women offenders, these populations do as well or better in HIV treatment cascade indicators.

EPC109

Prioritization of HIV services for young key populations in Ghana: Desk analysis of new evidence for programming

C. Asante[1], R. Afriyie[2], I. Kwao[1], P. Ayamah[3], D. Annang[1], K. Gyimah[1], E. Larbi[1], A. Kyeremeh[2]

[1]*Ghana AIDS Commission, Research, Monitoring and Evaluation, Accra, Ghana,* [2]*Ghana AIDS Commission, Accra, Ghana,* [3]*Ghana AIDS Commission, Technical Services, Accra, Ghana*

Background: In 2020, young people aged 15-24 accounted for 28% of new HIV infections in Ghana. Addressing this challenge calls for evidence-based tailored interventions for adolescent and young key populations. This desk review is to contribute evidence to inform interventions in this regard.

Methods: This was a secondary analysis of data from the integrated bio-behavioural surveillance survey (IBBSS) conducted among FSW in 2019 across the 16 regions of Ghana. Data was analysed using Stata IC 12. Descriptive statistics including frequencies & proportion for categorical data were calculated.

Results: Among 6,773 FSW who participated in the study, over 90% of respondents were under the age of 35 years. Of those aged 16-24 years, comprehensive knowledge on HIV was 32% and 4% expressed accepting attitudes towards Persons Living HIV. In the 12 months preceding the survey, 16% of young FSW reported having experienced forced sex whereas only 44% had benefited from education from a peer educator. In the past 3 months, about half (47%) of young FSW reported having received counselling on condom use and safe sex through an outreach service, drop-in center or sexual health clinic. One-third (33%) of young FSW reported being affiliated to a social network site or online community. While about 20% solicit for clients on the Internet or social media. Nearly 60% indicated their willingness to use an app that provides information on HIV.

Conclusions: Low comprehensive knowledge and accepting attitudes towards PLHIV calls for intensified education among the target group.

High level of violence experienced among young FSW heightens their risk of HIV acquisition and transmission and therefore requires remedial interventions. There is the need to empower health peer-educators and broaden their reach to cover more FSWs.

Virtual/internet space is a fertile ground to reach FSWs as one in every 5 (20%) already use it and a lot more (60%) are willing to patronise it. Development of KP Standard Operating Procedures for adolescent and young key population is necessary to give strategic guidance on the age-specific interventions.

EPC110

Did Nigeria achieve the UNAIDS 90-90-90 treatment target among key populations? An analysis of the national HIV treatment cascade

R. Aguolu[1], C. Ejeckam[2], K. Green[2], G. Ashefor[1]

[1]*National Agency for the Control of AIDS, Abuja, Nigeria,* [2]*University of Manitoba, Abuja, Nigeria*

Background: Key populations contribute significantly to the burden of HIV in Nigeria. In 2014, the UNAIDS and partners set the '90-90-90' targets; aimed at diagnosing 90% of all HIV positive people, providing antiretroviral therapy (ART) for 90% of those diagnosed and achieving viral suppression for 90% of those treated, by 2020.

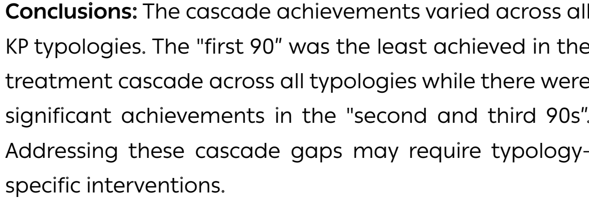
We analyzed the HIV treatment cascade among key populations (KPs) in Nigeria to assess the impact of programmatic efforts and identify gaps to inform more effective strategic interventions.

Methods: We conducted a biological behavioral survey in 12 states of the country between September to November 2020. A multi-stage sampling method was used to select sates and respondents. Blood samples were collected from consenting respondents after an interview. HIV status test and viral load test were done, guided by the national algorithm for HIV testing.

Data collected were analyzed using four stages; total HIV positive people, diagnosed, on treatment and virally suppressed.

Results: We surveyed 4974 female sex workers (FSW), 4397 men who sex with men (MSM), 4414 people who inject drugs (PWID), and 4190 transgenders (TG). The mean age of respondents was between 24-30 years across all typologies, with the TG group having the youngest population while the PWID group had most of the older population. The 90-90-90 HIV treatment cascade showed that 26.7%, 38%, 19% and 12% of FSW, MSM, TG and PWID that were diagnosed knew their status respectively.

Among those who were diagnosed and knew their status about 89%, 90%, 84% and 68% of the FSW, MSM, TG and PWID were on ART while 86%, 78%, 75% and 75% of the respective KPs on ART had achieved viral suppression.



Conclusions: The cascade achievements varied across all KP typologies. The "first 90" was the least achieved in the treatment cascade across all typologies while there were significant achievements in the "second and third 90s". Addressing these cascade gaps may require typology-specific interventions.
More importantly, further studies are needed to identify the factors associated with the poor achievement rate of the "first 90" across all typologies, and also to identify effective models that would scale-up HIV testing service delivery among KPs.

Determining the incidence of HIV

EPC111
HIV incidence in heterosexual sex work networks in the Middle East and North Africa

H. Chemaitelly[1,2,3], H.H. Ayoub[4], L.J. Abu-Raddad[1,2,3,5]
[1]Weill Cornell Medicine-Qatar, Infectious Disease Epidemiology Group, Doha, Qatar, [2]Weill Cornell Medicine–Qatar, World Health Organization Collaborating Centre for Disease Epidemiology Analytics on HIV/AIDS, Sexually Transmitted Infections, and Viral Hepatitis, Doha, Qatar, [3]Weill Cornell Medicine, Cornell University, Department of Population Health Sciences, New York, United States, [4]Qatar University, Mathematics Program, Department of Mathematics, Statistics, and Physics, College of Arts and Sciences, Doha, Qatar, [5]Qatar University, Department of Public Health, College of Health Sciences, QU Health, Doha, Qatar

Background: HIV incidences in female sex workers (FSWs) and clients, and contribution to the growing epidemic in the Middle East and North Africa (MENA) are unknown. We filled this gap using mathematical modelling based on systematically assembled data on HIV prevalence, sexual and injecting behaviors, and risk group size estimates.
Methods: We constructed an agent-based mathematical model to describe HIV transmission dynamics in heterosexual sex work networks (HSWNs) and estimate HIV incidence and impact of interventions in 12 MENA countries with sufficient data to conduct the modeling.
Results: Current annual number of new HIV infections was lowest in Djibouti and highest in South Sudan ranging from 21-2,345 in FSWs, 29-5,167 in clients, and 22-3,978 in clients' spouses. Incidence rate was lowest in Yemen and highest in South Sudan ranging from 0.4-34.3 per 1,000 person-years in FSWs, 0.03-2.5 in clients, and 0.07-6.7 in clients' spouses. HSWNs contributed >25% of total HIV incidence across MENA.
Even where HIV prevalence in FSWs was low (range: 0.8-2.2%), contribution to total incidence in the population ranged from 6.4-24.4%. Contribution reached 72% in high prevalence countries. Less than a third of incidence in HSWNs occurred in FSWs, the rest was split among clients and their spouses. Single and combination prevention interventions targeting only FSWs substantially reduced incidence in FSWs, clients, and clients' spouses.
A moderate intervention package targeting only FSWs averted 45%, 63%, and 34% of HIV incidence in FSWs, clients, and clients' spouses, respectively.
Conclusions: A large proportion of HIV incidence occurs in HSWNs in MENA. Substantial incidence in general population women arises through unprotected sex with HIV-positive clients. Scale-up of interventions among FSWs is critical to achieve UNAIDS 2030 targets.

EPC112
Reaching zero new HIV infections among key populations in Québec: monitoring elimination targets using mathematical modelling of routine surveillance data

C.M. Doyle[1], J. Cox[1,2,3], R.M. Milwid[1], R. Bitera[4], C. Lanièce Delaunay[1,3], M. Alary[4,5,6], G. Lambert[2], C. Tremblay[7,8], S. Mishra[9,10,11], M. Maheu-Giroux[1]
[1]McGill University, Department of Epidemiology and Biostatistics, Montréal, Canada, [2]Direction Régionale de Santé Publique de Montréal, Montréal, Canada, [3]Clinical Outcomes Research and Evaluation, Research Institute - McGill University Health Centre, Montréal, Canada, [4]Institut National de Santé Publique du Québec, Québec, Canada, [5]Centre de Recherche du CHU de Québec - Université Laval, Québec, Canada, [6]Université Laval, Département de Médecine Sociale et Préventive, Québec, Canada, [7]Centre de Recherche du Centre Hospitalier de l'Université de Montréal (CRCHUM), Montréal, Canada, [8]University of Montréal, Department of Microbiology Infectiology and Immunology, Montréal, Canada, [9]St. Michael's Hospital, University of Toronto, Department of Medicine, Toronto, Canada, [10]Institute of Medical Sciences, University of Toronto, Toronto, Canada, [11]Institute of Health Policy Management and Evaluation, Dalla Lana School of Public Health, University of Toronto, Toronto, Canada

Background: Montréal, Québec's HIV epidemic epicentre, was Canada's first Fast Track City. Reaching and maintaining zero new HIV infections and the 95-95-95 targets requires epidemic monitoring, especially among men who have sex with men (MSM) and people who inject drugs (PWID), groups disproportionately impacted by the epidemic. Using a back-calculation model, we estimated HIV incidence and other epidemic indicators among MSM and PWID in Montréal and across Québec.
Methods: We developed a deterministic, compartmental mathematical model stratified by HIV-status and stages of disease progression and clinical care, including testing and antiretroviral treatment (ART). Local epidemiological studies and scientific literature informed parameterization. With provincial surveillance data, we calibrated to AIDS cases and HIV diagnoses, self-reported time since

last negative HIV test, and CD4 cell count at diagnosis (stratified by region, exposure category, sex, and age). Using a cubic M-spline, we modelled HIV incidence curves for both MSM and PWID over 1975-2020. We also estimated prevalence, percent undiagnosed, percent diagnosed that took ART, and median time to diagnosis. Since the COVID-19 pandemic disrupted testing, we excluded 2020 data in sensitivity analyses.

Results: HIV incidence in both populations peaked early in the epidemic. In 2020, 56 (95%CrI: 26-121) and 140 (95%CrI: 63-281) new infections were estimated among MSM in Montréal and Québec, respectively.

Among PWID, 1 (95%CrI: 0-7) and 9 (95%CrI: 2-26) new infections were estimated. Without 2020 data, these estimates approximately doubled, except among Québec PWID, whose decreased.

Across all populations, the median time to diagnosis shortened to <2 years and the percentage undiagnosed decreased to <10%. The estimated percentage was higher in younger MSM, with 14.4% (95%CrI: 8-25%) of 15-24 year-olds living with HIV in Montréal and Québec undiagnosed by the end of 2020.

Conclusions: HIV incidence appears to have drastically decreased over time in MSM and PWID across Québec, alongside significant improvements in diagnosis and treatment coverage. Nevertheless, HIV transmission persists, and efforts to halt and diagnose new infections, especially among younger MSM, are still needed to achieve elimination.

Work exploring the population-level impact of preventive interventions that could be scaled-up, such as pre-exposure prophylaxis, could inform effective and sustainable elimination policies.

EPC113

Very high HIV incidence observed among men who have sex with men (MSM) and transgender women in Bali, Indonesia: a retrospective observational cohort study

B.D.K. Wardhani[1], G.B.S. Wirawan[1], P.E. Pradnyani[1], H. Luis[2], M.Y.O. Prasetia[3], A.E. Grulich[4], B.R. Bavinton[4], P.P. Januraga[1,5]

[1]*Center for Public Health Innovation, Faculty of Medicine, Udayana University, Denpasar, Indonesia,* [2]*Yayasan Bali Peduli, Denpasar, Indonesia,* [3]*Bali Medika Clinic, Denpasar, Indonesia,* [4]*The Kirby Institute, Faculty of Medicine, UNSW Sydney, Sydney, Australia, Sydney, Australia,* [5]*Udayana University, Department of Public Health and Preventive Medicine, Faculty of Medicine, Denpasar, Indonesia*

Background: There are few longitudinal data on HIV incidence in Indonesia, and no such data among men who have sex with men (MSM) and transgender women (also known as *waria*) populations specifically.

We aimed to estimate HIV incidence among MSM/*waria* in Bali, Indonesia. Secondary aims included estimating the HIV retest rate and HIV prevalence.

Methods: We conducted a retrospective observational cohort study using routinely-collected medical record data from four private/non-government sexual health clinics in Bali, Indonesia. We reviewed all HIV tests among self-reported MSM/transgender women aged ≥18 years and who resided in Bali at the time of HIV testing from 1 January 2017–31 December 2019. We calculated baseline HIV prevalence from the first visit.

Those with initial HIV-negative test and ≥1follow-up test were included in the longitudinal incidence rate and person-years (PY) at risk calculation. Person-years at risk was calculated since first observed negative test until seroconversion or last recorded negative test at which point the observation was censored.

Results: A total of 2,896 eligible individuals with 4,697 visits were included. Of those individuals, 626 tested HIV-positive at their first visit, resulting in a baseline HIV prevalence of 21.6% (95% confidence interval [CI]: 20.1-23.1). 2,270 patients (78.4%) tested negative for HIV at their first visit. Of these, 826 (36.4%) had repeat HIV testing during the study period, ranging from 2 to 13 HIV test visits, with a retest rate of 228.9 per 100 PY (95% CI: 202.9-381.1). The incidence rate was 8.4 per 100 PY (95% CI: 3.0-13.9) from 784 PY of observation.

Conclusions: In the first longitudinal study of HIV incidence among MSM/transgender women populations in Indonesia, we observed a very high HIV incidence rate. The observed HIV prevalence was much higher than in the general population of Indonesia.

Given the high risk and the relatively low repeat testing rate, measures to encourage regular HIV testing and effective use of HIV prevention methods are an urgent priority. In particular, access to HIV pre-exposure prophylaxis (PrEP) must be prioritised.

EPC114

Use of the recent infection testing algorithm to estimate background HIV incidence in micro-epidemic areas within Uganda

(bHIV) design to evaluate the efficacy of lenacapavir and of emtricitabine/tenofovir alafenamide for PrEP in adolescent girls and young women (AGYW) in South Africa and Uganda. High bHIV (>3.5/ 100 person years) is required for this design.
We sought to characterize bHIV in two locations with socioeconomic characteristics suggesting increasing HIV incidence (increased migrant workers and commercial sex), in Mityana/Mubende and Hoima regions, in Uganda that we were evaluating for inclusion in the PURPOSE 1 study.

Methods: A cross-section of AGYW aged 16-25 years of unknown HIV status and with no HIV testing in the past 3 months were recruited from HIV testing sites and commercial sex venues in Hoima (n=372) and Mityana/ Mubende (n=371). Participants were diagnosed and confirmed with HIV using Alere Determine HIV-1/2 and Oraquick HIV-1/2 tests.
Positive samples were further assessed for recent infection with the Sedia HIV-1 Limiting Antigen Avidity EIA (Sedia Biosciences, Beaverton, OR) and the following recent infection testing algorithm (RITA) parameters; cut-off time of 1 year, viral load threshold of >75 cp/mL, a normalized optical density cut-off of ≤ 1.5, mean duration of recent infection of 166.8 days, and a false recency rate of 6.47%.

Results: Thirteen percent of AGYW in Hoima(N=47) and 39% in Mityana/Mubende (N=144) were diagnosed with HIV. (Of the 47 AGYW with HIV in Hoima, 7 were classified as recent infections; of the 144 in Mityana/Mubende, 30 were recent. The estimated HIV incidence calculated from these recency results was 3.11 per 100 person-years (95% CI: 0.84-11.5) for Hoima and 23.2 per 100 person-years (95% CI: 13.1-41.2) for Mityana/Mubende.

Conclusions: We used a RITA incorporating viral load to estimate HIV incidence in AGYW in two micro-epidemic sites. Despite similar socioeconomic factors and a high incidence at both sites, Mityana/Mubende's was significantly higher and met criteria for participation in PURPOSE 1. These findings support the use of recency assays for identifying areas for recruiting participants for PrEP trials.

EPC115

Incidence of HIV infection and its burden of transmission among populations: a case study of Jos, North-Central Nigeria

D.S. Adeniyi[1], S. Wekpe[1], F.E. Owolagba[1], E.A. Ojo[1], E. Ofuche[1], J.O. Samuels[1], P. Okonkwo[1,1]
[1]APIN Public Health Initiatives, Directorate of Laboratory Services, Jos, Nigeria

Background: Controlling the spread of HIV/AIDS among populations requires the availability of real-time incidence data that will help inform intervention strategies. With HIV/AIDS prevalence in Nigeria still one of the highest in the world, this study aims to look at the incidence of HIV infections and the age group currently responsible for the burden of transmitting this disease in Jos, North-Central Nigeria.

Methods: HIV Rapid Testing for Recent Infection (RTRI) was introduced in Plateau State in August 2020 at three (3) Healthcare facilities in Jos. Randomly presenting individuals for HIV Testing Services between December 2020 and December 2021, who tested positive for HIV after screening were offered the RTRI Services.
Clients who consented to the RTRI services were serologically screened for HIV Recent Infection using the Asante® HIV Recent Infection Kit. Clients with Recent Asante® results were bled for HIV viral load assay on the Roche Cobas Ampliprep® and Cobas Taqman® Systems.
Participants with Recent Asante® test results and HIV viral load above 1000copies/ml were classified as True-Recent; while those with Recent Asante® results and HIV viral load below 1000copies/ml were classified as False-Recent. Collated data were analyzed using simple descriptive statistics.

Results: 839 clients participated in this surveillance exercise, of which 25% (n=208) had Recent Asante® test results. 77% (n=160) of the Asante® Recent clients were females while 23% (n=48) were males.
Of the 208 Asante® Recent clients, only 92 (44%) were True-Recent HIV infections (Incidence Cases), with 116 (56%) of the clients having False-Recent HIV Infections. Of the 92 HIV Recently infected clients, 62 (67%) were females with a mean age of 34 years; while 30 (33%) were males with a mean age of 37 years. The mean age of the population with Recent HIV Infection was 35 years.

Conclusions: The availability of Recent HIV Infection data can help guide our surveillance and intervention activities among communities and key demographics with active HIV transmissions.
This study shows that the burden of HIV disease still remains high among the female populations; while the age group responsible for the burden of transmission has significantly shifted from adolescents to the middle-aged populations.

EPC116

HIV Incidence among people who inject drugs in Nepal

K. Deuba[1], R.M. Rajbhandari[2], M.K. Shrestha[3], L.R. Pandey[3], D. Dahal[3], N.R. Awasthi[3], R. Bhattarai[3], A. Bhattachan[3], L. Johnston[4], S. Devkota[3], IBBS Study Group
[1]Save the Children Stationed at National Centre for AIDS & STD Control, Kathmandu, Nepal, [2]Intrepid Nepal (INPL), Kathmandu, Nepal, [3]National Centre for AIDS & STD Control, Ministry of Health and Population, Kathmandu, Nepal, [4]UNAIDS Consultant, Kathmandu, Nepal

Background: In routine surveillance surveys the prevalence of HIV has been used for many years to assess epidemic patterns and trends of HIV among key populations

like people who inject drugs (PWID) in many countries. However, such evidence is not much useful to understand the rate at which new HIV infections are acquired over the period due to increased coverage of HIV treatment services and improved survival among people living with HIV in many low-and middle-income countries like Nepal.

This first nationally representative surveillance survey aimed to assess recent infection (RI) among HIV positive samples to distinguish recently infected person from long-term infection (LTI).

Methods: This cross-sectional study included 1840 PWID (male: 1690, female: 150) who were recruited from March to October 2020 in all seven provinces of Nepal. Respondent driven sampling was used to recruit male injecting drug users whereas female injecting drug users were recruited using purposive sampling. Rapid tests were conducted to collect sample for HIV testing. An HIV recency test was eligible for those who had positive HIV test results for the first time.

Further confirmation of false RI was ruled out by a viral load more than 1000 copies/ml. Recency test was not performed for those PWID who have already known HIV positive status before survey. HIV incidence was defined as per the Recent Infection Testing Algorithm (RITA) and recency tests performed using Sedia Asante Rapid Recency Assay.

Results: HIV prevalence among male injecting drug users was 2.8% (n=37; CI=1.9-4.16) and the HIV recency test was done to all eligible HIV Positive cases, and all had HIV LTI. HIV prevalence among female injecting drug users was 2%, among which all (100%) had acquired LTI.

Conclusions: Study findings suggest that new HIV infections is almost nonexistent among Nepalese PWID, and this might be attributable to positive impact of harm reduction services in the country.

In addition, this study also provide evidence to include recency tests in routine surveillance surveys conducted among key populations in low-and middle-income countries.

Detecting and monitoring acute and recent HIV infections

EPC117
First national HIV recent infection surveillance in Lao PDR

B. Simanovong[1], P. Southalack[1], P. Xangsayarath[2], K. Thongkham[1], V. Somoulay[2], L. Sadettanh[1], S. Xayadeth[2], C. Siamong[2], K. Koummalasy[1], C. L. Sulpizio[3], P. Monkongdee[3], T. Tasaneeyapan[3], S. Nookhai[3], S. Aungkulanon[3], S. Northbrook[3]
[1]Centre for HIV/AIDS and STIs (CHAS), Communicable Diseases Control (CDC) Department, Sisathanak District, Lao People's Democratic Republic, the, [2]National Center for Laboratory and Epidemiology (NCLE), Communicable Diseases Control (CDC) Department, Sisathanak District, Lao People's Democratic Republic, the, [3]Division of Global HIV and Tuberculosis, U.S. Centers for Disease Control and Prevention, Nonthaburi, Thailand

Background: Given the global interest in integrating recent infection testing into routine services, Lao People's Democratic Republic (Lao PDR) developed a recent infection surveillance system at all antiretroviral treatment sites nationwide.

Description: HIV recent surveillance was integrated into HIV testing services in all 11 antiretroviral therapy (ART) sites and four point-of-care ART sites in October 2021. The Asante Rapid Test for Recent Infection (RTRI) with GeneXpert viral load (VL) test were used to determine recent infection testing algorithm (RITA) recent patients.

A health informatics tool was developed to link and analyze individual level data from the DHIS2 VCT Event and DHIS2 ART Tracker platforms for visualization with a real-time dashboard to identify and monitor recent and ongoing HIV transmission trends in population groups to inform and develop a public health response.

Lessons learned: From the first 2 months of implementation, 153/196 (78.1%) newly HIV diagnosed adults eligible for recency testing consented for RTRI. Of those, 7 cases (4.6.%) were RTRI-recent, 6 cases (3.9%) were confirmed RITA-recent with 1 case awaiting VL result, and 146 classified as RITA long-term (LT).

The preliminary data showed high recent infections in Vientiane Capitalcompared to other provinces. Men who have sex with men (MSM) (5/56 cases; 8.9%) had the highest proportion of RTRI recent infections compared to other groups. Close monitoring continues to confirm this finding.

Decentralized VL testing supports real-time RITA return of VL results to ART sites for real-time dashboard monitoring. Individual record linkage at the national level between the two DHIS2 systems enables real-time identification of newly diagnosed HIV cases, minimizes duplicate records, identifies pre-ART loss gaps, and provides more accurate ART linkage results. Recent infection data could inform resource allocation at the population level

to direct and prioritize targeted interventions to high-risk populations and to geographic areas where they are needed the most.

Conclusions/Next steps: HIV Recency is the first national surveillance program in Lao PDR using DHIS2 data and links to national dashboard for real-time HIV epidemic monitoring. Lessons learned from Lao PDR could guide countries currently implementing HIV recency surveillance to monitor HIV recent infection trends for strategic interventions.

EPC118

Concordance between laboratory serologic testing and HIV-1 RNA testing among participants who acquired HIV in the DISCOVER trial

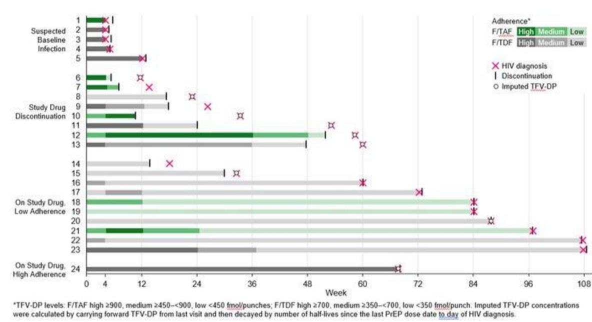
P. Ruane[1], C. Tremblay[2], K.H. Mayer[3,4], I. Brar[5], L. Salazar[6], J. Coll[7], C. Brinson[8], A. Mills[9], J.C. Hojilla[10], C. Carter[10], A. Kintu[10], J. Yager[10], S. Cox[10], M. Das[10], J. Baeten[10], R.M. Grant[11,12], B. Trottier[13]

[1]Ruane Clinical Research, Los Angeles, United States, [2]Université de Montréal, Département de Microbiologie, Immunologie et Infectiologie, Montreal, Canada, [3]The Fenway Institute, Fenway Health, Boston, United States, [4]Harvard Medical School, Department of Medicine, Boston, United States, [5]Henry Ford Hospital, Detroit, United States, [6]Hoag Medical Group, Newport Beach, United States, [7]IrsiCaixa AIDS Research Institute, Barcelona, Spain, [8]Central Texas Clinical Research, Austin, United States, [9]Men's Health Foundation, Los Angeles, United States, [10]Gilead Sciences, Foster City, United States, [11]University of California San Francisco, School of Medicine, San Francisco, United States, [12]San Francisco AIDS Foundation, San Francisco, United States, [13]Clinique de Medecine Urbaine du Quartier Latin, Montreal, Canada

Background: DISCOVER demonstrated the non-inferior efficacy of oral daily emtricitabine (F)/tenofovir alafenamide (TAF) compared to F/tenofovir disoproxil fumarate (TDF) for HIV pre-exposure prophylaxis (PrEP) in men who have sex with men and transgender women. We characterized the longitudinal adherence of participants who acquired HIV in DISCOVER and evaluated concordance between rapid point-of-care and laboratory serologic HIV testing and HIV-1 RNA assays.

Methods: Participants underwent rapid HIV (Ab or Ab/Ag) and laboratory HIV testing (Ab or Ab/Ag) at Screening, rapid HIV testing only at Day 1 (<30 days after Screening), and rapid plus laboratory HIV testing at Week (W) 4, 8, 12, and every 12 weeks thereafter through W96. HIV-1 RNA was evaluated for all participants with a positive rapid or laboratory HIV test during follow-up. We measured tenofovir diphosphate concentrations from stored dried blood spots (DBS) and assessed HIV test results for participants who acquired HIV.

Results: 24 participants acquired HIV through W96, 8 in the F/TAF arm and 16 in the F/TDF arm. Of these, 5 were retrospectively determined to have had suspected unrecognized baseline infection; 8 discontinued study drug ≥30 days before HIV diagnosis; 10 had DBS consistent with low adherence preceding diagnosis; only 1 had DBS consistent with high adherence at time of diagnosis, however this value was imputed due to a missing DBS sample (Figure). Seven cases had a negative rapid HIV test on the same day that laboratory HIV testing was reactive. There were no discrepant results between laboratory HIV testing and HIV-1 RNA tests.



Conclusions: F/TAF and F/TDF are highly efficacious for PrEP if taken as directed. Rapid HIV testing alone may miss HIV diagnoses in persons on PrEP. There were no discrepancies between laboratory HIV testing and HIV-1 RNA testing, suggesting that laboratory HIV Ab/Ag testing is appropriate for monitoring people on daily oral PrEP.

EPC119

Recent HIV infection surveillance and partner testing outcomes in Cambodia from March 2020 through September 2021

V. Ouk[1], K. Soch[2], B. Ngauv[3], S. Samreth[4], B. Eng[2], V. Ly[2], C. Yang[5], A. Suthar[5], C.L. Sulpizio[6], A. Ernst[7], G. Rutherford[7]

[1]National Center for HIV Dermatology and STD (NCHADS), Director, Phnom Penh, Cambodia, [2]Centers for Disease Control and Prevention (CDC) Phnom Penh, DGHT, Phnom Penh, Cambodia, [3]National Center for HIV Dermatology and STD (NCHADS), Technical Bureau, Phnom Penh, Cambodia, [4]National Center for HIV Dermatology and STD (NCHADS), Phnom Penh, Cambodia, [5]Centers for Disease Control and Prevention (CDC) Atlanta, DGHT, Atlanta, United States, [6]Centers for Disease Control and Prevention (CDC) Bangkor, DGHT, Bangkor, Thailand, [7]University of California San Francisco (UCSF), Institute for Global Health Sciences (IGHS), San Francisco, United States

Background: Cambodia has been implementing recent HIV infection surveillance since March 2020 to support identification of populations and geographies with ongoing HIV transmission and to accelerate achievement of the UNAIDS 95-95-95 targets. To assess the efficacy of recency testing, we compared HIV testing outcomes of partners of individuals with recent HIV infection (within 12 months) to those with long-term infection.

Methods: We used HIV testing and partner notification data collected in the National Voluntary Counselling and Testing (VCT) and treatment database from March 2020

through September 2021. Newly diagnosed HIV-positive clients (index) aged ≥15 years, males and females, were offered recency testing using the Asanté HIV-1 Rapid Test for Recent Infection (RTRI) at 66 facilities in 25 provinces countrywide. Recent Infection Testing Algorithm (RITA)-recent clients were those who tested recent on RTRI with a viral load ≥1000 copies/ml.

All index clients received recency results and were offered partner testing. Their sexual contacts were elicited to receive partner notification and VCT services. We compared HIV testing outcomes in partners of RITA-recent and RITA-long-term (RITA-LT) index clients using chi-square tests in STATA-16.

Results: Of 4,009 index clients with RITA results linkable to partner notification data, 198 individuals (5%) were RITA-recent and 3,811 (95%) were RITA-LT. Sixty-seven RITA-recent index clients (41%) named 66 partners (avg=0.99 partner/index) while 1,115 RITA-LT index clients (47%) named 1,060 partners (avg=0.95 partner/index).

Of partners of RITA-recent clients with unknown HIV status, 42/59 (71%) were tested and 15 (35.7%) were newly diagnosed with HIV-infection; among partners of RITA-LT clients, 690/960 (72%) were tested and 206 (29.9%) were newly diagnosed with HIV-infection (p=0.6) (Table).

Indicators	RITA-Recent clients (n=198)	RITA-Long-Term Clients (n=3,811)	p-value
Index clients offered partner notification services	162 (80.6%)	2,365 (62.8%)	<0.01
Index clients accepted	67 (41.4%)	1,115 (47.2%)	0.38
Partners elicited	66 (98.5%)	1,060 (95.1%)	0.84
Partners with previously reported HIV infection	7 (10.6%)	100 (9.4%)	0.77
Partners with unknown HIV-status	59 (89.4%)	960 (90.6%)	0.77
Partners tested	42 (71.2%)	690 (71.8%)	0.96
Partners newly diagnosed with HIV infection	15 (35.7%)	206 (29.9%)	0.56

Table: Testing outcomes of partners of clients testing RITA-recent and RITA-LT, March 2020-September 2021.

Conclusions: Results-to-date suggest that recent HIV infection may be an important biomarker to efficiently identify PLHIV through partner notification services.

Continued recency surveillance and data triangulation will help to better understand populations at-risk for ongoing transmission.

EPC120

Prevalence of reclassification of HIV infection from recent to long-term among newly diagnosed clients and associated factors in Nigeria, March 2020 – September 2021

I. Ahmed El-Imam[1], T. Lascko[2], H. Omari[2], M.-C. Lavoie[2], O. Adedokun[1], S. Adams-Daban[1], O. Alo[1], S. Ahmed[1], A. Abdulkadir[1], E. Iwara[1], G. Antonza[1], B. Sule Ibrahim[1], I. Adebobola[8], G. Dauda[8], S. Adebajo[1], K. Stafford[2]

[1]Maryland Global Initiatives Corporation (an affiliate of the University of Maryland, Baltimore), Abuja, Federal Capital Territory, Nigeria, [2]Center for International Health, Education and Biosecurity, Institute of Human Virology, University of Maryland, Baltimore, United States, [3]Center for Disease Control and Prevention - Nigeria, Division of Global HIV and TB, Abuja, Nigeria, [4]Center for Disease Control and Prevention - USA, Division of Global HIV and TB, Atlanta, United States, [5]ICAP at Columbia University, Mailman School of Public Health, Columbia University, Abuja, Nigeria, [6]ICAP at Columbia University, Mailman School of Public Health, Columbia University, New York, United States, [7]Columbia University, Mailman School of Public Health, Department of Epidemiology, New York, United States, [8]Federal Ministry of Health, National AIDS and STI's Control Programme, Abuja, Nigeria

Background: Nigeria's HIV surveillance program uses an antibody-based rapid test for recent infection (RTRI) which distinguishes recent from long-term infection. Reclassification from recent to long-term occurs if the viral load measured at diagnosis in the recent infection testing algorithms (RITAs) is <1000 copies/mL. Previous ART-use, variability in HIV-1 subtypes and immune response, advanced HIV disease have been reported to affect recency assay performance.

However, there is limited information on predictors of reclassification of recent to long-term infection. We determined the prevalence of re-classification from recent to long-term HIV infection and associated factors.

Methods: We conducted a cross-sectional analysis of consented clients aged ≥15 years,who were classified as RTRI-recent and had a documented viral load between March 2020 and September 2021 across 216 facilities from 20 states in Nigeria.

We used bivariate log-binomial regression models to estimate prevalence ratios (PR) for factors associated with reclassification from recent to long-term. Variables associated with the outcome at a significance level of ≤0.20 in the bivariate analyses were included in the multivariable analysis.

Results: Among the 1,190 clients included in the analysis, 60.5% were women, and 40.8% were aged 25-34 years. A total of 529 (44.5%) clients were reclassified as long-term. In the multivariable analysis, testing at South-East (aPR

1.76, 95% CI 1.36-2.28), South-West (aPR 1.48, 95% CI 1.16-1.88) and North-Central regions (aPR 1.63, 95% CI 1.30-2.04) compared to South-South, having more than one sex partner in the last three months (aPR 1.26, 95% CI 1.06-1.50), and not being previously tested for HIV compared to testing negative within the past year (aPR 1.38, 95% CI 1.12-1.70) were associated with increased likelihood of reclassification.

Conclusions: Nearly half of the clients identified as RTRI-recent were reclassified. Clients with more than one sex partner and those who had not had an HIV test in the past year were more likely to be reclassified.

Promotion of frequent testing, scale-up of biometrics to identify clients already on treatment at testing points, enhanced pre- and post-test counseling to test only eligible clients, and re-training on assay interpretation may help reduce the proportion of reclassification.

EPC121

Sociodemographic factors associated with recent HIV infection in Burundi

V. Havyarimana[1], B. Kiernan[2], C.C. Akiteka[1], C. Nintezimbere[1], L. Nsabimana[1], A. Kavungerwa[3], A. Ndayizeye[4]

[1]*Population Services International Burundi, Bujumbura, Burundi,* [2]*University of California, San Francisco, San Francisco, United States,* [3]*US Agency for International Development Burundi, Bujumbura, Burundi,* [4]*Programme Nationale de Lutte Contre le SIDA et les IST Burundi, Bujumbura, Burundi*

Background: In Burundi, about 82% of people living with HIV (PLHIV) are aware of their HIV status with the goal of reaching 95% by 2030. The Ministry of Health and PSI Burundi launched a real-time monitoring of recent HIV infections surveillance system using rapid tests for recent infections (RTRI) and viral load in 2021. Recent HIV infections are defined as infections acquired in the last 12 months. Results will be used to inform HIV transmission prevention strategies in Burundi.

Methods: A descriptive, cross-sectional study in 17 HIV testing sites with a sample of 517 newly diagnosed PLHIV was carried out from July 15, 2021, to December 31, 2021. The sample was composed of 16% sex workers and 1% MSM with a mean age of all study participants of 35 (± 12 years old). Newly diagnosed clients were eligible to participate if they were at least 15 years old with no known previous HIV history. Venous samples were analyzed at five laboratories in Bujumbura with Asante RTRI and viral load testing. Multivariate and bivariate analyses using logistic regression were used to identify key sociodemographic characteristics associated with recent infection.

Results: The results showed that 6.8% of newly diagnosed HIV infections were recent. The data showed 25% of the men who have sex with men (MSM) and 7% of female sex workers (FSW) had a recent infection compared to 6.8% in the overall sample. The only factor associated with HIV recent infection after multivariate analysis was key population group (p=0.03). The results showed that FSW were 95.7% more likely to have a recent HIV infection compared to the general population, while MSM were 97.1% more likely to have a recent HIV infection.

Conclusions: The results from the newly established HIV recency surveillance system in Burundi suggest that HIV prevention programs for MSM and FSW need to be strengthened, with a focus on targeted prevention interventions, including early identification of PLHIV, viral load monitoring, and improved access to pre- and post-exposure prophylaxis.

EPC122

Comparing HIV risk profiles of recent and long-term HIV infection cases using Population-based HIV Impact Assessment (PHIA) data from 12 countries in sub-Saharan Africa

C. Wells[1], G. Reid[1], Y.T. Duong[1], J. Justman[1], S. Saito[1]

[1]*ICAP at Columbia University, New York, United States*

Background: National HIV testing programs are increasingly using tests that distinguish recent HIV infections (RI, acquired in ≤12 months) from long-term infections (LTI, acquired >12 months prior). We hypothesized individuals with RI, compared to LTI, have characteristics associated with elevated risk of HIV acquisition and/or transmission.

Methods: We compared characteristics of adults (15 y+) with RI and LTI using publicly available PHIA data from Cameroon, Côte d'Ivoire, Eswatini, Ethiopia, Lesotho, Malawi, Namibia, Rwanda, Tanzania, Uganda, Zambia, and Zimbabwe (2015-2019). RI and LTI were unaware of their HIV status (self-report), tested HIV-positive during the survey, had viral load (VL) ≥1000 copies/mL and no evidence of selected antiretroviral drugs in their blood sample. Survey response frequencies and VL were compared using chi-square and t-statistics, accounting for complex survey design.

Results: There were 288 RI and 4874 LTI included from 12 countries. Compared to LTI, RI were more likely to be female, <30 y, report ≥1 partner and an HIV test within the preceding 12 months (Table 1).

Characteristic		Recent Infections (%) N=288	Long-term Infections (%) N=4874	p-value
Female sex		199 (66.5)	2894 (56.4)	0.018
Age (years)	15-29	160 (50.3)	1690 (33.4)	< 0.001
	30-39	77 (30.7)	1560 (31.3)	
	40+	51 (19.0)	1624 (35.2)	
Last HIV test in past 12 months		134 (44.6)	1272 (24.1)	< 0.001
Last HIV test more than 12 months ago or never tested		137 (55.4)	3332 (75.9)	
Report ≥1 sexual partners in last 12 months		238 (86.8)	3634 (78.7)	0.025
Report sexually transmitted infection (STI) symptoms in last 12 months		26 (27.2)	432 (19.0)	0.096

Table 1. Self-reported demographic characteristics and risk factors of recent and long-term HIV infection cases at diagnosis.

RI also more frequently reported STI symptoms in the last year. RI mean VL was higher in 7/10 countries evaluated (Figure 1), reaching statistical significance in Malawi, Namibia and Tanzania. LTI had a significantly higher VL in Zimbabwe.

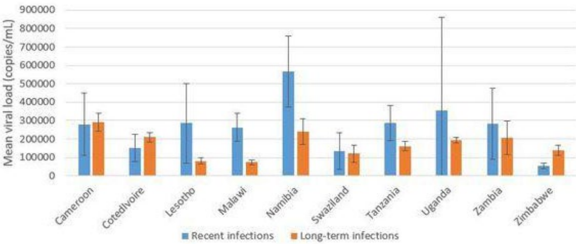

*Figure 1. Mean VL by country and recency status**
**Ethiopia and Rwanda were excluded from this analysis due to small numbers (<10) of recent cases.*

Conclusions: More individuals with RI, compared to those with LTI, reported HIV testing and risk-behavior in the year before diagnosis, with VL that reflects ongoing transmission risk. Programs implementing recency testing at scale should consider this risk profile when triaging services for RI and their partners, including prioritization for pre-exposure prophylaxis.

EPC123

The sociodemographic characteristics of HIV recent infections in Benue State, Nigeria

I. Ibeagha[1], C. Onyenezi[2], F. Peter[3], K. Ngwoke[4], O. Amoo[3], A. Ani[1], P. Daniel[5], A. Henshaw[6], S. Onoja[6], S. Inya[7], O. Olabanjo[5], O. Ginigeme[8], J.O. Samuels[9], P. Okonkwo[10]
[1]APIN Public Health Initiatives, Laboratory Services, Abuja, Nigeria, [2]APIN Public Health Initiatives, Strategic Information, Abuja, Nigeria, [3]APIN Public Health Initiatives, Prevention Services, Abuja, Nigeria, [4]APIN Public Health Initiatives, Clinical Services, Abuja, Nigeria, [5]APIN Public Health Initiative, Prevention Services, Abuja, Nigeria, [6]APIN Public Health Initiative, Strategic Information, Abuja, Nigeria, [7]APIN Public Health Initiative, Clinical Services, Abuja, Nigeria, [8]ICAP at Columbia University, Nigeria, Clinical Services, Abuja, Nigeria, [9]APIN Public Health Initiative, DCEO-Programs, Abuja, Nigeria, [10]APIN Public Health Initiative, Abuja, Nigeria

Background: Benue state has the second-highest HIV prevalence of 4.9% in Nigeria and is currently one of the subnational units in the country with >81% ART coverage by UNAIDS estimates. The CDC-funded APIN program initiated the HIV recency surveillance in Benue in March 2020 to monitor trends in recent infections, identify hotspots of potential active transmission of HIV, and guide tailored interventions across geographical settings and subpopulations to mitigate new infections. This study aims to determine the distribution pattern of the recent HIV infection in Benue State, Nigeria.
Methods: A descriptive analysis of retrospectively abstracted data of newly diagnosed HIV-positive individuals ≥15 years offered Recency testing in 95 activated Testing Points in Benue state using the Asante™ rapid test kits. The patients with recent Rapid Test for Recent Infection RTRI results and unsuppressed HIV viral load (VL) results (>1000 copies/ml) were classified as 'true' recent. Proportions of confirmed recent infections were deduced by sex, age group, marital status, geographical settings. Geospatial maps were generated using every patient's address and Geo-coordinate.
Results: A total of 10,738 newly diagnosed HIV-positive clients were tested for recent infection, out of which 10,607 (98.78%) were classified as LongTerm while 131 (1.22%) were classified as recent infections.
Analysis shows that 102 (0.95%) females testing HIV positive were true recent compared to 39 (0.36%) males. Confirmed recent infections were highest among age groups 25-29 and 20-24, with new infections as 27 (0.25%) and 26 (0.24%), respectively. District-level analysis shows that Benue Northwest senatorial district with 102 (0.95%) contributed 77.86% of the confirmed recent cases. The Recent infections were higher among the married population 93 (0.87%) followed by individuals who never married 40 (0.37%).

		Clients with Long-term infections (%)	Clients with 'True' Recent infections (%)
Sex			
	Female	6746 (62.77)	102 (0.95)
	Male	3861 (35.92	29 (0.36)
Age Group			
	15-19	215 (2.00)	7 (0.07)
	20-24	967 (9.00)	26 (0.24)
	25-29	1895 (17.63)	27 (0.25)
	30-34	2250 (20.93)	23 (0.21)
	35-39	1860 (17.31)	22 (0.20)
	40-44	1417 (13.18)	14 (0.13)
	45-49	938 (8.73)	11 (0.10)
	50+	1065 (9.91)	11 (0.10)
Senatorial Districts			
	Benue Northeast	5289 (49.25)	25 (0.23)
	Benue Northwest	5099 (47.49)	102 (0.95)
	Benue South	219 (2.04)	4 (0.04)
Marital Status			
	No Response	264 (0.10)	1 (0.01)
	Divorced	107 (1.00)	2 (0.02)
	Living with partner	5 (0.05)	0 (0)
	Married	8081 (75.19)	93 (0.87)
	Never Married	1766 (16.43)	40 (0.37)
	Separated	138 (1.28)	1 (0.01)
	Widowed	246 (2.29)	4 (0.04)

Table.

Conclusions: Recent infections are more common among females and young people in Benue State, with LGAs in Benue Northwest Senatorial district having higher recent infections.

[1]Malawi Liverpool Wellcome, Blantyre, Malawi, [2]London School of Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Disease, London, United Kingdom, [3]London School of Hygiene and Tropical Medicine, Faculty of Epidemiology and Population Health, London, United Kingdom, [4]Imperial College London, Faculty of Medicine, London, United Kingdom, [5]Government of Malawi, Blantyre District Health Office, Blantyre, Malawi, [6]Kamuzu University of Health Sciences, Helse Nord Tuberculosis Initiative, Blantyre, Malawi, [7]Government of Malawi, Department of HIV/AIDS, Lilongwe, Malawi, [8]University of Washington, I-Tech, Department of Global Health, Seattle, United States, [9]Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Background: HIV transmission increasingly occurs in cities, and is highly unevenly distributed by age, sex, and neighbourhood. We leveraged HIV prevalence data from multiple sources to develop fine-resolution estimates of people living with HIV (PLHIV) in Blantyre District, Malawi to better focus diagnosis, care and prevention services.

Methods: Between April 2019-March 2020, we did an HIV prevalence survey among 11,705 adults in randomly selected households in urban densely-populated areas of Blantyre City in Malawi ("MLW survey").

We combined MLW survey data (age, sex, and location) with Blantyre District data from two national surveys (MPHIA and MDHS 2015-16) and clinic antenatal prevalence data. We fitted a spatially-explicit Bayesian regression model to estimate age-, sex-, and location- (500m x 500m grid) HIV prevalence and uncertainty.

We used an offset term to account for differences in prevalence between 2015 (MPHIA and MDHS) and 2019, adjusting for temporal trends using Spectrum.

Results: HIV prevalence within the urban Blantyre City area was 15.2% (95% credible interval [CrI] 14.2–16.3%) among adults age 15-49y. This was higher than Blantyre rural (12.2%, 95%CrI 11.1–13.4%).

Within Blantyre City, prevalence was highest in women aged 49 years (44.8% HIV-positive, 95%CrI 40.6–48.9%) and among men prevalence was highest in men aged 54 (44.5% HIV-positive, 95%CrI 38.7–50.1%). HIV prevalence was highest in peri-urban areas around Blantyre City and lower in more central areas of the city. Across neighbourhoods in the MLW survey – all of which were in Blantyre City - prevalence ranged from 12.1% to 20.1%.

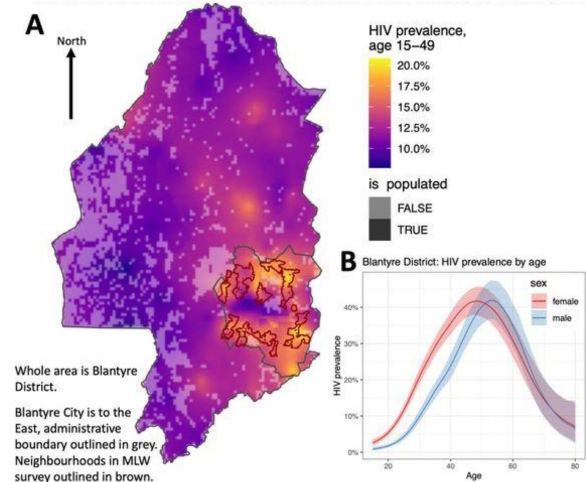

Figure. HIV prevalence Blantyre district (A) by neighbourhood and (B) by age and sex.

Conclusions: The age and sex distribution of prevalent HIV reflects heterogenous historical transmission dynamics and current HIV risk exposure across the city, and underscores the ageing population of people living with HIV. Highly spatially and demographically resolved estimates of HIV prevalence are useful for strategic service planning and understanding progression of HIV epidemic.

EPC125
Population sizes and characteristics of Men Sex with Men (MSM) in several cities in Afghanistan in 2019

E. Ehsan[1]

[1]Kabul Medical University, Curative Faculty, Kabul, Afghanistan

Background: Men Sex with Men (MSM) is known populations at risk for HIV, but little is known about their population size, locations and characteristics in Afghanistan.

The objective of this study was to provide these critical data for MSM populations in six cities and extrapolation to other major cities in Afghanistan.

Methods: Eligible MSM were interviewed at hotspots (public places like street corners, parks, etc).

We estimated their population size by several methods including:

i) Key informant interviews, mapping and enumeration with revers tracking method,

ii. The unique object and service multipliers,

iii. Capture-recapture,

iv. Wisdom of crowds, and

v. A Bayesian synthesis of the estimates from above methods.

Using the final estimates in the studied cities and their correlation with proxy indicators (population density, literacy, etc.), we estimated the population size for each

key population in 31 major cities in Afghanistan. Then, we added population size estimates across all major cities to estimate the overall prevalence estimates in adult population.

Results: We found 286 hotspots for MSM across the six cities. Majority of MSM were 25-34 years of age (41.2%), single (40.8%), exchanged sex for money in last 12 months (89.5%), and knew their HIV status (64.6%). The self-reported HIV prevalence was 3.2% (ranged from 0% to 9.2%). For MSM, the total number in 31 cities in Afghanistan was estimated to be 10,108 (95%CI 7,916 to 12,618) persons, which corresponds to 0.53% (95%CI 0.42% to 0.66%) of the adult male population.

Conclusions: Using multiple methods, our study provided basic characteristics and estimates for the population of MSM in major cities in Afghanistan. These estimates should be used for advocating and planning services for these vulnerable at-risk population in Afghanistan.

EPC126

Potential HIV-1 elite controllers in Malawian population and their impact on HIV epidemic control estimates

N. Kalata[1], N. Wadonda-Kabondo[1], A. Kabaghe[1], R. Nyirenda[2], M. Nyangulu[1], K. Brown[3], H. Patel[3], C. Braccio[3], F. Kayigamba[4], L. Tenthani[4], F. Ogollah[4], D. Payne[1], A. Auld[1], K. Mirkovic[1]

[1]*Centers for Disease Control and Prevention-Malawi, Lilongwe, Malawi,* [2]*Ministry of Health-Malawi, Lilongwe, Malawi,* [3]*Centers for Disease Control and Prevention-Atlanta, Atlanta, United States,* [4]*International Center for AIDS Care and Treatment at Columbia University, Lilongwe, Malawi*

Background: Countries have scaled up strategies to monitor progress towards achieving HIV epidemic control. However, it is not clear whether inclusion of elite controllers (ECs) affects accuracy of epidemic control estimates. Globally, <1% of people living with HIV (PLHIV) are ECs. We used data from 2020-21 Malawi Population-based HIV Impact assessment (MPHIA) to examine the role of potential ECs in achieving epidemic control.

Methods: The 2020-21 MPHIA was a cross-sectional multi-stage cluster probability-based sampling household survey targeting people 15 years and older. HIV diagnosis was conducted in the household and all HIV positive participants were tested for CD4, viral load (VL) and antiretroviral (ARVs). In this analysis, potential ECs were defined as HIV-positive individuals without ARVs detected in their serum (Dolutegravir, Atazanavir, Efavirenz or Nevirapine) but with suppressed VL (<50 copies/mL). Community viral load suppression was defined as the proportion of VL suppression among PLHIV. All analyses were weighted for sampling design, and we used STATA v16 svy commands to characterize ECs and compare them with unaware ART naïve HIV-positive individuals with unsuppressed VL.

Results: Prevalence of potential ECs was 3.8% (80/2464) among HIV positive individuals, with a median age of 32.2 years (95% CI: 28.8-35.6) and similar distribution by gender (51.5% were males 48.5% were females).

When compared to ART naïve-VL unsuppressed individuals, 80.5% (63/80; 95% CI: 70.0%-88.0%) of ECs had CD4 count above 500cells/mm^3 and 93.9% (74/80; 95% CI: 85.3%-97.6%) lived in rural areas, unlike 26.4% (85/301; 95% CI: 22.0%-31.5%) and 63.8% (197/301; 95% CI: 57.2%-70.0%) respectively for ART naïve VL unsuppressed individuals.

There was no difference in gender and education status between ECs and ART naïve VL unsuppressed individuals.

When ECs were removed from standard analysis, community viral load suppression reduced insignificantly from 87.3% (95% CI: 85.7%-88.7%) to 86.8% (95% CI: 85.1%-88.3%).

Conclusions: Prevalence of potential ECs is higher in the Malawian population compared to global estimates and this needs to be further characterized. However, their inclusion in epidemic control estimates may not affect accuracy of the results. Our study was limited in that ECs were defined based on single point VL testing.

EPC127

Implementation of web-based respondent-driven sampling among transgender people: Lessons learnt from the national transgender population size in South Africa

R. Chimatira[1], O. Mtapuri[1,2], E.M. Sibanda[1], T. Thengwa[1], P. Ndagurwa[1,2], T. Nyengerai[1,2], D. Jebese-Mfenqe[1], J. Chikwanda[1], T.N. Ndumiso[1,2], B. Futshane[1]

[1]*Beyond Zero, East London, South Africa,* [2]*Best Health Solutions, Johannesburg, South Africa*

Background: There is limited evidence on the use web-based respondent-driven sampling (WebRDS) use among transgender (TG) people in South Africa. This paper reports on the recruitment processes and the challenges and enablers of the WebRDS methodology as part of a multi-method national population size estimate (PSE) study for adult TG people (>18years) in South Africa.

Description: Beyond Zero conducted a PSE study between May and October 2021, during various lockdown restrictions which minimized the movement of people for non-essential services. Primary approaches (WebRDS, service multiplier, wisdom of the crowd) and secondary sources (administrative records, capture-recapture) were used to estimate the number of adult TG people. Pre-fieldwork formative assessment explored WebRDS suitability in each district (n=15).

WebRDS data collection was conducted using an online link shared via WhatsApp. Three digital coupons, determined using cellphone numbers as unique identifiers, were provided to each seed for use to recruit three TG within their social network, with successive waves of recruitment. Seeds were selected to ensure diversity based on age and gender identity (transmen, transmen, trans-

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

women, nonbinary, gender-queer, and gender non-conforming). Compensation was given for participating (equivalent to approximately US$6).

Post the PSE, we analysed process evaluation data collected by the field teams. In addition, we conducted virtual key informant interviews (KI) with field team members who identified as TG. Audio-recordings were transcribed verbatim, with data analysed using thematic content analysis.

Lessons learned: Using WebRDS resulted in significant improvements in the recruitment rate during the lockdown period. The formative assessment was critical as it provided key insights into the suitability of WebRDS. Key themes emerging from the data analysis include:

1. Compensation improved participation;
2. The approach made it easy to track and trace the network virtually;
3. WebRDS may have missed those without internet access;
4. Some participants only accessed the compensation and did not recruit any new participants.

Conclusions/Next steps: WebRDS is an effective and efficient method to recruit participants in resource-limited settings such as South Africa (internet penetration 63% and WhatsApp penetration 58% of the population). The potential effect of missing those without internet access should be considered when selecting the most appropriate data collection method.

Measuring the population impact of prevention and treatment interventions

EPC128

Factors associated with non-use of ART among HIV-positive men in South Africa: findings from a 2017 population-based household survey

N. Naqvi[1], X. Swart[2], J. Chikovore[3], S. Moyo[4,5], K. Ayalew[1], J. Bedford[1]

[1]Centers for Disease Control and Prevention, Division of Global HIV & TB, Pretoria, South Africa, [2]Stellenbosch University, Stellenbosch, South Africa, [3]Human Sciences Research Council, Durban, South Africa, [4]Human Sciences Research Council, Cape Town, South Africa, [5]University of Cape Town, School of Public Health and Family Medicine, Cape Town, South Africa

Background: Although South Africa has been a part of the World Health Organization's recommended Test and Treat program since 2016, treatment initiation and retention remain below target. In 2017, an estimated 56.3% and 65.5% of HIV-positive men and women, respectively, were on antiretroviral therapy (ART). We aimed to investigate determinants of low male use of ART in South Africa.

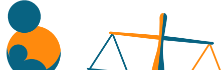
Methods: Utilizing data from the fifth South Africa National HIV Prevalence, Incidence, Behavior and Communication (SABSSM V) cross-sectional survey conducted in 2017, HIV-positive male records were extracted and stratified based on presence/absence of antiretroviral drugs (ARVs) detected in dried blood spot samples. Data was weighted to be representative of the national population, and a multivariate logistic regression was performed. Records with missing values were excluded and $p<0.05$ was considered significant.

Results: A total of 6,920 males age ≥15 years were enrolled in the study, and 953 (13.8%) had a laboratory confirmed HIV-positive result. Among those HIV-positive, 810 had a known ARV test result: 470 (58%) had ARVs detected, and 340 (42%) did not have ARVs detected.

Adjusting for age (and other known covariates), non-use of ART in males was associated with high alcohol use (AOR=4.15, 95%CI: 1.13-15.25, p=0.03), being a widower compared to being unmarried (AOR=7.28, 95%CI: 1.59-33.38, p=0.01), and having drug-resistant HIV (AOR=26.17, 95%CI: 12.90-53.08, p<0.001). Increased age (AOR=0.63, 95%CI: 0.44-0.91, p=0.01), residence in rural tribal localities compared to urban localities (AOR=0.39, 95%CI: 0.19-0.79, p=0.01), being too sick/disabled to work (AOR=0.02, 95%CI: 0.00-0.29, p<0.001), or having a co-morbidity such as tuberculosis or diabetes (AOR=0.07, 95%CI: 0.03-0.16, p<0.001) were negatively associated with ART non-use.

Conclusions: Young HIV-positive men, particularly those with high alcohol use, should be targeted for HIV programming at a greater scale to reach the UNAIDS 95-95-95 targets by 2030. Exposure to a health facility, whether by previous illness or co-morbidity, increases the likelihood of being on ART.

Identifying interventions that are effective at linking these men to ART and continuing to improve knowledge about HIV treatment will help reduce the national burden of disease and enable South Africa, a country with disproportional burden of infection, to finally reach epidemiological control.



EPC129

Self-reported antiretroviral therapy use and detection of antiretrovirals: findings from sequential population surveys in Malawi

M. Farahani[1], R. Bray[1], K. Brown[2], R. Nyienda[3], A. Kabaghe[4], F. Kayigamba[5], K. Mirkovic[6], L. Tenthani[5], N.W. Wadonda-Kabondo[4], A. Jahn[3], D. Payne[4], T. Dzinamarira[7], T. Dobbs[2], H.K. Patel[2], J. Justman[1], W.M. El-Sadr[1]

[1]Columbia University, ICAP, New York, United States, [2]U.S. Centers for Disease Control and Prevention (CDC), Division of Global HIV&TB, Atlanta, United States, [3]Ministry of Health, Lilongwe, Malawi, [4]U.S. Centers for Disease Control and Prevention (CDC), Division of Global HIV&TB, Lilongwe, Malawi, [5]Columbia University, ICAP, Lilongwe, Malawi, [6]U.S. Centers for Disease Control and Prevention (CDC), Lilongwe, Malawi, [7]Columbia University, ICAP, Johannesburg, South Africa

Background: Accurate estimates of the 90-90-90 HIV care continuum require identifying people receiving antiretroviral (ARV) therapy (ART) and determining viral suppression among those on ART. We compared the prevalence of self-reported ART use with and without adjustment for detectable antiretrovirals (ARVs) among adults (15-64 years) living with HIV (ALWH) in two sequential Malawi Population-based HIV Impact Assessments (PHIA) MPHIA.

Methods: Participants from randomly selected households in the 2015-16 and 2020-21 MPHIA surveys provided demographic, clinical information, and whole blood for household HIV testing. Household HIV+ results were laboratory-confirmed. Viral load suppression was defined as VL < 1000 cp/mL, and ARV non-adherence, as missed ARV doses ≥ one day in the past month.

Most prescribed first- and second-line ARVs, efavirenz, atazanavir, lopinavir in 2016, and dolutegravir in 2021, were assayed in dried blood spots.

Results: Of all participants aged 15-64 (17,187 in 2015-2016 and 21,208 in 2020-2021),2,227 ALWH were identified in 2016 and 2,340 in 2021. ART use was reported by 65.4 % (95% CI: 62.9-67.7%) in 2016 and 83.3% (95% CI: 81.5-85.0%) in 2021. Among those reported ART use, ARVs were not detected in 3.6% (95% CI: 2.5%-5.1%) and in 4.1% (95% CI: 3.3%-5.2%), respectively.

Among those who reported ART use but had no detectable ARVs, 23.0% (95% 7.5%-52.3%) in 2016 and 39.4% (95% CI: 26.0%-54.8%) in 2021 reported non-adherence, of whom 83.4% (95% CI: 76.8%-88.3%) and 45.2% (95% CI: 27.7%-64.0%) in 2016 and 2021, respectively, were without viral suppression. In 2016 and 2021 respectively, 4.0% (95% CI: 3.1%-5.3%) and 2.9% (95% CI: 2.1%-3.9%) of ALWH reported not being on ART but had detectable ARVs.

Controlling for the survey year and demographic covariates, ALWH were significantly less likely to have VL suppression if reported ART use but had no detectable ARVs (adjusted odds ratio: 0.15, 95% CI: 0.1-0.2, P<0.001).

Conclusions: The findings indicate consistency between self-reported ART use and ARV detection with evidence of high ART adherence. Unwillingness to disclose HIV+ status and ART use was rarely noted.

Measuring the population-level impact of policy-level HIV interventions

EPC130

Effect of cash transfer programs on HIV outcomes: a systematic review and meta-analysis

N. Sernizon Guimarães[1], L. Magno[2], A.A. de Paula[3], M. Silliman[4], D. Rasella[5], J. Macinko[4], L.E. de Souza[3], I. Dourado[3]

[1]Federal University of Bahia, Collective Health Institute, Salvador, Brazil, [2]State University of Bahia, Department of Life Sciences, Salvador, Brazil, [3]Federal University of Bahia, Institute of Collective Health, Salvador, Brazil, [4]University of California at Los Angeles, Fielding School of Public Health, Los Angeles, United States, [5]Barcelona Institute for Global Health, Barcelona, Spain

Background: Both poverty and social inequality play important roles in the HIV/AIDS epidemic. Trials assessing the impact of cash transfer programs (CTP) on HIV outcomes yielded divergent results.

This review aims to summarize the findings from randomized controlled trials evaluating the effects of CTP on some HIV outcomes.

Methods: A systematic review and meta-analysis was conducted in fifteen databases in August/2021 following the Cochrane and PRISMA guidelines. The study protocol was registered on PROSPERO [#CRD42021274452]. The intervention, CTP, was defined as monetary transfers for poor families aiming to alleviate poverty and provide social protection. We focused on CTP with education (i.e., children's school attendance) and health (i.e., uptake of health services for HIV testing) conditionalities.

The outcomes were HIV incidence and retention in HIV health care. The risk of bias and quality of evidence were evaluated by Cochrane Risk of Bias and GRADE, respectively. Meta-analysis was used for pooling risk ratios (RR). Sensitivity analyses were performed using the type of conditionality as subgroup.

Results: Seven studies conducted in Africa fulfilled inclusion criteria (n=5,241) with mean value of U$13.5 per family. CTP was associated with lower HIV incidence when receiving money was conditional on the uptake of health services for HIV testing (RR=0.74, 95%CI=0.56-0.98). There was no effect when the conditionality was school attendance (RR=1.13, 95%CI=0.78-1.64). CTP beneficiaries had higher retention in HIV health care vis-à-vis non-beneficiaries (RR=1.29, 95%CI=1.06-1.56). Evidence for both outcomes was moderate.

Conclusions: CTP had a positive effect in mitigating HIV incidence and increasing the retention in HIV health care. Our results show the potential of CTP on HIV prevention and treatment especially among people in extreme poverty, highlighting its importance when developing policies for HIV/AIDS epidemic control as stipulated by the UNAIDS Fast-Track 90-90-90 and 95-95-95 Target of HIV Care Continuum.

Monitoring and evaluation of health systems along the HIV cascade

EPC131

Measuring engagement with HIV care for people on antiretroviral treatment in sub-Saharan Africa: a scoping study

C. Keene[1], A. Ragunathan[2], M. English[1], J. McKnight[1], C. Orrell[3], . InCARE Stakeholder Group[4]

[1]University of Oxford, Health Systems Collaborative, Oxford, United Kingdom, [2]University of Oxford, Oxford Centre for Tropical Medicine and Global Health, Nuffield Department of Medicine, Oxford, United Kingdom, [3]University of Cape Town, Department of Medicine, Faculty of Health Sciences, Cape Town, South Africa, [4]Multiple institutions, Global representation, South Africa

Background: Engagement in HIV care is a multi-dimensional, dynamic process, critical to maintaining successful treatment outcomes. However, measures are not standardised nor comprehensive, undermining our understanding of intervention impact and complicating patient and programme-level decision-making. This study attempted to organise measures of engagement to support more consistent and comprehensive evaluation.

Methods: We conducted a scoping study to systematically identify and categorise measures the health system could use to evaluate engagement with antiretroviral care. Key terms were used to search literature databases (Embase, PsychINFO, Ovid Global-Health, PubMed, Scopus, CINAHL, Cochrane and the World Health Organization Index Medicus), Google Scholar and stakeholder-identified manuscripts, including English evidence published from sub-Saharan Africa since 2014. Data were extracted and measures organised by category, then sense-checked with key stakeholders.

Results: We screened 14 885 titles/abstracts, included 118 full-texts and identified 110 measures of engagement, categorised into three dimensions: 'retention', 'adherence' and 'active self-management' (Table 1).

As a consequence of engagement, 'treatment outcomes' (e.g. viral load) reflect a summary that engagement occurred. Adherence was measured by a range of primary and secondary measures. Retention reflected status in care, continuity of attendance and timing of visits. Active self-management reflected people's involvement and self-management. Three overarching use-cases were identified: research to make recommendations,clinical assessment of individuals and routine monitoring for quality improvement and strategic decision-making.

Engagement with services	Engagement with treatment		Engagement with both services and treatment	
Retention (18) *Sub-category (n)*	**Adherence (59)** *Sub-category (n)*		**Active self-management (18)** *Sub-category (n)*	**Treatment outcomes (8)** *Sub-category (n)*
• In care (5) • Continuity (7) • Timing of retention (3) • Composites of retention measures (3)	PRIMARY ADHERENCE (prescription not filled) • Pharmacy refill (5)	SECONDARY ADHERENCE (medication not taken as directed) • Antiretroviral concentrations (6) • Laboratory tests (5) • Healthcare-worker-assessed measures (2) • Pill counts (5) • Self-reported quantification of pill-taking through recall (13) • Self-reported timing (2) • Composite self-reports (13) • Composite of different adherence measures (8)	• Active involvement (4) • Self-care and self-management (14)	• Laboratory results (5) • Quality of life and health status (3)
Composites of different elements of engagement (7)				

Table 1. Sub-categories of measures of engagement with HIV care for people on antiretroviral therapy and the number of measures organised into each.

Conclusions: Heterogeneity in conceptualising engagement is reflected by the broad range of measures identified and the lack of consensus on 'gold-standard' indicators. This review organises options into four categories; further work could identify a standardised, minimum set of measures useful for comprehensive evaluation of engagement with HIV care for different use-cases.

Measurement of engagement could be advanced through assessment of multiple categories for more comprehensive evaluation, conducting sensitivity analyses with commonly-used measures for more comparable outputs and using longitudinal measures to evaluate nuanced patterns of engagement.

EPC132

Assessing the impact of coronavirus (Covid-19) on reflex cryptococcal antigenaemia (CrAg) testing in South Africa

N. Cassim[1,2], L.M. Coetzee[1,1], D.K. Glencross[2,1]

[1]University of the Witwatersrand, Faculty of Health Sciences, Molecular Medicine and Haematology, Johannesburg, South Africa, [2]National Health Laboratory Service, National Priority Programme, Johannesburg, South Africa

Background: Coronavirus disease (COVID-19) is an infectious disease caused by the SARS-CoV-2 virus, first reported from the city of Wuhan, China. Subsequently, it spread globally and was declared a pandemic in March 2020 by the World Health Organization. Many countries, including South Africa introduced social distancing and lockdown rules to limit transmission.

These lockdown strategies negatively impacted pathology services/laboratory testing, especially the diagnosis/treatment of patients with advanced HIV-disease (CD4<200 cells/µl) that could potentially develop crypto-

coccal disease. In South Africa, reflexed cryptococcal antigenaemia (CrAg) testing followed by pre-emptive antifungal therapy is recommended before antiretroviral initiation for patients with a CD4<100 cells/µl. The objective of this study was to assess the impact of Covid-19 on CrAg testing in South Africa.

Methods: Specimen-level CrAg data for a CD4<100 cells/µl was extracted for individuals ≥15 years from the corporate data warehouse for the period between January 2018 and December 2021. Test volumes (annual and monthly) and CrAg positivity were calculated by gender. The percentage change in annual and monthly CrAg test volumes for 2020 and 2021 with lockdown levels imposed were compared to data reported for 2018.

Results: Data for 1,306,456 reflexed CrAg samples were analysed. The number of reflexed tests performed reduced by 22.4% and 27.8% for 2020 and 2021 respectively relative to 2018. There were 23,670 CrAg positive outcomes reported in 2018 compared to 21,399 (-9.6%) and 17,847 (-24.6%) in 2020 and 2021.

During the Covid-19 waves, a reduction of 36.6%, 35.5%, 36.1% and 13.3% in CrAg tests performed were reported for August 2020 (1st wave), January 2021 (2nd), August 2021 (3rd) and December 2021 (4th) respectively, relative to the respective monthly volumes reported during 2018. CrAg positivity in vulnerable tested patients increased from 6.3% in 2018 to 7.5% for 2020, but reduced to 6.5% by 2021. During 2020, CrAg positive outcomes peaked at 8.0% in April between Covid-19 waves.

Conclusions: This study reports substantial reductions in reflexed CrAg testing due to the Covid-19 lockdown levels. An increase of CrAg positivity amongst vulnerable patients in 2020 may indicate that individuals presented later for care during this period.

EPC133

Potential impact of the COVID-19 pandemic on UNAIDS 95-95-95 targets in 10 Fast-Track Cities

S. Ravishankar[1], S. Denis[2], H. Olowofeso[3], C. Duncombe[4], J.M. Zuniga[4]

[1]International Association of Providers of AIDS Care, Fast-Track Cities Institute, Washington DC, United States, [2]International Association of Providers of AIDS Care, Strategic Information, Washington DC, United States, [3]International Association of Providers of AIDS Care, Strategic Information, Lagos, Nigeria, [4]International Association of Providers of AIDS Care, Washington DC, United States

Background: Fast-Track Cities are committed to attaining 95-95-95 targets by 2025. Access to critical services could have been affected during the COVID-19 pandemic resulting in impact on progress against the 95-95-95 targets.

Methods: 95-95-95 data from 10 Fast-Track Cities in North America (4) and Europe (6) were included in this analysis using the following parameters:

1. Reported all three 95 targets in 2018, 2019, and 2020;
2. COVID-19 first detected in the country between Jan-Mar 2020.

The average of each "95" target was taken for 2018, 2019, and 2020. The difference for each of the three targets was calculated for the following time periods: Dec 2018-Dec 2019 and Dec 2019-Dec 2020.

Results: The first 95 target across the 10 cities ranged from 73%-95% in 2018; 67%-95% in 2019; and 76%-96% in 2020. The second 95 target ranged from 67%-98% in 2018; 68%-98% in 2019; and 67-98% in 2020. The third 90 target ranged from 86%-97% in 2018; 85%-97% in 2019; and 88%-98% in 2020.

In North America the average 95-95-95 targets across the four cities was 87.5-79.0-89.0 in 2018, 88.3-78.5-91.3 in 2019, and 88.3-77.8-91.0 in 2020. In Europe the average 95-95-95 targets across the six cities was 87.0-90.5-95.8 in 2018, 86.8-93.2-95.5 in 2019, and 88.7-93.7-95.7 in 2020.

North American Cities (n=4)			
	Difference in First 95 Average	Difference in Second 95 Average	Difference in Third 95 Average
From Dec 2018 to Dec 2019	+.08 percentage points	-.5 percentage points	+1.5 percentage points

Table. Difference in Average 95-95-95 Targets.

Conclusions: Based on this assessment, the COVID-19 pandemic did not significantly impact progress towards the 95-95-95 targets through the end of 2020 in the ten cities. Limitations included the fact that most of the cities were high performing (targets >80%) and that data were collected between nine to eleven months during the respective local COVID-19 epidemics.

Future assessments including lower performing cities and cities in the global south; as well as data through the end of 2021, may provide more information on the potential impact of the COVID-19 pandemic on the 95-95-95 targets.

Understanding county-level variation in ART coverage as Kenya approaches epidemic control

S. Stash[1,2], M. Ruffner[3], S. Cavanaugh[2], T. English[3], C. Steers-McCrum[3]

[1]Henry Jackson Foundation, International HIV Prevention and Treatment, Bethesda, United States, [2]Walter Reed Army Institute of Research, U.S. Military HIV Research Program, Silver Spring, United States, [3]U.S. Department of State, Office of the U.S. Global AIDS Coordinator and Health Diplomacy (OGAC), Washington DC, United States

Background: The next U.S. President's Emergency Plan for AIDS Relief (PEPFAR) Strategy names six countries at epidemic control, with implications for future funding and programming. Among them, Kenya has made significant progress establishing people living with HIV (PLHIV) on antiretroviral therapy (ART). However, program data suggest sub-regional variations in epidemic dynamics and program results.

Description: We collaborated with PEPFAR country teams and county-level Ministry of Health (MOH) and other leaders to analyze program results against county-level population estimates of PLHIV (UNAIDS NAOMI). We also conducted a rapid assessment in each county using a standardized questionnaire on an online platform. ART coverage was calculated as the number of PLHIV on treatment divided by the estimated number of PLHIV in that county. We similarly compared county-level measures of program results and performance.

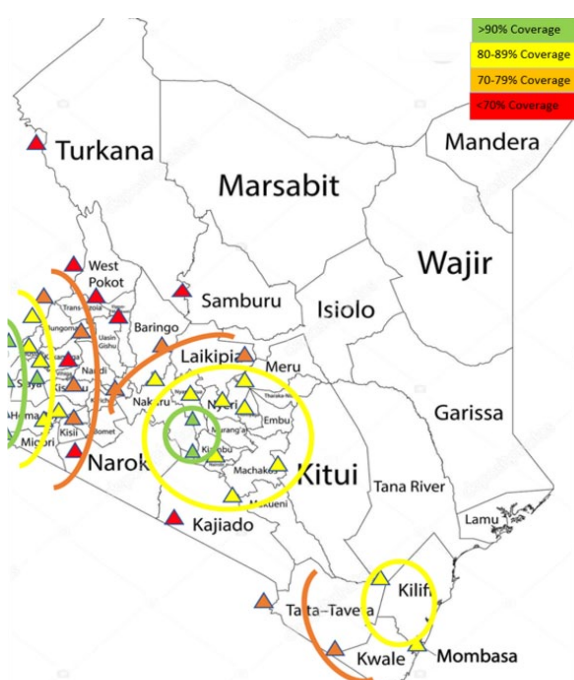

Figure 1. ART coverage gap in Kenyan counties, Dec. 2020

Lessons learned: More than 90% of the estimated PLHIV in five counties around Lake Victoria are on ART; with sustained high transmission, these counties now comprise 27% of PLHIV in Kenya. More broadly, fifteen counties, in concentric arcs surrounding Lake Victoria, account for 54% of undiagnosed PLHIV in Kenya. Eleven counties near Nairobi have an ART coverage of >80% and contribute 16% of Kenya's undiagnosed PLHIV. With about 16% of the undiagnosed PLHIV in the country, Rift Valley counties have less than 70% ART coverage, lesser levels of program investment, and poorer results across a range of measures.

Conclusions/Next steps: As PEPFAR's support and Kenya's epidemic evolve, systematic planning is essential to ensure that undiagnosed PLHIV are not left behind. We employed publicly available program results and population estimates to generate signals for interpretation locally. When integrated with other ongoing workstreams, for example, a recent review of human resources, these findings lay a basis for the next generation of case-finding services in Kenya, providing lessons for other counties planning similar transitions.

Describing the spread of HIV through geographical information systems

EPC135

Impact of HIV/AIDS epidemics in the Brazilian border strip

L.H. Lannoy[1,2], A.S.D. Santos[1,3], R.A. Coelho[1], G.F.M. Pereira[1], A.E. Miranda[2,1]

[1]Ministry of Health of Brazil, Department of Chronic Conditions and Sexually Transmitted Infections, Brasília, Brazil, [2]Federal University of Espirito Santo, Postgraduate Program in Infectious Diseases at Health Sciences Center, Vitória, Brazil, [3]University of Brasília, Public Health, Brasília, Brazil

Background: HIV does not recognize international borders. Despite its importance, HIV infection rates have been little explored in Brazil's border strip. The primary goal of this work is to analyze HIV/AIDS detection rate in Brazil's border strip.

Methods: An ecological and cross-sectional evaluation was performed in 2020, employing data from Brazilian Health's Ministry databases. The municipalities in the border strip were grouped by their geographical region (North, Central-west and South). Cases of HIV/AIDS were obtained from the National Notification Systems (SINAN, SIM, SISCEL and SICLOM) to analyze socio-demographics in the border and borderless areas. Historical series of HIV/AIDS incidence in adults and children under five years-old were collated.

Results: Brazil reported32,701 HIV cases and 29,917 AIDS cases in 2020 with AIDS incident rate of 14.1/100,000 persons. Analysis of the HIV data has shown that the Northern border (19.0/100,000) presented a higher detection rate than the other areas (Southern border (15.6/100,000), Central-western border (15.8/100,000) and borderless area (15.5/100,000).

Analysis of the AIDS data has shown that the Central-western border presented a higher incidence rate (15.5/100,000) than the other areas (Southern border (13.8/100,000), Northern border (13.1/100,000), and borderless area (14.3/100,000).

Among AIDS cases reported, the average sex ratio incidence in Brazil's strip border was two men per each woman, with the northern region presenting the highest rate (2.5). The most affected age group was 25-44 years-old. Historical trends have shown that there is an upward trend in HIV detection in all areas.

In general, the border rates remained below the rate of the corresponding geographical region. Unlike adults, HIV and AIDS detection rates in children under 5 in the three strip border regions remained above than the national average.

Conclusions: In 2020, Brazilian strip border had higher HIV AND aids detection rates than borderless areas. Nevertheless, the rates were different when compared the different regions. In 2010, notification of HIV infection was incorporated into the National Information System, which justifies the sharp increase in the HIV curve after 2015. These results show the importance to plan regional strategies and intervention in the strip border area.

EPC136

Geographic and risk variation in transmission clusters of HIV test recipients in Nagoya, Japan

M. Imahashi[1], T. Shiino[2], N. Kaneko[3], Y. Yokomaku[1], C. Hashiba[1]

[1]National Hospital Organization Nagoya Medical Center, Clinical Research Center, Nagoya, Japan, [2]National Center for Global Health and Medicine, Center for Clinical Sciences, Shinjuku-ku, Japan, [3]Nagoya City University, Graduate School of Nursing, Nagoya, Japan

Background: The number of people living with HIV (PLWH) in Japan continues to increase. That more than 30% of these patients are being diagnosed with AIDS suggests that the first step of the United Nations' "90-90-90" HIV treatment program does not work well in Japan.

Working with local government of Nagoya city, the National Hospital Organization Nagoya Medical Center has held HIV testing campaigns targeting men who have sex with men (MSM).

To assess the need for reframing the target audience, we compared sociological characteristics, geographical information on residential and activity areas, and transmission cluster connections of HIV-positive persons in Nagoya city with those of newly diagnosed persons from nearby cities who visited our clinic.

Methods: We recruited HIV-positive first-time visitors to the Nagoya Medical Center from 2019 through 2021. Sociological and behavioral information and motives for visiting the Center were collected in a patient questionnaire. Place of residence was extracted from patients' medical records with their consent. Information about HIV transmission clusters was obtained through genetic distance-based analyses of HIV pol gene sequences conducted by the Japan HIV Drug Resistance Network.

Results: Of the participating patients, 723 (81.6%) and 163 (18.4%) were recruited from the test campaign and the other sources, respectively. Individuals diagnosed outside of the campaign showed a significantly higher median age (35 vs. 32 years old, p<0.01) and a higher heterosexual proportion (11.6% vs. 1.7%, p<0.01).

While individuals in the largest cluster TC2 (n=47) generally lived in the center of Nagoya city, the second most common cluster TC3 (n=43) was more likely to have lived in Nagoya's suburbs.

However, campaign-associated individuals did not show statistically significant clustering; 5.9% of patients diagnosed with AIDS were also non-clustered and mostly lived in the suburbs.

Conclusions: Our study found that individuals within a transmission cluster were more likely to live in the city center, while those outside of clusters were more likely to live in the suburbs and have a late diagnosis. Continued research is needed on measures to convey the importance of HIV testing to PLWH who cannot be identified through clusters.

Advances in public health surveillance and new approaches

EPC137

Precision is key: improving HIV prevalence and risk estimates by a Bayesian small area estimation modelling approach

H. Wang[1], C. den Daas[2], E. Op de Coul[3], K.J. Jonas[1]

[1]Maastricht University, Department of Work and Social Psychology, Maastricht, Netherlands, the, [2]University of Aberdeen, Health Psychology, Aberdeen, United Kingdom, [3]National Institute for Public Health and the Environment (RIVM), Centre for Infectious Disease Control, Bilthoven, Netherlands, the

Background: Reliable HIV surveillance in areas with small population density (e.g., due to a decline in HIV infections) or lack of data is challenging. Therefore, this study proposed a Bayesian small area estimation (SAE) approach to unravel robust estimates of people with HIV (PWHIV), using data from an MSM population in the Netherlands on the Public Health Services (GGD) region level as an example.

Methods: Data from the European-MSM-Internet Survey 2017 (EMIS-2017, Dutch subsample, n=3,459) and the "Survey Men&Sexuality" 2018 (SMS-2018, n=5,653) were utilized. We first calculated the observed prevalence of MSM with HIV (MSMHIV) and the standardized prevalence ratio

through the frequentist approach to compare the observed risk of MSMHIV per GGD region. We then applied a Bayesian SAE approach accounting for a hierarchical spatial connection among GGD regions.

This hierarchical structure assumed that each region influences the risk of MSMHIV by sharing the border or by proximity. We first modeled the relative risk (RR) of MSMHIV by only considering spatial connections and the random effects, assuming the observed HIV cases in each GGD region to follow a Poisson distribution.

We then conducted a spatial ecological regression modelling (uni-/multivariably) to include known areal determinants of HIV such as HIV testing history, age, number of sex partners, injecting drug use, condom use and prevalence of other STIs to explore how the other spatial information impacts on the RR estimations.

Results: Results of the prevalence and risk estimations from EMIS-2017 and SMS-2018 revealed an overlapping estimation with minor differences. Both estimations converged that the risk of MSMHIV is heterogeneous within the Netherlands with some GGD regions, such as GGD Amsterdam [RR=1.21 (95% credible interval 1.05-1.38) by EMIS-2017, RR=1.39 (1.14-1.68) by SMS-2018], having a higher-than-average risk. Results from our regression modelling revealed significant areal determinants (e.g., lack of HIV testing) which can increase HIV risk.

Conclusions: Our proposed Bayesian SAE approach can obtain a smoother and more stable estimation over the frequentist observation, illustrating the feasibility and applicability of this approach for a better future HIV surveillance for local prevention in the context of the declining epidemic or due to data gaps.

EPC138

Estimating National and sub-National population size of men who have sex with men in Mexico

M. Valenzuela-Lara[1], R. Baruch-Dominguez[2], A.B. Algarin[3], L.R. Smith[3], C. Magis-Rodriguez[4], T.H. Sanchez[1]

[1]*Emory University, Department of Epidemiology, Atlanta, United States,* [2]*International Alliance for Sexual and Reproductive Health, Rights and Justice, Mexico City, Mexico,* [3]*University of California, Division of Infectious Diseases and Global Public Health, San Diego, United States,* [4]*Universidad Nacional Autónoma de México, Departamento de Salud Pública, Mexico City, Mexico*

Background: Population size estimates of gay, bisexual, and other cisgender men who have sex with men (MSM) are critical to calculating disease rates, illustrating disparities, and planning services. Yet, this information is either unavailable or often outdated for many countries. The most recent MSM population size estimates for Mexico are based on a 1992-1993 household survey in Mexico City. To guide HIV prevention strategies among MSM, we produced national and state-level estimates of MSM population size in Mexico using more recent nationwide data.

Methods: The 2017 National Survey on Discrimination (ENADIS) from 39,101 households measured the prevalence of same-sex sexual attraction among respondents, including gender, age, and urbanicity. Sampling weights were used to calculate MSM percentages among adult men by age group, urbanicity level, and state.

MSM percentages in the 32 states were multiplied by the number of adult men in each state to estimate the number of MSM, summing the state-level estimates to create a national estimate. The total adult male population by age group was obtained from the 2020 Mexico Census.

Results: Results estimated 1.3 million MSM in Mexico, comprising 3.5% of the adult male population. This is an increase in the percentage of MSM compared to the most recent estimates reported to UNAIDS (3.0%), most notably in the younger populations (18-24: 5.8%, 25-29: 4.3%). The largest percentage of MSM was observed in suburban areas (4.4%). Seven states represent 53.5% of the MSM population.

Rank	State	Adult males, N	MSM, n	MSM among adult men, %
1	Jalisco	2,788,221	183,186	6.6%
2	Mexico	5,714,023	114,852	2.0%
3	Yucatan	799,663	106,595	13.3%
4	Mexico City	3,363,182	98,205	2.9%
5	Michoacan	1,525,563	85,126	5.6%
6	Chihuahua	1,272,037	66,528	5.2%
7	Baja California	1,353,389	49,805	3.7%

Table 1. But only 40.1% of the adult male population. Yucatan and Jalisco had the largest MSM percentages.

Conclusions: Using publicly available data, we generated more recent population size estimates for MSM in Mexico and provided state-level estimates to facilitate epidemiological research and service planning.

The large variability observed in the proportion of MSM across Mexico, and by age groups, supports the need for more refined surveillance that would allow for estimating MSM population by smaller geographic areas.

Phylodynamic structure of the Botswana HIV epidemic

K. Kotokwe[1,2], S. Moyo[2,3], S. Gaseitsiwe[2,3], M. Pretorius Holme[3], J. Makhema[2,3], M. Essex[3,2], V. Novitsky[4], F.F. Nascimento[1], E. Volz[1], M. Ragonnet-Cronin[1], C. Pangea[5]

[1]Imperial College London, MRC Global Infectious Disease Analysis, London, United Kingdom, [2]Botswana Harvard AIDS Partnership, Research Laboratory, Gaborone, Botswana, [3]Harvard T.H. Chan School of Public Health, Department of Immunology and Infectious Diseases, Boston, United States, [4]Brown University, Providence, RI, United States, [5]PANGEA Consortium, Oxford, United Kingdom

Background: Botswana has one of the world's highest HIV prevalence and incidence despite a successful program for free antiretroviral treatment (ART). Understanding population-level patterns of HIV transmission is vital for effective public-health-interventions.

Methods: As part of the Botswana Combination Prevention Project (BCPP), 20% adults residing in 30 villages were tested for HIV-1 between 2013-2018. Extensive demographic data was collected from participants and next-generation full-genome HIV sequences were generated from HIV positive participants (n=4,164), 78% were on ART.

We inferred the stage of infection (< or >1 year) among HIV cases based on nucleotide diversity and clinical data using a previously trained machine learning model.

We reconstructed time-resolved pol phylogenies from BCPP sequences (n=4,164), other Botswana cohorts (n=352) and publicly available sequences that were genetically close to those from Botswana (n=448).

We statistically evaluated phylogenies for subtrees with diverging patterns of coalescence and estimated viral effective population size through time, a measure of viral incidence.

Finally, we compared the demographic makeup and clinical characteristics across subtrees using $\chi 2$ test, ANOVA and tukey analysis.

Results: We identified eight subtrees within the pol phylogeny with different patterns of coalescence, indicating divergent patterns of transmission from sequences across Botswana. Four subtrees displayed a recent origin (post-1995), with rapid growth followed by rapid declines ("group 1) (figure 1).

Another four subtrees ("group 2") originated earlier (pre-1990) and continued to grow steadily. Two subtrees in group 2 showed a recent rise in growth (post-2016) continuing until present day.

Group 2 participants had the most recent infections ($p < 0.001$), while group 1 participants were mostly chronically-infected and on ART. Sequences from outside Botswana (99%) clustered in group 2 subtrees.

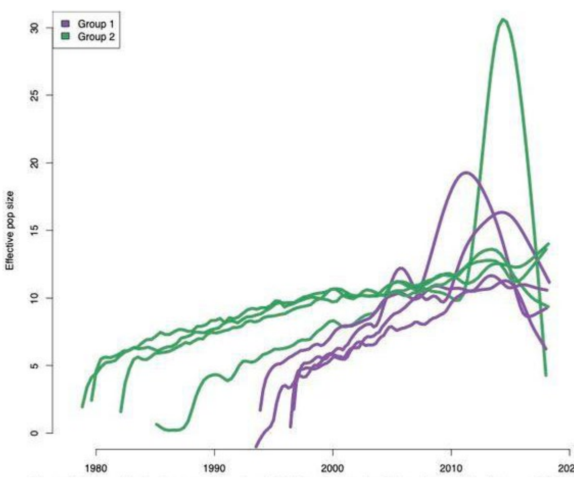

Figure 1. Estimated effective population size (Ne(t)) through time for eight subtrees in the Botswana HIV-1 phylogeny. The Ne(t) was estimated using the mlesky method with precision parameter Tau = 10.

Conclusions: Phylodynamic analysis suggests that geographically targeted HIV interventions may not work in Botswana because of high mobility of the population. Transmission rates appear to be slowing in segments of the population with high access to ART. However, transmission is ongoing in sub-epidemics that include recent infections and sequences from participants outside Botswana.

EPC140

Programmatic non-retention in prevention of mother-to-child transmission (PMTCT) programs: estimated rates and cofactors using different measures

W. Jiang[1], K. Ronen[1], L. Osborn[2], A.L. Drake[1], J.A. Unger[1], B.A. Richardson[1], D. Matemo[2], J. Kinuthia[2], G. John-Stewart[1]

[1]University of Washington, Seattle, United States, [2]Kenyatta National Hospital, Nairobi, Kenya

Background: Because PMTCT programs include women continuing and starting ART in pregnancy, and follow-up aligns with delivery rather than ART initiation, conventional HIV care retention measures assessed from time of ART initiation are challenging to apply.

In the absence of a standard definition for PMTCT non-retention, we evaluated three measures of programmatic non-retention in Kenyan women living with HIV from pregnancy to 2-years postpartum. We also identified cofactors for each measure.

Methods: This cohort study used data from the Mobile WAChX trial. Outcomes included loss to follow-up (LTFU) (no visit for ≥6 months), incomplete visit coverage (<80% of 3-month intervals with a visit), and late visits (% of visits >2 weeks late). Predictors were determined by site-adjusted Cox proportional hazard, Log-binomial and GEE models, respectively.

Oral abstracts

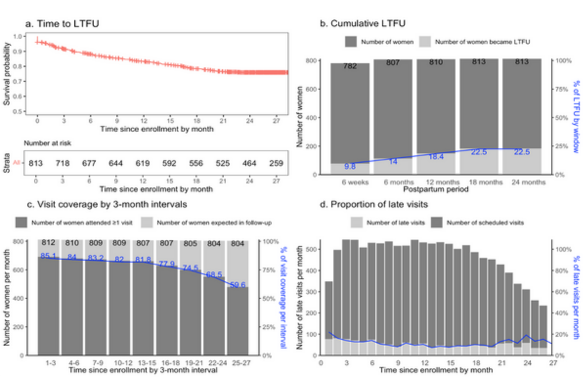
Poster exhibition

E-posters

Late-breaker abstracts

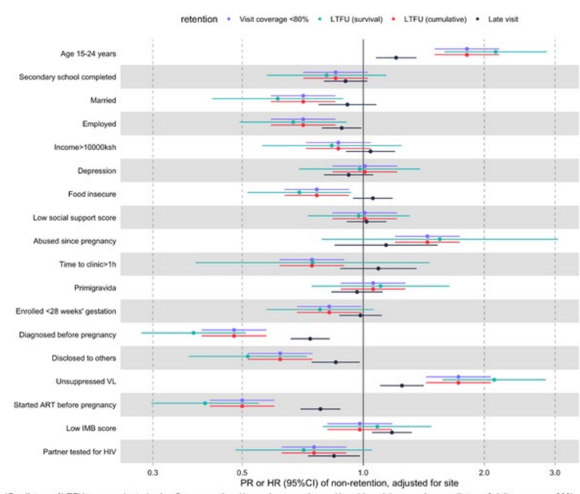
Author Index

Results: Among 813 women, incidence of LTFU was 13.6/100 person-year. By 2-years postpartum, 22.5% women were LTFU. 35.5% of women had incomplete visit coverage. Among 794 women with 12,437 scheduled visits, a median of 11.1% of visits per woman were late (IQR 4.3%-23.5%).
Younger age, unsuppressed viral load, unemployment, ART initiation in pregnancy, and non-disclosure were significantly associated with higher rates of non-retention for all measures. Partner involvement was associated with better visit coverage and timely attendance. LTFU was higher among women with ≥10% of previous visits being late (25.8% vs. 14.5%, p<0.001).



a. Time-to-LTFU (no visit for ≥6 months since last visit) was described by Kaplan-Meier survival curves; b. cumulative incidence of LTFU was calculated as the proportion of women ever LTFU among women in follow-up; c. visit coverage was calculated as the proportion of 3-month intervals with a visit; d. late visit was defined as no visit within 2 weeks of scheduled date.

Figure 1. Retention over the follow-up period using the 3 measures (loss to follow-up, visit coverage, late visits).



*Predictors of LTFU were evaluated using Cox proportional hazards regression and Log-binomial regression; predictors of visit coverage <80% were evaluated using Log-binomial regression; predictors of late visit were evaluated using Generalized estimating equations clustered by women, with log-binomial link and exchangeable correlation structure. Study site (Nairobi versus Western Kenya) was identified as an a priori confounder in all regression models to account for potential geographical differences in maternal characteristics and underlying retention in care. All models used robust standard errors.

*Figure 2. Forest plot of cofactors for non-retention, by non-retention measure**

Conclusions: Late visit is a potentially sentinel indicator predicting LTFU. Assessing visit timeliness and coverage may enhance retention evaluation. Distinct cofactors identified using different measures highlight the need for standardized assessments of retention in PMTCT programs.

Measuring and evaluating quality of service provision and health outcomes through public health surveillance

EPC141

Factors associated with viral load non-suppression among children living with HIV in four provinces in Mozambique

J. Moiane[1], L. Armando[1], J. Alexandre[1], S Goncalves[1], M. Prieto[1], W.M. Olivier[2]
[1]*ThinkWell, ECHO Project, Maputo, Mozambique,*
[2]*Pathfinder International, Maputo, Mozambique*

Background: Globally, children are lagging behind the UNAIDS' "third 95" target, in which 95% of people on treatment have a suppressed viral load (VL). Only 40% of children initiated on antiretroviral therapy (ART) achieve VL suppression, compared to 67% among adults(UNAIDS, 2021). Despite improvements enrolling children on ART and increased access to testing, Mozambique is still far from achieving the 2030 UNAIDS target.
This study investigates the factors associated with VL non-suppression among children under 15 in four provinces in Mozambique supported by USAID's Efficiencies for Clinical HIV Outcomes (ECHO) project.

Methods: This is an observational cross-sectional study of routine data collected from electronic medical records. ECHO extracted data such as age, sex, ART regime, ART duration, inclusion in multi-month dispensing, and availability of at-risk child consultations from 118 health facilities for the period between September 2019 and May 2021. All children aged 0-14 with at least 6 months on ART and a VL result registered during this period were included.
Descriptive analysis was done to describe study sample characteristics, and to determine the prevalence of the outcome variable (VL non-suppression, defined as a VL ≥1,000 copies/ml after at least 6months on ART). We used a logistic regression to assess factors associated with VL non-suppression among children.

Results: 1,261 children were included; 56% were female, 55% were children aged 0-5,and 77% began ART in 2020. The overall non-suppression rate was 45%; 51%of children non-suppressed were male, 65%wasaged 0-5 years old and 52% had a non-optimized ART regime(without DTG).
Being Female (OR = 0.71; 95%CI: 0.604,0.829), age ≥2 years (OR = 0.716; 95%CI: 0.557,0.920),in monthly ART dispensing (OR = 3.078; 95%CI: 2.313,4.097) and health facility without at-risk children consultation (OR = 2.032; 95%CI: 1.086,3.804) were significantly associated with VL non-suppression.

Conclusions: Non-suppression of VL was associated with being female, age ≥ 2 years old, being in monthly ART dispensing and in a health facility without at-risk children consultation.
Our findings suggest a need for age-specific interventions, as well as scaling-up the provision of multi-month ART dispensing for all eligible children and increasing the availability of at-risk children consultations.

EPC142

Trends in HIV annual test uptake and retesting among gay and bisexual men and other men who have sex with men in Australia with no evidence of PrEP use between 2013-2021

J. Asselin[1], M.W. Traeger[1,2], J. Dittmer[1], N. Roth[3], M. Bloch[4], C.K. Fairley[5], A. Carter[6,7,8], B. Donovan[6], R. Guy[6], M. Hellard[1,2], M. Stoove[1,2], on behalf of the Australian Collaboration for Coordinated Enhanced Sentinel Surveillance (ACCESS)
[1]Burnet Institute, Public Health Discipline, Melbourne, Australia, [2]Monash University, School of Public Health and Preventative Medicine, Melbourne, Australia, [3]Prahran Market Clinic, Melbourne, Australia, [4]Holdsworth House, Sydney, Australia, [5]Melbourne Sexual Health Centre, Melbourne, Australia, [6]Kirby Institute, UNSW, Faculty of Medicine & Health, Sydney, Australia, [7]Australian Human Rights Institute, UNSW Sydney, Sydney, Australia, [8]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada

Background: Frequent HIV testing and timely diagnosis and treatment are key parts of Australia's HIV prevention strategy. Monitoring test frequency and adherence to guidelines that recommend three-monthly testing for sexually active gay and bisexual men and other men who have sex with men (GBM) is complicated by the rapid scale of PrEP, where HIV testing also occurs at recommended three-monthly PrEP visits.
Using data from clinics in the ACCESS sentinel network, we examined trends in HIV retesting among HIV-negative GBM with no evidence of PrEP use (GBM-NeverPrEP).
Methods: HIV testing data were extracted from 29 specialist general practice and sexual health services across Australia. GBM-NoPrEP were classified as having no evidence of a PrEP prescription at any point between 2013-2021. HIV test uptake (individuals tested/individuals attended) and mean number of tests/individuals (among those tested) were calculated per calendar year.
Annualised three- and 12-month retesting rate was calculated as the proportion of GBM-NoPrEP whose last HIV test within a calendar year was preceded by at least one test within three and 12 months. To account for impacts of the COVID-19, Poisson regression assessed trends from 2013-2019 and 2019-2021.
Results: Of 88,258 HIV-negative GBM who attended services between 2013-2021, 58,942 (67%) were GBM-NeverPrEP. Between 2013 and 2019, annual HIV test uptake among GBM-NeverPrEP increased from 53% to 64% ($p<0.001$), and declined to 55% in 2021 ($p<0.001$). From 2013 to 2019, mean number of tests increased from 1.4 to 1.5 per year ($p<0.001$), declining to 1.4 in 2021 ($p<0.001$).
Between 2013 and 2019, the proportion of GBM-NeverPrEP retested within three months increased from 16% to 19% ($p<0.001$) and declined to 16% in 2021 ($p<0.001$). Between 2013 and 2019, the proportion retested within 12 months increased from 46% to 50% ($p<0.001$) before declining to 43% in 2021 ($p<0.001$).
Conclusions: While there were modest increases in HIV test uptake and retesting rates among GBM who have never used PrEP, an overwhelming majority were not testing at recommended frequencies. Testing frequency was further impacted during the COVID-19 pandemic. A renewed focus on HIV risk and the importance of regular testing in GBM not using PrEP is required.

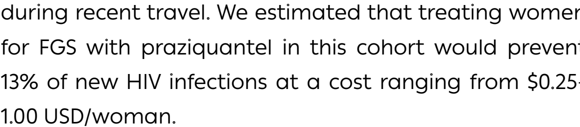
Modelling the impact of prevention strategies on the HIV epidemic

EPC143

Modeling HIV infections averted by treating urban, adult Zambian women at high-risk for HIV and female genital schistosomiasis

K. Wall[1], W. Kilembe[2], M. Inambao[3], S. Mwangelwa[3], C. Kabengele[2], B. Vwalika[2], E. Rogers[1], R. Parker[1], A. Tichacek[1], S. Allen[1]
[1]Emory University, Atlanta, United States, [2]Center for Health Research Zambia, Lusaka, Zambia, [3]Center for Health Research Zambia, Ndola, Zambia

Background: Female genital schistosomiasis (FGS) is one of the most common neglected tropical diseases. The WHO estimates that 56 million women and girls are living with FGS in sub-Saharan Africa. FGS causes infertility, pregnancy complications, lost productivity, extreme stigma, and is associated with a doubling in HIV risk.
Despite an urgent call by WHO for treatment of FGS in adults, adult praziquantel coverage is currently low at 14% and most healthcare professions still view FGS as a disease affecting children in rural areas. FGS prevalence in adult women in urban Africa, where HIV risk is highest, is largely unknown, including in Zambia where schistosomiasis is endemic.
Methods: From March 2020-October 2021, we recruited adult HIV-negative female sex workers and single mothers and assessed FGS risk factors and positivity using colposcopy. This cohort was recruited in the two largest cities in Zambia. We evaluated factors associated with FGS positivity using logistic regression.
We also used data from a recent meta-analysis, the HIV seroincidence rate observed in our cohort, and current drug prices for praziquantel in Zambia to parameterize a compartmental model outputting the number of HIV infections prevented by treating women for FGS and the cost to prevent these infections.
Results: Among 400 urban adult women, we found an unexpectedly high prevalence of FGS (25%). HIV seroincidence in this cohort was also high at 2.7/100 person-years. Factors associated ($p<0.05$) with FGS positivity included younger age, history of pregnancy disturbances, menstrual irregularities, vaginal hygiene, incontinence, childhood freshwater exposure, and exposure to freshwater



during recent travel. We estimated that treating women for FGS with praziquantel in this cohort would prevent 13% of new HIV infections at a cost ranging from $0.25-1.00 USD/woman.

Conclusions: We found a concerningly high prevalence of FGS in adult women living in urban Zambia who were concurrently at high-HIV risk. It is urgent that FGS diagnosis and praziquantel coverage, which is an inexpensive drug with few side-effects, improve among urban adult populations in schistosomiasis endemic countries.

Understanding factors associated with FGS positivity could lead to development of a simple diagnostic screening algorithm. Given that this high FGS prevalence was observed

EPC144

Hepatitis C virus elimination among people who inject drugs living with HIV in Montreal, Canada, by 2030: a modelling study

C. Lanièce Delaunay[1,2], M.B. Klein[2,1], A. Godin[1], J. Cox[1,2], N. Kronfli[2,1], C.M. Doyle[1], B. Lebouché[2,1], M. Maheu-Giroux[1]

[1]McGill University, Montreal, Canada, [2]Research Institute of the McGill University Health Centre, Montreal, Canada

Background: People who inject drugs (PWID) and those living with HIV (LHIV) are priority populations for the elimination of hepatitis C virus (HCV), defined as reducing chronic HCV incidence by 80% and HCV-related mortality by 65% from 2015-2030.

We assessed the potential of various interventions to achieve HCV elimination among PWID and PWID LHIV by 2030 in Montreal, Canada.

Methods: We used a model of HCV-HIV co-transmission among PWID calibrated to local epidemiological data (2003-2018). Informed by literature reviews, we simulated the following interventions from 2022-2030, comparing them to status quo: increased HCV diagnosis rate (gradual increase from 10-30 per 100 person-years [PY] in 2022 to 100 per 100 PY as of 2024), increased treatment rate (from 85 to 200 per 100 PY), and increased harm reduction coverage (from 33% to 40% opioid agonist therapy coverage; from 83% to 95% needle and syringe program coverage).

We also varied priority populations (all PWID/PWID LHIV; active/ever-injectors regardless of HIV status), totalling eight scenarios. HCV outcomes modelled included reductions in chronic incidence, prevalence, and mortality from 2015-2030, and proportions of chronic cases and HCV-related deaths averted over 2022-2030.

Results: Status quo intervention levels were insufficient to achieve elimination targets in PWID and PWID LHIV, and accelerating HCV diagnosis made little difference (Table).

Despite preventing new infections, greater harm reduction coverage did not lead to elimination by itself. Scaling-up treatment was key to reaching targets among PWID, regardless of HIV status. Including ex-injectors in this scenario was important to prevent HCV-related deaths.

Conclusions: In settings with moderately high diagnosis rates and relatively high harm reduction coverage, scaling-up HCV treatment among all PWID is the key to eliminating HCV among both PWID and PWID LHIV.

Scenario (priority population) Scenario (priority population)	Median reduction in chronic HCV incidence from 2015-2030 (95% credible interval)		Median reduction in chronic HCV prevalence from 2015-2030 (95% credible interval)		Median reduction in HCV-related mortality from 2015-2030 (95% credible interval)		Median proportion of cumulative chronic HCV infections averted from 2022-2030 (95% credible interval)		Median proportion of cumulative HCV-related deaths averted from 2022-2030 (95% credible interval)	
	All PWID	PWID LHIV	All PWID	PWID LHIV	All PWID	PWID LHIV	All PWID	PWID LHIV	All PWID	PWID LHIV
Status quo	55% (29-80)	57% (31-82)	60% (34-82)	64% (37-87)	74% (46-90)	86% (66-96)	Referent	Referent	Referent	Referent

Supporting achievement of the state of Georgia's 25% HIV incidence reduction target among MSM: a mathematical model to evaluate the potential impact of long-acting preexposure prophylaxis in Atlanta

R. Blissett[1], F. Aragao[1,2], S.-J. Anderson[3], S. Sarkar[4], J. Fraysse[4]
[1]*Maple Health Group, New York, United States,* [2]*NOVA National School of Public Health, Public Health Research Centre, Universidade NOVA de Lisboa, Lisbon, Portugal,* [3]*GlaxoSmithKline, Brentford, United Kingdom,* [4]*ViiV Healthcare, Brentford, United Kingdom*

Background: Despite ambitious US HIV incidence reduction goals at national and regional levels, new infections remain high in numerous communities and demographics, including among men who have sex with men (MSM) in the US South. The Georgia Department of Health has targeted a 25% HIV incidence reduction among MSM, with specific focus on increasing use of preexposure prophylaxis (PrEP) to 50% of indicated MSM. We used mathematical modelling to estimate the impact of introducing long-acting (LA) PrEP among MSM in Atlanta, Georgia on achieving such a target.

Methods: We expanded a previously developed dynamic network model of HIV transmission (EpiModelHIV) calibrated to the HIV epidemic among MSM in Atlanta by incorporating the HPTN083 results and association between demographic characteristics and PrEP utilization based on real-world US PrEP studies. We investigated 10-year HIV incidence reductions resulting from plausible LA-PrEP use ranges between 5% to 25% of indicated MSM while maintaining daily-oral (DO)-PrEP use at current levels. HIV incidence and infections averted were estimated in the overall MSM population and by race and age sub-groups.

Results: Baseline HIV incidence in the overall MSM population before the introduction of LA-PrEP was 1.28 per 100 person-years (100py), with DO-PrEP use varying by age and race. Increases in LA-PrEP usage up to 25% in indicated MSM resulted in overall MSM population incidence reductions between 7.0% and 28.1% (*Figure*). Over 10 years, with 25% LA-PrEP usage, most infections averted (73.2%) occurred in the Black MSM community, with incidence falling from 2.67/100py to 1.94/100py. PrEP benefits were also captured by non-PrEP users among all MSM, who experienced a 15% incidence decline (1.38/100py to 1.17/100py).

Figure. Proportion of PrEP-indicated MSM population using PrEP by modality and resulting 10-year reduction in HIV incidence in overall MSM population.

Conclusions: LA-PrEP has the potential to contribute to substantial reductions in HIV incidence among MSM and can support achievement of regional reduction targets at plausible usage levels by decreasing primary and secondary infections.

EPC146

Achieving the 95-95-95 HIV cascade of care targets will not be enough to meet the incidence reduction goal among MSM in Cyprus

I. Gountas[1], G. Siakalis[2], A. Demetriou[3], I. Demetriades[2], G. Nikolopoulos[1]
[1]*University of Cyprus, Medical School, Nicosia, Cyprus,* [2]*AIDS Clinic, Larnaca General Hospital, Larnaca, Cyprus,* [3]*Ministry of Health, Health Monitoring Unit, Nicosia, Cyprus*

Background: The 95-95-95 strategy aims to end the AIDS epidemic by 2030 by diagnosing 95% of all people living with HIV (PLHIV), by administering antiretroviral therapy (ART) to 95% of the diagnosed, and by achieving viral suppression (VS) on 95% of those on ART. Mathematical modeling predictions highlight that the aforementioned targets could reduce the HIV incidence by 90% in 2030 compared to 2010. However, several studies have underlined that in high-income countries, HIV cascade of care (CoC) targets may be insufficient to achieve the incidence goal and that additional interventions, like pre-exposure prophylaxis (PrEP), will be needed. Currently, PrEP is not available in Cyprus.

In Cyprus, men who have sex with men (MSM) is the most prevalent HIV risk group, accounting for more than half of all diagnoses. This study aims to estimate the expected reduction in HIV incidence under the status quo scenario and to highlight the required healthcare interventions to achieve the UNAIDS incidence target.

Methods: A previously published stochastic, dynamic mathematical model was used to simulate HIV transmission among MSM (Gountas, PLOS 2021). The population was stratified by risk behaviours according to the EMIS study (high=15.1%/medium=28.7%/low=56.2% and 42.5% are willing to use PrEP if offered). The model was calibrated to match the trajectories of the HIV CoC in the years 2014-2020. Infection rate, diagnosed probability, and ART initiation probability were varied until the model reproduced the observed HIV epidemic.

Results: The model showed that although the MSM could reach the 95-95-95 target in 2030, this would not be enough to achieve the 90% reduction in HIV incidence (estimated reduction of 58.9% in 2030 compared to 2010). Launching a PrEP intervention only for those who are willing to use it (i.e., without any awareness campaigns), would cause a modest reduction (69.0% in 2030 compared to 2010). To achieve HIV elimination by 2030, the 95-95-95 target should be achieved, and awareness campaigns should be implemented so all the high-risk MSM be on PrEP by 2030 (Figure).

Conclusions: Reaching the 95-95-95 CoC targets among MSM is not enough. To achieve HIV elimination, gradually all high-risk MSM should be on PrEP by 2030.

EPC147

The impact of prevention-effective PrEP use on HIV incidence: a mathematical modeling study

A. Roberts[1], D. Bridenbecker[2,3], J. Haberer[4], R. Barnabas[4], A. Akullian[2,3]
[1]University of Washington, Seattle, United States, [2]Bill & Melinda Gates Foundation, Seattle, United States, [3]Institute for Disease Modeling, Seattle, United States, [4]Massachusetts General Hospital, Boston, United States

Background: Models that project the impact and cost-effectiveness of HIV pre-exposure prophylaxis (PrEP) must specify how PrEP use aligns with HIV exposure. We hypothesize that varying PrEP use according to individual-level partnership dynamics rather than prioritization to population subgroups based on average risk will result in larger HIV incidence reductions and greater efficiency.

Methods: We used an individual-based network transmission model calibrated to HIV dynamics in Eswatini to simulate PrEP use among individuals ages 15-34 between 2022 to 2031 under two paradigms of PrEP delivery: "Risk Group" and "Partnership." In the "Risk Group" paradigm, we varied PrEP coverage by risk groups (low, medium, and high) defined by average partnership frequency and concurrency. In the "Partnership" paradigm, all individuals are potentially eligible for PrEP, but we assumed use occurs only during partnerships and varied prioritization by partner HIV status (no prioritization to high prioritization with HIV-positive partners). We calculated person-time on PrEP and incidence relative to a no PrEP scenario and estimated efficiency as the person-years of PrEP needed to avert one additional infection (NNT).

Results: In the Risk Group paradigm, restricting PrEP to the high-risk group was the most efficient (NNT = 17), but the number of infections averted was limited by the small size of the high-risk group. Expanding PrEP use to all risk groups averted up to three times more infections but with lower efficiency (NNT = 202). PrEP use under the Partnership paradigm was 2 to 6 times more efficient (NNT = 33 to 102) than the Risk Group paradigm with all groups eligible for PrEP. A 33% reduction in incidence among 15-34-year-olds was achieved at 46% (95% CI: 39%-53%) PrEP coverage in the Risk Group paradigm and 6% (95% CI: 5%-7%) to 17% (95% CI: 14%-20%) in the Partnership paradigm.

Conclusions: Modeling PrEP use based on risk groups resulted in a sharp tradeoff between PrEP efficiency and impact, whereas PrEP use predicated on partnerships resulted in much higher efficiency for widespread PrEP availability. Model estimates of PrEP impact and cost-effectiveness in generalized epidemics are strongly influenced by assumptions about how PrEP use aligns with individual-level HIV exposure heterogeneity.

EPC148

Modelling how strengthening HIV prevention cascade could impact the HIV epidemic in Manicaland, Zimbabwe

M. Pickles[1], S. Gregson[1,2], L. Moorhouse[1], T. Dadirai[2], F. Dzamatira[2], P. Mandizvidza[2], R. Maswera[2], R. Schaefer[1], M. Skovdal[3], R. Thomas[4], B. Tsenesa[2], C. Nyamukapa[1,2], T. Hallett[1]
[1]Imperial College London, Medical Research Council Centre for Global Infectious Disease Analysis, School of Public Health, London, United Kingdom, [2]Biomedical and Research Training Institute, Harare, Zimbabwe, [3]University of Copenhagen, Department of Public Health, Copenhagen, Denmark, [4]London School of Economics and Political Science, Department of Health Policy, London, United Kingdom

Background: HIV prevention cascades offer valuable insight into barriers to accessing prevention methods such as pre-exposure prophylaxis (PrEP), voluntary male medical circumcision (VMMC), and condoms. We need to understand how these barriers influence and sustain HIV epidemics in real-world situations.

Methods: We use an individual-based model of HIV transmission (PopART-IBM), parameterised using sexual behaviour, prevention, and treatment data from Manicaland, Eastern Zimbabwe, and calibrated to seven survey rounds of HIV prevalence and treatment data by age and sex. The model represents HIV prevention cascades for each priority population (men aged 15-29/30-54; women 15-24/25-54) as probabilities that individuals are motivated to use a prevention method (condoms, PrEP, VMMC), have access, and use it effectively.

We estimate the extent to which these probabilities may be increased by plausible real-world interventions to reduce the associated barriers (Table 1 contains the parameters for 15-29-year-old men for illustration). We examine the reduction in HIV infections over a 10-year period resulting from these interventions compared to the observed cascade probabilities from the latest Manicaland survey.

	Current situation (Manicaland survey)			With plausible intervention		
	Conditional Probability (Motivation)	Conditional Probability (Access)	Conditional Probability (Effective use)	Conditional Probability (Motivation)	Conditional Probability (Access)	Conditional Probability (Effective use)
PrEP (probability of using at current time)	0.048	0.500	0.043	0.300	1.000	0.900
VMMC (annual probability of getting VMMC)	0.115	0.184	0.092	0.185	0.205	0.185
Condoms (probability of using within a partnership)	0.639	0.933	0.742	0.650	1.000	0.750

Table 1.

Results: Figure 1 shows the percentage of infections averted by interventions to reduce barriers for each method in each priority population. Overall, women aged 25-54 experience the greatest barriers to uptake of prevention methods.

Across all methods, reducing "effective use" barrier leads to the largest decrease in infections. Addressing all barriers for all methods would avert 50% of infections in Manicaland over the next ten years.

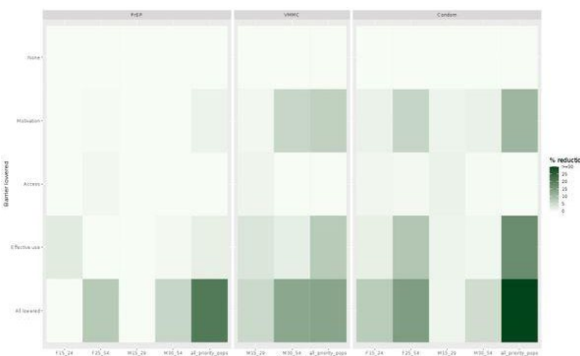

Figure 1.

Conclusions: These findings highlight the need for multi-layered interventions addressing multiple barriers to effective use of prevention methods.

EPC149

Rethinking resources for HIV prevention: the need for couples-based testing in Zambia

S. Sarkar[1,2], A. Bershteyn[3], B. Jewell[4], D. Bridenbecker[5], M. Sharma[6], K. Wall[1]

[1]Rollins School of Public Health, Emory University, Epidemiology, Atlanta, United States, [2]ViiV Healthcare, Research Triangle Park, United States, [3]New York University Grossman School of Medicine, Population Health, New York City, United States, [4]UK Health Security Agency, London, United Kingdom, [5]The Bill and Melinda Gates Foundation, Seattle, United States, [6]University of Washington, Global Health, Seattle, United States

Background: Zambia has experienced tremendous success by achieving the UNAIDS Fast Track targets, 90-90-90, by 2020. However, there has been a recent decline in domestic and international monetary investment for HIV which may threaten the country's progress. In response to these funding uncertainties, innovative and cost-effective strategies are needed in Zambia to reach the 95-95-95 Fast Track goal, and to ultimately end the epidemic.

Methods: We modeled 10-year projected epidemiologic and economic impacts of nationwide scale-up of two HIV testing scenarios in Zambia using EMOD-HIV, an agent-based model calibrated to simulate the HIV epidemic in Zambia. From a payer perspective, we compared the current standard of care (SoC) for HIV testing and treatment, in which adults who test positive for HIV are eligible to initiate ART immediately, to a counterfactual testing program incorporating couples voluntary counseling and testing (CVCT) with the SoC by encouraging married and cohabitating couples to receive HIV testing together (SoC+CVCT). We estimated HIV incidence, HIV infections averted, HIV deaths averted, quality-adjusted life years (QALYs), and incremental cost-effectiveness ratio (ICER).

We assumed a 3% annual discount rate for outcomes and costs and used a Zambia-specific cost-effectiveness threshold between $76-$878 USD per QALY gained based on previous literature.

Results: Our model projects that the SoC+CVCT would reduce adult HIV incidence by 79% (78.23% – 80.28%) over 10 years in Zambia, compared to the 72% (71.89%–72.7%) reduction by the SoC. A national testing approach that incorporates CVCT into current HIV testing practices could avert 23,018 HIV infections and 6,506 (5,501–7,100) HIV-related deaths, and could result in over 162,583 (128,420–263,690) QALYs gained compared to the referent SoC. Additionally, we find SoC+CVCT to be cost-effective with an ICER of $445 ($298–$522) per QALY gained (Table).

	10-yr HIV Incidence Reduction	HIV Infections Averted	HIV-related Deaths Averted	QALYs gained	ICER (Cost* per QALY gained)
Referent Scenario, SoC	71.65% (71.89% – 72.7%)	--	--	--	--
Counterfactual Scenario, SoC+CVCT	79.16% (78.23% – 80.28%)	23,017 (15,755 – 29,173)	6,506 (5,501 – 7,100)	162,582 (128,420 – 263,690)	$445 ($298 - $522)

Abbreviations: CVCT = couples voluntary counseling and testing; ICER = incremental cost-effectiveness ratio; QALYs = quality-adjusted life year; SoC = standard of care
* Costs are measured using 2020 USD

Table: Cost-effectiveness of two testing scenarios in Zambia over a 10-year time horizon.

Conclusions: As countries like Zambia continue to improve upon their HIV programs, they may consider bolstering test-and-treat strategies in a cost-effective approach with CVCT, a WHO recommended strategy not yet scaled up in most African countries.

EPC150

Population-level impact of expanding PrEP coverage among men who have sex with men with long-acting injectable cabotegravir: model comparison analysis for Atlanta, US and Montreal, Canada

S. Stansfield[1], K.M. Mitchell[2], C.M. Doyle[3], R.M. Milwid[3], M. Moore[1], J. Heitner[4], D. Donnell[1], M. Maheu-Giroux[3], M.-C. Boily[2], D. Dimitrov[1]

[1]Fred Hutchinson Cancer Research Center, Seattle, United States, [2]Imperial College London, London, United Kingdom, [3]McGill University, Montreal, Canada, [4]University of Washington, Seattle, United States

Background: Long-acting injectable cabotegravir (CAB-LA) demonstrated superiority to daily oral tenofovir disoproxil fumarate/emtricitabine (TDF/FTC) for HIV pre-exposure prophylaxis (PrEP) in the HPTN 083/084 trials and is currently approved for HIV prevention in the United

States. We compared the potential impact of expanding PrEP coverage by offering CAB-LA to men who have sex with men (MSM) in Atlanta, US/Montreal, Canada, cities with different HIV epidemics.

Methods: Two age- and risk-stratified HIV transmission models were independently parameterised and calibrated to local data. Scenarios achieving 40% and 50% PrEP coverage after 5 and 10 years by switching 0%-50% of TDF/FTC users to CAB-LA in 2022 and recruiting additional CAB-LA users were simulated. Intervention impact was measured as the proportion of cumulative HIV infections averted over 20 years compared to base-case scenarios with TDF/FTC use only (median values presented).

Results: Model simulations predict that, in the base-case without CAB-LA, overall PrEP coverage in Atlanta/Montreal could reach 32%/10% by 2042 with HIV prevalence decreasing to 17%/2%. Achieving 40% PrEP coverage in 2027 by adding CAB-LA is expected to avert 37%-40% of new HIV infections over 20 years in Atlanta and 47% in Montreal (Figure).

Switching TDF/FTC users to CAB-LA (0% vs 50%) has a modest impact (~3 percentage points increase (pp)) in Atlanta with no clear effect in Montreal where base-case PrEP coverage is significantly lower.

Delaying achieving 40% coverage until 2032 reduces the impact by 4pp and 9pp in Atlanta and Montreal, respectively. Reaching 50% PrEP coverage in 2027 increases the impact in Atlanta by 16pp-18pp and by 8pp-10pp in Montreal compared to 40% coverage.

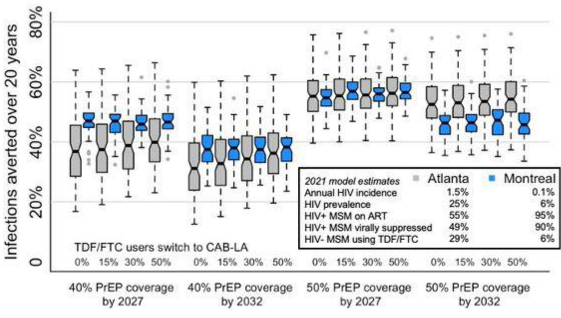

Figure. Proportion of infections averted with 40 or 50% PrEP coverage achieved in 2027 or 2032 in Atlanta (gray) or Montreal (blue). 0-50% of TDF/FTC users switch to CAB-LA. Both models used CAB-LA effectiveness and retention rates estimated from HPTN 083 data and setting-specific TDF/FTC effectiveness and retention.

Conclusions: Achieving high PrEP coverage by offering CAB-LA could impact the HIV epidemics substantially if rolled out without delays. Recruiting additional new CAB-LA users is expected to have a greater impact on preventing new HIV infections than switching current TDF/FTC users to CAB-LA.

EPC151
The role of HIV pre-exposure prophylaxis (PrEP) in reaching UNAIDS HIV incidence reduction goals among men who have sex with men (MSM) and transgender women (TGW) in Peru by 2030

A. Borquez[1], O.A. Elorreaga[2], K. Konda[2], J.V. Guanira[3], G. Calvo[2], S. Vargas[2], C.F. Cáceres[2]

[1]University of California San Diego, Medicine, La Jolla, United States, [2]Universidad Peruana Cayetano Heredia, Centro de Investigación Interdisciplinaria en Sexualidad, SIDA y Sociedad, Lima, Peru, [3]INMENSA, Lima, Peru

Background: UNAIDS called for a 90% reduction in HIV incidence by 2030 compared to 2010 levels and a 75% interim reduction by 2020. We set out to estimate observed and expected incidence reductions in 2020 and 2030, respectively, among MSM and TGW in Lima, Peru, using dynamic modeling.

We then used data from the ImPrEP demonstration project, which characterized PrEP uptake, retention and adherence among MSM and TGW in Peru, to model a PrEP intervention accordingly and estimate the PrEP coverage required to reach the UNAIDS goal by 2030.

Methods: Using a dynamic compartmental model of HIV transmission among MSM and TGW calibrated to HIV sentinel surveillance data among MSM/TGW in Lima from 1996 to 2019, we calculated the observed HIV incidence reduction between 2010 and 2020, as well as the expected reduction by 2030 in the absence of additional interventions.

We then used ImPrEP project data, which enrolled 781 MSM and 120 TGW in public sexual health clinics and an NGO in Lima from Jan/2018-Jan/2020, to parameterize a PrEP intervention in the model between 2022 and 2030 and estimated the coverage level required to achieve a 90% HIV incidence reduction by 2030.

Results: We found that compared to 2010, HIV incidence among MSM and TGW in Lima was 46.6% (95%CI: 36.3%-57.0%) lower in 2020. In the absence of additional interventions, it is expected to be 72.5% (95% CI: 60.7%-83.8%) lower in 2030, failing to achieve the UNAIDS goal.

A 50% PrEP coverage, mirroring ImPrEP patterns of use, maintained from 2022-2030, would lead to a 90.6% (95% CI: 84.3%-95.8%) HIV incidence reduction in 2030, or a 58% probability to achieve or exceed the 90% incidence reduction target.

Conclusions: Achieving the UNAIDS 90% HIV incidence reduction goal among MSM and TGW in Lima is feasible through providing PrEP to 50% of MSM and TGW between 2022-2030 in addition to current coverage of other HIV prevention and treatment interventions.

More strategic PrEP allocation by risk behaviors and implementation of HIV combination prevention packages, including further scale up of ART treatment as prevention, would reduce the required PrEP coverage.

EPC152

The population impact of herpes simplex virus type 2 (HSV-2) vaccination on HIV, HSV-2 and genital ulcer disease in South Africa: a mathematical modelling study

J. Stone[1], K.J. Looker[1], R. Silhol[2], K.M.E. Turner[3], S.L. Gottlieb[4], M.-C. Boily[2], P. Vickerman[1]
[1]University of Bristol, Bristol Medical School, Bristol, United Kingdom, [2]Imperial College London, MRC Centre for Global Infectious Disease Analysis, Department of Infectious Disease Epidemiology, London, United Kingdom, [3]University of Bristol, Bristol Veterinary School, Bristol, United Kingdom, [4]World Health Organization, Department of Reproductive Health and Research, Geneva, Switzerland

Background: South Africa (SA) has some of the highest rates of HIV and herpes simplex virus type 2 (HSV-2) infection worldwide. Biological and epidemiological evidence suggests that HSV-2 and HIV interact to affect acquisition and transmission risks.
We analysed the potential impact of HSV-2 vaccines on HIV and HSV-2 transmission and days with genital ulcer disease (GUD).
Methods: We extended an existing dynamic HIV transmission model for SA to include HSV-2 transmission, assuming thatHSV-2 increases HIV acquisition and transmission risk and that HIV increases rates of HSV-2 shedding and so transmission.
The model was parameterized and calibrated using demographic, behavioural and epidemiological data from national household surveys and key population surveys.
We estimated the impact over 2020-2060 of:
i. Cohort vaccination of 9-year-olds with a partially-effective prophylactic vaccine that reduces susceptibility to HSV-2 acquisition;
ii. Vaccination of symptomatically HSV-2 infected individuals with a partially-effective therapeutic vaccine that reduces asymptomatic and symptomatic shedding.
In baseline analyses, both vaccines were assumed to provide lifelong protection with degree-type efficacy.
Results: Prophylactic HSV-2 vaccination was projected to have a moderate to substantial impact on HSV-2/HIV incidence and GUD days, depending on efficacy and uptake. An 80% efficacious prophylactic vaccine with 80% uptake could reduce incidence of HSV-2, HIV and GUD days by 84.1% (95% Credibility Interval: 81.2-86.0), 65.4% (56.5-71.6), and 58.8% (52.6-62.8) over 40 years.
In contrast, much less impact on HIV/HSV-2 incidence is projected for a therapeutic vaccine. An 80% efficacious therapeutic vaccine which achieves a coverage of 60% among symptomatic individuals by 2040 could reduce incidence of HSV-2, HIV and GUD by 42.7% (32.0-55.8), 38.1% (28.0-51.7), 67.7% (63.2-73.7), respectively, after 40 years.
However, there are substantial differences in the number vaccinated for each scenario, with the impact per vaccination on HSV-2, HIV and GUD being approximately 3-times, 4.5-times, and 14-times greater for a therapeutic vaccine, respectively.
Conclusions: Prophylactic and therapeutic vaccines offer two contrasting but promising approaches for reducing the burden of HSV-2 infection and disease. Both vaccines could also have additional important impact on HIV.

Modelling the role of syndemics on the HIV epidemic

EPC153

The contribution of binge drinking and inequitable gender norms to HIV transmission in South Africa

L. Johnson[1], M. Kubjane[1], J. Ohrnberger[2], M. Tlali[1]
[1]University of Cape Town, Centre for Infectious Disease Epidemiology and Research, Cape Town, South Africa, [2]Imperial College London, School of Public Health, London, United Kingdom

Background: Binge drinking, inequitable gender norms and sexual risk behaviour are closely interlinked: binge drinking is strongly associated with casual and condomless sex, while inequitable gender norms are associated with male partner concurrency, binge drinking and male perpetration of intimate partner violence.
This study aims to model the potential effect of alcohol counselling interventions (in men and women) and gender-transformative interventions (in men) as strategies to reduce HIV transmission.
Methods: We developed an agent-based model of HIV and other sexually transmitted infections (STIs) in South Africa, allowing for effects of binge drinking on sexual risk behaviour, and effects of inequitable gender norms (in men) on sexual risk behaviour and binge drinking.
The model was calibrated using data from randomized controlled trials of alcohol counselling interventions (n=10) and gender-transformative interventions (n=4) in sub-Saharan Africa, using a Bayesian approach to identify the model parameters that give the best model fit to the trial outcome data.
The model was also calibrated to South African data on alcohol consumption and acceptance of intimate partner violence (to identify risk factors for inequitable gender norms). Binge drinking was defined as five or more drinks on a single day, in the last month.
Results: Binge drinking is estimated to be highly prevalent in South Africa (52% in men and 34% in women, in 2020). Over the period 1990 to 2021, binge drinking accounted for 2.9% of new HIV infections and 6.0% of incident curable STIs (gonorrhoea, chlamydia and trichomoniasis).
This was mediated mainly by an effect of binge drinking in women on engagement in casual sex (RR 1.63, 95% CI: 1.00-5.21). Inequitable gender norms did not significantly influence the incidence of either HIV or other STIs, despite

Author Index

a substantial effect of inequitable gender norm endorsement on alcohol consumption (RR 1.44, 95% CI: 1.00-2.33). A multi-session alcohol counselling intervention that reaches 50% of binge drinkers would reduce HIV incidence by 3.3%, over a 5-year period.

Conclusions: Although alcohol counselling and gender-transformative interventions are important in improving health outcomes, they are likely to have only modest effects on HIV incidence in South Africa.

Modelling future healthcare needs

EPC154

What is the best policy option for Indonesia to eliminate AIDS in 2030?: The Investment Case Analysis consideration

A.T. Endarti[1,2], W. Peerapatanapokin[3], L. Wahyuniar[4], L. Lanny[5], L. Sekarrini[6]

[1]*MH. Thamrin University, Central Jakarta, Indonesia,* [2]*Indonesia Public Health Association, East Jakarta, Indonesia,* [3]*East West Center, Hawaii, United States,* [4]*UNAIDS Indonesia, Central Jakarta, Indonesia,* [5]*National AIDS Program Ministry of Health, South Jakarta, Indonesia,* [6]*MH Thmarin University, Central Jakarta, Indonesia*

Background: HIV control in Indonesia is facing considerable challenges toward the global target of 95-95-95 in 2030. Acceleration programs must be done, and its resource need must be calculated. This activity aimed to calculate the Investment Case Analysis (ICA) of the potential scenario for the acceleration program.

Methods: ICA was calculated by the AEM and it was conducted through several activities.

First, gathering national data of the current behavioral, program, and funding data.

Second, conducting focused group discussion of the potential acceleration scenario and its target.

The informants consisted of the national HIV program, UNAIDS Indonesia, public health experts, academicians, and NGOs.

Results: There were five scenarios of acceleration program offered, namely National Baseline 2020, Scenario 90-90-90 in 2024, Scenario 95-95-95 in 2030, Fast Tract Scenario(95-95-95) in 2025, National Action Plan (NAP) Target and Funding Analysis Result Scenario. The fastest reduction in HIV incidence occurred in the fasttractscenario (95-95-95) in 2025, the 90-90-90 scenario in 2024, and the NAP scenario.

In terms of estimated deaths, the NAP scenario can reduce the HIV-AIDS-related mortality rate the fastest among other scenarios, from around 22,272 deaths in 2020 to 7,392 deaths in 2024. The total investment of this scenario was USD 3,218,391,000 or an increase of 154% from the baseline condition.

With this total cost, it is estimated that in 2030 there will be 187,929 deaths related to HIV/AIDS, 107,994 new preventable cases, and 9,009,324 DALYs that can be reduced. This scenario provides the highest return of investment (USD 19.61) compared to other scenarios.

Conclusions: It is recommended that the government of Indonesia consider the NAP scenario. An additional investment (USD 1,954,199,000 of 54% higher than the baseline) is required and two-thirds of this fund will be used for treatments. This recommendation is also officially written at the updated HIV Strategic National Action Plan.

Modelling the impact of service models on the HIV epidemic

EPC155

Closing the gaps in the continuum of depression care among persons with HIV: modeling the impact on viral load suppression in the United States

L.J. Koenig[1], N. Khurana[1], M.H. Islam[1], P.G. Farnham[1]

[1]*U.S. Centers for Disease Control and Prevention, Division of HIV Prevention, Atlanta, United States*

Background: Depression is prevalent among persons with HIV (PWH) and associated with decreased odds of medication adherence and retention in care, as well as increased risk for detectable viral load. Due to missed diagnoses, under-utilization of treatment, and inadequate treatment, only a small proportion of PWH have their depression effectively treated to remission. PATH (3.0), a dynamic, stochastic simulation model, was used to model the impact on viral load suppression (VLS) of (1) diagnosing all depression among PWH, and (2) treating depression among all PWH with depression.

Methods: We incorporated into PATH a multi-step depression care continuum whereby every PWH moves from getting diagnosed for depression if depressed, to getting treated for depression if diagnosed. We assumed a depression prevalence of 34.7% (DiPrete, et al., 2019) and modeled change over eight years. In the status quo scenario, 45% of PWH with depression were diagnosed with depression (Pence et al, 2012).

Of PWH diagnosed with depression, 55.3% were treated, and of those treated for depression, 33% achieved remission (DiPrete, et al, 2019). PWH with depression are less likely to attain and sustain viral suppression.

Compared to PWH without depression, we assumed the probability of being non-VLS changed by 1.57 times for PWH with depression, and by 0.95 times for PWH with remitted depression (Lesko, et al, 2021). The 'enhanced' scenario presumed that all depression among PWH was identified and treated, and the proportion of PWH with treated depression who achieved and maintained remission was 50% (Gaynes, et al., 2008).

Author Index

Results: Among the subgroup of PWH with depression, 75.9% had VLS in the enhanced scenario compared to 65.3% in the status quo scenario. Among all PWH, 74.1% had VLS in the enhanced scenario compared to 70.5% in the status quo scenario.

Conclusions: Fully diagnosing and adequately treating depression would result in a 5.1% increase in the proportion of all PWH who would have achieved VLS in 8 years without enhanced intervention (equating to approximately 42,892 additional PWH with viral suppression). These findings call attention to the importance of addressing mental health among PWH to improve health and prevention outcomes as well as quality of life.

EPC156

Testing strategies to achieve the goal of 95% knowledge of status by 2025

J. Stover[1], E. Korenromp[2]

[1]Avenir Health, Center for Modeling, Policy and Analysis, Glastonbury, United States, [2]UNAIDS, Strategic Information, Geneva, Switzerland

Background: The UNAIDS Global AIDS Strategy 2021-2026 aims to reach treatment cascade targets of 95-95-95 by 2025. We examined whether the target is achievable with current testing approaches and the impact of new strategies.

Methods: We developed a testing strategy model that divides PLHIV into 13 groups and examines effects of combining nine testing modalities, on numbers of tests, new diagnoses and cost. The model was applied to the global population, split into high- and low-prevalence countries in sub-Saharan Africa, and countries with concentrated epidemics.

Current testing patterns were compared against alternatives designed to increase yield by focusing on populations with the most undiagnosed PLHIV, use of high-yield testing approaches and risk assessment.

Results: Currently 140 million tests are conducted annually in LMIC excluding China, producing about 1.7 million new diagnoses, for a yield of about 1.2%. Reaching 95% knowledge of status (KOS) by 2025 requires nearly 3 million new diagnoses per year. In all three regions, current testing approaches will not reach 95% KOS. The target could be achieved by maximizing testing among people in contact with the health system, but this would require 15-fold increased test volumes. A focus on key populations improves yields but would not produce all the required additional diagnoses.

Two targeted approaches can increase yields enough to reach 95% KOS and lower testing volumes. Index testing (for partners of PLHIV) and social network approaches can achieve yields up to 20%, a typical 4-fold increase. Risk screening tools, to focus testing on those most likely infected, will miss some people but can increase yields 4-fold, to 10-25%, even in low-prevalence populations. Combining both approaches and complementing with universal access to HIV self-tests would reduce costs yet ensure access to testing for anyone who wants it.

Conclusions: Current testing approaches fall short of the target of 95% KOS by 2025. The target can be achieved with widespread implementation of index partner testing, social networking and risk assessment tools. Widespread availability of self-tests can help control costs for general population testing. Testing strategies need to be tailored to each context, but these concepts are key to cost-effective strategies.

Reaching and recruiting key populations for HIV prevention services (online, offline, online-to-offline)

EPC157

Comparing the characteristics of Brazilian gay, bisexual and other cisgender men who have sex with men (MSM) according to recruitment strategy: online approach as an useful tool during COVID-19 pandemic

T.S. Torres[1], E.M. Jalil[1], C.C.d.A. Pereira[2], D.R.B. Bezerra[1], A. Farias[3], J.D. Brito[4], M. Lacerda[5], D. Silva[6], G. Ribeiro[1], M. Rebouças[3], V. Casaroto[6], A. Barbosa[5], J. Cunha[4], J. Pimenta[4], M. Benedetti[1], C. Pimenta[7], B. Hoagland[1], B. Grinsztejn[1], V.G. Veloso[1], ImPrEP DCE Study Group

[1]Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz, Rio de Janeiro, Brazil, [2]Escola Nacional de Saúde Pública Sérgio Arouca, Fundação Oswaldo Cruz, Rio de Janeiro, Brazil, [3]Centro Estadual Especializado em Diagnóstico, Assistência e Pesquisa (CEDAP), Salvador, Brazil, [4]Hospital Dia Asa Sul, Brasília, Brazil, [5]Fundação de Medicina Tropical Doutor Heitor Vieira Dourado (FMT), Manaus, Brazil, [6]Centro de Testagem Aconselhamento (CTA) Santa Marta, Secretaria Municipal de Saúde de Porto Alegre, Porto Alegre, Brazil, [7]Ministério da Saúde do Brasil, Brasilia, Brazil

Background: Complementary recruitment strategies are necessary to reach heterogeneous populations. Online strategies may reach MSM engaging in HIV high-risk behavior, but may not reach hard to reach populations, such as MSM of younger age, lower income and living outside main urban areas. Social distancing measures during COVID-19 pandemic may preclude on-site strategies.

We aim to describe the applicability of different strategies to recruit Brazilian MSM for a pre-exposure prophylaxis (PrEP) survey during COVID-19 pandemic.

Methods: Cross-sectional study using on-site and online strategies to recruit self-reported HIV negative MSM aged ≥18years. On-site recruitment occurred in five PrEP/HIV services in all country regions: Manaus, Salvador, Brasília, Rio de Janeiro and Porto Alegre. Online recruitment accurred through advertisements on GSN dating apps (Hornet

and Grindr) to recruit MSM living in any Brazilian city. HIRI-MSM scale assessed HIV high-risk behavior. We compared the different recruitment strategies using chi-square test. Multivariate logistic regression models identified predictors of online recruitment among non-PrEP users.

Results: Through October/December-2020, 3553 participants were recruited, 2874 (80.9%) online and 679 (19.1%) on-site. Most of participants were from Southeast Brazil (67.2%). Compared to on-site sample, MSM self-identified as gay, older, white, with high education and high income were more frequently recruited online (Table).

	Total N=3553	On-site N=679	Online N=2874	p-value

High	2402 (49.5)	498 (73.3)	1904 (66.2)	
PrEP use				<.001
Never	2303 (64.8)	252 (37.1)	2051 (71.4)	
Current	1032 (29.0)	391 (57.6)	641 (22.3)	
Past	218 (6.1)	36 (5.3)	182 (6.3)	

HIRI-MSM: The HIV Incidence Risk for MSM Scale was calculated based on sexual behavior in the previous 6 months (number of partners, condomless receptive anal intercourse, sex with HIV-positive partner), age and use of stimulants; High risk ≥10 points; Low risk < 10 points).

Table.

Overall, 1032(29.0%) MSM were currently using PrEP (daily oral: 93.0%, injectable: 4.0%, on-demand: 3.0%). Among non-PrEP users, 62.0% engaged in HIV high-risk behavior. Non-PrEP users recruited online had higher odds of being gay (aOR:1.42 [95%CI:1.01-1.98]), white (aOR:2.11 [95%CI:1.59-2.82]), having higher education (aOR:3.46 [95%CI:2.53-4.75]), higher income (aOR:1.52 [95%CI:1.12-2.04]), living in Southeast Brazil (aOR:3.15[95%CI:2.34-4.22]) and willingness to use PrEP (aOR:2.56 [95%CI:1.91-3.44]). HIV high-risk did not differ per recruitment approach (aOR:0.92 [0.69-1.22]).

Conclusions: Online approach may replace in-person strategies during COVID-19 pandemic to recruit MSM engaging in HIV high-risk behavior in Brazil. Nevertheless, recruitment of socially vulnerable MSM would be lower if restricted to online strategies.

EPC158

Reaching the unreached: leveraging social media networks to recruit transgender men into HIV prevention research in Uganda

M. Bagaya[1], A. Mujugira[1], J.E. Haberer[2], V. Kasiita[1], T.R. Muwonge[1], A. Nakyanzi[1], T. Ssebuliba[1], O. Nampewo[1], R. Nsubuga[1], O. Sapiri[1], K.R. Nyanzi[1], F. Bambia[1], J. Mugisha[1]

[1]Infectious Diseases Institute, Makerere University, Research, Kampala, Uganda, [2]Massachusetts General Hospital, Boston, United States

Background: Transgender (trans) men in sub-Saharan Africa have mostly been ignored in HIV prevention research, resulting in a lack of data to inform HIV strategies, programming, and policy. Effective recruitment and retention strategies are needed to enhance their participation in biomedical research, which will help tailor public health programs to address the unmet health needs of this population.

Description: From January-October 2020, we conducted a cross-sectional evaluation of HIV and STI risk behaviors, prevention needs, and sexual decision-making among trans men using quantitative and qualitative methods. We recruited 50 trans men into this study through snowball sampling. Initial peer recruiters were identified by transgender-led community organisations and asked to recruit from their social networks.

Enrolled study participants were also requested to recruit from their networks. Peer recruiters introduced the study team to trans men social media groups on WhatsApp and Facebook, which were used to disseminate study information. Trans people were included in multiple aspects of study implementation.

Lessons learned: Hidden and under-researched populations, such as African trans men, can be meaningfully engaged in biomedical research despite significant social, cultural, and legal challenges. Key facilitators for fostering participation of trans men in research include incorporating social media and trans-inclusive approaches in community engagement, provider sensitization training, and inclusion of trans people as members of the community advisory group.

Feedback from quarterly community consultation meetings helped improve cultural sensitivity of study staff and create a friendly, welcoming clinic environment. Trans men welcomed the opportunity to engage in HIV prevention research and were passionate about study participation.

Initial fears by potential study participants about discrimination by healthcare providers and entrenched social stigma were addressed through real-time WhatsApp discussions moderated by the research team. Social media interactions provided a platform for discussing health needs of trans men and the study objectives.

Conclusions/Next steps: Trans men were successfully recruited in the first study to evaluate HIV/STI risk among this trans men in sub-Saharan Africa. Innovative peer-led

social media approaches can accelerate recruitment of populations perceived as 'hard to reach" into biomedical research that could positively impact their lives.

EPC159

Using online platforms to reach men who have sex with men (MSM) during the COVID-19 pandemic in Ghana

S.E. Owusu[1], C. Asamoah Adu[2], S.K. Wosornu[3], K.M. Diaba[4], C. Yalley[1]

[1]Maritime Life Precious Foundation, Programs, Takoradi, Ghana, [2]Ghana-West Africa Program to Combat AIDS and STIs (WAPCAS), Executive Directorate, Accra, Ghana, [3]Maritime Life Precious Foundation, Executive Directorate, Takoradi, Ghana, [4]Ghana-West Africa Program to Combat AIDS and STIs (WAPCAS), Programs, Accra, Ghana

Background: Men who have sex with men (MSM) in Ghana often face challenges accessing routine HIV prevention and testing services for reasons including stigma, discrimination, and societal exclusion.

During the COVID-19 pandemic, MSM faced greater challenges accessing HIV services because of factors such as social distancing policies which restricts large group outreaches; reduced uptake of services because of fear of transmission of COVID-19 in facilities; and the shift of health resources away from HIV to COVID-19 prevention and treatment services. In the era of COVID-19, the use of online platforms can help reach MSM with essential HIV services.

Description: Peer Educators and Nurses were trained to engage MSM for HIV outreach and referral through social networking platforms such as Facebook, WhatsApp, Grindr, etc. HIV prevention messages and short videos were developed and posted on selected social media platforms to raise awareness and promote HIV services.

MSM who accessed these platforms were engaged through a one-on-one interaction and online counselling with confidentiality assurance by the Peer Educators and Nurses.

MSM recruited were given different timed appointments to access in-person services at community Drop-In-Centers (DIC) and homes of peers at their own convenience.

Lessons learned: During the pandemic, online platforms helped to maintain contact with beneficiaries and reached new MSM using social media and online networking platforms. MSM were free to discuss sexual issues without fear of stigma.

Through the online interactions, a total of 603 new MSM were reached with HIV prevention information from March to July 2020. 198 (32%) MSM recruited online reported had not been tested for HIV within the last six months. 59% of MSM recruited reported they had engaged in inconsistent use of condoms for casual anal sex.

Additionally, among the MSM recruited online, 213 were linked for HTS and 32 were diagnosed HIV positive.

Conclusions/Next steps: Delivery of service using online networking platforms encourages broader inclusion, differentiated and tailored services among MSM. Hence, implementing partners can adopt it as an effective tool of linking testing and prevention services to MSM even after the pandemic. HIV organizations can invest in online interventions to reach MSM across a wide geographic range.

EPC160

Prevalence of HIV serodiscordant couples within TB-affected households in a setting with a high burden of HIV-associated TB

G. Anguzu[1,2], A.J. Gupta[3,4], E. Ochom[4], R. V. Barnabas[5,6], A. D. Flaxman[7], A. Katamba[8,4], J.L. Davis[9,10], J. M. Ross[11,12]

[1]Duke University, Social Science Research, Durham, United States, [2]Makerere University, Part Fellowship Fogarty International Center, Training Grant, Kampala, Uganda, [3]Yale School of Public Health, Department of Epidemiology of Microbial Diseases, New Haven, United States, [4]Uganda Tuberculosis Implementation Research Consortium, Kampala, Uganda, [5]Massachusetts General Hospital, Division of Infectious Diseases, Boston, United States, [6]Harvard Medical School, Boston, United States, [7]University of Washington, Institute for Health Metrics and Evaluation, Department of Health Metrics Sciences, Department of Global Health, Seattle, United States, [8]Makerere University College of Health Sciences, School of Medicine, Kampala, Uganda, [9]Yale School of Public Health, Center for Methods in Implementation and Prevention Science, New Haven, United States, [10]Yale School of Medicine, Pulmonary, Critical Care, and Sleep Medicine Section, New Haven, United States, [11]University of Washington, Department of Global Health, Seattle, United States, [12]University of Washington, Division of Allergy and Infectious Diseases, Department of Medicine, Seattle, United States

Background: Strong epidemiological links between HIV and TB may make household TB contact investigation an efficient strategy for HIV screening and finding individuals in serodiscordant partnerships at risk of HIV and linking them to HIV prevention services. We aimed to compare the prevalence of HIV serodiscordant couples in TB-affected households and in the general population of Kampala, Uganda.

Methods: We included data from a cross-sectional trial of HIV counselling and testing (HCT) in the context of home-based TB evaluation in Kampala, Uganda in 2016-2017. After obtaining consent, community health workers visited the homes of participants with TB to screen contacts for TB and offer HCT to household members ≥15 years.

We defined index patients and their spouses and parents of the same index patient as couples, and classified couples as serodiscordant if confirmed by self-reported HIV status or by HIV testing results.

Author Index

We used a two-sample test of proportions to compare the prevalence of HIV serodiscordancy among couples in the study to prevalence among couples in Kampala in the 2011 Uganda AIDS Indicator Survey (AIS).

Results: We included 323 index TB patients and 919 household contacts. Most index patients (55%) were male, while most (61%) contacts were female. HIV prevalence was 13.6%. There was ≥1 couple in 115/323 (35.6%) households, with most couples (98/116, 84.5%) including the index participant and spouse. Among these households, the prevalence of HIV-serodiscordant couples was 18/323 (5.6%), giving a number-needed-to-screen of 18 households.

The prevalence of HIV serodiscordancy was 18/116 (15.5%) among couples in the trial, which was significantly higher than among couples in the AIS (15.5% vs 8%, p=0.043).The 18 serodiscordant couples included 14 (77.8%) where the index patient was HIV-positive and the spouse was HIV-negative, and 4 (22.2%) where the index partner was HIV-negative, while spouse was HIV-positive.

Conclusions: The prevalence of HIV serodiscordancy among couples in TB-affected households was higher than in the general population. TB household contact investigation may be an efficient strategy for encountering people at substantial risk of HIV and linking them to HIV prevention services.

EPC161

Challenges in recruiting HIV-1 high risk adolescent girls and young women for HIV prevention research studies in rural settings in Uganda

J. Nabawanuka[1], T.R. Muwonge[2], Z. Lukyamuzi[1], M. Nabwana[1], J.V. Kasozi[1], D. Nabulumba[1], M.A. Lwanga[1], F. Matovu Kiweewa[1]
[1]*MUJHU Research Collaboration, Kampala, Uganda,* [2]*Infectious Diseases Institute, Kampala, Uganda*

Background: The rise in the number of new HIV infections remains unacceptably high among Adolescent Girls and Young Women (AGYW) with 6,000 AGYW being infected every week worldwide. Therefore, prevention trials aimed at developing different methods of preventing these infections should be a top priority. However**,** there are several challenges ineffectively recruiting AGYW in HIV prevention research.

In this abstract, we describe the challenges involved in recruiting AGWY in the SIENA study and the strategies we employed in addressing them.

Description: We set out to describe the challenges faced while recruiting AGYW in a crossectional survey that was aimed at assessing incidence rates among AGYW in Mityana/Mubende districts and near areas in Uganda.

We recruited from health centres and high risk places including lodges, bars, restaurants, energy drinks producing companies, gold mines and fishing areas. The level of risk was assessed by using a set of prescreening questions about alcohol use, nature of work, pre exposure prophylaxis use and recent sexual behavior capturing number of sexual partners and condom use.

Lessons learned: Of the 1029 AGYW pre-screened, 371 were screened and enrolled. The pre-screening: enrollment ratio was 3:1. A high proportion of potential participants pre-screened were not enrolled for various reasons; more than half, 54%, (N=555) could not be reached due to lack of access to mobile phones, the majority, 60%, (N=648) had busy work schedules, 10% (N=112) were intoxicated with alcohol, and 15%, (N=162) gave inconsistent information. Challenges included failure to disclose their true identity and high mobility rates as many who were prescreened shifted before their screening visit.

The mitigation strategies included; working with managers of the places they operate from, capturing common/most preferred names, flexibility of working hours, constant community sensitization, working with their peers and village health team members.

Conclusions/Next steps: Several challenges were encountered in recruiting AGYWs in an HIV incidence survey. A large number of AGYW needed to be prescreened in order to enroll the target sample size.

Our findings underscore the need for adopting client specific and flexible methods while recruiting AGYW in HIV prevention research studies. Community involvement is crucial to achieving these rates.

EPC162

Implementation of HPV vaccination among HIV-positive adolescent girls and young women aged 15 to 26 years old, in Gutu District, Zimbabwe

W. Ngwa[1,2], P. Manangazira[3], T. Mupepe[4], S. Kuchicha[4], K. Kuwenyi[5], A. Mafumo[6], M. Mandizvo[6], D. Garone[5], I. Panunzi[7], Y. Rono[5], R.O. Gutierrez[5], D. Some[5]
[1]*Médecins Sans Frontières, Medical, Kinshasa, Congo, Democratic Republic of the,* [2]*Atlantic Internal University, School of Science and Engineering, Honolulu, United States,* [3]*Ministry of Health and Child Care, Epidemiology and Disease Control, Harare, Zimbabwe,* [4]*Ministry of Health and Child Care, Harare, Zimbabwe,* [5]*Médecins Sans Frontières, Medical, Harare, Zimbabwe,* [6]*Médecins Sans Frontières, Medical, Gutu, Zimbabwe,* [7]*Médecins Sans Frontières, Medical, Brussels, Belgium*

Background: Cervical cancer is the second most common cancer among women in the developing world, and the largest cancer killer among women in most developing countries.In Zimbabwe, HPV vaccination of girls aged 9 to 13 years was approved in 2009 but was only implemented in 2014 when a demonstration project was initiated in two districts, targeting 10-year-old girls. The MOHCC had a target of 85% HPV vaccine coverage among girls aged 9-to-13 years, and the "Bridging" project conducted in three districts which broadened the target age group demonstrated this achievement to be possible.

This study was carried out to access the acceptability and feasibility of HPV vaccination among girls/young women aged 15-26 years old and living with HIV integrated into the HIV clinic model of care.

Methods: The study employed a prospective study design.The Cervarix HPV vaccine was given on a three-dose schedule at 0, 1, and 6 months to 816 eligible participants. Vaccine uptake and completion rates were monitored as well as site effects following immunization. Reasons for refusal/withdrawal by beneficiaries at each stage between recruitment and dose administration were captured. Opinions about challenges of implementation by nurses were also captured.

Results: HPV vaccine uptake rate was high;with a primary uptake rate of 90.6%(95%CI: 88.3%-92.5%), secondary uptake rate of 93.2%(95%CI: 91.2%-94.9%) and tertiary uptake rate of 85.5%(95%CI: 82.6%-88.0%). The 3-dose HPV vaccine completion rate was 79.7% (95%CI: 76.6%-82.5%) with a first to third dose dropout rate of 20.3% (95% CI:17.4%-23.4%). Site effects due the vaccine was very low. Only 1 in 100 participants reported aside effect.No severe adverse event was reported.

Acceptability of HPV vaccination integrated into HIV care was very high among both the health staff and participants. Integration of HPV vaccination into health staff workload was found to be feasible. There was a high-level knowledge about HPV vaccination among girls and young women aged 15-26 years living with HIV.

Conclusions: Implementation of HPV vaccination in rural settings and integration into HIV care seems to be feasible and well accepted by recipients and health staff. It is therefore highly recommended that HPV vaccination be integrated into the HIV clinic model of care and decentralised nationwide.

EPC163

"PrEP means that I have control over my health": preparate.pe as a virtual tool in the promotion of PrEP among MSM and TGW for the ImPrEP study in Peru

D.L. Adriazola Oquendo[1], D. Caviedes[1], F. Olivos[1], K. Konda[1], J. Vicente[1], J.P. Jiron[1], C. Cáceres[1], I.D. Study Group[1]

[1]*Universidad Peruana Cayetano Heredia, Interdisciplinary Research Center of Sexuality, AIDS and Society, Lima, Peru*

Background: The ImPrEP Study has been offering PrEP to MSM and TGW since 2018. In order to effectively promote PrEP use, we developed PrEParate.pe, a social media campaign to generate demand and provide accurate information. Using social media platforms (Facebook & Instagram), we established an interactive communication channel to support potential users. We analyzed the attitudes and perceptions about PrEP through interactions maintained in PrEParate.pe.

Methods: We carried out a systematic review of 770 interactions (MSM and TGW) through messages on Facebook and Instagram. The data was analyzed using an inductive thematic approach and focused on four aspects: Attitudes towards PrEP, reasons to use PrEP, frequently asked questions, and community communication channels. The data was collected between July 2018 and December 2021.

Results: Potential users showed positive attitudes towards PrEP, referring to it as an effective preventive method offering them greater control of their sexual health and as a great alternative for sero-discordant couples, reducing their fear of HIV. Some potential users expressed mistrust about PrEP effectiveness, and mentioned difficulties in coping with severe side effects and PrEP-related stigma.

Among their reasons for using PrEP, potential users reported self-perceiving a high risk of HIV that they wanted to reduce by controlling their sexual behaviors (i.e. multiple sex partners, condomless sex).

Also, they mentioned a preference for PrEP over condoms. Potential users were interested in information about PrEP, its use, cost, how to access it, effectiveness and side effects.

An important aspect for potential users was PrEP effectiveness (i.e. whether it replaces a condom or protects against HIV and STIs). Finally, their introduction to PrEP had been through friends' recommendations and through health centers.

Conclusions: There were mostly positive attitudes towards starting PrEP. Potential users described it as a self-care matter, while certain concerns related to effectiveness and side effects represented barriers to uptake.

Reasons to use PrEP were linked to sexual health awareness, high self-perceived HIV risk and the search for alternative protection methods.

The most frequently asked questions were related to PrEP cost and coverage. Finally, they stated that their awareness of PrEP was a product of their social environment.

EPC164

Increasing uptake of PrEP through community distribution: the case of a CSO in Western Region of Ghana

M. Owusu[1], A. Dambesa[1], S. Wosornu[1], E. Owusu[1], H. Tagoe[2], L. Gold[2], K. Eifler[2]

[1]*Maritime Life Precious Foundation (MPLF), Monitoring, Evaluation and Research, Sekondi-Takoradi, Ghana,*
[2]*JSI Research & Training Institute, Inc., USAID Ghana Strengthening the Care Continuum Project, Takoradi, Ghana*

Background: PrEP is a very efficacious tool for HIV prevention among key populations. However, this is dependent on its availability, accessibility, uptake and usage. While initial PrEP Policy in Ghana required that it should be delivered only at the health facility, this was not in sync with international best practice of multiple delivery channels, and led to low uptake.

As a pioneering CSO in HIV service provision for key populations (KPs) in Ghana, Maritime Life Precious Foundation (MLPF) piloted a community based service delivery model for PrEP.

Description: MLPF, a sub- grantee CSO of the JSI-led USAID Strengthening the Care Continuum project, provides HIV services including PrEP to key populations in the Western region of Ghana. Within the period of April to June 2021, MLPF introduced community distribution of PrEP in its outreach activities by adding a team of trained nurses responsible for PrEP to the already existing HTS outreach team. KPs who test positive are put on ART and those testing negative are referred to the PrEP team for PrEP initiation at the same venue. This approach was carried out in two of the project sites.

Lessons learned: Within the first six months (October 2020 to March 2021) of facility distribution of PrEP, before the introduction of community distribution, only 179 clients were initiated on PrEP across all our implementing sites. In contrast, the new community-based delivery channel which was carried out within the period of three months (April to June 2021) saw 330 clients initiated on PrEP.

From the figures above, MLPF has achieved 184% increment in PrEP initiation within a shorter period which suggests that community distribution is gaining acceptance among the target population and it should be replicated across other project sites.

Conclusions/Next steps: Community based distribution of PrEP is very effective and should be employed to compliment the facility based initiatives. Implementing partners should not limit PrEP to health facilities only but consider more delivery channels such as community distribution. Results of this case study have intrinsic benefits for the review of national PrEP policy.

Demonstration and pilot projects for prevention (including PrEP, PEP, male circumcision)

EPC166

Association of post-traumatic stress disorder symptoms with sexual behaviour and PREP preferences among young people in South Africa, Uganda and Zimbabwe

E. Webb[1], J. Dietrich[2], A. Ssemata[3], T. Nematadzira[4], S. Hornschuh[2], N. Ahmed[5], G. Tshabalala[2], R. Muhumuza[3], M. Atujuna[6], M. Abas[7], H. Weiss[1], J. Seeley[3], L. Stranix-Chibanda[4], J. Fox[7]

[1]London School of Hygiene and Tropical Medicine, London, United Kingdom, [2]University of the Witwatersrand, Johannesburg, South Africa, [3]MRC/UVRI and LSHTM Uganda Research Unit, Entebbe, Uganda, [4]University of Zimbabwe, Harare, Zimbabwe, [5]Central North West London NHS Trust, London, United Kingdom, [6]University of Cape Town, Cape Town, South Africa, [7]King's College London, London, United Kingdom

Background: It is not known whether post-traumatic stress disorder (PTSD) increases HIV-risk behaviours among young people in sub-Saharan Africa. We assessed associations of self-reported PTSD symptoms with sexual behaviour, HIV risk perception, and attitudes towards PrEP among young people taking part in the CHAPS community survey.

We hypothesised that PTSD symptoms would increase sexual behaviours associated with HIV risk, hinder PrEP uptake and lead to a preference for daily over on demand PrEP.

Methods: Young people without HIV, aged 13-24 years, were purposively recruited in Johannesburg and Cape Town in South Africa, Wakiso in Uganda, and Chitungwiza in Zimbabwe, and surveyed on socio-demographic characteristics, PrEP knowledge and attitudes, sexual behaviour, HIV perception and salience, and mental health. PTSD symptoms were measured using the Primary Care PTSD Screen for the Diagnostic and Statistical Manual of Mental Disorders 5 (PC-PTSD-5); participants with PC-PTSD-5 ≥3 were classified as having symptoms consistent with PTSD. Logistic and ordinal logistic regression was used to assess associations between PTSD symptoms and socio-demographic characteristics, sexual behaviour, HIV risk perception, PrEP attitudes, and substance use, adjusting for age, sex, setting, depression and anxiety.

Results: Of 1,330 young people (51% male, median age 19 years), 254 (19%) had symptoms consistent with PTSD. PTSD symptoms were more common in females (adjusted OR 1.68, 95%CI 1.27-2.22) and in older participants.

There was strong evidence that PTSD symptoms were associated with reported forced sex (OR 3.62, 95%CI: 2.22-5.90), self-perception as a person who takes risks (OR 1.53, 95%CI: 1.16-2.01), and increased frequency of thinking about risk of HIV acquisition (OR 1.70, 95%CI: 1.29-2.24).

PTSD symptoms were not associated with willingness to take PrEP, preference for on-demand versus daily PrEP, or actual HIV risk behaviour such as condomless sex.
Conclusions: PTSD symptoms were common among young people in South Africa, Uganda and Zimbabwe but did not impact risk behaviour, PrEP attitudes or PrEP preferences. However, evaluation for PTSD might form part of a general assessment in sexual and reproductive health services in these countries. More work is needed to understand the impact of PTSD on HIV-risk behaviour, forced sex and response to preventive strategies including PrEP.

EPC167

Feasibility and safety of estrogen ring and/or probiotics for improving vaginal health in African/Caribbean/Black women: results from a prospective, randomized, open-label, phase I trial (CTN 308)

C. Hayes[1], J. Ratcliffe[1], J. Wokuri[2], G. Reid[3,4,5], R. Kaul[6,7,8], J. Rana[2], M. Alkhaifi[2], W. Tharao[2], F. Smaill[9,10], C. Kaushic[1]
[1]*McMaster University, Medicine, Hamilton, Canada,* [2]*Women's Health in Women's Hands Community Health Centre, Toronto, Canada,* [3]*Western University, Microbiology & Immunology, London, Canada,* [4]*Western University, Surgery, London, Canada,* [5]*The Lawson Health Research Institute, Canadian Research and Development Centre for Human Microbiome and Probiotics, London, Canada,* [6]*University of Toronto, Immunology, Toronto, Canada,* [7]*University of Toronto, Medicine, Toronto, Canada,* [8]*University Health Network, Medicine, Toronto, Canada,* [9]*McMaster University, Pathology and Molecular Medicine, Hamilton, Canada,* [10]*McMaster University, Michael G. DeGroote Institute for Infectious Disease Research, Hamilton, Canada*

Background: Vaginal inflammation, diminished *Lactobacillus*colonization and increased microbiota diversity (dysbiosis) are associated with increased risk of HIV infection. Studies indicate that ~40% of African/Caribbean/Black (ACB) women have dysbiotic vaginal microbiota.
To determine if probiotics and intravaginal estrogen are acceptable and safe interventions to improve vaginal health in pre-menopausal ACB women, a prospective, randomized, open-label, intervention phase I trial (CTN 308; clinicaltrials.gov NCT03837015) was conducted.
Methods: Pre-menopausal ACB women aged 18-49 from the Toronto area were enrolled and baseline samples collected. Participants were randomized to: low dose intravaginal estradiol (Estringâ; 7.5mg/day), a twice daily vaginal probiotic (RepHreshä Pro-Bä; 1x10^{7} cfu total of *L. rhamnosus*GR-1 and *L. reuteri* RC-14 per capsule), or a combination of oral or vaginal probiotic with Estring for 30 days. Participants returned a week after intervention for final assessment. Enrolment, retention, and intervention protocol (IP) adherence rates were calculated to assess trial feasibility. Adverse events (AEs) and blood markers were monitored to evaluate safety.
Results: Between November 2019 and December 2021, 63 ACB women were screened, 51 (81%) enrolled, and 41 completed the study (80% retention of enrolled).
Enrolment and retention rates met or exceeded targets of 70% and 80%, respectively. During the study, 6 (12%) participants withdrew consent, 4 (8%) withdrew due to IP non-compliance, and 1 (2%) was lost to follow up.
Of those that completed the study, IP adherence was high among all treatment groups, with an overall Estring adherence rate of 94% (12% SD, IQR 93%-100%) and an overall probiotic adherence rate of 91% (13% SD, IQR 87%-100%).
A total of 92 AEs were reported by 29 (57%) participants, 66 (72%) of which were mild in intensity and 86 (93%) resolved by the end of the study. No severe AEs were reported, and no clinically significant blood marker changes were observed.
Conclusions: Enrolment, retention and adherence rates demonstrate low dose intravaginal estrogen and/or twice daily probiotics are well tolerated interventions. Most AEs were mild and short-term, and no severe AEs occurred.
Overall, administration of intravaginal estrogen and/or twice daily probiotics are safe, acceptable interventions. Analysis of biological samples will determine whether interventions augmented vaginal Lactobacillus colonization.

EPC168

Between- and within-individual sociodemographic and behavioural determinants of daily PrEP use and adherence among men who have sex with men in Wales

D. Gillespie[1], M. de Bruin[2], D. Hughes[3], R. Ma[4], A. Williams[1], F. Wood[5], Z. Couzens[6], A. Jones[6], K. Hood[1]

Background: The transient nature of HIV risk means measuring adherence to PrEP requires concurrent measures of medication use and potential risk exposure. Investigating determinants of non-adherence to PrEP using a definition which incorporates both enables identification of individuals who may be at risk of non-adherence and drivers that may be amenable to intervention. The aim of this work is to investigate the determinants of PrEP use and adherence among daily PrEP users in Wales.
Methods: This was a secondary analysis of an ecological momentary assessment study of individuals accessing oral PrEP through sexual health clinics in Wales, UK. Daily

PrEP use was ascertained via electronic monitors and daily condomless sex via brief web surveys. Participants were defined as adhering to their daily PrEP regimen when condomless anal sex (CAS) was preceded by at least three days of daily PrEP and followed by at least two days of daily PrEP. We fitted multilevel logistic and multinomial logistic regression models for PrEP use and adherence respectively.

Results: Data for PrEP use were available for 50 participants covering 5,463 person-days and for PrEP adherence 49 participants covering 4,728 person-days. All participants were cisgender male, majority identified as White British, and the median age was 35 years.

Participants were predominantly single (77%), gay (93%), and having sex exclusively with other men (98%). Participants took PrEP on 68% of observed days (3,695/5,463 days). Over 384 reported CAS episodes, daily PrEP regimens were adhered to 54% of the time (207/384 CAS episodes). Key determinants of daily PrEP use were age, chronic health condition, prior experience with PrEP, STI diagnoses, PrEP-related stigma, and components of the extended theory of planned behaviour (ETPB, capacity, intentions, self-regulatory processes, action planning, anticipated regret). Key determinants of PrEP adherence were STI diagnosis, HIV risk perceptions, and components of ETPB (behavioural norms, autonomy, action planning, and anticipated regret).

Conclusions: Our finding highlight key determinants of daily PrEP use and adherence. Different determinants may imply a need to focus on considering PrEP use within the context of risk episodes when identifying individuals at risk of non-adherence and designing intervention to optimise PrEP adherence.

EPC169
Characteristics associated with PrEP pilot program participation among MSM in the Netherlands

D. Sarink[1], J.C.M. Heijne[1], E. Hoornenborg[2], F. de la Court[2], F. van Aar[1]
[1]National Institute for Public Health and the Environment (RIVM), Centre for Infectious Disease Control, Bilthoven, Netherlands, the, [2]Public Health Service Amsterdam, Department of Infectious Diseases, Amsterdam, Netherlands, the

Background: Dutch Sexual Health Centers (SHC) have been offering pre-exposure prophylaxis (PrEP) and associated care to individuals at high risk for HIV infection since August 2019, as part of a five-year pilot program with a maximum capacity of 8,500 participants. In this interim evaluation we investigated whether the PrEP-pilot program enrolled men who have sex with men (MSM) at highest risk for acquiring HIV.

Methods: Between July 2019 and August 2021, 97,866 consultations were completed among 42,508 MSM at 24 SHCs. We selected the first PrEP consultation for MSM participating in the PrEP-pilot program as cases. Controls were selected as the first consultation among MSM who were eligible for (HIV-negative, recent anal STI/syphilis diagnosis or condomless anal sex), but not participating in, the program.

We used logistic regression models adjusting for the eight SHC regions (strata) to calculate odds ratios (OR) and 95% confidence intervals (CI) for associations between demographic and behavioral factors and program participation.

Results: This study includes 7.952 cases and 23.369 controls. Cases were significantly older than controls, less likely to be Dutch, and more likely to have more sexual partners in the past six months, to have had chemsex (GHB/GBL, mephedrone, or crystal meth use before or during sex) in the past six months, and to be sex workers (p chi^2 for all: <0.0001).

In mutually adjusted models, we observed associations with program participation for age (≥45 vs 18-24 OR 1.90 [CI 1.73-2.09]), migration background (non-Dutch western OR 1.14 [CI 1.06-1.23] and non-western OR 1.49 [CI 1.39-1.60] vs Dutch), number of partners (≥10 vs 0-2 OR 2.17 [CI 2.01-2.34]), chemsex (yes vs no OR 2.66 [CI 2.48-2.84]), and sex work (yes vs no OR 1.94 [CI 1.68-2.25]). Education was the only factor not associated with program participation (low/medium vs high, OR 0.98 [CI 0.92, 1.03]).

Conclusions: Our results show that the PrEP-pilot program reaches MSM with higher risk behaviors, as well as key demographic groups. However, younger MSM are less likely to participate.

Future efforts should be made to ensure that PrEP care in the Netherlands reaches young MSM, which may help to maximize population health benefits.

EPC170
Barriers and facilitators to uptake and retention on PrEP among key and priority populations in Southern Province, Zambia

K. Stoebenau[1], C. Bwalya[2], S. St-Onge Ahmad[1], G. Muchanga[2], M. Simuyaba[2], L. Gwanu[2], M. Mwamba[2], M. Mwale[2], C. Peters[1], S. Toussaint[1], I. Kafunda[3], L. Mwango[3], S. Shiyanda[3], H. Sakala[3], S. Nsanganya[3], J. Mukuka[2], A. Chilambe[2], S. Malupande[2], N. Mugwira[3], J. Okuku[4], M.-C. Lavoie[5], R. Sheneberger[5], C. Claassen[5]
[1]University of Maryland School of Public Health, Behavioral and Community Health, College Park, United States, [2]Maryland Global Initiatives Corporation, Lusaka, Zambia, [3]Ciheb Zambia, Lusaka, Zambia, [4]U.S. Centers for Disease Control and Prevention, Lusaka, Zambia, [5]Center for International Health, Education, and Biosecurity, University of Maryland School of Medicine, Baltimore, United States

Background: While PrEP holds promise for HIV prevention, studies have found high rates of early discontinuation among many sub-populations in sub-Saharan Africa; including within a demonstration trial in Zambia (2017-2019)

with key populations (KPs) and priority populations (e.g., men who have sex with men (MSM); female sex workers (FSW); members of sero-discordant couples (SDC)). In Zambia, PrEP is now widely available in government clinics, but few studies have assessed the determinants of PrEP use in this setting.

This qualitative study aims to address the facilitators and barriers to uptake and retention among targeted populations, and serves as the first such assessment with these groups in Zambia.

Methods: In 2021, we conducted semi-structured interviews (n=43) and focus groups (n=4) with providers (facility-based healthcare workers and community health workers) and potential PrEP clients (SDCs, MSM, FSW) from a clinic in Southern, Zambia.

Purposively sampled participants were stratified by sub-population and level of experience with PrEP including those who were invited, but never initiated on PrEP; initiated, but discontinued within 3 months; and continued on PrEP for 3+ months.

A research team coded resulting narrative data. Codes captured the individual, interpersonal, healthcare, and community barriers and facilitators to PrEP uptake and retention.

Results: Many barriers to uptake and retention were shared across group. The single greatest barrier was the anticipated stigma of being perceived as HIV-positive and on ART. This perception was reinforced at the community-, interpersonal- (family, partner implications), and individual level (barrier to accessing PrEP at the clinic).

Other barriers included PrEP side-effects (perceived/experienced); misinformation from peers or family members about PrEP (e.g., it causes cancer, infertility); anticipated or experienced stigmatization at the clinic due to one's identity as a KP, particularly acute for MSM; and logistical barriers including distance and wait times.

Facilitators for use include peer and partner support, strongest for MSM, high motivation to remain HIV free, and community-based delivery of care.

Conclusions: There are ongoing barriers to PrEP uptake and retention among KP in Zambia, many of which are centered around stigma. Future programmatic interventions would benefit from mitigating these barriers as they scale up PrEP.

EPC171

Delays to PrEP initiation among female sex workers in Côte d'Ivoire (ANRS 12381 PRINCESSE project)

M. Plazy[1], M. Nouaman[2,3], V. Becquet[4,5], A. Agoua[6], C. Zebago[6], H. Dao[6], P.A. Coffie[2,7], S. Eholie[2,7], J. Larmarange[5]

[1]Bordeaux Population Health Research Center, Université de Bordeaux, Inserm, IRD, Bordeaux, France, [2]PAC-CI, Abidjan, Cote D'Ivoire, [3]Université Félix Houphouet-Boigny, Département de Santé Publique, UFR d'Odonto-Stomatologie, Abidjan, Cote D'Ivoire, [4]Ined, Paris, France, [5]Ceped, IRD, Université de Paris, Inserm, Paris, France, [6]ONG Aprosam, San Pedro, Cote D'Ivoire, [7]Université Félix Houphouet-Boigny, Département de Dermatologie et Infectiologie, UFR des Sciences Médicales, Abidjan, Cote D'Ivoire

Background: To describe the delays to initiation of oral pre-exposure prophylaxis (PrEP) among female sex workers (FSW) in Côte d'Ivoire.

Methods: The ANRS 12381 PRINCESSE project is a single-arm interventional cohort aiming to evaluate the implementation of a comprehensive and community-based care offer among FSW aged ≥18 years in the San Pedro region since end-2019, through a mobile clinic operating on 10 prostitution sites (visited every two weeks). PrEP is offered to all HIV-positive FSW after verifying the creatinine level (results valid for one month).

We described the time between FSW's interest for PrEP and PrEP initiation (or end of follow-up) among HIV- and hepatitis B virus-negative (HBsAg-) FSW included until end-October 2021. The probability of PrEP initiation since PrEP interest is described through a Kaplan-Meier curve censored on end-November 2021 (an analysis censored at the date of the last visit was also conducted).

Results: Of the 362 FSW included in the PRINCESSE cohort, 302 were HIV-/AgHBs-, and for 296 of them, PrEP was presented by medical staff (95.2% at inclusion). In total, 292 FSW expressed PrEP interest, and 192 (65.8%) initiated PrEP: 18 on the same day (the biological test having been performed during a previous visit), 148 during the next visit (median time since interest: 3 weeks [Inter-Quartile Range: 2-6]) and 26 during a subsequent visit (median time: 20 weeks [9-36]). The probability of PrEP initiation after PrEP interest was 39.0% at 1 month and 56.6% at 3 months (censoring on the date of the last visit, these proportions were 50.7% and 74.6%, respectively). Among the 100 FSW who did not initiate PrEP despite expressing interest, 68 were never seen again in the project; 4 declared that they were no longer interested in PrEP (median time since interest: 12 weeks [10-19]), 1 was tested HIV+ (delay of 2 weeks), and 27 were seen >1 month later (their biological tests were no longer valid).

Conclusions: Despite strong PrEP interest among FSW, PrEP initiation remained suboptimal. Barriers to PrEP initiation should be more explored and considered to find appropriate solutions to make PrEP effective among this specific key population.

EPC172

The PrEP care continuum among men who have sex with men and transwomen: ImPrEP Mexico

S. Aguilera-Mijares[1], A. Martínez-Dávalos[1], S. Bautista-Arredondo[1], H. Vermandere[1]
[1]*National Institute of Public Health of Mexico, Cuernavaca, Mexico*

Background: To succeed, pre-exposure prophylaxis (PrEP) programs need to promote adequate levels of PrEP awareness, acceptability, uptake, adherence, and retention (i.e., engagement in the PrEP care continuum) among people with high HIV risk. Mexico implemented a PrEP demonstration project (ImPrEP) targeting two key populations: men who have sex with men (MSM) and transwomen (TW).

This study's goal was to describe the perceptions and experiences related to the PrEP care continuum of MSM and TW, and to identify barriers and facilitators for scaling up PrEP services.

Methods: From June to July 2020, online semi-structured interviews were conducted with MSM and TW: PrEP users, ex-users, and potential users (screened, but not enrolled). Through purposive sampling, these profiles were balanced by sexual identity (MSM/TW), age, and education level. The interviews underwent a directed content analysis to identify factors per step of the PrEP care continuum.

Results: Ten users, six ex-users and eight potential users (fourteen MSM and ten TW) were interviewed.

Awareness: MSM commonly learned about PrEP and ImPrEP during HIV testing. TW mainly did so through informative talks about PrEP and TW associations, but knowledge gaps persisted.

Acceptability: Participants principally wanted to start PrEP because of its HIV protection during risky sex behaviors. However, potential users expressed doubts about wanting PrEP due to its potential side effects (e.g., interacting with hormonal treatment, for TW).

Uptake: Potential users missed their enrollment visit for varied reasons (e.g., work/school, the distance, forgetting, and COVID-19) and did not know how to reschedule.

Adherence: Users and ex-users overall reported taking PrEP adequately, yet some mentioned barriers like fear of side-effects, routine changes, and PrEP-related stigma.

Retention: Ex-users quit ImPrEP services, mostly without reducing their HIV risk, due to fearing the medication's effects and difficulties keeping their trimestral appointments.

Conclusions: The PrEP care continuum's barriers must be addressed for PrEP's scale-up to be effective. Awareness activities are crucial to reach persons who do not attend health services and to dispel PrEP myths, especially among TW, as misconceptions can diminish PrEP acceptability, adherence, and retention. PrEP services should also offer a more flexible schedule to facilitate uptake and retention.

EPC173

Adherence, safety, and feasibility of HIV pre-exposure prophylaxis among adolescent men who have sex with men and transgender women in Brazil

I. Dourado[1], F. Soares[1], L. Magno[2], L. Amorim[3], M. Eustorgio[1], D. Greco[4], U. Tupinambás[4], A. Grangeiro[5], and The PrEP1519 Brazil Study Group
[1]*Federal University of Bahia, Collective Health Institute, Salvador, Brazil,* [2]*State University of Bahia, Department of Life Sciences, Salvador, Brazil,* [3]*Federal University of Bahia, Department of Statistics, Salvador, Brazil,* [4]*Federal University of Minas Gerais, School of Medicine, Belo Horizonte, Brazil,* [5]*University of São Paulo, Department of Preventive Medicine, São Paulo, Brazil*

Background: Despite reports of worrisome trends in HIV incidence among men 15-19 years old (yo) in Brazil the country does not yet have PrEP guidelines for adolescents. Thus, we aimed to evaluate the adherence, safety, and feasibility of PrEP in real-world settings among adolescent men who have sex with men (aMSM) and transgender women (aTGW).

Methods: PrEP1519 is a single-arm, demonstration cohort study of daily TDF/FTC as PrEP among aMSM/aTGW aged 15-19 yo. It is ongoing in Brazil and eligible are those HIV uninfected, at high risk of HIV, and with no risk of kidney and liver damage. Follow-up data is from February 2019-February 2021 (96 weeks). Study visits occurred at baseline, weeks 4, 12, and then quarterly. Demographic/sociobehavioural data were collected by a questionnaire. A mixed logistic model for longitudinal data evaluated the factors associated with high adherence, measured by medication possession ratio (i.e., MPR ≥ 1).

Results: The intention-to-treat population included 684 adolescents enrolled in PrEP, who initiated PrEP on the same day. Most MSM (91.9%), 18-19 yo (80.8%), self-identified as black/brown (69.7%). There was no significant increase in creatinine clearance and two participants had grade III TGO-AST. Incident HIV infection occurred in nine participants (overall incidence rate (IR)= 1.85 per 100 person-years (PY); 95%CI: 0.64–3.05): 4 in 15-17 yo (IR= 4.46 per 100 PY; 95%CI: 0.07–8.85) and 5 in 18-19 yo (IR= 1.26 per 100 PY; 95%CI: 0.15–2.36).

Multivariate analysis showed that MPR ≥ 1 was higher among those in a lover like relation (OR=1.31; 95%CI: 1.08–1.57), who perceived themselves at high risk of an HIV infection (OR=1.35; 95%CI: 1.02–1.67), and among aMSM (vs. aTGW) (OR=1.22; 95%CI: 0.84–1.79).

Conclusions: IR was higher among young adolescents enrolled in PrEP. But, lower when compared to an IR of 7.78% among MSM and TGW aged 30 years or less tested in Rio de Janeiro. PrEP adherence seems lower among aTWG, indicating the need for greater monitoring and care for TGW. Effective PrEP use must consider that adolescents are dynamic and fluid and, therefore, continually adapt to their context to improve adherence to PrEP.

EPC174

Contingency management for integrated harm reduction among methamphetamine-using MSM in Los Angeles: a pilot assessment

J. Clark[1], S. Shoptaw[2], C. Blades[2], M. Gandhi[3]
[1]University of California, David Geffen School of Medicine, Medicine/Infectious Diseases, Los Angeles, United States, [2]University of California, David Geffen School of Medicine, Center for HIV Prevention and Treatment Studies (CHIPTS), Los Angeles, United States, [3]University of California, School of Medicine, Medicine/Infectious Diseases, San Francisco, United States

Background: Methamphetamine (MA) use is associated with HIV acquisition and transmission among men who have sex with men (MSM). Contingency Management (CM) is effective in reducing frequency of MA use and of accompanying sexual risk behaviors, but has not been used to support adherence to biomedical HIV prevention.

We conducted a pilot trial of the logistics and feasibility of a combined CM intervention to reduce MA use and improve PrEP/ART adherence among MSM in Los Angeles.

Methods: Enrollment was limited to MSM currently using MA (verified by urine drug screen), not seeking addiction treatment, and prescribed a Tenofovir (TFV)-based regimen for HIV prevention or treatment (verified by demonstration of medication or prescription). Participants were randomly assigned to receive incentives for MA abstinence or medication adherence, and to a monitoring schedule of 2 or 3 visits per week.

Monitoring visits included motivational interviewing and urine testing for presence of MA metabolites and TFV. An escalating scale of incentives (range: $3-27 USD) was provided for either absence of MA or presence of TFV in urine, according to randomization arm. Participants answered questions about drug use and sexual behavior at each visit and reported their satisfaction with the intervention at the final visit.

Results: We enrolled 22 MSM (median age: 37; IQR: 28-45), 14 living with HIV. Three HIV-uninfected participants were excluded after not attending any post-enrollment visits. Remaining participants attended 96.2% (77/80) of scheduled visits in the 2x/week arm and 78.7% (85/108) in the 3x/week arm. During Follow-up, MA was detected in 89.1% (57/64) of samples in the MA-incentive arm and 91.2% (73/80) of samples from participants receiving TFV adherence incentives. TFV was detected in 78.1% (50/64) and 95.0% (76/80) of samples in the MA and TFV arms, respectively. Among 16 participants completing the exit survey, 81.2% (13/16) described themselves as "Very Satisfied" or "Extremely Satisfied" with the CM program.

Conclusions: A combined CM model using twice-weekly visits for MA-using MSM is feasible and potentially effective as an integrated harm reduction strategy among MA-using MSM. While we observed limited reductions in MA use, targeted incentives were associated with a high frequency of PrEP/ART adherence, assessed via objective metrics.

EPC175

An evaluation of the HIV risk screening and enrollment process in Mexico's pre-exposure prophylaxis demonstration project— the ImPrEP study

H. Vermandere[1], G. Martínez-Silva[1], S. Aguilera-Mijares[1], A. Martínez-Dávalos[1], S. Bautista-Arredondo[1]
[1]National Institute of Public Health of Mexico, Cuernavaca, Mexico

Background: Pre-exposure prophylaxis (PrEP) programs need to identify and enroll persons with high HIV risk (HHR) to achieve an impact. Consequently, Mexico's PrEP demonstration project (ImPrEP) seeked to offer PrEP to two key populations: men who have sex with men (MSM) and transwomen (TW). Our study aimed to assess whether the project succeeded in identifying and enrolling MSM and TW with HHR.

Methods: MSM and TW were screened at four ImPrEP sites by filling in a questionnaire about HIV risk factors. HHR was defined by reporting at least one of four criteria: condomless anal sex (CAS), transactional sex, a partner living with HIV, or a sexually transmitted infection (STI).

In order to verify whether the four criteria effectively identified HHR, a score was composed based on the four HHR criteria and compared with seven other reported risk behaviors through Poisson modelling.

In addition, among persons at HHR, we assessed the proportion of those enrolled, lost-to-follow-up (LTFU), and excluded (not considered at sufficient risk according to the staff, despite the HHR).

Finally, through logistic models we compared the sociodemographics and sexual behaviors of those enrolled with those LTFU and with those excluded.

Results: A total of 2,518 candidates were screened (2,417 [96%] MSM and 101 [4%] TW). Only 137 (5%) did not report any of the four HHR criteria. The Poisson modelling confirmed that a higher score based on the four HHR criteria was associated with other risk factors, such as more male partners (coef=0.24) and more insertive CAS (coef=0.16). As for those at HHR, 1,701 (72%) were enrolled, 351 (15%) were LTFU, 247 (10%) were excluded, and 82 (3%) had medical contraindications.

The odds of being excluded were higher for those reporting a sex partner living with HIV (adjusted odds ratio [aOR]=2.53). The odds of being LTFU were lower for those older than 25 years of age (aOR=0.73), yet higher for TW (aOR= 5.56).

Conclusions: The four HHR criteria were useful to identify and enroll individuals at HHR, yet evaluating risk takes more than asking four questions. Strategies are needed to keep those with higher vulnerability (TW and young persons) from being LTFU.

EPC176

Socio-demographics, risk and eligibility of MSM clients accessing PrEP services through a pilot model using telemedicine in India

A. Royal[1], D. Naren[2], R. Rinku[2], V. Rai[2]
[1]YRG CARE, PrEP & STI Consultant, New Delhi, India, [2]YRG CARE, Sexual Health Manager, Yes4Me, New Delhi, India

Background: Pre-Exposure Prophylaxis (PrEP) has become an integral part of comprehensive HIV prevention package. There is a limited access of PrEP services to MSM population in India. This abstract presents the socio-demographics, risk & eligibility assessment of MSM clients who received PrEP services though a pilot telemedicine model in India.

Methods: The e-case sheets and e-prescriptions of the clients who received PrEP services between June 2020 – December 2021 were retrieved, and identifiers were removed. The data on socio-demographics and risk and eligibility assessment was extracted from these documents and analyzed in MS Excel 365.

Results: A total number of 243 MSM from 37 districts received PrEP services through this virtual service delivery model. Out of 243, three accessed these services for their female partners as a means of safer conception (discordant couples) and 240 for HIV prevention.

Of 240 clients, 20% were youth and 80% aged between 25 – 62 years; 86.25% were never married to a female and 3/5thself-identified as 'Gay'. Only 6.67% were monogamous but reached out for PrEP due to involvement with a risky partner. 64.2 % of the clients reported to be involved in receptive anal sex with a consistent condom usage in 60% clients only.

Of total clients, 12%, 30% and 9% reported to indulge in ‚*chem'* sex and have a treatment history of STDs & availed PEP following a high-risk exposure respectively. One-tenth of the clients was not eligible to use PrEP due to various reasons namely risky exposure in last 72 hours (n=19, eligible for PEP), not at risk (n = 4) and HIV reactive (n = 1). 7% of the eligible clients were further eligible to use PrEP on-demand.

Conclusions: Delivering PrEP services through telemedicine could be an effective strategy to reach out to hidden MSM population. There is a need to explore the scalability, and cost effectiveness of delivery of these services to MSM population through telemedicine in India.

EPC177

PrEP and telemedicine in times of COVID-19: experiences of health professionals in Mexico

A. Cruz-Bañares[1], A. Rojas-Carmona[1], A. Martínez-Dávalos[1], S. Aguilera-Mijares[1], S. Bautista-Arredondo[1], H. Vermandere[1]
[1]National Institute of Public Health, Cuernavaca, Mexico

Background: ImPrEP Mexico was a pre-exposure prophylaxis (PrEP) demonstration project offering PrEP for populations at high HIV risk. To provide continuity of PrEP services during the first year of the COVID-19 pandemic, telemedicine strategies were adopted to reduce face-to-face on-site attendance and risk of contagion.

This study's goal was to document experiences and lessons learned among ImPrEP health professionals using tele-counselling, as to determine the acceptability of such strategies and the willingness to continue to use them post-COVID19.

Methods: In May 2021, we conducted 16 online interviews with health professionals from the 4 ImPrEP implementation sites located in Mexico City, Guadalajara, and Puerto Vallarta. We used a semi-structured interview guide to explore the seven dimensions posed by the Theory of Acceptability (affective attitude, burden, perceived effectiveness, ethicality, intervention coherence, opportunity costs, and self-efficacy). Interviews were audio recorded, with prior informed consent, and were subsequently transcribed and coded using the software Atlas.ti.

Results: All the interviewed professionals had carried out telemedicine strategies. Their experience was mediated by the pandemic context, available technological infrastructure and logistics, as well as by their personal disposition, attitudes, knowledge and previous experience. They perceived this strategy as appropriate strategy for specific user groups. They perceived benefits from telemedicine such as the reduction of the risk of COVID19-infection and the diminished time in terms of transfers, duration of sessions and waiting times.

Amongst its barriers, they mentioned the impossibility of physical examinations and the difficulty for users to acquire medicines using prescriptions received electronically. They also perceived that the implementation could lead to economic, work, and emotional burdens, may violate personal privacy, and can hinder the therapeutic relationship.

Conclusions: Telemedicine strategies are a tool that can facilitate PrEP access for specific groups of users (e.g., with telephone access). It is necessary to consider it as a complement or as part of a hybrid model alternating both face-to-face and virtual care.

To enhance benefits and guarantee success, requirements include clear implementation guidelines, providing up-to-date electronics devices, guaranteeing adequate Internet connectivity and infrastructure, and strengthening the skills of professionals and users for using this form of care.

EPC178

PrEP on the street: broadening prevention strategies for the most vulnerable populations in the city of São Paulo

C. M. M. Noguti[1], A. Q. Silva[1], M. S. Oliveira[1], A. P. M. Silva[1], S. M. Rodrigues[1], L. Pinheiro[1], C. L. Soares[1], R. F. Camargo[1], M. C. Abbate[1]
[1]*Coordination of STI/Aids of the Municipal Health Secretariat, São Paulo, Brazil*

Background: In Brazil, the HIV/AIDS epidemic is concentrated in a few population segments that account for the majority of new infection cases, such as gays and other men who have sex with men (HSH), trans people and sex workers and young people. These populations not only present a bigger risk of contracting HIV, they are also often subjected to situations of discrimination, targets of stigma and prejudice, increasing their vulnerability to HIV/Aids.

Therefore, for the strategy of pre-exposure prophylaxis (PrEP) to be effective, it is necessary that the public health system lowers the barriers for access to these populations, and welcome them fully and ensure their rights to quality health care.

Description: In order to reach a larger share of a population that a lot of times don't arrive to the health services, the Coordination of STI/Aids of the Municipal Health Secretariat, started offering PrEP in mobile units, named "PrEP on the Street" broadening the possibilities of prevention strategies performed during its outreach work.

Following the criteria defined in the Clinical Protocol and Therapeutic Guidelines for Pre-Exposure Prophylaxis of Infection Risk (PCDT PrEP) point of care creatinine tests and rapid HIV tests are performed before the dispensation of PrEP.

Lessons learned: In 2021, 14 events of the project *PrEP na Rua* took place, with 468 people beginning prophylaxis, 14 Post Exposure Prophylaxis (PEP), 896 rapid HIV tests were performed and 6 thousand self-testing kits were distributed. It was observed that the offering of PrEP in mobile units expands the access to the prevention strategies to the populations that often don't arrive at the health services. In the same year for the 4th consecutive year the city of São Paulo managed to reduce the number of new HIV cases.

Conclusions/Next steps: With the "PrEP on the Street" events, it was observed a high demand and user acceptance, mostly gays and HSH, which demonstrates the importance of executing these activities outside of healthcare units, in alternative hours and on weekends. Of the people who began PrEP in this project, 63% followed up with the prophylaxis.

EPC179

Characterising heterosexual men's demand for and uptake of pre-exposure prophylaxis (PrEP) for HIV prevention in South Africa

L. Rambally Greener[1], S. Malone[1], S. Mabaso[2], N. Hasen[1]
[1]*Population Services International, HIV / TB, Johannesburg, South Africa,* [2]*Foundation for Professional Development, Johannesburg, South Africa*

Background: While most PrEP programs focus on reaching men having sex with men, high-risk heterosexual men may also benefit from PrEP. We piloted a project to increase awareness of PrEP among heterosexual men and then provide it to them through private clinics, with the aim of assessing their demographic and behavioural characteristics, interest in PrEP, and experience of PrEP use.

Methods: Data were collected as part of an ongoing demonstration project in Johannesburg, South Africa. Community health workers engaged men on the street to discuss PrEP and link them to services. Private doctors then provided HIV testing and PrEP at no cost to clients. Routine intake and monitoring data were collected by community health workers as well as 10 participating practices from September 2021 (ongoing).

We analysed data in StataIC to summarize relevant clinical, demographic, and behavioural characteristics. Research activities were approved by the Foundation for Professional Development Research Ethics Committee (FPDREC).

Results: Demand creation reached 20,201 people. Among those reached, 19.8% had ever heard of PrEP, 91.9% were interested in learning more, and 56.3% were interested in trying PrEP. Within three months, 552 men had been initiated on PrEP. Of those, 59% were between ages of 25-39 years, and 47% were employed. Only 12% reported consistent condom use, with 24% never using condoms, and 61% using them inconsistently. 72% reported having more than one sexual partner in the past three months, with 45% reporting three partners or more. Alcohol use was reported by 64% and drug use by 11%. 48% percent of eligible clients had returned for a PrEP refill by end of the reporting period and 63% of those initiated were current users.

Conclusions: Early results of this study show low awareness of PrEP among heterosexual men but high interest once aware. Roughly three-quarters reported multiple sexual partners and inconsistent or no condom use, against a high background prevalence of HIV, making them good candidates for PrEP.

Uptake and continuation rates were high, even with minimal follow-up support provided. Targeting high-risk heterosexual men with PrEP could have both individual and population-level benefits.

EPC180

Effectiveness of a culturally tailored HIV Prevention intervention in promoting PrEP among Black women in community supervision programs in New York City: a randomized clinical trial

T. McCrimmon[1], D. Goddard-Eckrich[2], N. El-Bassel[2], A. Dasgupta[2], K. Bond[3], K. Johnson[4], A. Richer[2], M. Chang[5], T. Hunt[2], E. Wu[2], L. Gilbert[2]
[1]Columbia University, Mailman School of Public Health, New York, United States, [2]Columbia University, Social Work, New York, United States, [3]The City College of New York, New York, United States, [4]University of Alabama, Social Work, Tuscaloosa, United States, [5]Columbia University, School of Social Work, New York, United States

Background: In the U.S. there is a significant racial and gender disparity in the uptake of pre-exposure prophylaxis (PrEP).Despite Black cisgender women experiencing a disproportionate burden of HIV acquisition, they are four times less likely to have initiated PrEP than their non-Hispanic white women. Few PrEP uptake interventions focus on cisgender women, and none have targeted women in community supervision programs (CSPs), which predominately serves Black women.
Advancing an effective PrEP intervention for Black women in CSPs holds great promise for reducing inequities in PrEP uptake and increasing HIV prevention among this vulnerable group.
Methods: We conducted a randomized clinical trial among 352 eligible Black women recruited from CSPs in NYC (probation, parole, alternative-to-incarceration programs) with a recent history of drug use. Participants were randomized to either E-WORTH (N=172) or an HIV testing control (N=180).
E-WORTH participants received a 5-session, culturally-tailored, group-based HIV prevention intervention plus HIV testing; Control participants received HIV testing alone. Both conditions were delivered by Black female staff at a large CSP. We evaluated the effectiveness of the E-WORTH intervention on increasing awareness, intention and use of PrEP.
Primary outcomes included: awareness of PrEP as a biomedical HIV prevention strategy, willingness to use PrEP and PrEP use over the prior 12-month period.
Results: A total of 336 participants women tested HIV negative at baseline and therefore were considered PrEP-eligible and included in this sample.
Compared to control participants, E-WORTH participants had significantly greater odds of being aware of PrEP as a biomedical HIV prevention strategy (AOR=3.25, 95% CI=2.01- 5.25, p<.001) and indicating a willingness to use PrEP (b= 0.19, 95% CI=0.001-0.38, p=.049). No significant difference between conditions was found with respect to PrEP use, which was low in both conditions.
Conclusions: These findings suggest the effectiveness of a culturally-tailored intervention for Black women in CSP settings in increasing awareness, willingness, and intention to initiate PrEP. The low uptake of PrEP in both arms may be due to lack of access, but also may highlight the need for providing more robust PrEP-on-demand strategies (e.g., PrEP telemedicine) during the intervention rather than linkage to a PrEP provider.

Demand creation for PrEP use

EPC181

PrEP demand creation can attract higher risk individuals and be a gateway to other HIV services in Ghana

T. Lillie[1], A. Amedzi[2], G. Nunoo[2], G. Sorensen[3], P. Sowah[3], C. Asamoah-Adu[4], K. Diaba[4], P.K. Thakur[1], C.F. Walker[1]
[1]Family Health International (FHI) 360, District of Columbia, United States, [2]Family Health International (FHI) 360, Accra, Ghana, [3]West Africa AIDS Foundation, Accra, Ghana, [4]Ghana-West Africa Program to Combat AIDS and STIs (WAPCAS), Accra, Ghana

Background: The PEPFAR- and USAID-funded Meeting Targets and Maintaining Epidemic Control (EpiC) project implemented pre-exposure prophylaxis (PrEP) for the first time in Ghana.
The purpose of the program was to initiate higher risk men who have sex with men (MSM), female sex workers (FSWs), and transgender individuals on PrEP to reduce HIV acquisition.
Description: PrEP was implemented in six health facilities in the Greater Accra and Ashanti regions from October 2020 to September 2021. Key-population-led community-based organizations (CBOs) utilized social media and online networks to conduct demand creation activities and were not physically present in hot spots or gathering places.
Once clients were reached through social media, peer educators referred them for eligibility screening at the facility or mobile clinic. HIV testing was provided for the first time during the screening process.
Screening included a behavioral risk assessment, HIV test, and a review of possible acute infection or recent exposure to HIV. If an individual had a recent HIV exposure, post-exposure prophylaxis (PEP) was recommended.
We reviewed the PrEP screening through initiation cascade, and used a chi-square test to determine if there were differences in PrEP eligibility between FSW and MSM/TG.
Lessons learned: There was a high demand for PrEP among all KP (Table 1); however, it was found that a higher portion of MSM and TG were not able to start PrEP because of being HIV+ or other ineligibility criteria compared to FSW (Table 1).
A chi-square test of independence showed that KP type was associated with PrEP eligibility (p<.001).

	FSW	MSM & TG
Screened for PrEP	975	567
HIV+	9	65
Case Finding	0.91%	11.5%
Referred/Initiated on PEP	3	13
Total Ineligible for PrEP • including PEP • including HIV+	25	79
% Ineligible	2.6%	13.9%
Eligible for PrEP	950	488
Initiated on PrEP	867	462
Chi-square	p<.001	

Table 1: PrEP Cascade—screening to PrEP initiation

Conclusions/Next steps: There was high demand for PrEP services among higher risk MSM but were ineligible due to being HIV positive, or having another ineligibility criteria, which demonstrates the need for expanded HIV prevention services. PrEP offers an opportunity to reach individuals who may not otherwise seek services.

EPC182

Changes in awareness and willingness to use pre-exposure prophylaxis (PrEP) among men who have sex with men (MSM) in Latin America between 2018 and 2021: results from the ImPrEP project

T.S. Torres[1], H. Vega-Ramirez[2], K. Konda[3], O.A. Elorreaga[3], C. Guillén-Díaz-Barriga[2], D. Diaz[2], B. Hoagland[1], J.V. Guanira[3], M. Benedetti[1], C. Pimenta[4], H. Vermandere[5], S. Bautista-Arredondo[5], V.G. Veloso[1], C.F. Caceres[3], B. Grinsztejn[1], ImPrEP Study Group

[1]Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz, Rio de Janeiro, Brazil, [2]Instituto Nacional de Psiquiatria Ramon de la Fuente Muñiz, Mexico City, Mexico, [3]Universidad Peruana Cayetano Heredia, Centro de Investigaciones Interdisciplinaria en Salud, Lima, Peru, [4]Ministério da Saúde, Brasilia, Brazil, [5]Instituto Nacional de Salud Pública (INSP), Mexico City, Mexico

Background: Although daily oral PrEP was recommended by WHO for HIV prevention since 2015, PrEP availability is still limited in Latin America. The ImPrEP project aimed to generate evidence on the feasibility, acceptability, and cost-effectiveness of PrEP among MSM and transgender women in the context of the Public Health Systems of Brazil, Mexico, and Peru. Educational campaigns on social media have been promoted during ImPrEP to increase PrEP awareness and create demand.

This study aims to compare awareness and willingness to use PrEP among MSM collected during two ImPrEP formative surveys.

Methods: We conducted two online surveys among MSM aged ≥18 years living in Brazil, Mexico and Peru during the first (2018) and last (2021) year of ImPrEP. Participants were recruited on Grindr, Hornet and Facebook/Instagram. Awareness of PrEP was accessed with the question: "Have you ever heard of PrEP?" (yes/no). We used a 5-point Likert scale to assess willingness to use PrEP with the statement: "I would use a daily pill for PrEP". Responses options were dichotomized: yes="highly likely" and no=other responses. We used chi-square tests to verify changes in frequency of awareness and willingness to use PrEP between 2018 and 2021 by country.

Results: A total of 19,487 MSM were included in 2018 and 13,476 in 2021. Characteristics of participants per country and year are described in Table. PrEP awareness increased in all countries: Brazil (68.6% to 94.1%; *p*<.001), Mexico (64% to 82.7%; *p*<.001) and Peru (46.5% to 77.1%; *p*<.001). Willingness to use PrEP increased in Brazil (62.5% to 67.4%; *p*<.001), slightly decreased in Mexico (70.1% to 68%;*p*=.02), and did not change in Peru (57.6% to 58%;*p*=.84).

	Brazil		Mexico		Peru	
	2018 N=11,367	2021 N=8302	2018 N=5934	2021 N=4398	2018 N=2156	2021 N=1046
Age (year)						
18-24	3222 (28.3)	922 (11.5)	1766 (29.8)	911 (20.7)	889 (41.2)	423 (40.4)
25-35	5364 (47.2)	3808 (47.4)	2991 (50.4)	2202 (50.1)	970 (44.5)	475 (45.4)
>35	2780 (24.6)	3302 (41.1)	1177 (19.8)	1285 (29.2)	297 (13.8)	148 (14.2)
Race						
White	5999 (52.8)	4561 (56.8)	Not available	717 (18.8)	408 (19.6)	121 (11.6)
Black/Mixed-race	5363 (47.2)	3471 (43.2)		3090 (81.2)	1672 (80.4)	925 (88.4)
Education						
≤ secondary	4378 (38.9)	2594 (32.3)	1395 (23.6)	1259 (28.6)	461 (21.7)	326 (31.2)
> secondary	6876 (61.1)	5438 (67.7)	4516 (75.4)	3139 (71.4)	1663 (78.3)	720 (68.8)

Table.

Conclusions: PrEP awareness among MSM increased in Brazil, Mexico, and Peru, and ImPrEP educational campaigns may have contributed to this finding.

However, willingness to use PrEP increased only in Brazil. The availability of PrEP at no cost as a public health policy in Brazil and limited access to PrEP in Mexico and Peru may explain these disparities.

EPC183

Profiles of Pre-Exposure Prophylaxis (PrEP) modality preferences among Brazilian, Mexican and Peruvian Sexual and Gender Minorities (SGM)

K. Konda[1], O. Elorreaga[1], T.S. Torres[2], H. Vega-Ramirez[3], C. Guillén-Díaz-Barriga[3], D. Diaz[3], B. Hoagland[2], J.V. Guanira[4], M. Benedetti[2], S. Bautista-Arredondo[5], V.G. Veloso[2], C.F. Caceres[1], B. Grinsztejn[2], for the ImPrEP Study Group

[1]Universidad Peruana Cayetano Heredia, Centro de Investigación Interdisciplinaria en Sexualidad, Salud, y SIDA, Lima, Peru, [2]Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz (INI-Fiocruz), Rio de Janeiro, Brazil, [3]Instituto Nacional de Psiquiatria Ramon de la Fuente Muñiz, Mexico City, Mexico, [4]Inmensa, Lima, Peru, [5]Instituto de Salud Pública (INSP), Mexico City, Mexico

Background: Daily oral PrEP is highly effective for HIV prevention, yet its use remains limited in Latin America. Additionally, adherence difficulties compromise its effectiveness. The efficacy/effectiveness of other PrEP modalities have been demonstrated.

We analyze the characteristics associated with willingness to use four PrEP modalities: daily oral, event-driven, monthly oral, and injectable.

Methods: A cross-sectional online survey was conducted from April-August 2021 among sexual/gender minorities (SGM) aged 18+ years. Participants were asked to report their willingness to use PrEP modalities and to assume equal effectiveness and availability. Willingness was assessed using a 4-point Likert scale combining *Likely* and *Very likely* as 'willing'. We conducted multivariate Poisson regression estimating prevalence ratios to determine differences in willingness to use each PrEP modality. Models were developed for each PrEP modality, including age, country, race, education, income, HIRI-risk score (combining sexual risk and substance use), HIV testing, and HIV risk perception variables.

Results: Among 35,541 individuals who initiated the survey, 24,573 were eligible. Mean age was 33.4 years (Brazil: 64.9%; Mexico: 27.8%; Peru: 7.4%. Most were cisgender men (95.8%) and had >secondary education (66.2%). Most were willing to use: monthly oral (74.6%), daily oral (66.1%), and injectable (60.4%), while only 38.1% were willing to use event-driven PrEP. Across modalities, willingness to use PrEP was higher with increased HIV risk perception. Willingness was higher in individuals deemed high-risk (HIRI-score>=10) and lower among Peruvian respondents for all modalities except event-driven PrEP. Mexicans and Peruvians reported higher willingness for event-driven PrEP compared to Brazilians. Higher-income and education were associated with higher willingness for monthly and injectable PrEP only.

	Daily oral aPR (95% CI)	Event-driven aPR (95% CI)	Monthly oral aPR (95% CI)	Injectable aPR (95% CI)
Income (effect of an additional minimum wage per month)	0.99 [0.98,1.00]	1.00 [0.94,1.06]	**1.01 [1.00,1.02]**	**1.01 [1.00,1.02]**

HIV test >6 months (Ref. ≤6 months)	**1.05 [1.00,1.09]**	1.05 [0.99,1.11]	1.01 [0.97,1.05]	**1.12 [1.07,1.17]**
Bolding indicates statistical significance at p-value<0.05; all models were adjusted for age, race, sex work, and self-reported STI diagnosis.				

Table: Characteristics Associated with Preferred PrEP Modalities among an online sample of MSM and TGW from Brazil, Mexico and Peru

Conclusions: Higher willingness to use monthly oral and injectable PrEP indicates preference for long-acting formulations among SGM in Latin America. Research is needed to address the gaps in knowledge of prevention modalities and help potential users choose the available PrEP modality that fits their needs.

Community interventions to reach Adolescent Girls and Young Women (AGYW) supporting Pre-Exposure Prophylaxis (PrEP) initiation and continuation in Rwanda

M. Ribakare[1], M. Mutabazi[2], P. Mugwaneza[2], C. Makufa[3], E. Kuhlik[4], C. Ndikubwimana[1], M.R. Kayirangwa[1], S. Kelbert[5]
[1]Jhpiego, Kigali, Rwanda, [2]PACT, Kigali, Rwanda, [3]PACT, Leeds, United Kingdom, [4]PACT, Washington, United States, [5]Jhpiego, Baltimore, United States

Background: While Rwanda has nearly reached the 95-95-95 goals, adolescent girls and young women (AGYW) remain disproportionately affected by HIV: prevalence among AGYW and their male counterparts is 0.5% vs 0.3% [10-14 years], 0.8% vs 0.4% [15-19] and 1.8 vs 0.6% [20-24] (2018 Rwanda PHIA). Since 2018, Rwanda has used PrEP as an HIV prevention choice for AGYW, female sex workers, men who have sex with men and discordant couples at substantial risk of HIV infection.

Though PrEP is initiated at facility level, community interventions are critical for success through demand creation, education, identification and referral of at-risk AGYW, and follow up.

Description: ACHIEVE Rwanda, a USAID- and PEPFAR-funded project, had implemented DREAMS activities in two Kigali City districts since October 2020. Through two local partners: YWCA and DUHAMIC-ADRI, ACHIEVE serves 24,974 AGYW (10-24 years) with HIV prevention education and services; and PrEP interventions (education, demand creation, community screening, referrals to health facilities, and adherence counseling) targeting AGYW age 18+ who are sexually active and at risk of HIV infection.

From October 2020-September 2021, 5,145 HIV-negative AGYW were screened and 668 (13%) were found at risk of HIV and referred to health facilities for PrEP eligibility screening and initiation.

Sixty percent (402; 23% [18-19], 72% [20-24], 5% [24-29]) were eligible and initiated PrEP. The project, through training, coaching, and mentoring, prepared 159 DREAMS mentors to deliver community PrEP services.

Lessons learned: Mentors facilitate PrEP community interventions through the safe space model for demand creation and community screening; effective linkage and coordination with health facilities; community adherence support; and routine engagement with AGYW.

This strategy contributed to PrEP initiation among AGYW with a continuation rate of 94% and 91% respectively at one- and three-months' post-initiation.

Mentors further support those who discontinued PrEP, empowering them to use other prevention measures and reinitiate PrEP when needed.

Conclusions/Next steps: Community HIV prevention interventions capacitating and engaging mentors have shown contribution to PrEP strategy implementation through demand creation, identification, referral, adherence counseling, and community follow-up.

EPC185

Successful experience using PrEP champions to boost PrEP enrollment for Key Populations at a newly opened men's clinic in Port-au-Prince, Haïti

M. Leonard Galbaud[1], E.J. Pericles[1], V. Jean-Pierre[1], E. Emmanuel[1], G. Galbaud[1], E. Michel[1], J.W. Domercant[1], D. Dure[2]

[1]Institut pour la Santé, la Population et le Développement, Petion-Ville, Haiti, [2]United States Agency for International Development Haiti (USAID), Tabarre, Haiti

Background: PrEP is a highly effective HIV prevention tool which, when used properly, reduces rates of HIV transmission and acquisition by more than 90% notably in high risk populations. Oral daily PrEP was introduced in Haiti in March 2019 and progressively integrated as a component of a combined HIV prevention package.

Through USAID funding, ISPD implemented a men's clinic where PrEP was included as part of a comprehensive and complete package of HIV prevention, care and treatment in March 2020.

Description: To increase client enrollment on PrEP especially in the MSM population, we adopted a peer led approach using MSM clients as PrEP champions. In May 2021, from a pool of clients already on PrEP at the men's clinic, three MSMs were selected for their communication skills and their adherence to both site visits and PrEP. They received an 8-hour training course using adapted versions of national curricula covering topics such PrEP, HIV and other STIs.

The PrEP champions were to report to the site twice weekly for onsite patient education and client referrals. Their goal was to increase awareness and enrollment on PrEP among their peers through onsite and community level sensitization.

Lessons learned: Since the implementation of PrEP Champions, when compared to the previous 6 months (October-April 2021), the men's clinic experimented 84% increase for MSM counselling for PrEP (from 88 to 162), 109% increase for MSM interest for PrEP (from 74 to 155), 129% increase for MSM enrollment on PrEP (from 42 to 96), and 34% increase for overall enrollment on PrEP (from 131 to 176). The high risk 20-29 age group saw 80% increase (from 59 to 106) during the studied period (May-September 2021).

The men's clinic created the demand for PrEP in a high-risk group which also led to an overall increase in PrEP enrollment; the site is now ranking fifth in terms of PrEP enrollment nationwide.

Conclusions/Next steps: We will scale up this peer led demand creation and community engagement strategy throughout our network using a population specific PrEP Champion approach to boost PrEP enrollment per category of population at risk.

EPC186

A conjoint analysis of injectable PrEP preferences among young sexual minority men

J. Bauermeister[1], R. Drab[1], P. Valente[2], D. Teixeira da Silva[3], W. Lin[1], L. Hightow-Weidman[4], K. Mayer[5], K. Biello[2]

[1]University of Pennsylvania, Family and Community Health, Philadelphia, United States, [2]Brown University, Providence, United States, [3]University of Pennsylvania, Philadelphia, United States, [4]University of North Carolina - Chapel Hill, Chapel Hill, United States, [5]Fenway Health & Beth Israel Deaconess Medical Center/Harvard Medical School, Boston, United States

Background: With the recent approval of injectable cabotegravir for Pre-Exposure Prophylaxis (PrEP) and in preparation for large-scale rollout, it is essential to obtain end-user perspectives.

In a conjoint experiment, ATN 141a (Next Choices) evaluated young men who have sex with men's (YMSM; ages 15-24) acceptability of a PrEP injectable.

Methods: We enrolled 150 HIV-negative YMSM in the United States in an online conjoint experiment. As part of the conjoint experiment, YMSM selected between random sets of product profiles using 6 features (delivery: provider vs self-injected; duration of protection: 1, 2, 4, 6 and 12 months; prevention efficacy: 50%, 65%, 80%, 95%, and 99% efficacious; potential side effects: none, soreness at injection site, fever, fatigue, nausea, and weight gain; cost per month in US dollars: $0, $25, $50, $100, $150). A subset of participants completed a follow-up in-depth-interview (IDI; n=10) to discuss their product preferences.

Results: Efficacy was the most important feature in a PrEP injectable (39%), followed by cost (20%), side effects (20%), duration of protection (18%), and mode of delivery (3%). We then estimated YMSM's willingness to pay for a PrEP injectable, considering the trade-offs between features (see Table 1).

Feature		Willingness to Pay (in $USD)
Delivery	Provider Self-injected	$0 -$12.20
Duration of protection	1 month 2 months 4 months 6 months 12 months	$0 $37.30 $57.20 $95.80 $122.70
Efficacy	50% 65% 80% 95% 99%	$0 $69.10 $170.70 $250.80 $290.70
Side Effects	None Soreness at injection site Fever Fatigue Nausea Weight gain	$0 $-27.50 -$46.40 -$41.30 -$54.10 -$132.50

Notes. Willingness to pay are computed within feature; negative values in $USD indicate YMSM's desire for a lower cost in the presence of a given element of the feature

Table 1. YMSM's willingness-to-pay for a PrEP injectable by feature.

Overall, participants' willingness to pay more than $100 per month was driven by three considerations: achieving at least 80% efficacy ($170.70), having 12 months of protection ($122.70), and avoiding weight gain (-$132.50). In IDIs, participants' acceptability of a PrEP injectable was informed by the aforementioned features, personal considerations (e.g., relationship status, income), and context (e.g., access to care, stigma).

Conclusions: YMSM weighed the features of a PrEP injectable differentially and made cost-related trade-offs regarding its acceptability. Variations in acceptability based on the injectable's features highlight the need to develop and test campaigns, with the greatest focus accentuating the efficacy of injectable PrEP while addressing perceived cost and side-effects among YMSM.

EPC187

#SummerFunCollab: engagement of online anonymized influencers in creating awareness and demand of HIV pre-exposure prophylaxis among high-risk men who have sex with men in the Philippines

J.D. Rosadiño[1,2], P.V. Junio[1], R. Domingo[1], G. Aspiras[1], D. Cruz[1], J.L. Dinglasan[1], J. Ramilo[1], J.O. Corciega[1], R. Pagtakhan[1]
[1]*LoveYourself, Inc., Mandaluyong City, Philippines, the,* [2]*University of the Philippines - Open University, Faculty of Management and Development Studies, Los Baños, Philippines, the*

Background: WHO recommended the use of PrEP in addition to other prevention methods to halt and reverse the HIV epidemic in the Philippines. While it is being brought to scale, PrEP enrollment remains low among Filipino MSMs. The project aims to bring PrEP awareness to MSMs and lead them to PrEP enrollment by engaging anonymous online community influencers.

Description: Coming from the previous experience of LoveYourself in its #MenOfPrEP campaign, a new campaign plan was developed, keeping in mind the market: High-risk MSMs in Twitter, promoting their sexual activities anonymously (alters). The messages focused on PrEP information, access, and its impact on their lifestyle. The visual theme and key messages developed are sex-positive and sexually explicit, with a motivational tone of espousing self-empowerment. The developed plan was then cascaded to people who are the following: a known member of the MSM alter community and has an established online presence.

The following were then shared with the influencer as part of the campaign development: A PrEP 101 briefer, training, and an "influencer package" containing FAQs should they receive inquiries regarding PrEP on their personal accounts. These influencers were also given PrEP, to share their experiences while taking it, and using it in their sexual lifestyle. The influencers were then given the creative freedom on how to promote and share their PrEP experience and post it on their personal Twitter accounts.

Lessons learned: A total of 13 Twitter alter influencers agreed to participate in the campaign. Each post has received unique engagements ranging from 3,000 to 70,000, with a total of 239,382 for the entire campaign. Total impressions made amounted to 4,478,986. These numbers are organic, and no advertising/boosting funds were spent. The sign-up link for PrEP registration was accessed 25,000 times. Inquiries regarding PrEP in LoveYourself's social media channels increased by 3,500%. The campaign has helped increase the number of PrEP enrollees under LoveYourself's care by 194% (2,673 by December 2021).

Conclusions/Next steps: It was seen that a sex-positive campaign powered by the community is effective in bringing awareness of PrEP. Community consultations are essential in creating PrEP demand generation programs for other key communities.

EPC188

Increasing demand for Pre-Exposure prophylaxis (PrEP) among pregnant and breastfeeding women (PBFW) to prevent mother to child HIV transmission in 3 SAFE supported Provinces in Zambia

T. Tulli[1], L. Kalima[1], V. Peleka[1], R. Mvula[1], R. Makufele[1], B. Kafulubiti[2], S. Zulu[2], M. Chanda[2]
[1]*John Snow Inc, Monitoring and Evaluation, Lusaka, Zambia,* [2]*John Snow Inc, Technical, Lusaka, Zambia*

Background: The USAID SAFE program (SAFE) supports the HIV program of the Ministry of Health (MOH) in Zambia by providing clients who have been exposed to HIV with antiretroviral pre-exposure prophylaxis (PrEP) to prevent HIV infection. SAFE targets HIV negative pregnant and breast-feeding women (PBFW), victims of rape and gender based violence (GBV), sexually active adolescents and sex workers. Implementation of PrEP among PBFW has slowly been adopted in SAFE facilities and surrounding communities.

Description: SAFE recruited, trained and mentored health care workers to support MOH efforts to provide PrEP to PBFW and their infants. Campaigns and demand creation was done through radio programs, community outreach services, in churches, weekend clinics and engagement with traditional leaders on the promotion of PrEP among PBFW in the communities. PBFW were screened for HIV and those who tested negative and found eligible for PrEP were counselled and started on PrEP.

Lessons learned: Between October 2019 to December 2021, a total of 36,668 clients were initiated on PrEP and among them 6,111 (17%) were PBFW. The PrEP Initiation differed by Quarter (See figure 1).

The Number of PBFW on PrEP was low from October 2019 to December 2020 as there were no demand creation and advocacy. The increase in PrEP initiation between January to December 2021 could be attributed to an increased campaign to initiate PrEP to PBFW with a peak in April to June 2021 with 2457 PBFW which is 34% contribution among all clients on PrEP.

The drop in initiation in the month of October-December 2021 could be attributed to COVID 19 wave 4 which resulted in restrictions of community outreach services.

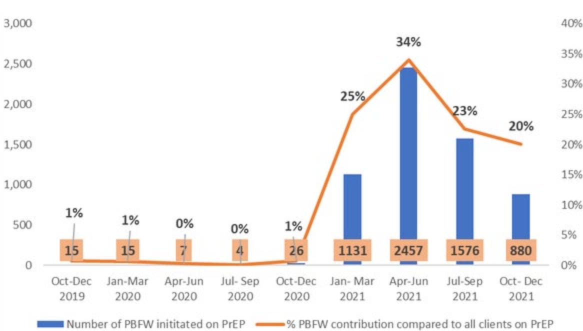

Figure 1. PBFW PrEP initiation and their contribution among clients on PrEP.

Conclusions/Next steps: Creating awareness through radio health talks and general population advocacy increases awareness on the importance of PrEP and therefore, increases the number of PBFW accessing PrEP to prevent transmission of infection to their children.

EPC189

Creating demand for HIV pre-exposure prophylaxis services among men who have sex with men and transgender people in the Eastern Cape Province of South Africa

R. Chimatira[1], D. Jebese-Mfenqe[1], B. Futshane[1], S. Gaga[1]
[1]*Beyond Zero, East London, South Africa*

Background: A mid-term evaluation of the intervention programme implemented to reduce HIV incidence among men who have sex with men (MSM) and transgender (TG) people was conducted during February and March 2021. The intervention model introduced and piloted HIV pre-exposure prophylaxis (PrEP) as an additional HIV prevention method to the existing prevention methods.
This paper reports factors influencing uptake and barriers to uptake amongst these populations in the rural setting of South Africa.

Methods: Qualitative data collection methods including in-depth interviews and Focus Group Discussions (FGDs) in line with the evaluation objectives, explored various categories of the intervention programme stakeholders including programme beneficiaries, peer educators/ navigators and programme managers as well as other key informants involved in policy formulation including LGBTI, AIDS Council and Civil Society.

Results: PrEP uptake amongst the MSM did not meet the mid-term targets and performed overall at 25% among MSM. A significant increase in uptake, from 11% at end of March 2020 to 35% at end of September 2020 was recorded. Amongst the TG people, PrEP use performed overall at 80% of the mid-term target ranging from 14% to 145 % in implementing districts. Policy focus on the use of PrEP directed only towards high-risk population groups results in stigmatization of PrEP. Uptake and discontinuation of use were influenced by the health service delivery factors:

- The need for ensuring an uninterrupted supply of PrEP in facilities and avoiding PrEP outages.
- Labelling of PrEP to articulate prevention as it is easily mistaken as ART, further stigmatizing one as HIV positive
- Taking PrEP daily was cited as a challenge; long-acting injectable PrEP was recommended.
- Some saw PrEP as medicine, therefore preferring condom use as their choice of the protection method.
- Side effects of PrEP use were cited.

Conclusions: For successful roll-out of PrEP, the SA government needs to ensure proper implementation readiness, budget availability over and above external funding as well as the proper introduction of PrEP at all levels of government.

Scale up of PrEP

EPC190

Awareness of and willingness to use on-demand pre-exposure prophylaxis (PrEP) and associated factors men who have sex with men (MSM) in China

C. Hong[1], I.W. Holloway[1], S.M. Graham[2,3,4], J.M. Simoni[5,2], F. Yu[6], H. Xue[6], D. Zhang[7], G. Mi[6]
[1]*University of California, Los Angeles, Department of Social Welfare, Los Angeles, United States,* [2]*University of Washington, Department of Global Health, Seattle, United States,* [3]*University of Washington, Department of Epidemiology, Seattle, United States,* [4]*University of Washington, Department of Medicine, Seattle, United States,* [5]*University of Washington, Department of Psychology, Seattle, United States,* [6]*Danlan Beijing Media Limited, Beijing, China,* [7]*Chinese Center for Disease Control and Prevention, National Center for AIDS/STD Control and Prevention, Beijing, China*

Background: To maximize PrEP's benefit and provide prevention options tailored to individual risk, the U.S. CDC and WHO recommend "on-demand" PrEP dosing for individuals with infrequent sexual exposure. PrEP was officially approved for HIV prevention in China, yet little is known about awareness and willingness to use on-demand PrEP among Chinese MSM. This study describes awareness and willingness to use on-demand PrEP and their correlates among a sample of sexually active Chinese MSM.

Methods: Data were collected from *Blued*, a gay social networking (GSN) app, in July 2020. Active *Blued* users aged 18 and above were invited to complete a survey including questions on demographics characteristics, sexual behaviors, perceptions on on-demand PrEP use, perceived PrEP efficacy, and perceived MSM community's acceptance of PrEP, and health-related outcomes. Par-

ticipants who reported no anal sex in the past 6 months were excluded from analysis. All participants provided informed consent. Multivariable logistic regression was used to evaluate factors associated with awareness of and willingness to use on-demand PrEP.

Results: Of all eligible participants (*n*=956), only 56% had heard of on-demand PrEP, and 41% were willing to use on-demand PrEP. Nearly half (42%) reported not always using a condom, and 10.3% reported engaging in group sex.

In the multivariable model, MSM who engaged in group sex or had anal sex after using substances had a higher willingness to use on-demand PrEP (AOR=1.82, 95% CI:1.15-2.92; AOR=1.98, 95% CI:1.09-3.68). Higher perceived PrEP efficacy (AOR+1.97, 95% CI: 1.34-2.94) and higher perceived MSM community's acceptance of PrEP (AOR=2.06, 95% CI: 1.55-2.75) were statistically significantly associated with greater willingness to use on-demand PrEP.

Conclusions: Among a sample of high-HIV-risk MSM in China, both awareness and willingness to use on-demand PrEP for HIV prevention were low. Both awareness and willingness to use on-demand PrEP were correlated with individual risk behaviors, suggesting this might be a useful prevention tool for those at risk.

Future research and programs to promote on-demand PrEP use among MSM in China should focus on targeted messaging among individuals and communities. Disseminating information regarding PrEP and its efficacy in preventing HIV using GSN apps, is warranted.

EPC191

Willingness and preferences for long-acting injectable PrEP among US men who have sex with men

S.W. Beckham[1], T. Sanchez[2], S. Sarkar[3], V. Vannappagari[3], A. Rinehart[3], M.K. Rawlings[3], P.S. Sullivan[2]

[1]*Johns Hopkins School of Public Health, Health, Behavior and Society, Baltimore, United States,* [2]*Emory University Rollins School of Public Health, Altanta, United States,* [3]*ViiV Healthcare, Research Triangle Park, United States*

Background: Cabotegravir long-acting injectable HIV pre-exposure prophylaxis (LA-PrEP) is shown to be efficacious with a good safety profile in clinical trials. Understanding potential user preferences for LA-PrEP is important to increase uptake and persistence.

Methods: Willingness to use and preferences for LA-PrEP and oral PrEP were measured in HIV-negative, sexually active men who have sex with men (MSM) in the 2020 American Men's Internet Survey.

Randomly selected MSM were randomized to a discrete choice experiment (DCE) module that presented paired profiles of hypothetical LA-PrEP alternatives with four attributes: out-of-pocket cost ($10, $30, $50), chance of side effects (25% pain, 15% headache, 5% rash), level of protection (90.0%, 95.0%, 99.9%), and total clinic time (1, 2, 3 hours), with an opt-out option (i.e., choose no LA-PrEP profile). Using Stata 17, conditional logit models estimated coefficients representing preferences, from which relative importance was calculated.

Results: Overall, 21% (1256/5,982) heard of LA-PrEP; 62% were likely to use it. Given a hypothetical choice, 74% (n=3,642) chose LA-PrEP, 16% (n=771) daily oral PrEP, and 10% (n=504) neither. Among n=2,647 DCE respondents, the greatest relative importance was placed on level of protection (Table). Respondents preferred lower costs, with $50 having 3 times higher disutility than $30. Respondents also preferred lower probability of side effects and shorter total time spent in clinic.

In relative importance, higher level of protection was important (55% of relative importance), followed by lower cost, shorter time spent, and side effects. The opt-out option (no injection) had the largest negative coefficient, indicating that holding all else constant, respondents strongly prefer the injection to no injection overall.

Attribute	Referent Level	Level	Coefficient (Mean)	SE	p-value	Relative Importance
Level of Protection	999/1000 Level of Protection 999/1000	950/1000	-1.3978	0.0265	<0.0001	55.29% 55.29%
		900/1000	-3.3130	0.0534	<0.0001	
Out-of-Pocket Cost	$10 Out-of-Pocket Cost $10	$30	-0.4973	0.0240	<0.0001	25.12% 25.12%
		$50	-1.5051	0.0420	<0.0001	
Total Clinic Time	3 hours Total Clinic Time 3 hours	2 hours	0.7411	0.0270	<0.0001	12.37% 12.37%
		1 hour	0.5607	0.0275	<0.0001	
Side effects	25% chance of pain Side effects 25% chance of pain	15% chance headache	0.4325	0.0287	<0.0001	7.22% 7.22%
		5% chance rash	0.3075	0.2782	<0.0001	
Neither option (Alternative-specific constant)			-8.324	0.2782	<0.0001	-

Table.

Conclusions: A large proportion of MSM expressed preference for LA-PrEP over daily oral pills. Respondents preferred that an injectable product be highly effective, with some concern for out-of-pocket cost, and relatively little concern for side effects and time spent obtaining.

Background: While recognized as a key HIV prevention strategy, pre-exposure prophylaxis (PrEP) availability and accessibility are not well documented globally. We aimed to describe PrEP drug registration status and PrEP service availability across HIV care sites in the International epidemiology Databases to Evaluate AIDS (IeDEA) research consortium.

Methods: We used country-level PrEP drug registration status from the AIDS Vaccine Advocacy Coalition and data from HIV clinics caring for adult patients that participated in IeDEA-wide surveys conducted in 2014, 2017 and 2020 across seven regions: Asia-Pacific; North America; Caribbean, Central and South America; Central, East, Southern and West Africa.

We used descriptive statistics to assess PrEP availability, either onsite or offsite via referral, across participating sites and examined trends in availability among sites responding to all three surveys.

Results: PrEP was registered in 60% of countries (n=42), overall, and was lowest in Central (0%) and West African countries (43%). Of 199 eligible sites completing the 2020 survey, PrEP was available in 161 (80%). PrEP availability was highest at sites in North America (96%) and East Africa (94%) and lowest at sites in Central (50%) and West Africa (16%). Availability was higher at health centers (90%) and district hospitals (87%), versus referral/teaching hospitals (60%), and higher at sites serving predominantly rural (93%) versus urban (78%) or mixed (76%) populations. Among sites where PrEP was available, it was more frequently distributed at the HIV clinic (81%) versus elsewhere at the same facility (12%) or offsite via referral (6%). Among 94 sites responding to all three surveys (Figure), PrEP availability increased from 47% in 2014, to 60% in 2017, to 75% in 2020.

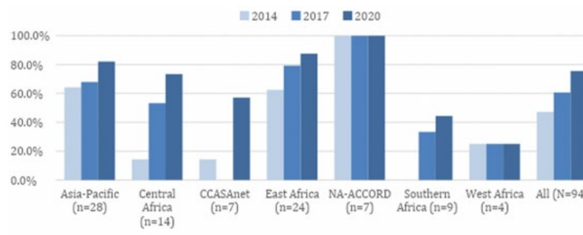

Figure 1. Availability of PrEP, either onsite or via offsite referral, by survey year and IeDEA region among 94 sites participating in 2014, 2017 and 2020 site surveys.
CCASAnet: Caribbean, Central and South America Network; NA-ACCORD: North American AIDS Cohort Collaboration on Research and Design

Conclusions: PrEP availability substantially increased across IeDEA sites since 2014.However, PrEP service provision varies markedly by region, underscoring the need to identify and address barriers to service provision.

EPC193

Correlates of adherence to daily oral HIV Pre-Exposure Prophylaxis among men that have sex with men in Nigeria

O. Adeyemi[1], R. Nowak[1], M. Marzinke[2], D. Morgan[1], N. Sam-Agudu[3], J. Craddock[4], M. Zhan[1], N. Ndembi[5], R. Adebiyi[5], S. Baral[6], T. Crowell[7], S. Adebajo[8], M. Charurat[1]
[1]University of Maryland, Epidemiology, Baltimore, United States, [2]The John Hopkins School of Medicine, Pathology and Medicine, Baltimore, United States, [3]University of Maryland, Pediatrics and Immunology, Baltimore, United States, [4]University of Maryland, Social Work, Baltimore, United States, [5]Institute of Human Virology, Nigeria, Abuja, Nigeria, [6]The John Hopkins Bloomberg School of Public Health, Baltimore, United States, [7]Henry M Jackson Foundation, Bethseda, Nigeria, [8]Center for International Health,Education and Bio Security, Abuja, Nigeria

Background: When taken correctly, HIV pre-exposure prophylaxis (PrEP) significantly reduces the risk of HIV acquisition. However, studies have demonstrated discordance between subjective self-reported measures and objective biomedical benchmarks of PrEP adherence. We estimated the correlation between self-reported PrEP adherence and PrEP biomarkers and explored factors associated with adherence among men that have sex with men (MSM) in Nigeria who are vulnerable to HIV.

Methods: TRUST-PrEP was an open-label, single-site, prospective, one-year study conducted in Abuja between April 2018 and May 2019, using clinic provider-initiated and community-based peer-to-peer PrEP introduction methods. MSM who were at least 18 years with substantial HIV risk were enrolled.

Participants were asked to report PrEP adherence over the last month using a 4-point scale from "poor" to "perfect" monthly and serum samples for PrEP biomarkers were collected at months 3 and 9. Self-reported adherence was correlated with serum tenofovir concentration, with serum tenofovir ≥ 4.2ng/mL (measured via liquid chromatography-tandem mass spectrometry) considered indicative of adherence.

Spearman's rank correlation was used to estimate correlations between self-reported adherence and measured tenofovir levels. Logistic regression with generalized estimating equations was used to estimate adjusted odds ratios (aORs) and 95% confidence intervals (CIs) for associations between self-reported adherence and laboratory-measured adherence.

Results: Of 219 MSM (median age 23 [IQR 20-27] years) that initiated PrEP, 314 samples were analyzed. Only 66/219 (30%, 95% CI: [24-36%]) had at least one record of PrEP adherence assessment.

Furthermore, 56/219 (26%, 95% CI: [20-31%]) showed concordance between tenofovir and self-reported adherence and 17/219 (8%, 95% CI: [4-11%]) and 49/219 (22%, 95% CI: [17-28%] had serum tenofovir of 4.2-35.4 ng/mL and ≥ 35.5 ng/mL, corresponding to at least 4 and 7 days' PrEP use, respectively, in a week.

In a longitudinal multivariable regression, PrEP adherence was more common among participants who received clinic-based PrEP introduction compared with community-based (aOR: 8.35, 95%CI: [3.24, 21.5]) and disclosed same-sex sexual practices to their family (aOR: 3.60 95% CI: [1.73, 7.51]).

Conclusions: Facilitating clinic-based PrEP introduction and disclosure of same-sex practices to family among MSM may improve PrEP adherence. Objective, cost-effective methods of assessing PrEP adherence would be useful in this setting.

EPC194
People who inject drugs: missed opportunities to discuss HIV pre-exposure prophylaxis

W. Vincent[1], W. McFarland[2,3]
[1]Temple University, Department of Psychology, Philadelphia, United States, [2]University of California, San Francisco, Department of Medicine, San Francisco, United States, [3]San Francisco Department of Public Health, San Francisco, United States

Background: People who inject drugs (PWID) are at increased risk of HIV infection. HIV pre-exposure prophylaxis (PrEP; the use of antiretroviral treatment medications to prevent HIV infection) is an effective yet underutilized HIV prevention strategy for PWID. However, studies rarely examine correlates of whether healthcare providers discuss PrEP with PWID.

Thus, this exploratory study aimed to identify missed opportunities for healthcare providers to discuss PrEP with PWID.

Methods: Participants were 395 HIV-uninfected PWID recruited in the 2018 National HIV Behavioral Surveillance wave in San Francisco, California via respondent-driven sampling. We used simple and multiple logistic regression to test whether the following factors were associated with discussing PrEP with a healthcare provider in the past 12 months: demographic characteristics; incarceration; HIV testing; seeing a healthcare provider; receiving various forms of HIV/STI/hepatitis prevention, such as exchange services for syringes and injection equipment and receiving free condoms from a program; receiving or seeking substance use treatment, such as treatment programs and medication-assisted treatment; and overdosing.

We report odds ratios (ORs) with 95% confidence intervals (CI_{95}) for simple logistic regression analyses and adjusted odds ratios (aORs) with CI_{95} for the multiple logistic regression model.

Results: Most participants, 86.3%, reported seeing a healthcare provider, but only 15.0% of these reported discussing PrEP with a healthcare provider. Primary correlates of discussing PrEP included: sexual minority (non-heterosexual) status (*OR*=2.68, CI_{95}: 1.44-5.00; *aOR*=2.28, CI_{95}: 1.09-4.77), being tested for HIV (*OR*=7.28, CI_{95}: 2.22-23.93; *aOR*=4.33, CI_{95}: 1.21-15.47), having a healthcare provider recommend HIV testing (*OR*=3.05, CI_{95}: 1.42-6.54; *aOR*=3.28, CI_{95}: 1.34-7.99), and receiving free condoms (*OR*=7.00, CI_{95}: 2.47-19.86; *aOR*=5.90, CI_{95}: 1.92-18.15).

Conclusions: In the face of many missed opportunities to discuss PrEP, public health efforts must be more strategic to target services and circumstances encountered by PWID (e.g., receiving or seeking substance use treatment, seeing any healthcare provider who is aware of their injection drug use). Increased efforts are also needed to reach PWID who do not identify as sexual minority people.

Given that the present study occurred in San Francisco, which is among the leaders of PrEP coverage in the United States, missed opportunities are likely even more problematic outside of San Francisco.

EPC196

The best thing about PrEP is ____: benefits of HIV PrEP according to PrEP-using gay, bisexual and other men who have sex with men in Ontario and British Columbia, Canada

O.J. Pico Espinosa[1], M. Hull[2], R. Truong[1], E. Peters[3], P. MacPherson[4], K. Woodward[5], D. Grace[6], M. Gaspar[6], N. Lachowsky[7], S. Mohammed[2], K. Fisher[8], S. Rayek[9], M. Kilduff[10], C. Arkell[11], T. Cordeiro[12], G. Durrant[13], W. Greene[14], D. Hall[15], J. Jollimore[16], J. Maxwell[17], L. Mitterni[18], D. Tan[1]

[1]St. Michael's Hospital, Unity Health Toronto, Options Lab, Toronto, Canada, [2]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [3]The Gay Men's Sexual Health Alliance, Toronto, Canada, [4]University of Ottawa, Ottawa, Canada, [5]McMaster University, Hamilton, Canada, [6]University of Toronto, Toronto, Canada, [7]University of Victoria, Victoria, Canada, [8]Toronto General Hospital, Toronto, Canada, [9]Health Initiative for Men, Vancouver, Canada, [10]AVI Health and Community Services, Victoria, Canada, [11]Canadian AIDS Treatment Information Exchange (CATIE), Toronto, Canada, [12]Alliance for South Asian AIDS Prevention (ASAAP), Toronto, Canada, [13]Black Coalition for AIDS Prevention (Black CAP), Toronto, Canada, [14]Canadian Aboriginal AIDS Network, Fort Qu'Appelle, Canada, [15]Vancouver Coastal Health, Vancouver, Canada, [16]Community-Based Research Centre, Vancouver, Canada, [17]AIDS Committee of Toronto, Toronto, Canada, [18]Hassle Free Clinic, Toronto, Canada

Background: To describe positive aspects of HIV pre-exposure prophylaxis (PrEP) as identified by PrEP-using gay, bisexual and other men who have sex with men (GBM), and to explore their association with demographic characteristics.

Methods: We conducted a cross-sectional survey from JUL2019-AUG2020 among GBM in five cities in British Columbia and Ontario, Canada as part of 'PRIMP', a multi-component implementation project. We recruited participants at least 19 years old from sexual health clinics and various social media platforms.

Participants with current or prior experience taking PrEP were asked to describe with a few words "*the best thing about taking PrEP*". Each participant's responses were coded independently by two authors. Themes were created using content analysis. We created contingency tables between themes, and ethnicity and income; and tested for differences using χ^2 tests.

Results: Of 702 GBM with experience taking PrEP, 523 codes were generated from 459 responses. The median age was 35 (IQR: 29-42) years and most were currently on PrEP (79%, n=359). Seven themes emerged (see Figure and Table).

Black and Latin respondents tended to focus on the effectiveness of PrEP (p=0.014). GBM with higher income tended to focus on aspects such as reduced anxiety, less fear, less worry and less stigma (p=0.002). There were no differences based on age or former/current PrEP use (p>0.05).

	Health and personal gains 26 (5%)	Sex affirming 37 (7%)	A good head-space 183 (35%)	A calming effect 98 (19%)	A con-venient product 20 (4%)	PrEP works 152 (29%)	Everything about PrEP is good 7 (1%)
Ethnicity (p=0.014)							
White	20 (6%)	24 (7%)	121 (36%)	63 (19%)	16 (5%)	89 (26%)	5 (1%)
Black or Latin	1 (2%)	1 (2%)	15 (29%)	7 (14%)	0 (0%)	27 (53%)	0 (0%)
East Asian	2 (5%)	6 (16%)	9 (24%)	12 (32%)	2 (5%)	6 (16%)	0 (0%)
Other	3 (3%)	6 (7%)	37 (40%)	16 (17%)	2 (2%)	26 (28%)	0 (0%)
Income (p=0.002)							
<$40K CAD	6 (4%)	9 (7%)	54 (39%)	14 (10%)	9 (7%)	46 (33%)	0 (0%)
$40K-60K CAD	8 (7%)	7 (6%)	38 (32%)	19 (16%)	2 (2%)	40 (34%)	4 (3%)
>$60K CAD	11 (5%)	20 (9%)	77 (33%)	60 (26%)	7 (3%)	54 (23%)	2 (1%)

Table.

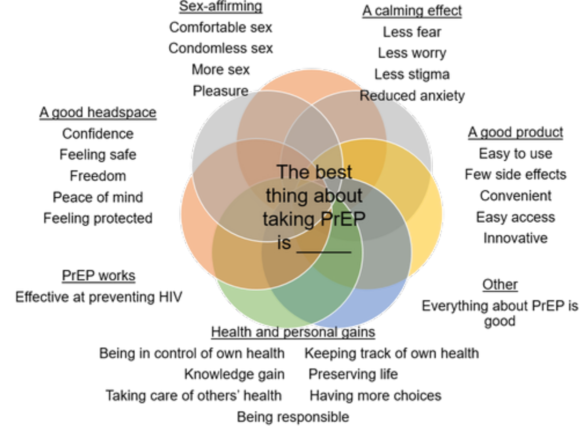

Figure.

Conclusions: The benefits of PrEP go beyond the obvious effectiveness against HIV infection. Ethnicity and income influence what positive aspects of PrEP might feel more relevant to GBM and could be incorporated into tailored health promotion messages.

EPC197

Missed opportunities for HIV testing and PrEP education in a high-risk population

L. Shipton[1], F. Ue[2], C. Marvin[3]

[1]Cambridge Health Alliance, Infectious Disease, Cambridge, United States, [2]Cambridge Health Alliance, Medicine, Cambridge, United States, [3]Cambridge Health Alliance, Nursing, Cambridge, United States

Background: The U.S. Department of Health and Human Services launched the Ending the HIV Epidemic initiative in 2019 with a goal of reducing new HIV infections in the U.S. by 90% by 2030. Core components include early diagnosis of HIV and scale-up of PrEP.

Methods: We conducted a retrospective review from 1/1/2019-12/31/2019 of all positive gonorrhea and chlamydia tests in patients 18yrs and older at Cambridge Health Alliance.

Patients with greater than 1 positive result on the same day were counted as one "encounter" whereas patients with greater than one positive result on separate days were counted as separate "encounters."

For those without HIV, we gathered data on whether HIV testing occurred within 90 days after the encounter for the positive gonorrhea or chlamydia test. For the subset of patients without HIV and not on HIV PrEP who had a positive test for gonorrhea, we determined if PrEP was discussed within 180 days after the positive gonorrhea test.

For encounters in which only chlamydia was identified, we elected not to assess if a PrEP discussion occurred because isolated chlamydia infection is not considered a specific indication for PrEP among women or heterosexual men in the PrEP guidelines.

Results: During the calendar year 2019 there were 1,015 positive gonorrhea and chlamydia tests in HIV-negative individuals, representing 980 separate encounters. 57.7% of these encounters were followed by an HIV test within 90 days, 2 of which were positive. Rates of follow-up HIV testing varied by department in which the gonorrhea or chlamydia test was obtained and by patient gender.

Of these 980 encounters, 93 were in HIV-negative individuals not receiving PrEP who tested positive for gonorrhea. Education about PrEP was documented in 19.4% within 180 days. PrEP education after a positive gonorrhea test varied by ordering department and gender.

Conclusions: Missed opportunities to offer HIV testing and PrEP education to individuals at high risk of HIV acquisition exist. In particular, patients who were tested for an STI in an emergency department and female patients were more often overlooked. Working with our emergency department colleagues and addressing gender imbalance is critical to reducing new HIV infections.

EPC198

Audience segmentation of preferences for long-acting injectable among US MSM: a latent class analysis

S.W. Beckham[1], T. Sanchez[2], S. Sarkar[3], V. Vannappagari[3], A. Rinehart[3], M.K. Rawlings[3], P.S. Sullivan[2]

[1]Johns Hopkins School of Public Health, Health, Behavior and Society, Baltimore, United States, [2]Emory University Rollins School of Public Health, Altanta, United States, [3]ViiV Healthcare, Research Triangle Park, United States

Background: Cabotegravir long-acting injectable HIV pre-exposure prophylaxis (LA-PrEP) is superior to daily oral PrEP and has a good safety profile. Understanding variations in preferences for LA-PrEP is important for audience segmentation to tailor implementation strategies.

Methods: Preferences for LA-PrEP were measured in HIV-negative, sexually active men who have sex with men (MSM) in the 2020 American Men's Internet Survey.

Randomly chosen respondents were offered a discrete choice experiment (DCE) with paired profiles of hypothetical LA-PrEP alternatives: out-of-pocket cost ($10, $30, $50, $75), side effects (25% chance of pain, 15% chance of headache, 5% chance of rash), level of protection (90.0%, 95.0%, 99.9%), and total clinic time (1, 2, 3 hours), with an opt-out option.

Latent class analysis was conducted to estimate preference heterogeneity, and within-class coefficients calculated into relative importance.

Results: Three latent classes of preferences for LA-PrEP emerged among n=2,657 respondents (Table).

Class 1 (41% of respondents) cared largely about level of protection (72% of total utility). This class strongly preferred LA-PrEP to opting out if it is highly effective.

Class 2 (44%) placed relatively more importance on cost (38% of utility), cared about protection level (27%) and time spent (23%), and preferred the injection to no injection.

Class 3 (15%) was like Class 2, caring about protection, cost, and time, but preferred opting *out* of the injection.

Attribute	Referent Level	Levels	Class 1 (44% of respondents) Coefficient (mean)	Class 1 Relative importance of attribute	Class 2 (41% or respondents) Coefficient (mean)	Class 2 Relative importance of attribute	Class 3 (15% of respondents) Coefficient (mean)	Class 3 Relative importance of attribute
Side effects	25% chance of pain	15% chance of headache	0.361	12.04%	0.483	5.73%	0.147	8.74%
	Side effects 25% chance of pain	5% chance of rash	0.0470	12.04%	0.130	5.73%	0.336	8.74%
Out-of-pocket costs	$10	$30	-0.591	38.38%	-0.642	13.20%	-0.758	29.90%
	Out-of-pocket costs $10	$50 or $75	-1.498	38.38%	-1.112	13.20%	-1.149	29.90%
Level of protection	999/1000	950/1000	-0.484	26.98%	-3.520	72.28%	-1.005	33.52%
	Level of protection 999/1000	900/1000	-1.053	26.98%	-6.088	72.28%	-1.288	33.52%
Total Clinic time	3 hours	2 hours	0.720	22.60%	0.74	8.79%	0.570	27.84%
	Total Clinic time 3 hours	1 hour	0.882	22.60%	0.054	8.79%	1.070	27.84%
Preference for no LA-PrEP, given the options (alternative-specific constant)			-2.786	-	-6.536	-	2.423	-

EPC198 Table.

Conclusions: The vast majority of respondents consistently chose LA-PrEP regardless of cost, clinic time, side effects, or protection level; however, preferences among these attributes varied. About 40% of MSM placed highest importance on effectiveness over other attributes.
Others valued a balance of cost, time, and effectiveness, with most of them wanting the injection despite those factors, and a small proportion preferring to opt out of the injection altogether. These varied groups likely require tailored communication strategies to achieve maximum LA-PrEP uptake and persistence.

EPC199
Awareness and willingness to pay for dapivirine vaginal ring by female undergraduate students of the University of Nigeria

G. Ezenri[1], A. Isah[1], N.A. Okibe[1], C.C. Eze[1], C.V. Ukwe[1]
[1]University of Nigeria, Clinical Pharmacy & Pharmacy Management, Nsukka, Nigeria

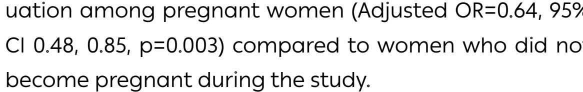
Background: Dapivirine vaginal ring (DPV-VR) is a pre-exposure prophylaxis strategy that reduces the risk of HIV transmission in women at high risk of the infection. The uptake of DPV-VR will reduce the prevalence of HIV infection in Nigeria which contributes a significant proportion to the global burden.
This study assessed the acceptability and willingness to pay (WTP) for DPV-VR by undergraduate female students of the University of Nigeria (UNN).
Methods: This study adopted a cross-sectional design to obtain responses from female students of UNN in January 2022 using a 23-item questionnaire. A sample size of 500 was estimated from five faculties. Their acceptability was accessed before and after educating them on DPV-VR. WTP choice and amount were obtained in Naira using contingent valuation.
Descriptive statistics were used to summarize the variables, while chi-square test was used to evaluate the impact of the educational intervention. $P<0.05$ was considered statistically significant. Ethical approval was obtained from the university's Institutional Review Board.
Results: A total of 385 students responded to the questionnaire (77.0% response rate). The modal age was 18–24 years: 321(83.4%). Majority of the students were not married, expressed by 363(94.3%). When asked if they had ever tested for HIV, 198(51.4%) responded in the affirmative.
Whereas 172 students responded that they had receptive vaginal sex with their male partners within the past four weeks (before the study), 77(44.77%) reported that they did not use condom during the sex acts.
There was about a two-fold increase in the acceptability of the DPV-VR among the students (128 to 223) after the device and its importance were described to the students: $\chi^2(2)$, $p\leq0.001$. Majority of the students (174, 45.2%) indicated that they would be willing to pay N410.00 – N8,200.00 for a single DVP-VR, with a mean of N4217.29 and minimum/maximum amounts of N0.00/N50,000.00 (N415/$1).

Conclusions: Many of the female students of the University of Nigeria were willing to use dapavirine vaginal ring. More were willing to use the ring after they were informed of its importance. They were also willing to pay (out-of-pocket) to be provided the ring if it was not freely provided for them.

EPC200
The effect of pregnancy on daily oral PrEP use among adolescent girls and young women in Uganda

K. Zewdie[1], F. Matovu[2], T. Ssebuliba[3], S. Morrison[4], T. Muwonge[3], J. Boyer[4], F. Bambia[3], J. Badaru[3], M. Bagaya[3], G. Stein[4], K. Mugwanya[1], C. Wyatt[5], M.T. Yin[6], A. Mujugira[3], R. Heffron[1]
[1]University of Washington, Epidemiology, Seattle, United States, [2]Makerere University-Johns Hopkins University Research Collaboration, Kampala, Uganda, [3]Makerere University, Kampala, Uganda, [4]University of Washington, Global Health, Seattle, United States, [5]Duke University School of Medicine, North Carolina, United States, [6]Columbia University, New York, United States

Background: Pregnancy is a period with elevated risk for acquiring HIV and oral pre-exposure prophylaxis (PrEP) is recommended during pregnancy for at-risk women. However, little is known about how pregnancy impacts oral PrEP continuation among young women.
Methods: We used data from an ongoing open-label prospective study aimed to address safety questions with concurrent tenofovir (TDF)-based PrEP and contraceptive use.
The study enrolled sexually active, HIV-negative women, ages 16-25 years, initiating contraception in family planning clinics and health centers in Kampala, Uganda.Over 24 months, women were followed quarterly with rapid testing for HIV and pregnancy, PrEP adherence counseling, and PrEP refill. Women who become pregnant were counseled about the benefit and risk of PrEP use during pregnancy per national guidelines.
We used a multivariable generalized estimation equation to compare PrEP continuation between women who became pregnant and those who did not become pregnant during the study with adjustment for age, income, education, relationship status, and partner's HIV status.
Results: Among 499 women enrolled in the study, 440 initiated PrEP at any point during the study. Among those who initiated PrEP, the median age was 20 years (IQR 18-21), median education level was 11 years (IQR 7-12), 56% earned an income of their own, and 86% had a steady sexual partner at enrollment.
The majority (62%) had multiple sexual partners and 66% were unsure of their partner(s)' HIV status during the study period, 79 (18%) women became pregnant, 60 (76%) continued PrEP use during pregnancy. There was a statistically significant 36% reduction in the odds of PrEP contin-



uation among pregnant women (Adjusted OR=0.64, 95% CI 0.48, 0.85, p=0.003) compared to women who did not become pregnant during the study.
Among women who became pregnant, there was a statistically significant 30% reduction in the odds of PrEP continuation during pregnancy (adjOR=0.70, 95% CI 0.52-0.96, p=0.025) compared to their PrEP use during non-pregnant periods.
Conclusions: Women who experienced pregnancy while using PrEP were less likely to continue using PrEP than those who did not experience pregnancy. Innovative strategies are needed to support PrEP use during pregnancy.

EPC201
Incidence of HIV infection after initiation of Australian government-subsidisedpre-exposure prophylaxis (PrEP): a national whole-of-population cohort study using dispensing data

N. Medland[1], H. McManus[1], D. Fraser[1], B. Bavinton[1], A. Grulich[1], S. McGregor[1], H. Paynter[2], R. Guy[1]
[1]Kirby Institute, University of New South Wales, Sydney, Australia, [2]Australian Federation of AIDS Organisations, Sydney, Australia

Background: PrEP has been publicly funded since April 2018. We used national dispensing data to examine HIV incidence in a national real word cohort of all people prescribed government-subsidised PrEP.
Methods: We used linked de-identified dispensing records of all government-subsidised PrEP and antiretroviral therapy (ART) up to September 2021 for people who initiated PrEP between April 2018 and September 2020. Incident infection was defined as ART dispensed more than 60 days after PrEP initiation. Medication possession ratio over the last 90 days (90day-MPR) and incidence rate from the time of PrEP initiation were calculated and Poisson regression analysis performed using: patient sex, age-group, location, subsidy level (based on employment, health, disability), Hepatitis C treatment history, year of PrEP initiation, 90day-MPR and prescriber location and caseload (number of PrEP patients per prescriber).

	n	1000PY	IR	(95% CI)	aIRR	(95% CI)	p
90 day MPR>= 60%	12	39.2	0.31	(0.17-0.54)	ref		
90 day MPR > 0% and < 60%	10	7.80	1.28	(0.69-2.37)	4.35	(1.88-10.09)	.001
90 day MPR = 0 & received PrEP once	26	11.9	2.19	(1.49-3.21)	10.33	(5.13-20.83)	<.001
90 day MPR = 0 & rec'd PrEP more than once	47	41.1	1.14	(0.86-1.52)	4.39	(2.32-8.30)	<.001
Higher subsidy level	41	19.7	1.67	(1.19 -2.36)	2.20	(1.42-3.42)	<.001
History of Hepatitis C Treatment	5	0.60	7.73	(3.22 - 18.56)	6.16	(2.44-15.6)	<.001
PrEP caseload <=100	11	30.0	0.37	(0.20 -0.66)	0.24	(0.13-0.46)	<.001
PY= person years, IR=incidence rate per 1000 person years, CI=confidence interval, aIRR= adjusted incidence rate ratio.							

Table.

Results: Amongst 39,817 PrEP users (99.8% male, median age 34 years), 95 HIV incident infections were identified over 100,064 person-years (PY), representing an incidence rate of 0.95/1000PY (95%CI 0.78-1.16) and with a median 220 days (0-740 days, IQR 97-421 days) without PrEP prior to HIV diagnosis. Incident rates were lowest with 90-dayMPR >60% and amongst patients of low caseload prescribers and highest with people dispensed PrEP only once, higher subsidy level and history of Hepatitis C treatment (see table); other variables were not associated.
Conclusions: Overall HIV incidence in PrEP users is low and is more than five times lower than national levels in MSM in Australia before PrEP. Active support and follow-up of those with delayed PrEP collection (particularly after one prescription), hepatitis C treatment history (a possible marker of injection drug use and/or high sexual risk) and higher subsidy level (a possible marker of disparities in the social determinants of health) may drive incidence even lower.

EPC202
PrEP eligibility and willingness among sex-workers (SW) in Ukraine

O. Kovtun[1]
[1]ICF ,Alliance for Public Health', Monitoring and Evaluation Department, Kyiv, Ukraine

Background: SWs are still a stigmatized and hard-to-reach group in Ukraine, and HIV has shifted towards the sexual transmission, mainly through heterosexual contact. HIV prevention services (consultations, HIV testing, condoms) are provided with annual coverage of >50k SWs of the 86K estimated population. In 2021, about 5k people received PrEP, but only 5% of them were SWs.
In this analysis, we have estimated the share of SWs who are eligible and willing to take PrEP in 7 Ukrainian cities.
Methods: We analyzed data of the 2021 integrated bio-behavioral survey (IBBS) among SW (n=4,961). The study was conducted in 7 cities of Ukraine using the time-location method.
Within the survey, we asked participants about their perception of PrEP and their willingness to take it under the required conditions.
We measured the willingness of SWs to use PrEP and estimated the number of SWs who meet the eligibility criteria and are willing to take it.
Results: 96.9% of SWs received HIV-negative test result, only 1/3 of them have heard about PrEP and 3% have used it. 94.9% of SWs were eligible for PrEP according to HIV-negative test result and risk behavioral criteria (having HIV-positive client or sex partner, unsafe sex more than one partner in the last 30 days). 18.8% of SWs have demonstrated willingness to use PrEP and agreed to take it following the conditions of its prescription and monitoring of use (daily intake, using condoms, regular HIV and other medical testing, receiving at the AIDS Center).
Opportunity to receive PrEP at NGOs, not only AIDS Centers, increases willingness by +3%. Thus 17% of SWs were eligible and willing for PrEP (or 7k SWs in 7 IBBS cities). PrEP

willingness significantly depends on the city, age groups, monthly income groups, current occupation, and using NGO services as a client.

Conclusions: In 2021, the Ministry of Health of Ukraine adopted the Standard on PrEP, which means scaling up of PreP among key populations, including SWs. The presented results of the analysis are important strategic information for improving SWs' awareness of PrEP and implementation of it among the target group.

EPC203

Qualitative study on PrEP implementation among men who have sex with men and transgender women in Brazil: the user's perspectives

M.R. Benedetti[1], X.P. Bermúdez[2], A.M. Godoi[2], I. Maksud[3], B. Kauss[4], T.S. Torres[1], B. Hoagland[1], B.G. Grinsztejn[1], V.G. Veloso[1], M.C. Pimenta[5], ImPrEP Study Group

[1]*Oswaldo Cruz Foundation, Evandro Chagas National Institute of Infectious Disease, Rio de Janeiro, Brazil,* [2]*University of Brasília, Laboratório de Antropologia da Saúde, Brasília, Brazil,* [3]*Oswaldo Cruz Foundation, Fernando Figueiras Institute, Rio de Janeiro, Brazil,* [4]*Federal University of Rio Grande do Sul, Faculdade de Educação, Porto Alegre, Brazil,* [5]*Ministry of Health, Department of Chronic Conditions and STIs, Brasília, Brazil*

Background: HIV/AIDS epidemic persists in Brazil among key populations such as men who have sex with men (MSM) and transgender women (TGW). Changes in recent prevention strategies, with the incorporation of Pre-Exposure Prophylaxis (PrEP), create challenges and opportunities for its implementation, such as user knowledge, perception, and access to daily oral PrEP. Moreover, PrEP uptake and continuation are of global concern as access barriers for MSM and TGW.

This abstract presents results of a qualitative study assessing perceptions and attitudes of PrEP users during the implementation of PrEP policy in Brazil (ImPrEP Stakeholders study).

Methods: Qualitative study, based on in-depth interviews with PrEP users in 6 cities of all 5 administrative regions of Brazil. Interviews were recorded, transcribed, organized, and categorized using NVivo12 Plus software. The central axes analyzed were:

i. PrEP knowledge,

ii. accessibility,

iii. users' experiences and interaction with public health services.

This analysis looked at PrEP implementation based on these narrative categories.

Results: Twenty PrEP users were interviewed; age 26-47 years; 80% MSM, and 20% transgender women. Most participants obtained knowledge of PrEP through peers, communication technologies/internet, implementation studies, and health professionals. Participants expressed concerns related to the dissemination of PrEP information. More accessible language is needed to increase PrEP literacy among key populations. In terms of accessibility, lack of service availability and difficulties to initiate same-day oral PrEP at public health services were reported as concerns.

Regarding PrEP use, all interviewees emphasized the importance of PrEP for HIV prevention and sexual pleasure. PrEP use was reported as easy to take, and PrEP services were said to reinforce the importance of care and prevention of other sexually transmitted infections.

Conclusions: Understanding the experiences of PrEP users and their interaction with health services, socioeconomic context, subjectivities, and cultural specificities are crucial for an effective PrEP implementation policy. Perceived practices of health professionals (subjectivities, values, and beliefs) should attend to the concerns of key populations.

Stigma-free health service environment, targeted communication, community mobilization, and peer support are strategies perceived as effective facilitators to access, linkage, and retention to PrEP services, and enablers to PrEP roll-out in Latin America and globally.

EPC204

The best predictor of future behavior may be the past: exploring behavior change in men who have sex with men using pre-exposure prophylaxis in the Netherlands

D.A. van Wees[1], L. Coyer[2], M. van den Elshout[2,3], E. Op de Coul[1], F. van Aar[1]

[1]*National Institute for Public Health and the Environment (RIVM), Center for Infectious Disease Control, Bilthoven, Netherlands, the,* [2]*Public Health Service of Amsterdam, Department of Infectious Diseases, Research and Prevention, Amsterdam, Netherlands, the,* [3]*Municipal Health Service for the Utrecht Region, Utrecht, Netherlands, the*

Background: Pre-exposure prophylaxis (PrEP) use reduces HIV transmission, but may lead to changes in sexual behavior and increased sexually transmitted infection (STI) incidence. We aimed to explore predictors of behavior change in men who have sex with men (MSM) using PrEP at sexual health centers (SHC) in the Netherlands.

Methods: We used longitudinal data from the national STI surveillance database (2018-June 2021) of HIV-negative MSM who first initiated PrEP in the national PrEP pilot (start July 2019). We modelled behavior change over time, and identified predictors of behavior change using multi-state Markov models.

Results: Of all MSM included in the analysis (n=4,981, n SHC visits=27,937), 60% was ≤35 years old, 63% was highly educated (i.e., university degree), and 59% was of Dutch origin. Recent PrEP use was reported at 56% of all visits, any STI (i.e., chlamydia, gonorrhea or syphilis) positivity was 22%, and 12 MSM (0.2%) were diagnosed with HIV.

Author Index

Furthermore, ≥10 partners (34% of all visits), groupsex (22%), chemsex (21%), use of poppers/erection stimulants (24%), and inconsistent condom use (90%) were commonly reported behaviors. Anal STI or syphilis diagnosis was a predictor of starting chemsex and poppers/erection stimulants, and of continuing to engage in groupsex.

Furthermore, visiting the SHC more often/regularly (vs. less often) was a predictor of changing from inconsistent to consistent condom use, but also of starting with groupsex, chemsex, and poppers/erection stimulants, and increasing partner numbers (≥10).

Furthermore, young age (16-35 years), and visiting the SHC in Amsterdam (vs. other regions) were predictors of behavior change (i.e., both stopping or starting groupsex, chemsex, poppers/erection stimulants, and condomless anal sex, and of changes in partner numbers).

Recent PrEP use was not a predictor of behavior change, nor was the COVID-19 pandemic (i.e., visits from March 2020 onwards vs. visits pre-COVID-19).

Conclusions: We identified several predictors of behavior change among MSM in the national PrEP pilot, but PrEP use was not one of them. Although regular SHC visits may improve condom use, STI prevention efforts during SHC consultations could be more focused on other behaviors associated with STI risk, especially for MSM who tested positive for anal STI or syphilis.

EPC205

Oral PrEP use acceptability and feasibility among Uganda fisherfolk communities in central Uganda: a qualitative study

W. Musoke[1], L. Bogart[2], R.K. Wanyenze[3], J. Mayatsa[3], T. Marsh[2], S. Mukama[1], S. Alupo[1], A. Banegura[1], M. Odiit[1], B. Mukasa[1]

[1]Mildmay Uganda Limited, Kampala, Uganda, [2]RAND Corporation, Santa Monica, United States, [3]Makerere University School of Public Health, Kampala, Uganda

Background: HIV is hyperendemic among fisherfolk in Sub-Saharan Africa. Research is needed to determine acceptability of pre-exposure prophylaxis (PrEP) and identify feasible and sustainable intervention strategies to improve PrEP implementation and social marketing messages to encourage PrEP use in fisherfolk communities. Mildmay Uganda, the research setting, is implementing PrEP at the Nakiwogo and Kigungu fishing communities on Lake Victoria, Uganda.

Methods: To inform PrEP implementation, semi-structured interviews were conducted with 35 HIV-negative testing clients at Nakiwogo and Kigungu (15 women, 20 men: fishermen, other fishing industry workers, commercial sex workers, and unemployed individuals) and 10 key stakeholders (4 women, 6 men: 2 Ministry of Health policymakers, 1 district focal person, 4 healthcare workers, 2 fishing community leaders, and 1 Village Health Team provider). Interviews aimed to understand what is currently being done regarding current PrEP implementation and how it can be improved; marketing messages to introduce PrEP to fisherfolk; and ways to support adherence and medication refill.

Transcripts were analyzed using a directive content analysis approach based on implementation science and social marketing frameworks.

Results: Participants showed misconceptions and a lack of knowledge about the purpose of PrEP, how it works, and how it should be taken. Other barriers included stigma (due to similar medications/packaging as HIV treatment); mobility, competing needs, poverty, and fear of partner conflict. Providers discussed insufficient staffing to provide PrEP in fishing communities.

Misconceptions included fear of side effects, doubts about effectiveness, beliefs that PrEP cannot be taken with alcohol or on an empty stomach, and concerns that it is experimental or poisonous.

Recommendations included: change PrEP packaging; integrate PrEP with other services; decrease PrEP refill frequency; give transportation resources to providers; train more healthcare workers to provide PrEP in fisherfolk communities; and use positively framed messages to promote PrEP.

Conclusions: Inadequate knowledge and misconceptions may be due to inadequate explanation by healthcare providers, as well as low education levels in fisherfolk communities. Results can inform policymakers and healthcare organizations on how to overcome barriers to PrEP scale-up in most at-risk populations.

EPC206

Scaling-up PrEP delivery in South Africa: lessons from 2nd year of implementation

V. Naidu[1], Z. Makaba[1], Z. Shelembe[1], A. Nel[1], G. Mata[2], Z. Dlamini[2], N. Mdletshe[2], K. Dom[2], M. Prins[3], K. Malekela[3], A. Ncube[3], C. Serrao[1], D. Naidoo[4], T. Malone[4], N. Hlatshwayo[5]

[1]BroadReach, Technical Services, Cape Town, South Africa, [2]BroadReach, Programme Delivery, Cape Town, South Africa, [3]BroadReach, Strategic Information, Cape Town, South Africa, [4]BroadReach, Leadership, Cape Town, South Africa, [5]Department of Health, Gert Sibande District, Ermelo, South Africa

Background: HIV oral Pre-Exposure Prophylaxis (PrEP) was first launched in South Africa in 2016 in selected sites as part of a combined HIV prevention strategy. Evidence to inform scale-up of PrEP is needed to meet the National Department of Health's target of 676,970 individuals on PrEP by March 2022.

Description: PrEP was launched at the clinic level in 18 sub-districts in South Africa in October 2019 targeting adolescent girls and young women (AGYW) 15–24-year-olds who are HIV negative and at significant risk of acquiring HIV infection. In South Africa, AGYW account for a quar-

ter of all new HIV infections. To accelerate the program in 2021, the following efforts produced lessons learned for scaling-up PrEP delivery.

Lessons learned: *PrEP Integration:* To increase the identification of high-risk HIV negative individuals and serodiscordant index contacts, it is necessary to integrate PrEP with HTS and across all clinic service delivery points.

Formal partnerships: Signed partnership agreements are essential for encouraging joint planning and agreement to implement a bi-directional referral system.

Capacity-building of healthcare workers & PrEP clients: PrEP implementation requires capacity-building of healthcare workers and PrEP literacy for beneficiaries and caregivers to accept and continue on PrEP Treatment.

Granular Site Management approach: Setting targets at the clinic level and identifying high-volume testing clinics with low PrEP initiations was prioritised for site-level interventions.

These scale-up activities resulted in 86% of those screened, being eligible and 64% of those eligible to be initiated on PrEP which was a 15-fold increase (from 2,850 to 43,822) from the previous year's PrEP initiations. Males and females outside of the AGYW age band accounted for 55% (23,951/43,822) of PrEP initiations. Females contributed 74% (32,238/43,822) to the overall performance.

Conclusions/Next steps: PrEP as a prevention method should be extended to all high-risk individuals irrespective of age. Clinics need to prioritise adolescent and youth-friendly services to attract AGYW to health care facilities. PrEP integration into ANC and PNC services is necessary for scale-up in pregnant and breastfeeding women to prevent mother-child transmission of HIV. Differentiated care models have recently been approved for dispensing of multi-month PrEP treatment.

EPC207

Acceptance of HIV home self-testing to follow-up PrEP users from a community center in Barcelona. A response to the pandemic-related barriers to maintain prevention programs and scale up PrEP usage

J.M. Cabrera Guarin[1,2,3], F. Pérez[1], M. Meulbroek[1], P. Coll[1,4], Á. Rivero Calaf[1,3], M. Łucejko[1,2,3], J. Fernández[1,2], J. Reguant[1,2], J. Romero[1], J. Calderón[1], F. Pujol[1], J. Saz[1]

[1]HISPANOSIDA-Projecte dels NOMS, Barcelona, Spain, [2]Hospital Germans Trias i Pujol, Infectious Diseases Service, Badalona, Spain, [3]Fight AIDS and Infectious Diseases Foundation, Badalona, Spain, [4]IrsiCaixa - AIDS Research Institute, Badalona, Spain

Background: In 2021 BCN PrEP-Point modified the follow-up protocol, requiring a complete appointment every 6 months, rather than 3, and using "quick follow-up" appointments using a HIV home self-test and STIs screening in between. Those who had taken PrEP for longer than 1 year with good adherence and adequate kidney function were eligible. These changes aimed to respond to the pandemic situation and allow more people to be included in the program, while also involving PrEP users in their own care. We wanted to evaluate the implementation of such changes.

Description: This paper is an evaluation of the usage of HIV home self-testing to follow-up with men who have sex with men and transgender people taking PrEP in a community-based center in Barcelona. An online-based survey invitation was sent, informed consent was requested and local data protection laws were assured.

The survey asked about: accuracy and clarity of the information/instructions given; experience of performing the HIV home self-test and STIs samples collection; the convenience of this "quick follow-up" visit; and difficulties faced during the process. Responses were collected, analysed and discussed.

Lessons learned: 434 participants answered the survey. 94.1% of participants agreed that the information and instructions for HIV home self-testing were clear and adequate. 75.5% found it easy to perform the HIV home self-test, and 92.9% found it easy to read the result. 95.8% of respondents found the "quick follow-up" visit convenient and agile.

However, 31.8% of the users felt anxiety about performing the HIV home self-test and 15.2% suggested they didn't feel like using this service. Since implementation, the number of PrEP users has increased 18.9%.

Conclusions/Next steps: These changes have allowed the PrEP program to expand and were well received, encouraging users to be more responsible for their own care. Additional support was offered to users who experienced anxiety or didn't feel like using the service.

We expect the number of people that feel uncomfortable and/or anxious to reduce as users become accustomed to performing home self-testing in the future. Home self-testing has become increasingly popular and offers a cheap, simple and useful tool in HIV prevention.

EPC208

Assessing PrEP uptake for HIV negative contacts of index client: RISE experience

Y. Ogundare[1], B. Dare[1], B. Obasa[1], G. Ikaraoha[1], C. Laube[2], E. Atuma[1], M. Strachan[2], K. Curran[2], I. Iyortim[3], P. Anyanwu[4]

[1]Jhpiego, Program, Abuja, Nigeria, [2]Jhpiego, Program, Baltimore, United States, [3]USAID, Nigeria, Nigeria, [4]ICAP, Nigeria, Nigeria

Background: The Reaching Impact, Saturation, and Epidemic control (RISE) project is funded by PEPFAR via USAID in support of the national HIV response in Nigeria. PrEP has been integrated into routine health services in 103 RISE-supported facilities. The HIV-negative partners of newly diagnosed index cases are the primary population offered PrEP. While there has been a steady uptake in PrEP, there is a need to accelerate this intervention as a proven method of prevention; uptake of PrEP ranges widely, from

60 to 95% of those at risk who test negative. This analysis aims to evaluate the testing, eligibility and PrEP enrollment cascade of HIV negative partners/contacts of index clients who receive care at sites supported by the RISE project.

Methods: A risk screening tool was used to determine the HIV negative at-risk population eligible for PrEP. Eligible individuals were counseled and, if interested and clinically eligible, enrolled into the program and initiated on PrEP. Data from electronical medical records for services provided between October 2020 and September 2021 were analyzed to describe the proportion of individuals who were screened, eligible and subsequently received PrEP by cascade. Pearson's Chi-square test with Yates correction was utilized using a p-value of 0.05 as benchmark for statistical significance.

Results: A total of 10,027 HIV-negative individuals were screened between October 2020 and September 2021; 8,610 (86%) were eligible; of whom 8,385 (97%) accepted PrEP. Of the individuals who accepted PrEP 3,089 (37%) were female. Among HIV-negative partners of index cases, 2,493 HIV negative individuals were screened, 1,892 (76%) were eligible and 1,847 (98%) accepted PrEP. There was no significant difference between PrEP uptake in index modalities and other modalities for either men or women (p = .3234). PrEP uptake amongst women was highest 146 (22%) among ages 25-29, while PrEP uptake was highest 231 (21%) amongst Men aged 30-34.

Conclusions: Over 95% of eligible individuals-initiated PrEP from both index and non-index modalities. However, focus on strategies on raising risk awareness among female counterparts is essential in the program.

EPC209

Uptake of Pre-exposure Prophylaxis among key populations in Nigeria: evidence from the 2020 integrated biological & behavioural surveillance survey

B. Olakunde[1], C. Ujam[1], C. Ndukwe[1], Y. Folala-Anoemuah[1], T. Oladele[1], Y. Olaifa[1], K. Essomeonu[1], M. Egemba[1], H. Yahaya[1], H. Bello[1], A. Ogundipe[1]

[1]*National Agency for the Control of AIDS, Abuja, Nigeria*

Background: Key populations (KPs) are at increased risk of HIV due to specific higher-risk behaviours and structural factors that increase their vulnerability. Although KPs represent less than 2% of the total population in Nigeria, they are estimated to account for about 11% of new HIV infections. While interventions to prevent new infections among KPs in Nigeria have included oral pre-exposure prophylaxis (PrEP), there is limited evidence on its coverage. This study explored the uptake of PrEP and the disparities among KPs in Nigeria.

Methods: This study was a secondary data analysis of the 2020 Integrated Biological & Behavioural Surveillance Survey (IBBSS). Using a two-stage cluster sampling approach, the survey was conducted in 12 states across the six geopolitical zones in Nigeria, to obtain serological and behavioural information on KPs, including female sex workers (FSW), men who have sex with men (MSM), people who inject drugs (PWID) and transgender people (TG).

In the survey, KPs who had heard of PrEP were asked: "Have you ever taken PrEP?" We restricted our analysis to 6,069 KPs who responded "yes" or "no" to ever taking PrEP. We performed weighted descriptive statistics and univariate and multivariate regression analyses.

Results: Overall, 22.3% reported that they had ever taken PrEP (Table 1). The uptake of PrEP varied by KP group: MSM (27.5%), TG (24.1%), FSW (20.4%), and PWID (11.4%). After adjusting for sociodemographic factors, the odds of ever taking PrEP among MSM were about twice that of FSW (aOR=1.6, 95%CI=1.30-2.02) (Table 1). However, compared with FSW, PWID had lower odds of reporting ever taking PrEP (aOR=0.5, 95%CI=0.36-0.62).

Table 1: Uptake of PrEP by KP groups and logistic regression analyses, IBBSS, 2020

Conclusions: The uptake of PrEP among KPs in Nigeria is suboptimal and varies significantly by KP group. There is a need to identify and address barriers that limit the uptake of PrEP among these vulnerable populations.

EPC210

Long-acting injectable HIV pre-exposure prophylaxis interest among people who inject drugs in the San Diego-Tijuana border region

H.A. Pines[1,2], C.J. Valasek[3], S.A. Streuli[2], C.F. Vera[4], A. Harvey-Vera[4], S.A. Strathdee[4], A.R. Bazzi[2,5]

[1]San Diego State University, School of Public Health, San Diego, United States, [2]University of California, San Diego, Herbert Wertheim School of Public Health, La Jolla, United States, [3]University of California, San Diego, Sociology, La Jolla, United States, [4]University of California, San Diego, Medicine, La Jolla, United States, [5]Boston University, School of Public Health, Boston, United States

Background: Long-acting injectable HIV pre-exposure prophylaxis (LAI-PrEP) holds promise in overcoming challenges with daily oral PrEP adherence among people who inject drugs (PWID). However, PWID have been excluded from most LAI-PrEP research to date, and data on their LAI-PrEP interest remains limited. To advance equity in PrEP implementation for PWID, we examined LAI-PrEP interest among PWID in the San Diego-Tijuana border region (SDTBR) of the United States (US) and Mexico.

Methods: From 2020-2021, 612 PWID in the SDTBR were enrolled into a prospective study. Participants completed interviewer-administered surveys and HIV testing at baseline and 6 months. Multivariable multinomial logistic regression models examined associations between past-6-month sexual and injection behaviors, perceived HIV risk, and PrEP interest outcomes (interested in both oral and LAI-PrEP, only oral PrEP, only LAI-PrEP, or neither).

Results: Among 563 HIV-negative participants at baseline, median age was 43.0 years (IQR=35.0-52.0), 74% identified as male, 71% identified as Latino, and 70% were US residents. Six-month HIV incidence was 5.7 per 100 person-years (95% confidence interval [CI]: 2.0-9.5). Overall, 84% (472/563) expressed interest in PrEP, with 15% (86/563) interested in both oral and LAI-PrEP, 44% (248/563) interested in oral PrEP only, and 25% (138/563) interested in LAI-PrEP only. Compared to the odds of being interested in LAI-PrEP only, the odds of being interested in neither oral nor LAI-PrEP were lower for those who reported injecting multiple times daily (adjusted odds ratio [aOR]=0.4, 95% CI: 0.2-0.9), using syringes known or suspected to have been used before (aOR=0.5, 95% CI: 0.3-0.9), sharing other injection equipment (aOR=0.4, 95% CI: 0.2-0.7), buying drugs in already-prepared syringes (aOR=0.4, 95% CI: 0.2-0.7), having sexual partners living with HIV (aOR=0.4, 95% CI: 0.2-0.8), using drugs before or during sex (aOR=0.4, 95% CI: 0.2-0.8), and perceiving oneself to be at higher HIV risk than other PWID (aOR=0.2, 95% CI: 0.1-0.4).

Conclusions: PrEP interest was high among PWID in the SDTBR where HIV incidence is very high. Interest in LAI-PrEP only was associated sexual and injection risk behaviors and high perceived HIV risk, suggesting that LAI-PrEP could be a pivotal HIV prevention intervention for this population.

EPC211

The Pre-exposure Prophylaxis (PrEP) cascade among gay, bisexual and other men who have sex with men (MSM) in Shanghai, China

D.-M. Chuang[1], F. Tavangar[2], H. Zheng[3], A.T.-W. Li[4,5], J.B. Mendelsohn[6], S. Mishra[7], D.H.S. Tan[2,7]

[1]National Taiwan Normal University, Graduate Institute of Social Work, Taipei, Taiwan, Province of China, [2]St. Michael's Hospital, Toronto, Canada, [3]Shanghai CSW&MSM Center, Shanghai, China, [4]Regent Park Community Health Centre, Toronto, Canada, [5]Committee for Accessible AIDS Treatment, Toronto, Canada, [6]Pace University, New York City, United States, [7]University of Toronto, Toronto, Canada

Background: This study aims to understand the impact of PrEP in gay, bisexual and other men who have sex with men (gbMSM) and to quantify an anticipated PrEP cascade in a community-based sample of MSM in Shanghai, China

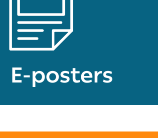
Methods: From July 2019 to December 2020, we conducted a cross-sectional online survey among a convenience sample of HIV-negative or HIV-unknown MSM recruited through a voluntary HIV testing clinic and smartphone app in Shanghai. We constructed a three-step PrEP cascade by sequentially quantifying respondents' PrEP awareness, acceptability, and drug coverage.

We also included correlates of PrEP usage, such as health-care access, sexually transmitted infection (STIs), self-assessed sexual risk, concerns about taking PrEP, perceived PrEP acceptability in the MSM community, PrEP-related stigma, and locations for PrEP access. Three multivariable logistic regression models were conducted to examine the association between potential correlates and the three-step PrEP cascade.

Results: Of 615 participants, the median age was 29 years; 35.9% were born in Shanghai and 64.1% in other cities in China. Most had an undergraduate degree or more (83.7%), full-time employment (77.9%), and health insurance (93.7%). Participants self-reported: a history of STIs (26.1%), high risk of HIV (12.4%), current recreational drug use (26.1%), and an HIRI-MSM score >10 (85.7%). Most participants felt comfortable telling their sexual partners that they were taking PrEP (65.5%), but not their friends (48.8%) and family (19.2%).

Of all participants, 66.2% were aware of PrEP; of those who were aware of PrEP, 69.8% were willing to use PrEP; and of those willing to use PrEP, 83.1% had any drug coverage, which may increase likelihood of PrEP usage. PrEP cascade engagement was associated with undergraduate education (OR=5.39, 95% CI=3.25-9.14), concerns about STIs (OR=1.93, 95% CI=1.18-3.17), self-assessed HIV risk (OR=2.61, 95% CI=1.09-7.07), past PEP use (OR=2.48, 95% CI=1.16-5.82), and anticipated PrEP disclosure to sexual partners (OR=2.46, 95% CI=1.54-3.96).

Conclusions: Our findings identified patient, community and health system factors that impact PrEP cascade engagement. Further interventions to raise PrEP awareness,



address PrEP-related stigma and ensure drug access are needed to promote effective PrEP scale up amongst MSM in Shanghai.

EPC212

Knowledge of and willingness to take PrEP in Zimbabwe – an analysis of the Zimbabwe Population-based HIV Impact Assessment (ZIMPHIA) 2020

S. Wallach[1], R. Weber[2], K. Mirkovic[2], A. Sciarratta[1], R. Malaba[2], O. Mugurungi[3], M. Farahani[4], G. Musuka[5], R.L. Laws[6], T. Dobbs[6], J.H. Rogers[2]
[1]Public Health Institute (PHI)/U.S. Centers for Disease Control and Prevention (CDC) Global Health Fellowship, Harare, Zimbabwe, [2]Division of Global HIV & TB, U.S. Centers for Disease Control and Prevention (CDC), Harare, Zimbabwe, [3]Ministry of Health and Child Care, Harare, Zimbabwe, [4]ICAP Global Health, New York, United States, [5]ICAP Global Health, Harare, Zimbabwe, [6]Division of Global HIV & TB, U.S. Centers for Disease Control and Prevention (CDC), Atlanta, United States

Background: In 2018, Zimbabwe launched pre-exposure prophylaxis (PrEP) as an HIV prevention strategy for those at high-risk of HIV infection. This analysis uses Zimbabwe Population-based HIV Impact Assessment (ZIMPHIA) 2020 data to investigate characteristics associated with knowledge of and willingness to take PrEP.

Methods: ZIMPHIA 2020 is a nationally-representative, cross-sectional, HIV-focused survey among adults age 15+ in randomly selected households. We examined associations between sociodemographic characteristics and risk-taking and health-seeking behaviors with knowledge of and willingness to take PrEP.

Factors significantly associated with the outcomes ($p<0.05$) in bivariate logistic regression models were included in multivariable models, stratified by sex, using jackknife methods to estimate variance.

Results: Among the sample population, (males=4,527; females=7,392), 9.99% of males and 10.95% of females heard of PrEP. Among those testing HIV-negative (males=3,743; females=5,701), 68.03% of males and 64.33% of females indicated willingness to take PrEP. Males (aOR 4.14 [95%CI: 2.51-6.83]) and females (aOR 2.46 [95%CI: 1.69-3.59]) with above a secondary education were more likely to have heard of PrEP than those with primary/no education. Males who tested for HIV in the last year (aOR 2.00 [95%CI: 1.31-3.07]) were also more likely to have heard of PrEP, and females ages 15-24 were more likely to have heard of PrEP (aOR 0.73 [95%CI: 0.55-0.96]) than those 35-44. Males ages 15-24 were more willing to take PrEP (aOR 1.38 [95%CI: 1.04-1.87]) than those 35-44, and divorced, separated, or widowed males were more willing to take PrEP (aOR 2.35 [95%CI: 1.52-3.63]) than those never married. Females were more willing to take PrEP if they worked for cash/goods as payment (aOR 1.21 [95%CI: 1.05-1.38]) or saw a healthcare worker in the last year (aOR 1.16 [95%CI: 1.00-1.33]).

Conclusions: Participants who did not access healthcare or had lower education were less likely to have knowledge of or be willing to take PrEP. Adolescent girls and young women (AGYW), who have disproportionately high-risk of infection, are also less likely to have heard of PrEP.

These results highlight the importance of community-based demand creation and education and scale-up of differentiated service delivery models, including AGYW-specific prevention programs, to better reach those at risk of HIV.

EPC213

Primary healthcare provider-related factors associated with oral pre-exposure prophylaxis (PrEP) provision for HIV prevention in the eThekwini municipality

V. Naicker[1]
[1]South African Medical Research Council, HIV and Other Infectious Diseases Research Unit, Durban, South Africa

Background: Oral HIV pre-exposure prophylaxis (PrEP) is safe, effective and approved but the uptake has been low. Low uptake may be due to user or provider-related factors. There is a paucity of information regarding factors that may influence whether oral PrEP is prescribed.

This study examined the primary health care (PHC) provider-related factors associated with oral PrEP provision in the eThekwini Municipality, KwaZulu-Natal, South Africa. The study assessed the socio-demographic provider profile and challenges experienced by providers when providing oral PrEP.

Methods: This was a quantitative, cross-sectional study with 160 participants (medical doctors, professional and enrolled nurses and counsellors) from both private and public PHC facilities, who completed a self-administered questionnaire between January 2020 and June 2021.

Although 92.5 % (n=147/160) of the respondents had patients who may benefit from oral PrEP, only 71.3 % (n=114/160) had prescribed or referred patients for oral PrEP.

Results: Socio-demographic factors were similar between oral PrEP adopters (prescribed PrEP) and non-adopters (did not prescribe PrEP). Oral PrEP was most likely to be prescribed when healthcare providers had 11 or more oral PrEP discussions with patients (OR= 9.12, CI= 3.05-27.25, $p<0.001$). Providers who requested≥6 HIV tests in the last month were 2.20 times more likely to provide or refer patients for oral PrEP than providers who requested ≤5 HIV tests (OR= 2.20, CI= 1.04-4.63, p=0.039).

Healthcare providers who had limited knowledge about oral PrEP were also 73% less likely to prescribe or refer a patient for PrEP than those who had attended training on oral PrEP (OR= 0.27, CI= 0.11-0.66, p= 0.004).

Majority of the healthcare providers reported concerns or challenges regarding adherence, increased risky sexual behaviour, increased STIs, increased counselling time, eliciting an accurate sexual history and eliciting accurate

risk perception. The majority of healthcare providers were also concerned about financing of oral PrEP, misperception that the patient was HIV-infected, patients not using adequate protection at the commencement of oral PrEP and the regular 3-monthly follow-up visits.

Conclusions: The results suggest large gap between PrEP awareness and provision and highlights the need for further education among providers to improve scale up of oral PrEP at PHC level.

EPC214

Scale-up and optimization of HIV self-testing for the last mile in Botswana

M.-C. Lavoie[1], A. Marwiro[2], A. Lefi[3], M. Montebatsi[3], C. Baumhart[1], N. Blanco Herrera[1], D. Laetsang[2], D. Baikgathi[2], O. Phuthego[3], G. Mogomotsi[4], C. Laube[5], N. Ndwapi[3]

[1]University of Maryland Baltimore, Ciheb, Baltimore, United States, [2]Jhpiego, Gaborone, Botswana, [3]Botswana–University of Maryland School of Medicine Health Initiative (Bummhi), Gaborone, Botswana, [4]Botswana Ministry of Health and Wellness, Gaborone, Botswana, [5]Jhpiego, Baltimore, United States

Background: Botswana is a high HIV-burden country, with 19.9% HIV prevalence among adults aged 15 to 49 years old in 2020. The UNAIDS estimates that 92% of people living with HIV know their status. Botswana deployed several HIV testing modalities, including HIV self-test kits (HIVST), to increase HIV case identification and reach the 95% UNAIDS target. HIV self-testing, a more discreet approach, was introduced in 2019 by the CDC-funded Accelerating Botswana through Last Mile to Epidemic Control (ABLE) project to reach clients beyond health facilities. We describe the experiences and lessons learned in implementing HIVST across 53 facilities in Botswana.

Description: The Bummhi/Jhpiego partnership consulted with health authorities and providers, identified distribution points at facilities, and trained health workers on HIVST and HIVST monitoring tools. HIVST standard of procedures were developed and included distribution points, screening for intimate partner violence, return of results, confirmatory HIV testing for clients with reactive results, and linkage to antiretroviral therapy (ART).

A continuous quality improvement data-driven approach was used to optimize HIVST through monthly performance reviews and swift remediation to improve new client identification, return of results, linkage to HIV testing for confirmatory testing, and ART as key performance measures.

Lessons learned: Between Oct 2020 and September 2021, 7434 HIVST were distributed across 53 facilities. A total of 4242 (57.1%) clients returned their HIVST results. Among them, 157 (3.7%) had a reactive test, 111 (70.7%) performed HIV testing according to the national algorithm, and 102 (91.9%) were diagnosed with HIV. Among them, 92 (90.2%) were linked to ART. A total of 125 trained Lay Health Care Workers were integrated into all health service delivery points to assist with HIVST distribution. HIVST kits included health facility contact information to enable clients to reach providers for additional information or schedule follow-up appointment for HIV testing.

After three days, clients who received HIVST were contacted to obtain results and schedule HIV confirmatory if HIVST was reactive.

Conclusions/Next steps: Trained personnel, wide availability of HIVST, and longitudinal HIVST monitoring tools have contributed to the scale-up of HIVST. HIVST monitoring has enabled individualized longitudinal follow-up to optimize linkage to HIV services.

EPC215

Uptake of pre- exposure prophylaxis as a prevention tool among adolescent and young key population across seven states in Nigeria

H.D. Okpe[1], K. Adedokun-Ariwoola[1], S. Adamu-Oyegun[1], O. Ibiloye[1], O. Onumara[1], P. Jwanle[1], I. Onwuatuelo[1], J.O. Samuels[1], P. Okonkwo[1]

[1]APIN Public Health Initiatives, Abuja, Nigeria

Background: Pre-exposure prophylaxis (PrEP) is an effective HIV-prevention tool for protecting adolescents and young people (AYP) at risk for HIV acquisition. PrEP is strategic in reducing new infections. AYPs are at a stage of experimentation, self-discovery and low-perceived risk of contracting HIV. They are more vulnerable and have poorer negotiating skills to advocate for safer-sex practices due to discrimination, violence and imbalances especially with older partners. In 2021, the estimated cumulative number of people initiating PrEP was 124,000 – 125,000.

This study reviewed PrEP uptake among AYP key population (female-sex workers, men who have sex with men, persons who inject drugs and transgender) across 89 facilities in seven states in Nigeria.

Methods: A retrospective study of PrEP uptake among AYP key population(KP) aged 15 -24 years who accessed PrEP services from 89 (three one-stop-shops and 86treatment) facilities between April 2020 and December 2021 across seven states in Nigeria. Strategies to improve uptake included, stakeholder engagement for acceptability/buy-in by the KP communities, expansion into more communities to increase access, and assigned facility targets. PrEP was offered and prescribed to the AYP- KPs who accessed services. PrEP uptake was defined as new enrolment who got a PrEP prescription and medications dispensed. Data was extracted using an excel-based reporting tool, which collated patient-level data from the electronic-medical-records.

Results: During the period under review, 3109 AYP-KP enrolled on PrEP. The highest uptake was among females 20-24 years 1391 (45%) and lowest among males 15 -19 years

249(8%). PrEP uptake showed an upward trajectory-Fig 1. The proportion of PrEP uptake among AYPs also showed an upward trend from 7% in FY 20_Q2 to 24% in FY22_Q1.

Figure 1. Uptake of pre-exposure prophylaxis among adolescent and young key population.

Conclusions: Improvement in PrEP uptake among AYP-KPs shows acceptability among this age-band. With increased demand creation, correct risk perception and AYP-KP led/ friendly facilities there is room for improved uptake and reduction in HIV transmission among AYP-KPs.

EPC216

Outcomes of a pharmacist-led, same-day pre-exposure prophylaxis (PrEP) program in Mississippi: a mixed-methods study

C. Khosropour[1], T. Riley[1], K. Backus[2,3], C. Gomillia[2], F. Gordon[2], E. Healy[1], K. Lockwood[2], A. Means[1], L. Ward[2]
[1]*University of Washington, Seattle, United States,* [2]*University of Mississippi Medical Center, Jackson, United States,* [3]*Gilead Sciences, Rochester, United States*

Background: Mississippi has one of the highest rates of HIV in the United States but has low PrEP uptake. Understanding patterns of PrEP use can help improve PrEP uptake and persistence.

Methods: Between November 2018-December 2019, patients at high risk for HIV attending a non-clinical testing site in Jackson, Mississippi were referred to a pharmacist for same-day PrEP initiation. The pharmacist provided a 90-day PrEP prescription and scheduled an appointment within 3 months for patients to see a clinician. We linked records of patients to electronic health records from the two largest PrEP clinics in Jackson to determine linkage into ongoing clinical care. We identified four distinct PrEP use patterns:

1. Filled a prescription and linked into care within 3 months;
2. Filled a prescription and linked into care after 3 months;
3. Filled a prescription and never linked into care; and,
4. Never filled a prescription.

In 2021, we conducted 24 follow-up interviews with patients in the four groups to ascertain barriers and facilitators to PrEP uptake and persistence.

Results: There were 121 clients evaluated for PrEP; all were given a prescription. One-third were less than 25 years old, 77% were Black, and 59% were cisgender men who have sex with men. Around one-quarter (26%) never filled their PrEP prescription. Of those who filled their prescription, 59% never linked into clinical care and ultimately stopped PrEP, 17% linked into care at some point after 3 months (resulting in a gap in PrEP coverage), and 24% linked into care within 3 months, though only 41% of those individuals continued PrEP for another 3 months.

Qualitative data revealed that stigma related to sexuality (e.g., being gay) and HIV, misinformation about PrEP, lack of PrEP locations, and fear of side effects were barriers to uptake and persistence. Individuals' desire to stay healthy and the support of PrEP clinic staff were facilitators.

Conclusions: Only a quarter of individuals given a same-day PrEP prescription persisted on PrEP for 3 months without a gap in PrEP coverage. Addressing noted barriers of stigma and misinformation and increasing locations that provide PrEP may increase PrEP persistence.

EPC217

Discontinuation rate, associated factors and reasons for discontinuationof pre-exposure prophylaxis among sex workers attending the most at risk population clinic, Mulago Hospital in Uganda

R. Naturinda[1]
[1]*Makerere University, Epidemiology and Biostatistics, Kampala, Uganda*

Background: A substantial number of sex workers are initiated on (Pre-Exposure Prophylaxis) PrEP for HIV prevention. Retaining those initiated on PrEP is very important to achieve the goal of reducing new infections in Uganda. However, data on discontinuation and retention among key populations especially sex workers is generally limited in the country.

Methods: This was a cross-sectional study employing both quantitative and qualitative approaches of data collection. A total of 30 In-depth interviews were conducted for the qualitative data collection. A sample size of 484 client records were abstracted for the quantitative data. Systematic sampling technique was employed for the quantitative data. Qualitative data was analyzed using Atlas ti version 6 and results are presented under different themes. Quantitative data was analyzed using STATA version 14; Univariate, bivariate and multivariate analysis were conducted, and results are presented in tables using measures of central tendency, dispersion and associations. PrEP discontinuation was defined as missing refill of PrEP for two or more consecutive rounds of refill.

Results: The Prevalence of PrEP discontinuation was 76.0% (368/484). Factors associated with PrEP discontinuation included; age 30-34 years compared to age <20years adjusted PR=1.21, 95%CI [1.23-1.56]; Secondary school level of education compared to primary level, adjusted PR=0.92, 95% CI [0.86-0.99]; Duration on PrEp in months 3-6 months and >6months compared to 2< months adjusted PR=0.79, 95% CI [0.71-88] and PR=1.86, 95% CI [1.52-2.28]. The overall clients experience on PrEP were generally good. Facilita-

tors included perceived medical benefits, perceived sexual benefits, and most clients use it alongside condoms during a sexual encounter. Reasons for PrEP discontinuation included;change of sexual behaviors, fear of stigmatization, discomfort of having to consume PrEP every day / pill burden, fear of side effects like nausea, fatigue, vomiting, dizziness and loss of appetite, and limited access to medication.

Conclusions: Prevalence of PrEP Discontinuation among commercial sex workers was high. This could be because of limited access to the medication, medication side effects pill burden and stigmatization from the general population. Targeted strategies to prevent inappropriate discontinuations are needed to the commercial sex workers and general population as well.

EPC218

Facilitators and barriers of daily oral HIV pre-exposure prophylaxis use among men who have sex with men, Harare 2020

F.C. Chirongoma[1], G. Shambira[1], N Nyati-Jokomo[1], B. Madzima[2], R. Yekeye[2], E. Govha[1], N. Gombe[1], T. Juru[1], M. Tshimanga[1]
[1]University of Zimbabwe, Family Medicine, Global and Public Health Unit, University of Zimbabwe, Harare, Zimbabwe, [2]National AIDS Council Zimbabwe, Harare, Zimbabwe

Background: HIVPre-exposure prophylaxis (PrEP) when taken consistently reduces the risk of HIV infection by 92 to 99%. Key populations PrEP Program data demonstrated that against a targetofenrollingall eligible MSM on PrEP in Harare only 28% have accessed it since2019.

We investigated the barriers and facilitators to PrEP use among MSM to strengthen biomedical interventions for the control of the epidemic amongst this group.

Methods: We conducted a 1:1 unmatched case-control study, a case being an HIV negative MSM above18years-old receiving health services at PSI or Wilkins clinics in Harare between 1 October 2018 and 31 September 2019 and not on PrEP or has a self-reported PrEP adherence composite-score of less than 75%.

We randomly recruited 149 case-control pairs from three high volume sites offering services for MSM in Harare. Interviewer administered questionnaires were used to collect dataon thebarriersand facilitators to PrEP use among MSM.We generatedmeans, frequencies, proportions, odds ratios and their corresponding 95% confidence intervals. Stratified analysis was done to identify possible confounding or effect modification. Logistic regression analysis was done to determine the independent factors associatedPrEP use among MSM.

Results: Cases and Controls had comparable demographic data. Inconsistent condom use (aOR= 2,051, 95%CI: 1,231-3,419), receptive anal sex (aOR=2,865, 95%CI: 1,374-5,972), and HIV test done in the last 3 months (aOR= 2,61495% CI: 1,452-4,716) were independent risk factors associated with not using Pre-Exposure Prophylaxis. Being employed (aOR=0,526 95% CI:0,313-0,882) and being of transgender sexual orientation (aOR= 0,21295% CI: 0,042-0,997) were independent protective factors that facilitated PrEP use among MSM.

Conclusions: Sexual orientation affected the use of HIV PrEP, experiencing receptive anal sex, having taken an HIV test in the last 3 months and inconsistent condom use was associated with not using HIVPrEP.

We recommend strengthening PrEP differentiated service delivery including PrEP awareness targeting gay and bisexual men.PrEP education was given to 330 Men who have sex with men in Harare.

EPC219

Barriers to PrEP uptake in gay, bisexual, trans and queer men, two-spirit and non-binary people in Canada: an analysis considering ethnoracial and gender-diverse identities within a community-based health survey

A.T. Amato[1,2], K. Card[2,3], B. Klassen[2], M. Vattiata[2], M. Kwag[2], D.H.S. Tan[2,4], H. Pruden[2,3], N.J. Lachowsky[1,2]
[1]University of Victoria, School of Public Health and Social Policy, Victoria, Canada, [2]Community-Based Research Centre, Vancouver, Canada, [3]Simon Fraser University, Faculty of Health Sciences, Burnaby, Canada, [4]St. Michael's Hospital, Toronto, Canada

Background: Indigenous and ethnoracial minority Gay, Bisexual, Trans, Queer men, Two-Spirit, and non-binary (GBTQ2S+) people in Canada are often underrepresented in PrEP uptake within GBTQ2S+ population samples due to health and social inequities.

We sought to determine barriers to PrEP use for sub-populations of HIV-negative GBT2Q based on ethnoracial identity and gender diversity.

Methods: Participants self-completed the national, online, anonymous, community-based Sex Now 2019 behavioural surveillance survey. Recruitment occurred via GBTQ2S+-oriented sex-seeking apps, websites, and social media from November 2019 to February 2020 (pre-COVID). Participants completed questions on demographics and PrEP-related barriers (e.g., low self-perceived HIV risk, cost, judgement from healthcare providers).

Multivariable confounder bootstrapped (1000 iterations) logistic regression models assessed differences in various barriers to PrEP by ethnoracial identity, and stratified by cisgender/gender-diverse identity; possible confounders included age, income, and sexual orientation, if significantly correlated with the outcome. Beta coefficients (β) with 95% confidence intervals (CI) are presented.

Results: Of 1137 HIV-negative Indigenous and ethnoracial minority GBTQ2S+ participants (85.5% cisgender men, 14.5% gender-diverse), 17.2% were Black/African/Caribbean, 29.2% were Indigenous, 20.0% were Latinx, 28.9% were East/Southeast Asian, and 21.9% were Arab/South Asian.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Four ethnoracial differences in PrEP-related barriers were identified:
First, low self-perceived HIV risk was less likely to be reported by Latinx (15.6% versus 23.2%, β=-0.75, CI [-1.41,-0.15]) and Arab/South Asian (17.8% versus 22.8%, β=-0.53, CI [-1.10,-0.056]) participants.
Second, disliking taking pills was less likely to be reported by Arab/South Asian participants (8.7% versus 16.4%, β=-0.61, CI [-1.29,-0.11]).
Third, cost as a barrier was less likely to be reported by Indigenous participants (19.9% versus 28.9%, β=-0.61, CI [-1.16,-0.11]).
Fourth, judgement from healthcare providers was less likely reported by gender-diverse South Asian participants (8.0%, β=-1.54, CI [-22.33,-0.024]) versus all other gender-diverse participants (23.6%).
Conclusions: Commonly reported PrEP barriers for Indigenous and ethnoracial minority GBTQ2S+ were self-perceived risk, cost, and judgement from healthcare providers. However, specific ethnoracial groups, intersecting with gender diversity, experienced these less.
Although this data cannot encapsulate all PrEP barriers faced by these communities, it highlights the need for culturally-appropriate and gender-affirming health promotion strategies, new PrEP prevention efforts, and healthcare provider capacity-building to improve equitable PrEP implementation.

EPC220
The PrEP care continuum in men who have sex with men in China: a systematic review

C. Hong[1], L. Wang[2], L. Chen[3], C. Li[4], S. John[5], F. Wong[6], J. Simoni[2,7], I. Holloway[1]
[1]*University of California, Los Angeles, Department of Social Welfare, Los Angeles, United States,* [2]*University of Washington, Department of Psychology, Seattle, United States,* [3]*Vanderbilt University, Nashville, United States,* [4]*Georgia Institute of Technology, Atlanta, United States,* [5]*Medical College of Wisconsin, Milwaukee, United States,* [6]*Florida State University, Tallahassee, United States,* [7]*University of Washington, Department of Global Health, Seattle, United States*

Background: Pre-exposure prophylaxis (PrEP) could be a promising HIV prevention intervention among men who have sex with men (MSM) in China. Yet, aggregated evidence regarding the presentations and determinants of the PrEP Care Continuum remains absent. This review aimed to summarize the current status of the PrEP care continuum and synthesize the barriers and facilitators to inform future intervention efforts in China.
Methods: We conducted a systematic review searching both English and Chinese electronic databases for studies published since 2012. Four reviewers screened all studies independently, and relevant data were extracted and synthesized following the PRISMA guidelines.
Results: A total of 568 records were identified and 22 studies met the criteria and were included in the final synthesis, with 12,484 MSM in total. The proportion of MSM who were aware of PrEP was 32.6% (95% CI: 23.4-43.4), lower than the proportion of MSM willing to use PrEP 54.1% (95% CI: 38.8-68.5). The pooled prevalence of PrEP uptake from (n=5) studies was 1.67% (95% CI: 0.67-4.10). Only one study reported PrEP adherence (62.9%).
Factors associated with higher PrEP awareness include higher HIV knowledge, previous HIV testing, and higher education, while the barriers were short local residence time and internet-based partner seeking. Multilevel facilitators to PrEP willingness include previous sexually transmitted infection, partners at high risk of HIV infection, community engagement in sexual health, and difficulty of condom use. Barriers were mainly at the individual level, such as concerns about effectiveness and mental health issues.
Having multiple male partners, concerns about HIV infection, and ease and comfort of PrEP use were facilitators for PrEP uptake and adherence, while medical mistrust, low perceived risk of HIV infection, discriminatory treatment when seeking PrEP service, and high cost are barriers to uptake. Potential side effects of PrEP and substance use are barriers to PrEP adherence.
Conclusions: This review found relatively low levels of awareness of PrEP, while higher levels of willingness among MSM in China. More studies are needed to examine PrEP uptake and adherence. Policies and interventions can leverage the facilitators and address the barriers to promoting the PrEP care continuum among MSM in China.

EPC221
Primary care clinic health care workers' perspectives on PrEP implementation among men in rural South Africa

P. Chen[1], S. Shenoi[2], A. Moll[3]
[1]*Yale University School of Medicine, New Haven, United States,* [2]*Yale University School of Medicine, Infectious Diseases, New Haven, United States,* [3]*Philanjalo NGO, Tugela Ferry, South Africa*

Background: South Africa, home to the world's largest HIV epidemic, began implementing PrEP in primary care clinics in early 2020. We evaluated health care workers' (HCWs') experiences with the PrEP rollout among men and assessed perceived barriers and potential solutions.
Methods: Semi-structured qualitative interviews were conducted with senior-level nurses (n=24) across 16 primary care clinics and 1 mobile clinic in rural Msinga, Kwazulu-Natal province, South Africa. Nurses were eligible if they worked within Msinga, prescribed PrEP, and spoke English, and were recruited through purposive sampling until thematic saturation was achieved. Thematic analysis was performed.

Results: HCWs report slow PrEP rollout, particularly among men. PrEP barriers were characterized in a socioecological model at the individual-level, community-level, and society-level. Individual-level barriers included: low SES and health literacy, low PrEP knowledge and inaccurate information, low perception of HIV risk, daily pill burden, and preference for treatment over prevention.

Community-level barriers leading to PrEP not being offered to all eligible patients included: nurse workload, lack of time, variable PrEP education for patients, variable staff training and PrEP knowledge, poor clinic access, and lack of social support for PrEP.

On a society-level, HCWs report persistent HIV and gender-based stigmas. HCWs perceive men as higher HIV risk but worse PrEP candidates compared to women, and reported gender skew in PrEP uptake. HCWs view men to have more health negligence, HIV testing avoidance, skepticism towards new medications, low PrEP retention, poor engagement with female nurses, and high reliance on traditional healers, related to cultural norms for male health-seeking behavior.

Rollout was also negatively impacted by the COVID-19 pandemic due to low patient volumes and shift in public health focus. Despite challenges, HCWs generally view PrEP positively, though some view it as extra work. HCWs suggested potential solutions to facilitate implementation, including: more educational materials in Zulu and staff trainings, long-acting injectables, PrEP ambassadors, engaging male community leaders, and a men's clinic staffed by male nurses that accommodates work schedules.

Conclusions: HCWs play an important role in PrEP rollout and provide valuable suggestions for implementation, including improved PrEP education, injectable PrEP, and differentiated service delivery models for men.

EPC222

Missed opportunities for HIV prevention and pre-exposure prophylaxis (PrEP) prescription at a safety-net health system in the Southern U.S

M. Lopez[1], M. Smith[2], K. Alvarez[3], M. Harms[3], K. Bistransin[3], E. Levy Kamugisha[1], E.M. Arnold[1], H. King[1]

[1]UT Southwestern Medical Center, Dallas, United States, [2]Texas Tech University, Dallas, United States, [3]Parkland Health & Hospital System, Dallas, United States

Background: PrEP is a prophylactic drug up to 99% effective in reducing risk of HIV transmission. Despite this, prescription rates remain low and HIV incidence remains stable. Persons with HIV acquisition risk should be counseled on PrEP, however efforts to increase PrEP uptake in the South, where HIV rates are highest, have proven unsuccessful.

Methods: Retrospective chart review of patients newly diagnosed with HIV at a large public health system from January 1, 2015 to June 30, 2021. We analyzed interactions with the health system in the five years preceding HIV diagnosis and identified missed opportunities for discussing PrEP; defined as a recent bacterial sexually transmitted infection (STI), reported intravenous drug use (IVDU), or unprotected sex.

Outcomes included rates of documented PrEP counseling, PrEP educational handout, and condom discussion in the electronic medical record.

Results: We identified 454 patients with a new HIV diagnosis who had previous health system interactions (average number of visits 9.8). In total, 29.5% had at least one identifiable HIV risk factor (9.9% bacterial STI, 14.1% inconsistent condom use, and 5.5% IVDU) prior to HIV diagnosis. Only 1.5% of patients were directly counseled on PrEP, and 3.7% received a PrEP educational handout at their visit.

The majority of patients (67.8%) had no documented condom discussion. No PrEP education occurred for those who exclusively interacted with the emergency department, urgent care, or inpatient settings, and 85% had no documented discussion about condoms in those practice settings.

In contrast, 20% of those who exclusively interacted with an outpatient primary care or subspecialty clinic had no documented condom discussion.

Conclusions: Data from this large health system suggest multiple missed opportunities to discuss PrEP and HIV risk with patients prior to HIV diagnosis. From these findings, it does not appear that these discussions are routinely taking place, or at a minimum, being documented in the patient's electronic health record. Documented PrEP education and condom discussion varied depending on the clinical setting and was underutilized overall.

Educational interventions may be needed to ensure that those treating patients at risk have the knowledge, skills, and resources to discuss the benefits of PrEP with patients.

EPC223

Population-level trends in HIV pre exposure prophylaxis (PrEP) knowledge, interest and use among indigenous two-spirit and gay, bisexual, queer, and trans men and non-binary people in Canada, 2015-2020

N. Lachowsky[1,2], S. Arthur[1], K. Card[2,3], B. Klassen[2], C. Draenos[2], A. Hu[1], A. Amato[1,2], D. Ho[2], M. Vattiata[2], M. Kwag[2], M. Hull[4], D.H.S. Tan[2,5], H. Pruden[2,3,6], T. Salway[2,3], M. Gilbert[2,4,6], O. Ferlatte[2,7]

men and non-binary people of all ethnicities (2S/GBTQ). We sought to examine population-level trends and demographic correlates of PrEP knowledge, interest and use among 2S/GBTQ in Canada.

Methods: We pooled data (N=18,805) from a community-based cross-sectional bilingual survey repeated in 2015 (online), 2018 (pride festivals), 2019 (online), and 2020 (online). Online recruitment used advertisements on socio-sexual websites/apps, and community-based organizations' social media and email lists. Our analytic sample included 2S/GBTQ participants who were HIV-negative, >15 years old, and lived in Canada.

We evaluated demographic correlates and temporal trends (survey year as a continuous explanatory variable) of four PrEP outcomes (knowledge, interest, current use, lifetime use) using four multivariable logistic regression models, each adjusting for sexual orientation, gender, ethnoracial identity and age. We report adjusted odds ratios (AOR) with 95% confidence intervals (95%CI).

Results: Knowledge of PrEP increased from 57.3% to 88.5% (2015-2019, AOR=1.56, 95%CI:1.53-1.59). Interest in PrEP decreased from 48.0% to 38.4% (2015-2020, AOR=0.93, 95%CI:0.91-0.94).

Current PrEP use increased from 12.6% to 20.4% (2018-2020, AOR=1.37, 95%CI:1.26-1.48). Lifetime PrEP use increased from 15.5% to 30.7% (2018-2020, AOR=1.62, 95%CI:1.50-1.74).

Younger 2S/GBTQ were more likely to know about PrEP (AOR=0.99, 95%CI:0.98-0.99), be interested in PrEP (AOR=0.99, 95%CI:0.99-0.99), but less likely to currently use it (AOR=1.01, 95%CI:1.00-1.01).

Non-binary 2S/GBTQ were more likely to know about PrEP (AOR=1.36, 95%CI:1.08-1.71), but less likely to use PrEP currently (AOR=0.58, 95%CI:0.40-0.81) or ever (AOR=0.75, 95%CI:0.57-0.98).

Bisexual-identified men were less likely to know about (AOR=0.32, 95%CI:0.29-0.35), be interested in (AOR=0.91, 95%CI:0.84-0.98), and to use PrEP currently (AOR=0.43, 95%CI:0.36-0.50) or ever (AOR=0.40, 95%CI:0.35-0.46).

Compared with white participants, each of African/Black/Caribbean, Asian, and Latin GBTQ2 were more likely to know about, be interested in, and use PrEP currently or ever (all p<0.05). Indigenous 2S/GBTQ were less likely to know about PrEP (AOR=0.77, 95%CI:0.66-0.90), and use PrEP currently (AOR=0.67, 95%CI:0.50-0.87) or ever (AOR=0.77, 95%CI:0.60-0.97).

Conclusions: PrEP knowledge and use has generally increased for 2S/GBTQ, hence decreased interest levels, but population-specific approaches are needed to support under-served 2S/GBTQ groups (e.g. Indigenous, non-binary, youth, bisexual).

EPC224

Acceptability of long-acting injectable prep administration by health workers in Kampala, Uganda; a cross-sectional study

M. Baguma[1], A. Kaguta[1], D.J. Lukubuya[2], W. Nambatya[2], E. Laker[3], T. Muwonge[3]

[1]Makerere University, Department of Pharmacy, Kampala, Uganda, [2]Makerere University, Kampala, Uganda, [3]Infectious Disease Institute, Kampala, Uganda

Background: The FDA recently approved long-acting injectable PrEP (LAI-PrEP) formulation of Cabotegravir® for HIV prevention It is important to understand what clinicians' perspectives about use of LAI-PrEP are even before it is widely rolled out. This is because there are implementation differences in the use of LAI-PrEP and oral PrEP, which might affect clinicians' attitudes.

We aimed to determine the acceptability of injectable PrEP use among health workers in HIV prevention clinics in Uganda.

Methods: We conducted a cross-sectional study with convenient sampling of health workers between November-December 2021 at several HIV prevention clinics in Kampala, Uganda. Self-administered structured questionnaires were used to assess the acceptability of health workers to administer LAI-PrEP and implementation preferences.

We used descriptive statistics to characterise the population and logistic regression methods to determine factors associated with health workers willingness to administer LAI-PrEP.

Results: Among 101 health workers of median age 32 [IQR=26−41] years, 93.07% were willing to administer LAI-PrEP when it becomes available. Those who were comfortable with giving injections were more likely to accept the administration of LAI-PrEP (P <0.001) as well as those who did not have concerns that it increased high-risk sexual behaviour (P <0.001). Majority (87%) believed their facilities were well equipped to provide LAI-PrEP.

Preferences for places of administration were hospital (46%), home (12%), community drug distribution points (11%), and pharmacies (4%)

Conclusions: There is high willingness among health workers to administer LAI-PrEP when it becomes available. Factors that could hinder use warrant further investigation.

EPC195

Socio-behavioral correlates of PrEP uptake and correct PrEP adherence in men who have sex with men in West Africa (CohMSM-PrEP – ANRS12369 – Expertise France)

A. Eubanks[1], B. Coulibaly[2], B. Dembélé Keita[2], C. Anoma[3], T.T. Dah[4,5], E. Mensah[6], M. Diarra[2], K.J. Lokrou[3], J. Ouedraogo[4], A.M.F. Badjassim[6], G. Maradan[1,7], M. Bourrelly[1,8], M. Mora[1], L. Riegel[8], D. Rojas Castro[1,8], I. Yaya[9], B. Spire[1], C. Laurent[9], L. Sagaon-Teyssier[1,2], the CohMSM-PrEP Study Group

[1]Aix Marseille Univ, INSERM, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, ISSPAM, Marseille, France, [2]ARCAD Santé PLUS, Bamako, Mali, [3]Espace Confiance, Abidjan, Cote D'Ivoire, [4]Association African Solidarité, Ouagadougou, Burkina Faso, [5]Institut National de Santé Publique, Centre Muraz, Bobo-Dioulasso, Burkina Faso, [6]Espoir Vie Togo, Lomé, Togo, [7]ORS PACA, Observatoire Régional de la Santé Provence-Alpes-Côte d'Azur, Marseille, France, [8]Coalition Plus, Community-Based Research Laboratory, Pantin, France, [9]TransVIHMI, Univ Montpellier, IRD, INSERM, Montpellier, France

Background: For men who have sex with men (MSM), multiple barriers compromise pre-exposure prophylaxis (PrEP) engagement. However, in low and middle-income countries little is known about PrEP engagement for MSM. In West Africa, the CohMSM-PrEP demonstration project was one of the rare interventions providing PrEP to MSM.

We investigated the rate and factors associated with PrEP uptake and correct adherence in CohMSM-PrEP.

Methods: CohMSM-PrEP recruited MSM in four community-based clinics in Mali, Côte d'Ivoire, Burkina Faso, and Togo. Quarterly follow-up included a prevention package, PrEP (daily or event-driven), peer-led counselling (prevention and adherence) and psychosocial support, as well as socio-behavioral data collection.

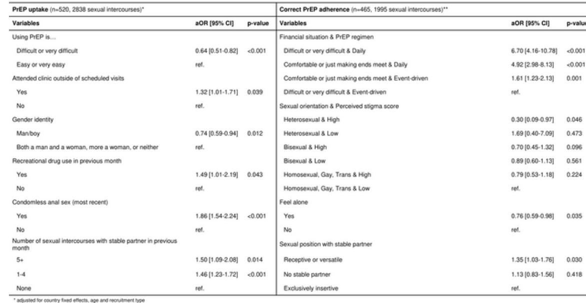
Multivariate generalized estimating equations (GEE) models were used to identify the factors associated with:

1. PrEP uptake during most recent anal intercourse and
2. Correct self-reported PrEP adherence.

Results: 520 participants were retained for analysis and had a median follow-up time of 12 months (IQR 6-21). They declared 2838 sexual intercourses, of which 1995 (70%) were protected by PrEP. Among PrEP-protected intercourses, correct adherence accounted for 1461 (73%) of sexual intercourses. The multivariate analyses for both outcomes are in Table 1.

Those who found PrEP use to be difficult had less uptake, while those with increased clinic attendance had more uptake.

After uptake, incorrect adherence was more likely for socioeconomically vulnerable event-driven users, highly stigmatized heterosexual-identifying participants, and those who felt alone. Both outcomes were associated with behavioral characteristics.



PrEP uptake (n=520, 2838 sexual intercourses)*

Variables	aOR [95% CI]	p-value

** adjusted for country fixed effects
PrEP: pre-exposure prophylaxis; GEE: Generalized estimating equation; aOR: adjusted odds ratio; CI: confidence interval; ref: reference.

Table 1. Multivariate analyses of factors associated with PrEP uptake and correct PrEP adherence (GEE, binary logistic distribution).

Conclusions: In the region's hostile sociocultural context, socially and economically marginalized participants struggled to use PrEP sufficiently. Support for PrEP use is an essential part of PrEP delivery. As scale-up continues in West Africa, we recommend using MSM-friendly clinics and providing extra support for vulnerable PrEP users to ensure adequate PrEP engagement.

Scale up of PEP

EPC225

Trends in HIV post-exposure prophylaxis following sexual exposure (PEPSE) in Brazil (2011-2019)

K. Crepalde-Ribeiro[1], J. de Oliveira Costa[2], S.-A. Pearson[2], M.R. Silveira[1], J.C. Mendes[1], S.F. dos Santos[1], M.A. Cruz[3], M.d.G.B. Ceccato[1]

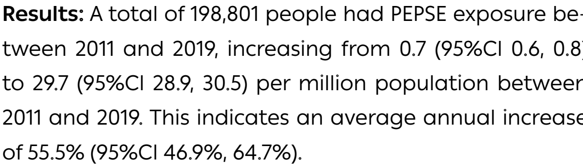
[1]Universidade Federal de Minas Gerais, Farmácia Social, Belo Horizonte, Brazil, [2]UNSW Sydney, Centre for Big Data Research in Health, Sydney, Australia, [3]Universidade FUMEC, Belo Horizonte, Brazil

Background: HIV post-exposure prophylaxis following sexual exposure (PEPSE) is a fully subsidized HIV prevention strategy offered in Brazil. However, there is a paucity of data on patterns of PEPSE use, particularly repeated PEPSE use, which may indicate repeated risky behaviour. Here, we evaluated trends in the prevalence of PEPSE and repeated PEPSE among people aged 14 years or older in Brazil.

Methods: We used nationwide routine dispensing data and joinpoint regression to estimate trends in PEPSE prevalence over time. We considered the period between 2011-2019 to analyse PEPSE trends, and 2011-2018 for repeated PEPSE trends.

We defined repeated PEPSE as multiple PEPSE exposures within 365 days of the first observed dispensing in the data, thus excluding people who had an index date in 2019 due to incomplete follow-up data.

We also performed a descriptive analysis comparing the characteristics of people with repeated PEPSE to those who did not repeat PEPSE in the most recent year (2018).



Results: A total of 198,801 people had PEPSE exposure between 2011 and 2019, increasing from 0.7 (95%CI 0.6, 0.8) to 29.7 (95%CI 28.9, 30.5) per million population between 2011 and 2019. This indicates an average annual increase of 55.5% (95%CI 46.9%, 64.7%).

Also, the prevalence of repeated PEPSE increased 11.8% (95%CI 6.0%, 18.0%) in the study period, from 3.8% (95%CI 2.9%, 4.7%) of people who had their index dispensing in 2011 to 8.4% (n=3,867 95%CI 8.1%, 8.7%) in 2018. PEPSE was associated with cisgender men (20,784 - 45.0%), homosexuals (15,742 – 18.7%), people aged 25-29 years (10,781 – 23.7%), filling prescriptions in HIV services located in populous cities >500,000 inhabitants (31,817 - 67.1%) and with elevated caseload, equal to or above the 90th percentile compared with other facilities (30,681 - 66.4%).

Conclusions: Our findings showed that PEPSE and repeated PEPSE have considerably increased in Brazil over the years. There is the need to reinforce other HIV prevention strategies, thus reducing repeated risky exposures, especially among young people or gay men.

EPC226

Long-term follow-up of individuals using HIV post-exposure prophylaxis-in-pocket ("PIP") for high risk, low frequency exposures

M.J. Billick[1], K.N. Fisher[2], D.H.S. Tan[1,3], I.I. Bogoch[1,2,4]

[1]University of Toronto, Department of Medicine, Toronto, Canada, [2]Toronto General Hospital Research Institute, Department of Infectious Diseases, Toronto, Canada, [3]St. Michael's Hospital, Division of Infectious Diseases, Toronto, Canada, [4]University Health Network, Division of Infectious Diseases, Toronto, Canada

Background: Pre-exposure prophylaxis (PrEP) and post-exposure prophylaxis (PEP) are two established methods to prevent HIV acquisition. However, there remain gaps in HIV prevention care, and the value of these tools for individuals with very infrequent, higher-risk HIV exposures might be limited due to cost, high pill burden, or barriers to care. HIV post-exposure prophylaxis-in-pocket (PIP) involves prospectively identifying individuals with a very low frequency of high-risk exposures and providing them with 28 days of PEP medication before an exposure occurs, along with instructions of when to initiate medications and how to follow up with care. We present long-term follow-up of a cohort of patients provided with PIP for HIV prevention.

Methods: We conducted a retrospective evaluation of the clinical characteristics and outcomes of patients initiated on PIP as a primary HIV prevention modality. The cohort includes all patients who initiated PIP between February 2016 and December 2021 at two large HIV-prevention and care centres in Toronto, Canada.

Patients were initially referred for biomedical HIV prevention (PrEP or PEP) and transitioned to PIP if they had an ongoing risk of low frequency (0-4 exposures per year), high-risk HIV exposures (any type). Participants were followed at regular 4-6 months intervals. Demographic and clinical data was collected with a standardized form.

Results: PIP was prescribed as part of a bundle of HIV prevention care for 101 patients, giving a combined total of 104.6 patient-years. The average age was 36 years-old (range 20-70), with 97 (96%) patients assigned male at birth. Twenty-five (24.8%) patients self-initiated their prescribed PIP, with 47 courses of PIP taken during the observed time. Patients fluidly transitioned between HIV prevention modalities as circumstances warranted: 23 individuals (22.8%) shifted from PrEP to PIP, and 27 (26.7%) changed from PIP to PrEP. In the 80 patients for which there are data, there were 11 episodes of bacterial sexually transmitted infections in 6 individuals (7.5%). No HIV seroconversions were detected.

Conclusions: Increasing evidence shows PIP as an innovative and useful HIV prevention modality for individuals with a low frequency of higher-risk HIV exposures.

EPC227

Awareness and openness to using PrEP among a nationally representative sample of South African Adults

I. Agaku[1], L. Nkosi[2], Q. Agaku[3], J. Gwar[4], T. Tsafa[5]

[1]Harvard School of Dental Medicine, Boston, United States, [2]Sefako Makgatho Health Sciences University, Pretoria, South Africa, [3]Zatum LLC, Grand Blanc, Michigan, United States, [4]Federal Medical Centre, Makurdi, Nigeria, [5]Benue State University, Makurdi, Nigeria

Background: South Africa adopted PrEP in 2016, becoming the first African country to do so. Yet to date, uptake has been underwhelming, only about 165,000 South Africans reported being on PrEP in mid-2021. Lack of awareness has been cited as a contributory factor for the low uptake, but this has never been examined using a nationally representative sample.

Methods: We investigated this among a national sample of HIV seronegative adults. Data were from the 2017/2018 South African National HIV Prevalence, Incidence, Behaviour and Communication Survey. Awareness and openness to using PrEP were self-reported. Weighted percentages were calculated overall and by demographic characteristics.

Results: Overall, only 3.2% of seronegative adults spontaneously reported PrEP as a way of preventing HIV. Overall, 69.6% were open to using PrEP, from 58.2% in Western Cape, to 78.5% in Western Cape. Prevalence of openness to using PrEP was highest among the youngest age group (18-29 y, 78.3%) and lowest among the oldest (60+ years, 45.6%).

Striking racial differences were observed with openness among Black Africans (75.4%) being 2.5 times higher than Whites (29.0%). Among women, the prevalence of openness to using PrEP was 64.7% among those currently preg-

nant, 80.4% among those pregnant in the past two years but not now, and 67.8% among those who were not pregnant in the past two years). Among males, the prevalence of openness to using PrEP was higher among those circumcised (75.6%) than uncircumcised (64.5%).

Conclusions: Awareness of PrEP was low; however, close to 7 in 10 seronegative adults were open to taking PrEP if it were available. Planning for broad-scale implementation of PrEP within the South African context could build on knowledge gained from recent implementation and scale-up of relevant biomedical interventions (e.g., ART, voluntary medical male circumcision, and family planning).

EPC228

Evaluation of the use of post-exposure prophylaxis for HIV in transgender women a few months before the implementation of pre-exposure prophylaxis in Goiânia, Brazil

K. Cardoso dos Santos[1], P. Santos[1], L. Magalhães[1], B. Oliveira[1], B. Silva[1], G. Silva[1], P. Junqueira[1], M. Souza[1], M. Carneiro[1], K. Caetano[1], S. Teles[1]

[1]*Federal University of Goiás, College of Nursing, Goiania, Brazil*

Background: Transgender women are a key population for HIV control. Globally, 2 in 10 transgender women are infected by HIV. Although Post-Exposure Prophylaxis (PEP), an emergency form of HIV prevention, has been available for more than 20 years, transgender women are still reluctant to use it.

The aim of this study is to analyze factors that facilitate and hinder the use of Post-Exposure Prophylaxis for HIV among transgender women two months before the implementation of pre-exposure prophylaxis in the metropolitan region of Goiânia, Goiás, Brazil.

Methods: A descriptive-exploratory qualitative study was conducted between April 2018 to July 2019, wherein 90 transgender women participated. Data collection began two months before implementing Pre-Exposure Prophylaxis (PrEP). Data was collected through a structured interview, and interpretative thematic analysis was performed.

Results: The median age was 24 years (IQR: 20.0-27.0), and formal education time of 11 years (IQR: 9.0-12.0). The qualitative analysis showed that more than half of the participants (61.1%) knew about PEP, and more than half reported knowing that PEP is used after accidentally having sex with someone living with HIV. Also, they showed no interest in seeking knowledge about pre-exposure prophylaxis. Those who used PEP found some facilitating factors, including reception, testing and counseling, the public health network, and information within the social network itself. The significant obstacles reported were related to motivation, i.e., they reported anticipated stigma, fear of the possibility of a positive diagnosis, deficit in self-care, and adverse effects.

Conclusions: In general, not acquiring HIV is the reason that encourages people to use PEP, but for transgender women, this is not reason enough to transpose the social stigma and fear of a positive diagnosis for HIV.

A few months before the end of this study, pre-exposure prophylaxis (PrEP) was made available in Brazil. Therefore, new studies are necessary to evaluate the adherence of this crucial population to this pharmacologically preventive strategy.

Scale up of medical male circumcision

Background: Since 2007, the U.S. President's Emergency Plan for AIDS Relief (PEPFAR) has supported voluntary medical male circumcision (VMMC) programs in 15 sub-Saha-

ran African countries. This analysis evaluates the seasonality of VMMCs performed during 2016-2019, and how this seasonality might vary by region in sub-Saharan Africa.

Methods: PEPFAR monitoring, evaluation, and reporting data were analyzed from 14 countries that had a PEPFAR-supported VMMC program during 2016-2019. We report the calendar-year quarter during which the most VMMCs were performed each year, by country and region. Multi-level generalized linear regression models were used to estimate the effect of quarter on VMMCs performed by country.

Results: The most VMMCs were performed during the same quarter each year in 6 (42.8%) of the 14 countries (Figure 1).

Among these 6 countries, all in Southern Africa, there was a statistically significant association (*P* value of < 0.05) between the increase in VMMCs performed and the corresponding highest performing quarter. Five of the 6 countries performed the most VMMCs during Quarter 3 (July – September), and one country had the highest performance in Quarter 2 (April – June).

Four countries performed the most VMMCs during the same two quarters each year. Among these 4 countries, 3 are in Southern Africa. Another 4 countries, all in Eastern Africa, had their highest performing quarter vary year to year, and no statistical associations between quarter and VMMCs performed were identified.

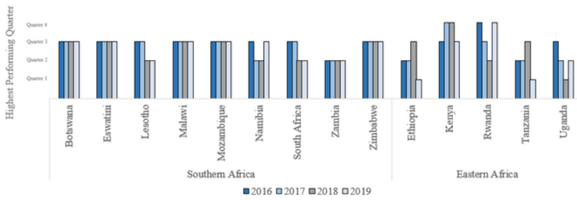

Figure 1. Calendar year and quarter with the most performed voluntary medical male circumcisions, among 14 sub-Saharan African countries, 2016 - 2019

Conclusions: Most PEPFAR-supported VMMCs are performed during April – June and July – September, particularly among countries in Southern Africa. Previously reported factors influencing seasonality include perception of improved healing during colder months, seasonal work, school schedules, and traditional circumcision season. It is important to consider seasonality during VMMC program planning to ensure that there is a balance of labor and resources to meet demand.

EPC230

Timing for maximum anesthetic effect of topical cream during early infant male circumcision (EIMC) in Rakai, Uganda

S. Kiboneka[1], A. Anok[1], E. Kankaka[1], R. Nakabuye[1], S. Odiya[1], J. Magembe[1], R. Nazziwa[1], C. Ddamulira[1], A. Mukooki[1], J. Kagaya[1], S. Watya[1], P.S. Li[2], R.K. Lee[2], R.H. Gray[3], G. Kigozi[1]

[1]Rakai Health Sciences Program, Research, Kalisizo, Uganda, [2]Weill Cornell Medical College, Urology, New York, United States, [3]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States

Background: Male circumcision reduces male HIV acquisition by up to 60%. Early Infant Male Circumcision (EIMC) presents advantages, including faster wound healing, lower cost, and no risk of early sex resumption. Data from recent studies shows that device-based circumcision (ShangRing and Mogen Clamp) is safe in infants aged 0-60 days. However, success of future infant circumcision scale-up programs in sub-Saharan Africa depends on adequate pain control during the procedure. We assessed the optimal timing for application of topical anesthesia for device-based circumcision procedure.

Methods: 200 infants aged 0-60 days were enrolled in an EIMC trial comparing the Mogen clamp and ShangRing devices at 4 facilities in south-central Uganda. Topical anesthetic

(EMLA cream.) was applied on the entire penile shaft. The anesthetic effect was assessed every 5 minutes, starting at 10 minutes post-application until 60 minutes, the recommended time to start circumcision. Pain was tested at the tip of the foreskin using the Neonatal Infant Pain Scale (NIPS) to assess responses. Mean (SD) and median (IQR) NIPS scores at each time interval were used to determine the time range of maximum anesthesia.

Results: The median NIPS score dropped to zero between 25 to 55 minutes, with the narrowest IQR occurring between 35 and 45 minutes after applying topical cream. The effect started diminishing after 45 minutes. A similar trend was observed for the mean scores (Table 1).

Time in minutes	10	15	20	25	30	35	40	45	50	55	60
Median (IQR)	3.0 (4.0)	2.0 (5.0)	1.0 (4.0)	0.0 (2.0)	0.0 (2.0)	0.0 (1.0)	0.0 (1.0)	0.0 (1.0)	0.0 (2.0)	0.0 (2.0)	1.0 (2.0)
Mean (SD)	3.3 (2.3)	2.7 (2.4)	1.8 (2.2)	1.2 (1.7)	1 (1.6)	0.7 (1.3)	0.8 (1.3)	0.8 (1.4)	1 (1.5)	1.3 (1.7)	1.6 (1.9)

Table 1. Table showing the NIPS scores at the different time intervals. (N=200).

Conclusions: The optimal timing for maximum topical analgesia occurred 35 to 45 minutes after application which is less than the recommended 60 minute waiting time. A shorter waiting time may be efficient for mass device-based circumcision.

EPC231

Strengthening safety through surveillance: notifiable adverse events in the U.S. President's Emergency Plan for AIDS Relief's voluntary medical male circumcision program through 2020

T. Lucas[1], C. Cooney[2], A. Prainito[2], C. Godfrey[2], V. Kiggundu[3], A. Thomas[4], C. Toledo[1]
[1]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, HIV Prevention Branch, Atlanta, United States, [2]Office of the U.S. Global AIDS Coordinator and Health Diplomacy, U.S. Department of State, Washington D.C., United States, [3]U.S. Agency for International Development, Global Health, Office of HIV/AIDS, Washington D.C., United States, [4]Defense Health Agency, U.S. Department of Defense, HIV/AIDS Prevention Program, San Diego, United States

Background: Circumcision reduces males' risk of heterosexual HIV acquisition by ~60%. Since inception, the President's Emergency Plan for AIDS Relief (PEPFAR) has supported over 28 million voluntary medical male circumcisions (VMMCs) in 15 countries. PEPFAR monitors defined adverse events (AEs) occurring within 30 days of VMMC through its Notifiable Adverse Event Reporting System (NAERS). Systematic reporting of deaths started in 2014, expanding to other event types in 2015.

Methods: Standardized forms are used to report notifiable adverse events (NAEs) which include: death, hospitalization ≥3 days, penile injury, permanent or probable deformity or disability, tetanus, and circumcision device displacement. Detailed case investigations by reviewing physicians further classify diagnoses and determine NAE relatedness to the VMMC procedure. We analyzed NAE reports submitted to PEPFAR since the first ad-hoc report in 2011 through December 2020.

Results: Fourteen countries reported 446 clients with NAEs; 394/446 (88%) were determined VMMC-related, 37/446 (8%) were unrelated, and 15/446 (3%) were unknown. There were 56 deaths reported, 24/56 (43%) were determined VMMC-related with 13/24 (54%) of these from tetanus. The remaining 390 NAEs were non-fatal with 370/390 (95%) VMMC-related. Of clients with a reported NAE, 16/446 (4%) were among infants aged ≤2 months, 5/446 (1%) were among clients aged 2 months-9 years, 236/446 (53%) were among clients aged 10-14 years, 182/446 (41%) were among clients aged ≥15 years, and 7/446 (2%) were of unknown age.

Infection was the most common cause of hospitalization ≥3 days. There were 175 severe non-tetanus infections and 26 cases of tetanus reported. Disability or anatomic deformity was reported for 115 clients, including 40 glans injuries and 51 fistulas. Severe bleeding was reported in 70 clients, with 18 having a secondary infection. There were 4 circumcision device displacements.

Conclusions: Although it is not possible to completely eliminate all AEs from surgical interventions, surveillance of rare but serious AEs can identify pre-existing or new safety concerns and guide continuous programmatic improvement. Several policy changes including updated guidance on surgical technique, restricting VMMC eligibility to clients ≥15 years old, and improving tetanus prevention practices, were made following analyses of NAERS data to improve program safety.

EPC232

Real-world impact of male circumcision on HIV seroprevalence in sub-Saharan Africa: a household fixed-effects analysis among 279,351 men from 29 countries

C. Bulstra[1,2], X. Dai[3], M.S. Rosenberg[4], B.M. Wamuti[5], K. Ngure[6], J.A.C. Hontelez[1], K. Ortblad[7], T. Bärnighausen[2,7,8]
[1]Erasmus Medical Center, Department of Public Health, Rotterdam, Netherlands, the, [2]Heidelberg University Medical Center, Heidelberg Institute of Global Health, Heidelberg, Germany, [3]University of Washington, Institute for Health Metrics & Evaluation, Washington, United States, [4]Indiana University School of Public Health-Bloomington, Department of Epidemiology and Biostatistics, Bloomington, United States, [5]University of Washington, Department of Global Health, Washington, United States, [6]Jomo Kenyatta University of Agriculture and Technology, Department of Community Health, Nairobi, Kenya, [7]Harvard T.H. Chan School of Public Health, Department of Global Health and Population, Boston, United States, [8]Africa Health Research Institute (AHRI), Durban, South Africa

Background: Medical male circumcision reduced the individual-level risk of female-to-male HIV transmission by approximately 60% in randomised-controlled trials, but little is known about the impact of male circumcision on HIV prevention in a 'real-world' setting. Understanding the impact of male circumcision outside of randomised clinical trials is important for understanding how to support the implementation of voluntary medical male circumcision (VMMC) campaigns in high HIV prevalence settings.

Methods: We pooled individual-level nationally-representative survey data (Demographic and Health Surveys and AIDS Indicator Surveys) from all sub-Saharan African countries that included information on male circumcision status (self-reported) and HIV status (determined using blood-based testing). We estimated the effect of men's circumcision status on HIV-seropositivity using modified Poisson regression models (adjusted for age, educational level, and marital status) with household fixed-effects, which control for heterogeneity in observed and unobserved factors that might confound the association shared by men living in the same household.

Results: We included data from 279,351 male respondents to 48 surveys conducted in 29 countries between 2003 and 2018. Mean survey-level male circumcision prevalence was 65.9% (median 84.5%, IQR 28.8%–68.1%) and mean survey-level HIV prevalence was 5.6% (median 2.5%, IQR 1.2%–

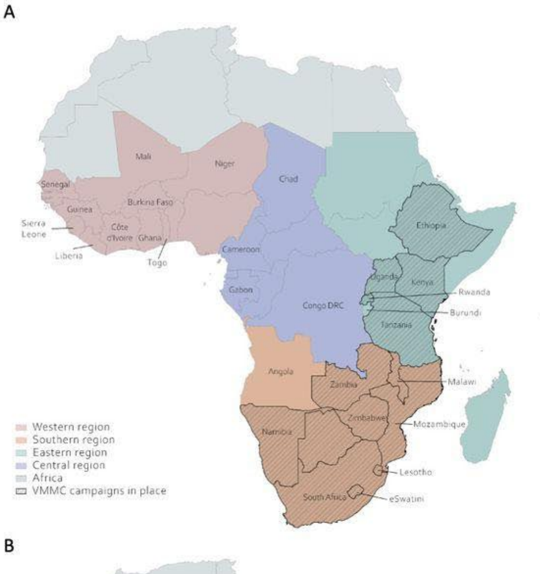
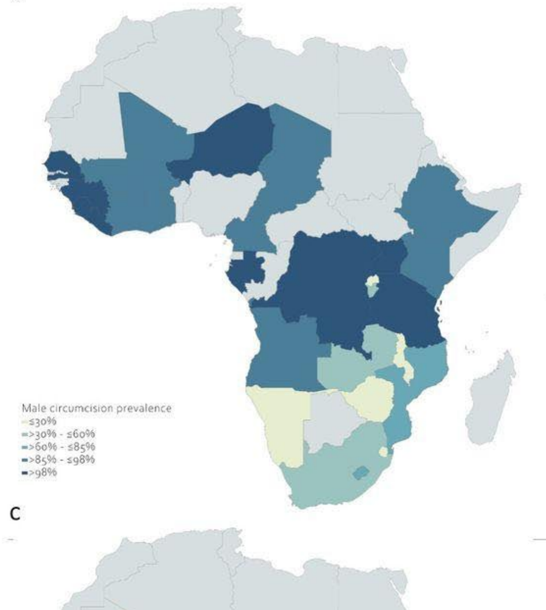
10.2%). In our analysis, we found that circumcised men had 0.80 times (95% CI 0.73-0.88) the risk of living with HIV compared to uncircumcised men, implying that circumcision reduces the risk of HIV transmission by roughly 20% (12%-27%).

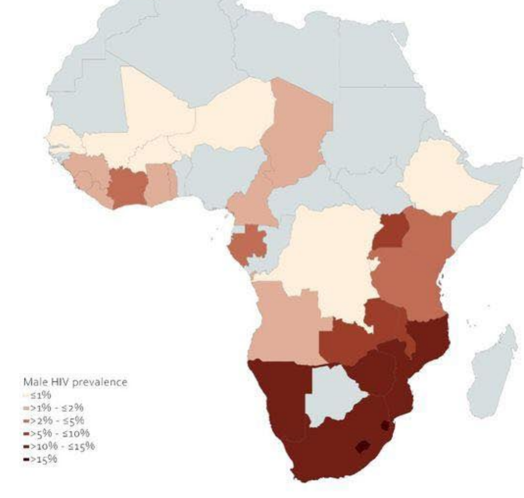
A



B



C



Conclusions: The population-level 'real-world' impact of male circumcision on HIV prevention was significant, but 2-to-3-fold less strong than demonstrated in previous randomised-controlled trials. Reasons for this could be suboptimal circumcision procedures (especially in cases of traditional circumcision), lack of abstinence compliance following the procedure, and sexual risk compensation behaviours. Implementation strategies to improve VMMC delivery in high prevalence settings are needed to maximise the full protective effects of the intervention.

EPC233

Knowledge, attitude and perception of uninitiated adolescents towards customary male initiation practices in selected schools in Buffalo City Municipality, Eastern Cape

N. Igaba[1], E. Oladimeji[1], D.T. Goon[1]

[1]*University of Fort Hare, Public Health, East London, South Africa*

Background: Based on evidence that Voluntary Medical Male Circumcision (VMMC) significantly reduces the risk of HIV transmission by 60%, the World Health Organization (WHO) recommends implementing VMMC programs in countries with a high HIV prevalence, considering the unique sociocultural and economic dynamics of each setting. In South Africa (SA), multiple tribes including the AmaXhosa in Eastern Cape (EC) province practice Customary Male Initiation (CMI) also known as *Ulwaluko* as a rite of passage of males from boyhood to manhood, and this involves circumcision.

However, in recent years, this practice has been riddled with deaths of initiates, admissions to hospital, amputation of penis, assaults, drug& alcohol, and crime.

Hence this study aimed at understanding the knowledge, attitude, and perceptions of uninitiated adolescents towards the CMI practice in Buffalo City Municipality (BCM), EC to aid in developing strategies to solve current challenges.

Methods: Between June and December 2021, this cross-sectional descriptive study was conducted in BCM, EC, using a quantitative research approach. The study population included male adolescents aged 15 to 19 who had not attended CMI. Applying a multistage random sampling technique, two (2) BCM towns (King William Town-KWT and East London) and the township of Mdantsane were selected and further the schools from which consenting pupils were enrolled into the study. Data was collected using a validated self-administered questionnaire which was captured on excel and analysed using STATA.

Results: Of 520 questionnaires distributed in 10 schools, 251 were both uninitiated and 15-29 years. Majority (35%) were 16 years and from Mdantsane township (48%). 95% spoke IsiXhosa language and majority (40%) lived with only a mother.

Majority (79%) preferred CMI to VMMC and surprisingly 54% did not have knowledge of laws governing CMI. Level of knowledge on benefits of VMMC was generally low; reduces risk of HIV-28%, reduces risk of STI-22%, reduces risk of penile cancer-14%. 41% did not know risks associated with Ulwaluko, with 14% indicating dehydration, 27% injury to penis.

Conclusions: To improve the outcome of CMI in BCM, implementation of strategies to educate uninitiated adolescents of benefits of VMMC, risks associated with CMI and laws governing Ulwaluko is critical.

EPC234

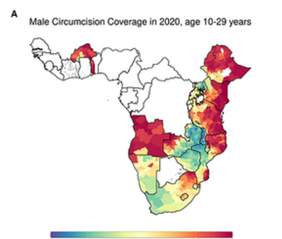
District-level coverage and unmet need for medical and traditional circumcision among men aged 10-29 years in sub-Saharan Africa

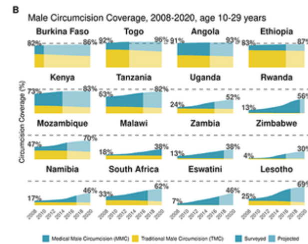
P. O'Toole[1], M.L. Thomas[1,2], O. Stevens[1], K. Lam[1,3], K. Kripke[4], R. Esra[1], I. Wanyeki[5], L. Zembe[5], J.W. Eaton[1]
[1]Imperial College London, MRC Centre for Global Infectious Disease Analysis, School of Public Health, London, United Kingdom, [2]University of Exeter & Met Office, Joint Centre for Excellence in Environmental Intelligence, Exeter, United Kingdom, [3]University of British Columbia, Department of Statistics, Vancouver, Canada, [4]Avenir Health, Takoma Park, United States, [5]Joint United Nations Programme on HIV/AIDS (UNAIDS), Geneva, Switzerland

Background: In 2016, UNAIDS developed a Fast-Track strategy that targeted 90% coverage of male circumcision (MC) among men aged 10-29 years by 2021 in priority countries in sub-Saharan Africa (SSA) to reduce HIV incidence. There is substantial variation across subnational regions within countries in both traditional male circumcision (TMC) practices and progress towards implementation of voluntary medical male circumcision (VMMC).
Tracking progress and remaining gaps towards VMMC HIV prevention targets requires detailed district-level circumcision coverage data.

Methods: We analysed self-reported data on male circumcision from 40 nationally representative household surveys conducted in 16 SSA countries between 2006-2020. A spatio-temporal Bayesian competing-risks time-to-event model was used to estimate rates of traditional and medical circumcision by age, location, and time. Circumcision coverage in 2020 was projected assuming continuation of estimated age-specific rates, with probabilistic uncertainty.

Results: Across 16 countries, from 2010 to 2020 an estimated 26.4 million men (95% CI 22.0-31.9 million) were newly circumcised, of whom 22.3 million (17.3-28.5 million) were medically circumcised, and 4.1 million (3.9-4.6 million) traditionally circumcised. In 2020, MC coverage among men 10-29 years ranged from 30.3% (20.8%-48.7%) in Zimbabwe to 95.5% (91.9%-98.7%) in Togo.
MMC coverage ranged from 24.6% (22.7%-27.9%) in Malawi to 62.1% (55.9%-67.9%) in Tanzania, and TMC coverage from 0.6% (0.4%-0.8%) in Eswatini to 62.1% (59.6%-64.2%) in Ethiopia. The largest increase in MMC coverage was in Lesotho from 10.2% to 57.9%.
Within countries, the median difference in MC coverage between the districts with lowest and highest coverage was 58.0%, with the smallest variation in Eswatini (42.4% to 48.3%) and largest in Zambia (8.9% to 98.7%). 17 million men aged 10-29 need to be circumcised to reach 90% coverage in all countries.





Conclusions: VMMC programmes have made substantial, but uneven, progress towards male circumcision targets. Granular district and age-stratified data provide information for focusing further programme implementation.

Integrating STI, sexual and reproductive health and HBV and HCV services in HIV prevention programmes

EPC235

Prevalence and factors of HCV infection among HIV-negative MSM, PrEP users versus non-PrEP users, in a community health center

A. Rivero Calaf[1,2,3], F. Perez Tejera[2], P. Coll Verd[3,4,2,1], J.M. Cabrera Guarin[2,1,3], M. Lucejko[2,1,3], J. Reguant Guitart[2,1], J. Fernandez Perez[2,1], J. Calderon Torres[2], J. Romero[2], G. Marazzi[2], A. Alonso Baile[2], C. Oro[2], D. Jacobs[2], H. Vicioso[2], L. Moises Enrique[2], M. Ristovsy[2], R. Lopez[2], M. Bernardi[2], E. Robles[2], E. Muñoz Campos[2], J.J. Sotomayor Cortes[2], H. Taboada Gonzalez[2], J. Saz Berges[2], F. Pujol Roca[2], M. Meulbroek[2], R. Paredes Deirós[3,1,4]
[1]Hospital Universitari Germans trias i Pujol, Infectious Disease Unit, Badalona, Spain, [2]Projecte dels NOMS HISPANOSIDA, Barcelona, Spain, [3]Fundació Lluita contra la SIDA i les Malalties Infeccioses, Badalona, Spain, [4]IrsiCaixa AIDS Research Institute, Badalona, Spain

Background: Since 2000, multiple HCV outbreaks have been reported in the community of people living with HIV, but to a much lesser extent in HIV-negative Men who have Sex with Men and Transgender Women (MSM). During the last decade new developments like the accepted U=U campaign, PrEP implementation, and extension of ChemSex use may have contributed to fueling the transmission chain. A community center with experience of early HIV detection, linkage to care, and treatment initiation might be able to create a model with Point-of-Care (PoC) HCV detection in an understudied population.
The study aims to determine the prevalence of acute and chronic HCV infection in HIV-negative MSM community and to assess risk factors associated with HCV infection.

Methods: All clients, PrEP users and non-PrEP users, coming for routine HIV testing to the community center were offered to be screened for HCV. Sexual behavior and drug use were assessed with questionnaires. A PoC serology test (Abbott® Bioline™ HCV) was performed. Positive results were immediately confirmed by a PoC PCR test (Xpert® HCV VL Fingerstick).
Additionally, clients with a negative serology and pre-defined criteria (e.g. ChemSex, fisting, recent HIV diagnosis) were offered a PCR test to detect a potential acute infection. All confirmed cases were referred to start treatment rapidly.
Results: Interim analysis: between August 23 and December 31, 2021 a total of 3,284 MSM were included (32.5% PrEP users). 19 cases with positive serology were found: 3 active infections (1 coinfection with HIV), 13 serological scars and 3 false positive results. All 3 active infections were detected in non-PrEP users and ChemSex use was 100% present, including 1 case of slamming. One case was considered acute, and another was a reinfection. Two cases have been genotyped as subtype 1a.
Conclusions: Preliminary results show a low prevalence of HCV in HIV-negative MSM (0.49%), and further screening will allow more insight. However, these results suggest that targeted screening may be effective, once criteria are established, for future HCV testing and treat strategies. Community centers play an important role in detecting cases not linked to the health system or subpopulations with difficulties in accessing the public system.

EPC236
Syphilis among pre-exposure prophylaxis initiators in selected districts of Nepal

U. Shrestha[1], N. Sedhain[1], Y.R. Sapkota[1], P.K. Thakur[2], C. Casalini[2], B. Shrestha[1], R.P. Khanal[1], I. Lohar[3], T. Weldegebreal[3], S. Rijal[1]
[1]EpiC Nepal, FHI 360, Kathmandu, Nepal, [2]EpiC, FHI 360, Washington DC, United States, [3]USAID Nepal, Kathmandu, Nepal

Background: HIV prevention services are crucial to achieve the goal of ending AIDS by 2030. In Nepal, the U.S. President's Emergency Plan for AIDS Relief (PEPFAR) and United States Agency for International Development (USAID)-supported Meeting Targets and Maintaining Epidemic Control (EpiC) project support provision of pre-exposure prophylaxis (PrEP) to key populations (KPs) such as female sex workers (FSWs), men who have sex with men (MSM), and transgender people. The project offers integrated PrEP and syphilis screening, as well education on risk reduction. We report syphilis prevalence among these KPs at PrEP initiation and follow-up in the 19 EpiC-supported sites.
Methods: Syphilis prevalence was measured at baseline among all clients initiated on PrEP from October 2020 through March 2021, and incidence was measured during follow-up visits in EpiC Nepal's STI clinic during April through September 2021. Syphilis was diagnosed through rapid plasma reagin and treponema pallidum particle agglutination performed by trained laboratory personnel. Those who tested positive received treatment. These data were collected through the individual reporting system used by EpiC Nepal.
Results: From October 2020 to March 2021, 1,780 KPs (43% FSWs, 34% MSM, 23% transgender people) were initiated on PrEP. Almost half (43%) were ages 15–24 years. Seventy percent of those who initiated PrEP continued to take it, whereas 30% discontinued PrEP. At the time of PrEP initiation, 13% (n=232) tested positive for syphilis (23% FSW, 42% MSM, 34% TG).
At follow-up (April–September 2021), 0.56% (n=7) of those who continued PrEP services and 0.75% (n=4) of those who discontinued the services tested positive for syphilis. Among the KP individuals who continued PrEP, 0.24% (n=3) tested positive for syphilis at baseline and follow-up.
Conclusions: KPs are not only at risk of HIV infection, but also other STIs, including syphilis. Our findings showed a significant decrease in the number of syphilis cases over the time among the PrEP initiators.
Since both PrEP and STI services are provided at the same sites, there is an opportunity to conduct comprehensive STI prevention, screening, and care among PrEP initiators.

EPC237
PrEP as an opportunity to prevent viral hepatitis among a high risk population in Buenos Aires, Argentina

M.V. Iannantuono[1], V.I. Fink[1], L. Spadaccini[1], M.M. Sandoval[1], C.F. Perez[1], C.T. César[1], A.M. Gun[1], P. Cahn[1], O. Sued[1], M.I. Figueroa[1]
[1]Fundacion Huesped, Research Department, Ciudad Autónoma de Buenos Aires, Argentina

Background: HIV pre-exposure prophylaxis (PrEP) programs are expanding in middle income countries, including Argentina. Its implementation is an opportunity for the timely diagnosis and treatment of other sexually transmitted infections (STIs), including viral hepatitis (VH). In Argentina, universal HBV immunization is provided at no cost for everyone as well as vaccines for HAV for children and high risk populations. Nevertheless cases and outbreaks of HBV and HAV still occur.
The aim of this study was to evaluate the proportion of HBV and HAV susceptible individuals among men who have sex with men (MSM) and transgender women (TGW) enrolled in a PrEP program.
Methods: From 2018 to 2020,VH serology results were collected from PrEP users. including HVA, HBsAb, HBcAb, HBsAg, HCV antibodies. Sexual risk assesment was evaluated through Sexual Health Promotion (SexPro). SexPro scores ≤16 identified users with higher risk.

Results: Two hundred and two participants were evaluated, 190 MSM and 12 TGW. The median age was 29 years (IRQ 25-33.25). 81% had a SexPro score <16 (mean 8; IQR 1-15), 23% (n=46) had a negative result of HBsAb: 25 were vaccinated during follow-up. 158 (78%) were tested for HAV, 5% (8/158) were negative for IgG HAV, and were vaccinated. all were HCV negative. During follow-up there was one case of acute HBV and one acute HCV.
Conclusions: PrEP programs are an opportunity to identify people at high risk of acquiring VH, prevent HAV and HBV and cure HCV. Close monitoring of serology and vaccination status can reduce the burden of VH in key populations.

EPC238

Gaps and opportunities for integrated HIV and STI testing for women sex workers: findings of a community-based cohort in Metro Vancouver, Canada

S. Goldenberg[1,2], J. Pearson[2], A. Krüsi[3,2], S. Moreheart[4,2], M. Braschel[2], H. Nazaroff[2], K. Shannon[3,2], AESHA Study Group
[1]*San Diego State University, Division of Epidemiology and Biostatistics, School of Public Health, San Diego, United States,* [2]*University of British Columbia, Centre for Gender & Sexual Health Equity, Vancouver, Canada,* [3]*University of British Columbia, School of Population and Public Health, Vancouver, Canada,* [4]*Simon Fraser University, Burnaby, Canada*

Background: Given the stark HIV and sexual health inequities experienced by sex workers, empirical evidence is needed to inform accessible and sex worker-friendly models of voluntary, confidential and non-coercive HIV and STI testing. In light of reports of barriers to health access reported by sex workers generally, and the individual and public health importance of regular HIV/STI testing, we evaluated patterns and correlates of HIV/STI testing in the last 6 months among women sex workers.
Methods: Data were drawn from An Evaluation of Sex Worker's Health Access (AESHA), a community-based open cohort of sex workers (January 2010-present) working across diverse street, indoor, and online environments in Vancouver, Canada.
Using semi-annual questionnaire data collected by experiential (sex workers) and community-based staff, we used logistic regression with generalised estimating equations (GEE) to model correlates of recent HIV/STI testing over a 9.5-year period (Jan 2010–Aug 2019).
Results: Of 898 participants, 334 (37.2%) identified as Indigenous, 286 (31.8%) as Black/Persons of Colour, and 278 (31.0%) as White. 8.4% and 36.3% identified as a gender or sexual minority, respectively. At baseline, 504 (56.1%) received an HIV and/or STI test in the last 6 months; over the study period, 71.4% (n=641) accessed HIV/STI testing offered by community- or clinic-based providers (e.g., community clinic, family doctor, outreach). In multivariable GEE analysis (Figure 1), odds of recent HIV/STI testing was higher among youth (<30 years), those facing enhanced sexual/drug risks (e.g., inconsistent condom use, non-injection drug use), and those accessing sex worker-led/specific services. Im/migrant sex workers and Black/Women of Colour had lower odds of HIV/STI testing.

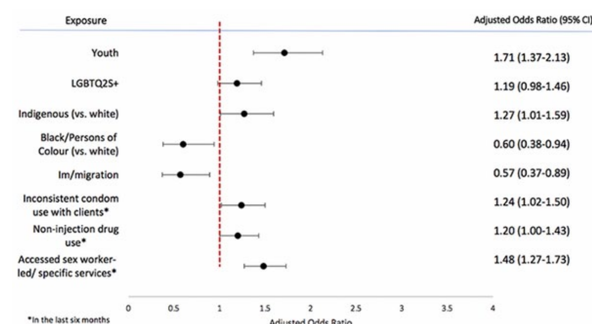


Figure 1. Adjusted odds ratios (AORs) and 95% Confidence Intervals (CIs) for the association between demographic and structural exposures and HIV/STI testing in the last 6 months among women sex workers in Metro Vancouver, Canada (N=898, 4083 observations), 2010-2019
Note: Analyses excluded observations where participants accessed testing safely through AESHA.

Conclusions: Scaling-up community-based, sex worker-tailored services is recommended to enhance voluntary, confidential, and safe access to integrated STI/HIV testing for sex workers. Culturally-safe, multi-lingual services are urgently needed to reduce inequities and improve testing access for im/migrant and racialized sex workers.

EPC239

Blazing a trail for MPT counseling: efforts to develop recommendations for the Dual Prevention Pill and reconcile inconsistent guidance for delivering PrEP and oral contraception

D. Harris[1], K. Segal[2], A. Carmone[3], L.B. Haddad[4], S. Hadigal[5], K. Hatzold[6], C. Jones[7], E. Lathrop[8], J. Mason[9], M. Mikulich[9]
[1]*WCG Cares, Carlsbad, United States,* [2]*AVAC, New York, United States,* [3]*CHAI, Singapore, Singapore,* [4]*Population Council, New York, United States,* [5]*Viatris, Bengaluru, India,* [6]*Population Services International, Cape Town, South Africa,* [7]*Mann Global Health, Sandpoint, United States,* [8]*Population Services International, Washington D.C., United States,* [9]*USAID, Washington D.C., United States*

Background: A range of multipurpose prevention technologies (MPTs) to simultaneously prevent HIV and unintended pregnancy are in development. The Dual Prevention Pill (DPP), a daily pill combining oral pre-exposure prophylaxis (PrEP) and combined oral contraception (COC), is the MPT likely to enter markets next. Consolidating guidance for PrEP and COC is needed to ensure effective provision of the DPP. The process described below offers one model for future efforts to develop appropriate counseling guidance for other MPTs.

Author Index

Description: Beginning in February 2021, a working group of eight clinical and implementation experts in HIV and family planning was convened to develop counseling recommendations for the DPP.

First, the group reviewed existing PrEP and COC counseling guidance and supporting tools across six topics: uptake, missed pills, side effects, discontinuation/switching, drug interactions and monitoring.

The group identified points of overlap and divergence, prioritizing outstanding questions to answer through additional desk research and expert consultation.

The group developed recommendations for the DPP across selected topics, which will inform counseling messages used in clinical acceptability studies for the DPP.

Lessons learned: Reconciling PrEP and COC guidance for missed pills to develop clear messages for DPP counseling posed unique challenges, with implications for efficacy, side effects, cost, user comprehension and burden. For example, providers counsel clients to "double up" on missed COC pills, yet limited evidence on the toxicity or side effects of doubling up on oral PrEP in women complicates recommendations for the DPP.

Furthermore, COC guidance allows women to skip placebo pills after missing multiple doses or to avoid monthly bleeding. Yet in the current formulation, the last week of DPP pills will contain TDF/FTC, adding costs to discarding a pack early. Crafting recommendations for the DPP as a novel MPT requires balancing the clinical and implementation implications of both products.

Conclusions/Next steps: Providers will need clear guidance to expand prevention options on offer without compromising effectiveness or increasing client health risks.

Reconciling PrEP and COC guidance for the DPP ensures providers will be equipped to deliver it and support users. The process to consolidate guidance may be applied to accelerate the development of counseling for other MPTs.

The role ofadolescent-friendlyhealthservices in HIV preventionandgender-based violenceresponse amongadolescentgirlsandyoungwomen in Namibia

T. Gwande[1], E. Ernest[1], A. Mwinyi[1], S. Kelbert[2], T. Ventimiglia[3], E. Kuhlik[3], K. Thura Tun[3], M. Manyando[4]

[1]JHPIEGO, Programs, Rundu, Namibia, [2]JHPIEGO, Programs, Baltimore, United States, [3]PACT, Washington, United States, [4]USAID, Windhoek, Namibia

Background: ACHIEVE Namibia, a USAID/PEPFAR-funded project, aims to achieve and sustain HIV epidemic control among adolescent girls and young women (AGYW) in northern Namibia. ACHIEVE builds on best practices in HIV prevention, sexual and reproductive health (SRH), and post-gender-based violence (GBV) care to strengthen adolescent-friendly health services (AFHS).

Description: ACHIEVE implemented DREAMS in four districts of two regions in Namibia from October 2020-September 2021 targeting AGYW aged 15-24 years old in 21 public health facilities. The DREAMS interventions include HIV prevention, GBV prevention and response, and SRH services, and are provided in adolescent-friendly clinics, DREAMS safe spaces in communities, and schools around the clinic.

To address barriers to care, the clinics have clear signage, are staffed by AFHS-trained providers, actively engage AGYW, and offer a comprehensive service package under one roof. Clinics offer HIV testing services (HTS), pre-exposure prophylaxis (PrEP), linkage to antiretroviral therapy, sexually transmitted infection screening/treatment, counselling/provision of contraception, and post-GBV clinical care, amongst other services.

Lessons learned: The service provision has closed the gap of SRH/HIV and GBV prevention missed opportunities among AGYW. From October 2020-September 2021, 21,801 AGYW visited the clinics, of whom 98% (21,334) were assessed for HIV risk using a standard tool. The majority of them, 76% (16,278) were found at risk. Of those at risk, 71% (11,487) were tested, and 99% (11,374) tested negative.

Among those who tested negative, 43% (4,929) were initiated on PrEP for the first time. Also, 4,090 received a modern contraceptive method, and 82% (1,187) of 1,441 reported GBV cases received post-GBV clinical care. The distribution of service provision by age group is in Figure 1.

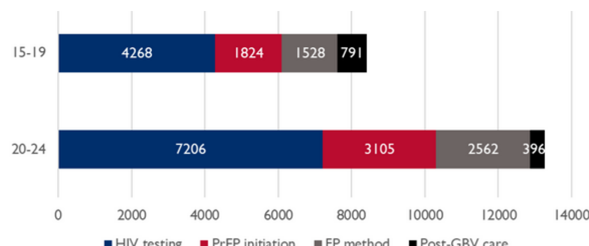

Figure 1. Number of AGYW receiving adolescent-friendly health services by service type and age.

Conclusions/Next steps: Offering integrated AFHS approaches and addressing the barriers faced by AGYW in accessing high-quality HIV/SRH services contributes to increased service uptake, better care, and improved health outcomes (ex. preventing unintended pregnancies and HIV acquisition) among AGYW.

EPC241

Sexually transmitted infections prevalence and incidence among HIV negative high risk men who have sex with men and transgender women, participating in HIV combined prevention study in Buenos Aires, Argentina

L. Spadaccini[1], M.I. Figueroa[1], V.I. Fink[1], C. Cesar[1], M. Ceschel[1], G. Mernies[1], C.F. Perez[1], M.V. Iannantuono[1], M.M. Sandoval[1], N.K. Panis[1], A. Gun[2], O. Sued[3], P. Cahn[1]
[1]Fundación Huésped, Research Department, Capital Federal, Argentina, [2]Centro Medico Huésped, Capital Federal, Argentina, [3]OPS, Washington, United States

Background: Men who have sex with men (MSM) and transgender women (TGW) are at increased risk for HIV and other sexually transmitted infections (STIs).
The objective of this study was to evaluate the prevalence and incidence of STI´s among high risk MSM and TGW in Buenos Aires, Argentina.
Methods: We conducted a retrospective analysis that included all positive STI tests (HIV, chlamydia, gonorrhea, and syphilis) performed between March 2020-January 2022 among asymptomatic, HIV negative MSM and TGW at substantial risk of HIV infection (defined as any of the following situations in the last 6 months: >5 sexual partners, anal unprotected sex, use of drugs, STIs or transactional sex) participating in HIV combined prevention study. Active syphilis diagnosis was made by VDRL and confirmed by a treponemal test (FTA-ABS). Chlamydia trachomatis (Ct) and Neisseria gonorrhoeae (Ng) infection were diagnosed by in-house PCR on first void of urine, rectal and pharyngeal swabs.
Results: we included 117 participants (111 MSM and 6 TGW), median age was 31 years (IQR 20-51). At entry, gonorrhea prevalences at urethral and rectal sites were 0.9% and 2.6%; one participant had both rectal and urethral infections; no pharyngeal infections were diagnosed. Chlamydia prevalences at urethral, pharyngeal and rectal sites were 2.6%, 1.7% and 1.7% respectively. Active syphilis was diagnosed in 8/117 (prevalence 6.8%).
Global STI prevalence at baseline was 14.5%. During follow-up (median 21,25 months), there were 8 new syphilis infections (incidence 7.3%), 4 cases of gonorrhea (incidence 3.7%) and 2 chlamydia infections (incidence 1.8%), 1 HIV diagnosis, 1 episode of rectitis, 1 episode of urethritis and 1 diagnosis of rectal T. vaginalis infection . The global incidence of STI among this population was 16,5%. 8 participants were lost to follow up.
Conclusions: Global STIs prevalence and incidence among this population is high, underlining the importance of periodically testing in this high risk population with focus on syphilis, extragenital gonorrhea and chlamydia that are usually asymptomatic. Testing and treatment so far is the most effective method to interrupt transmission and reduce the burden of illness.

EPC242

Factors influencing modern contraceptive choices among HIV positive women attending family planning clinic at the University College Hospital Ibadan

A.O. Makinde[1]
[1]University of Ibadan, Obstetrics and Gynaecology, Ibadan, Nigeria

Background: Choices about childbearing and contraceptive use are important health decisions among HIV/AIDS infected female population. This study assessed the factors influencing modern contraceptive choices among HIV positive women attending the Antiretroviral family planning clinic of University College Hospital, Ibadan.
Methods: A cross-sectional study using systematic random sampling technique to select 341 consenting women was conducted. A pre-tested interviewer-administered questionnaire which contained respondents' demographic characteristics, factors influencing the choice of modern contraceptives, factors responsible for continuation of chosen method of contraception etc, Contraceptive continuation scores were categorised into unlikely (≤ 4), likely (5-6) and very likely (≥7).
Satisfaction scores of ≤6 and >6 were categorized as low and high respectively. Data were analysed using descriptive statistics, Chi-square and multinomial logistic regression at 5% level of significance.
Results: Age of the respondents was 35.5 ± 6.4 years; 99.4% were married and 89.0% were in monogamous marriage. Forty-seven percent had tertiary education and 41.3% had senior secondary school certificate. Current method of contraception was influenced by perceived effectiveness (72.8%) and few side effects (56.1%). Implant was the commonest choice for women with secondary (48.2%) and tertiary education (42.9%).
Majority (78.5%) reported irregular menstruation, weight gain/loss (27.2%), breast tenderness (5.0%), stomach pain (4.1%) and frequent headache (1.7%). Factors influencing continuation of chosen method included availability (95.9%), easy discontinuation of method (90.3%) and husband support (88.3%).
A Major reason for being satisfied with chosen method was adequate information before choice (98.2%). A significant association was found between the chosen modern contraceptive and higher level of education. Women whose choice of a particular method was not because it had worked for their mothers were twice (OR=0.54, 95%: 0.39-0.94) less likely to have chosen IUCD over implant than women who said yes. Women who had secondary education were (0R=0.44, 95% CI: 0.24-0.82) less likely to have chosen IUCD over implant than women who had tertiary education.
Conclusions: Higher level of education and previous use of contraceptives by respondents' mothers are factors influencing modern contraceptive choices. More emphasis on male involvement in family planning programme and reproductive health is hereby recommended.

EPC243

STI incidence and care discontinuation among PrEP using Black men who have sex with men in New Orleans, Louisiana

M.E. Clement[1], J. Beckford[2], A. Lovett[1], S. LeGrand[3], K.H. Mayer[4], L. Hightow-Weidman[5], P. Kissinger[6], E. Oral[7], S. Naggie[8]

[1]Louisiana State University Health Sciences Center, Infectious Diseases, New Orleans, United States, [2]University of Washington, Seattle, United States, [3]Duke University, Duke Global Health Institute, Durham, United States, [4]Harvard Medical School, Boston, United States, [5]University of North Carolina - Chapel Hill, Division of Infectious Diseases, Chapel Hill, United States, [6]Tulane University, Department of Epidemiology, New Orleans, United States, [7]Louisiana State University Health Sciences Center, Biostatistics, New Orleans, United States, [8]Duke University, Division of Infectious Diseases, Durham, United States

Background: Studies of PrEP among men who have sex with men (MSM) have demonstrated reduced rates of HIV but high rates of STIs. Additionally, rates of gonorrhea, chlamydia, and syphilis in the United States are five times higher in Black men compared to White men, and a significant proportion of new HIV cases are attributable to these STIs. Few studies specifically address STI risk in Black MSM PrEP users.

Methods: We prospectively enrolled Black MSM PrEP users aged 18-35 in a longitudinal study to assess STI incidence including gonorrhea, chlamydia, and syphilis. Participants enrolled from July 2019 until May 2021 and were followed until December 2021.

We examined demographic characteristics and factors shown to be associated with STI risk, such as social isolation and medical mistrust. We also examined care discontinuation events, defined as six months or more between visits, or no visits during the last six months of the study period.

Results: We enrolled 63 Black MSM PrEP users; total follow up time was 81.8 person years (PY). Mean age was 29.9 (SD 4.3); 45 participants (71%) had insurance, and 30 (48.4%) had been diagnosed with an STI in the 12 months prior to enrollment. Social Isolation, Discrimination, and Medical Mistrust Scores are shown in the table.

There were 56 STI infections over follow-up (6 syphilis, 18 chlamydia, 32 gonorrhea), yielding an STI incidence of 68.5/100PY. There were 2 incident cases of HIV (2.4/100PY). Additionally, 32 (51%) participants had PrEP discontinuation events.

Conclusions: Overall, Black MSM PrEP users in New Orleans did not feel socially isolated and had low perceived levels of discrimination, although their sense of medical mistrust was moderate.

Additionally, they had poor engagement in PrEP care and high rates of STIs and HIV. Further efforts are needed to enhance PrEP use and prevent STIs in this population.

Demographic (n=63 unless otherwise noted)	N/mean (% or SD)
Age - mean	29.9 (4.25)
Self-identified ethnicity - Hispanic	3 (4.8%)
Self-identified race - multiracial including black	8 (12.7%)
Income per year	
$0 - $34,999	41 (69.4%)
Greater than or equal to $35,000	18 (30.5%)
Insurance	
Private	22 (34.9%)
Medicaid	23 (36.5%)
None / Unknown	18 (28.6%)
STI within 12 months (n=62)	
Yes	30 (48.4%)
# of partners in prior 3 months	
0 - 4	45 (74.6%)
5 - 9	11 (17.4%)
>/= 10	5 (7.9%)
Anal condom use (n=55)	
Always	8 (14.5%)
Sometimes	32 (58.1%)
Never	15 (27.3%)
Social provisions scale (SPS-10)* (n=54)	33.5 (7.8)

A pilot evaluation of integrating STI testing & expedited partner therapy into PrEP delivery within antenatal care for pregnant women in Kenya

S. Watoyi[1], A. Lasern[2], F. Abuna[1], N. Ngumbau[1], P. Owiti[1], B. Ochieng[1], L. Gomez[3], J. Dettinger[3], J. Pintye[3], G. John-Stewart[2,3,4,5], J. Kinuthia[1]

[1]University of Nairobi/Kenyatta National Hospital, Medical Research, Nairobi, Kenya, [2]University of Washington, Department of Epidemiology, Seattle, United States, [3]University of Washington Department of Global Health, Seattle, United States, [4]University of Washington, Department of Medicine, Seattle, United States, [5]University of Washington, Department of Pediatrics, Seattle, United States

Background: PrEP delivery integrated within antenatal care (ANC) is scaling up in Kenya, yet pregnant women may not accurately perceive their HIV acquisition risk. Incorporating testing for sexually transmitted infections (STIs) into ANC could increase their HIV risk perception and motivation for PrEP initiation.

Methods: From December 2020 to August 2021, we piloted integrating chlamydia and gonorrhea (CT/NG) testing and expedited partner therapy (EPT) at one ANC clinic

in Siaya, Kenya. HIV-negative ANC clients ≥15 years were counseled on and offered Xpert CT/NG® testing with instructions on vaginal swab self-collection.

If participants were uncomfortable with self-collection, nurses collected swabs. CT/NG results were returned to nurses who counseled participants on their results prior to offering PrEP. Women diagnosed with CT or NG were offered immediate supervised treatment per national guidelines and EPT with appropriate medication for their partner(s).

Results: In total, 300 HIV-negative ANC clients were enrolled at a median gestational age of 24 weeks (IQR 16-24); 23% reported having any STI symptoms. The most frequent STI symptoms were vulvar burning/itching (22%) and abnormal vaginal discharge (14%).

Overall, 82% of participants accepted CT/NG testing and 93% self-collected swabs. We did not detect differences between participants who accepted vs. declined testing, except in frequency of STI symptoms (28% vs. 2%%, p<0.001).

Among participants who declined testing, the most frequent reasons for declining were not having time to wait 90-minutes for results (80%) and feeling like they did not have STIs (20%). Among those who accepted testing, 9% had CT detected; no cases of NG were detected. All participants received their CT/NG results at the same visit. PrEP acceptance was higher among women who accepted CT/NG testing compared to those who declined (25% vs. 11%, p=0.03).

Among participants with CT detected (n=23), all were treated immediately and 61% accepted EPT; 35% accepted PrEP. Reasons for declining EPT included partners residing far away and fear of partner reactions. No adverse events occurred following EPT acceptance.

Conclusions: In this pilot, offering both CT/NG testing and PrEP integrated within ANC was feasible. HIV-negative pregnant women frequently accepted CT/NG testing and if CT was detected, frequently accepted EPT and PrEP.

EPC245

Impact of point-of-care testing and treatment of sexually transmitted infections and bacterial vaginosis on the genital epithelial barrier integrity

N. Ndlela[1], N. Garrett[2,3], A. Mtshali[1], F. Osman[1], R. Singh[4,5], N. Mitchev[4], H. Ngobese[6], S. Abdool Karim[1,7], K. Mlisana[4,5], J.-A. Passmore[1,8,9], A. Rompalo[10], A. Mindel[1], L.J.P. Liebenberg[1,4]

[1]Centre for the AIDS Programme of Research in South Africa (CAPRISA), Durban, South Africa, [2]Centre for the AIDS Programme of Research in South Africa, Durban, South Africa, [3]University of KwaZulu-Natal, Public Health Medicine, Durban, South Africa, [4]University of KwaZulu-Natal, Department of Microbiology, Durban, South Africa, [5]National Health Laboratory Service, Durban, South Africa, [6]Prince Cyril Zulu Communicable Disease Centre, Durban, South Africa, [7]Columbia University, Department of Epidemiology, New York City, United States, [8]University of Cape Town, Institute of Infectious Disease and Molecular Medicine, Cape Town, South Africa, [9]National Health Laboratory Service, Cape Town, South Africa, [10]Johns Hopkins University, School of Medicine, Baltimore, United States

Background: Genital inflammation and epithelial barrier damage can increase HIV susceptibility in women. Because sexually transmitted infections (STIs) and bacterial vaginosis (BV) directly contribute to these, effective treatments are necessary to improve genital health and limit HIV risk in women. A program of point-of-care (POC) STI/BV, immediate treatment, and expedited partner therapy is shown to clear STIs and reduce inflammation in a cohort of young women in South Africa.

Here we investigate the impact of this approach on the integrity of the genital epithelial barrier against HIV/STIs.

Methods: HIV-negative women with BV and/or POC diagnosis of Chlamydia trachomatis, Neisseria gonorrhoeae, or Trichomonas Vaginalis received immediate treatment and EPT for STIs. Participants were retested 6- and 12-weeks post enrolment. Concentrations of 48 cytokines and 5 matrix metalloproteinase (MMP) biomarkers of epithelial barrier integrity were measured in cervicovaginal fluid using multiplex ELISA technology.

Wilcoxon-Mann-Whitney tests were used to assess the relationship between MMP concentrations and STI/BV at baseline, with ANOVA and multivariable linear mixed models used to assess the impact of treatment on MMP concentrations.

Results: The study included 238 women with a median age of 23 (IQR 21-27) years. Women with STIs/BV at baseline (n=169/238) had significantly higher concentrations of MMP-1, MMP-2, MMP-7, MMP-9, and MMP-10 (p<0.01) compared to women without (n=69). Increased baseline MMP concentrations correlated significantly with that of several pro-inflammatory and chemotactic cytokines. While most women cleared their STIs by 12 weeks (34/37, 91.9%), only 16/63 (25.4%) cleared the BV/IM status to a Nugent

Oral abstracts

E-posters

Late-breaker abstracts

Author Index

score of less than four after treatment with oral metronidazole. Reduced MMP concentrations were associated with STI treatment (MMP-1, MMP-7, MMP-9; p=0.05), but not with post-treatment Nugent scores.
The most marked reduction was observed in MMP-1 levels, where concentrations were reduced, respectively, by 20.76% (adj p=0.003) and 13.21% (adj p=0.034) by 6- and 12-weeks after STI treatment.
Conclusions: Our findings indicate that POC STI/BV testing, immediate treatment, and EPT can clear STIs, reduce inflammation, and promote epithelial barrier integrity, thereby improving vaginal health and potentially reducing HIV risk. However, more effective BV treatments are required and may better restore the epithelial defense against HIV/STIs.

EPC246

Integration of female genital schistosomiasis into HIV/sexual and reproductive health and rights and neglected tropical diseases programs and services: a scoping review with a systematic search

F. Wong[1], I. Umbelino-Walker[2], M. Cassolato[3], J. Jacobson[2], A. Pantelias[2]
[1]Frontline AIDS, Health & Development Consultant, Worthing, United Kingdom, [2]Bridges to Development, Seattle, United States, [3]Frontline AIDS, Hove, United Kingdom

Background: Female genital schistosomiasis (FGS) affects 56 million women and girls across sub-Saharan Africa, and is associated with a threefold increased risk for HIV. Integrating FGS with HIV programmes as part of comprehensive sexual and reproductive health (SRH) services may be one of the most significant innovations for HIV prevention among girls and women in the region.
This scoping review with a systematic search assessed how FGS can be integrated into HIV/SRH and neglected tropical diseases (NTDs) programs.
Methods: A search of studies published until October 2021 via Scopus and ProQuest was conducted using PRISMA guidelines. Data extraction included studies that presented FGS integration interventions and described the associated opportunities and challenges.
A qualitative review was undertaken adapting a conceptual framework for integrated implementation of FGS, HIV and HPV/cervical cancer interventions to thematically organize the results.
Results: Of 334 studies identified, 22 were eligible for analysis. Majority of citations, 72% (n=16), were published in NTD journals. Studies were classified into six integration measures: awareness, diagnosis, treatment, burden assessment, community engagement and economic evaluation.
Most activities pertained to awareness (n=9), diagnosis (n=9) and community engagement (n=9) and primarily connected to HIV (n=8) and school-based (n=8) programmes.
The studies mainly proposed opportunities/challenges for integration, rather than presenting results of integrated interventions. They advocated for integration due to the importance of FGS as a significant co-factor for HIV acquisition and other SRH issues.
Advice included increasing: FGS awareness and education; effectiveness of FGS diagnostic tools; and praziquantel provision to women of all ages and out-of-school children for FGS prevention and treatment and as a novel HIV and cervical cancer prevention tool.
Conclusions: There is an evidence gap on FGS integration into HIV/SRHR/NTD programmes. Therefore, evidence supporting an integrated approach to preventing and treating FGS needs to be published in peer reviewed journals focused on women's health and embedded into medical training at all levels.
Existing evidence on the increased risk of HIV acquisition due to FGS must be translated into programming and operational research for delivering integrated services. Investments and political will are needed to realise the potential of FGS integration as an HIV prevention innovation.

HIV prevention services for key populations

EPC247

Frequent episodes of sexual risk among men who have sex with men who are non-adherent to pre-exposure prophylaxis: a longitudinal cohort study

J. Jones[1], S. Pampati[1], A. Siegler[1]
[1]Emory University, Epidemiology, Atlanta, United States

Background: Pre-exposure prophylaxis (PrEP) is a highly effective biomedical HIV prevention intervention. Among men who have sex with men (MSM) who take at least four daily doses per week, PrEP has been found to provide near compete protection against sexual transmission of HIV via anal sex. PrEP does not necessarily require constant adherence; rather, adherence to PrEP is most important during periods of sexual risk. Thus, measuring functional adherence to PrEP requires measuring PrEP use and concurrent sexual behavior. To optimally characterize how PrEP adherence aligns with sexual risk, frequent assessments with short recall periods are needed.
We assessed the feasibility of biweekly assessments of PrEP use and sexual behavior among MSM in the southern United States.
Methods: PrEP-using MSM were recruited online. Eligible and consenting men were enrolled and completed a baseline survey followed by brief check-in surveys every two weeks for 16 weeks. Each mobile-optimized survey assessed PrEP use and sexual behavior over the previous 2-week period.

Feasibility was assessed based on the proportion of surveys that were completed. Adherence was defined as reporting at least 4 doses per week on average over a 2-week period.

Results: Of 78 total participants, 35 (47%) were non-Hispanic white, 20 (27%) were non-Hispanic Black, 12 (16%) were Hispanic; the remainder reported other or multiple races. 25 (32%) participants lived in rural areas. Feasibility was high with 86% of all surveys completed; 65% of participants completed all nine study surveys. Self-reported adherence was >90% at all study time points.

We observed a total of 39 intervals in which a participant reported non-adherence or discontinuing PrEP across 14 participants; 14 (36%) of these intervals contained at least one episode of condomless anal sex.

Conclusions: Although adherence on PrEP was high, non-adherence frequently overlapped with periods of sexual risk. Frequent, short surveys are a feasible method for assessing PrEP adherence and alignment with sexual risk among MSM in the US South.

These methods will be key in understanding patterns of PrEP use, identifying barriers to and facilitators of sustained adherence during periods of sexual risk, and evaluating effectiveness of different PrEP adherence strategies in preventing HIV infections.

EPC248

Unmet service needs among PrEP-eligible MSM and TGW in THRIVE — United States, 2015–2020

A. Kimball[1], W. Zhu[1], M. Tanner[1], K. Iqbal[1], K. Hoover[1]
[1]*Centers for Disease Control and Prevention, Division of HIV Prevention, Atlanta, United States*

Background: Oral pre-exposure prophylaxis (PrEP) is highly effective for HIV prevention, but PrEP uptake has been low among U.S. Black/African American (Black) and Hispanic/Latino men who have sex with men (MSM) and transgender women (TGW), related to social and structural barriers.

Data from the THRIVE demonstration project were analyzed to describe unmet service needs among PrEP-eligible Black and Hispanic/Latino MSM and TGW.

Methods: THRIVE funded 7 U.S. health departments during 2015–2020 to provide HIV prevention and care services through community collaboratives, prioritizing Black and Hispanic/Latino MSM and TGW. All sites routinely screened clients for PrEP eligibility and 4 sites routinely screened for unmet mental health, substance use, housing, employment, transportation, and health insurance needs. Unmet service needs were described among Black and Hispanic/Latino MSM and TGW who were PrEP-eligible and enrolled at one of 4 sites with routine screening. Comparisons between groups were performed using chi-square tests.

Results: Among PrEP-eligible clients included in this analysis, 1,742 were Black MSM, 498 were Hispanic/Latino MSM, 201 were Black TGW, and 48 were Hispanic/Latino TGW. Hispanic/Latino TGW had the highest proportion with any unmet needs (88.4%). A higher proportion of Hispanic/Latino MSM had any unmet needs compared with Black MSM (71.5% vs. 47.1%, p<.001), and a higher proportion of Hispanic/Latino TGW had unmet needs compared with Black TGW (88.4% vs. 65.5%, p<.01).

Among Black MSM and Hispanic/Latino MSM, the most common single unmet need was health insurance (17.9% and 34.3%, respectively). Among Black and Hispanic/Latino TGW, the most common unmet need was employment (35.4% and 59.1%).

The highest proportion with unmet mental health needs was among Hispanic/Latino TGW (22.5%), followed by Hispanic/Latino MSM (22.0%). The highest proportion with unmet substance use needs was among Hispanic/Latino MSM (9.6%).

Conclusions: Black and Hispanic/Latino MSM and TGW who were eligible for PrEP in THRIVE had high unmet service needs. Hispanic/Latino clients had higher unmet service needs compared with Black clients, and Hispanic/Latino TGW had the most unmet needs.

Addressing the social determinants of health among persons at risk for HIV acquisition might help improve PrEP uptake among disproportionately affected populations.

EPC249

PrEP vs PEP: Awareness, use and preferences among Latina immigrant transgender women in the Washington DC metropolitan area

A.M. del Río-González[1], S. Poveda Lozada[2], N. Reyes[1], F. González[1], G. Came Fadul[1], M.C. Zea[1]
[1]*The George Washington University, Department of Psychological and Brain Sciences, Washington, United States,* [2]*The George Washington University, Milken Institute School of Public Health, Washington, United States*

Background: Latina immigrant transgender women (LITW) in the US are disproportionately impacted by HIV. However, their use of the pre- and post-exposure prophylaxis (PrEP and PEP) is low. This longitudinal mixed-methods research study explored awareness, use and preferences regarding PrEP and PEP among LITW.

Methods: Participants were 37 HIV-negative LITW living in the DC metropolitan area (M age=34.5; SD=8.4). Most participants were from Central America (n=28; 75.7%) and had been in the U.S. for over five years (M=10.5; SD=8.7). We conducted up to three in-depth, semi-structured mixed-methods interviews per participant.

All interviews were conducted, transcribed and analyzed in Spanish. For qualitative data we used a Rapid and Rigorous analysis (RADaR) technique to identify key themes. Quantitative analyses used descriptive and non-parametric statistics.

Results: Awareness, lifetime use and preference were higher for PrEP than for PEP. Participants who preferred PrEP (62.9%) felt it was safer because they were taking it

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

beforehand (e.g., "I have it in my system and now I am no longer worried of having sex"), and because there is more information about it (e.g., "It is talked about a lot, I feel safer"). Participants who preferred PEP (31.4%) liked it's limited time frame (e.g., "I prefer to take 28 days than my whole life") and the possibility of using it on a case-by-case basis (e.g., "If I have someone of dubious [status], I will take PEP to make sure I will be OK").

Regarding intentions to use, less than half of PrEP-naive participants (n=10; 45.4%) thought PrEP would be a good alternative for them. Conversely, the majority of participants, regardless of previous PrEP/PEP use, would use PEP if they were concerned about a recent sexual encounter (n=33; 89.2%), despite some concerns about access.

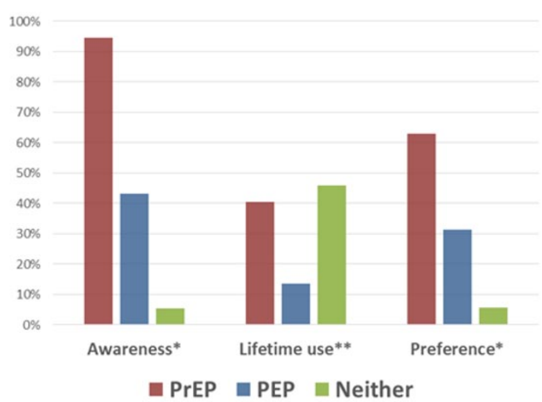

Figure 1. PrEP and PEP awareness, lifetime use and preference.

Conclusions: Despite higher awareness, use, and preference for PrEP, PEP is an important additional HIV-prevention strategy among LITW.

EPC250

Prevalence and factors associated with timeliness of partner services for persons newly diagnosed with HIV in the United States, 2019-2020

M.S. Mulatu[1], W. Song[1]

[1]*Centers for Disease Control and Prevention, Division of HIV Prevention, Atlanta, United States*

Background: Timely delivery of partner services (PS) is an important strategy to reduce HIV transmission by improving linkage to care and prevention services for persons with HIV and their partners. However, data on the timeliness of PS in HIV prevention programs are limited.

Methods: We used 2019-2020 HIV testing data submitted by 60 CDC-funded state and local health departments. Variables analyzed include date of interview for PS, demographic and behavioral risk characteristics, and testing site type for persons newly diagnosed with HIV (n=9,611). Timeliness of PS was operationalized by provision of an PS interview within 14 and 30 days of HIV diagnosis. We conducted multivariate Poisson regression to examine factors associated with timely delivery of PS.

Results: Overall, only 43.7% and 58.4% of persons newly diagnosed with HIV in 2019-2020 were interviewed for PS within 14 and 30 days of diagnosis respectively. Similar factors were associated with both measures of timely delivery of PS. Results for PS interview within 14 days of diagnosis indicate lower prevalence among 40-49 (38.8%; adjusted prevalence ratio [aPR]=0.86; 95% confidence interval [CI]=0.80-0.93) and ≥50 year olds (35.9%; aPR=0.80; 95% CI=0.74-0.88) compared to 20-29 year olds (46.8%). Hispanic/Latino persons (41.2%; aPR=0.89; 95% CI=0.83-0.95) were less likely to receive timely interview than White persons (47.1%). Timely interview was higher among persons from the South (38.3%; aPR=1.23; 95% CI=1.13-1.33), the Midwest (62.1%; aPR=1.77;95% CI=1.61-1.95) and the West (64.1%; aPR=1.99; 95% CI=1.83-2.18) compared to persons from the Northeast (33.9%). Timely interview was higher among persons tested in STD clinics (58.4%; aPR=1.56; 95% CI=1.46-1.67) and lower among those tested in emergency departments (18.7%; aPR=0.67; 95% CI=0.55-0.80) compared to those tested in HIV testing sites (37.4%).

Conclusions: More than 40% of persons newly diagnosed with HIV were not interviewed for PS within 14 or 30 days of diagnosis indicating missed opportunities at preventing further transmission of HIV to partners. Demographic, regional, and testing site type differences suggest inequitable delivery of PS.

Further research is needed to identify and remove the barriers to timely and equitable provision of PS and contribute to ending the HIV epidemic in the United States.

EPC251

Which men who have sex with men are most in need of pre-exposure prophylaxis in Amsterdam, the Netherlands? A reappraisal of eligibility criteria

F. de la Court[1], A. Boyd[1,2], U. Davidovich[1,3], E. Hoornenborg[1], M.F. Schim Van Der Loeff[1,4], H.J.C. De Vries[1,5], D.A. Van Wees[6], B.H.B. Van Benthem[6], M. Xiridou[6], A. Matser[1], M. Prins[1,4]

[1]*Public Health Service of Amsterdam, Department of Infectious Diseases, Research and Prevention, Amsterdam, Netherlands, the,* [2]*HIV Monitoring Foundation, Amsterdam, Netherlands, the,* [3]*University of Amsterdam, Department of Social Psychology, Amsterdam, Netherlands, the,* [4]*Amsterdam UMC, University of Amsterdam, Department of Infectious Diseases, Amsterdam institute for Infection & Immunity (AII), Amsterdam, Netherlands, the,* [5]*Amsterdam UMC, University of Amsterdam, Department of Dermatology, Amsterdam, Netherlands, the,* [6]*National Institute for Public Health and the Environment (RIVM), Center for Infectious Disease Control, Bilthoven, Netherlands, the*

Background: Pre-exposure prophylaxis (PrEP) distribution is restricted within the Dutch national PrEP program and should target those at highest HIV-risk. To reappraise eligibility criteria, we assessed the men who have sex with men (MSM) most in need of PrEP.

Methods: We used Amsterdam Cohort Studies (ACS) data from 2011-2017 for non-PrEP using HIV-negative MSM. PrEP need, defined as HIV-risk, was assessed using outcomes:
1. Incident HIV-infection and;
2. Newly-diagnosed anal STI (proxy for HIV-risk).
Determinants included:
1. Dutch PrEP eligibility criteria: anal STI and condomless sex with a steady or casual partner (PEP use and syphilis were excluded due to insufficient data), and;
2. Additional determinants: age (16-35/35+), education (yes/no college or university), group sex, alcohol during sex, and chemsex.
We estimated relative risks (RR) and 95% confidence intervals (CI) of determinants on outcomes at visit level using targeted maximum likelihood estimation (TMLE).
We assessed population-level effects by calculating population attributable fractions (PAF) with 95%CI using RRs from TMLE.
Results: Among 810 included MSM, the median age was 36.1 (IQR=29.6-43.0) and most (76.9%) were highly educated. During follow-up, 22 HIV-infections and 436 anal STIs (n= 218; median=2[IQR=1-2]) were diagnosed.
Chemsex (RR=5.8 [95%CI=2.0-16.9]; PAF=55.3 [95%CI=43.3-83.4]), condomless sex with a casual partner (RR=3.3 [95%CI=1.3-8.7]; PAF=38.0 [95%CI=18.3-93.6]) and anal STI (RR=5.3 [95%CI=1.7-16.7]; PAF=22.0 [95%CI=-16.8-100.0]) were significantly (p<0.05) associated with HIV, and were among the most attributable risk behaviors for HIV.
Chemsex (RR=2.0 [95%CI=1.6-2.4]; PAF=19.5 [95%CI=10.6-30.6]) and condomless sex with a casual partner (RR=2.5 [95%CI=2.0-3.0]; PAF=28.0 [95%CI=21.0-36.4]) were also significantly associated with anal STI, as well as younger age (16-34 versus 35+; RR=1.7 [95%CI=1.4-2.1]; PAF=15.5 [95%CI=6.4-27.6]) and group sex (RR=1.3 [95%CI=1.1-1.6]; PAF=9.0 [95%CI=-2.3-23.7]).
Despite non-significant RR estimates for HIV, PAF estimates indicated that group sex was the third (PAF=26.7 [95%CI=1.6-100.0]) and younger age was the sixth (PAF=10.7 [95%CI=-24.10-100.0]) most attributable factor for HIV-risk.
Conclusions: Encouraging PrEP use among MSM having chemsex as a new criterium alongside the current criteria of condomless sex with casual partners and anal STI could improve HIV prevention. The additions of group sex and younger age may also help prioritize PrEP.
Future research must assess these criteria among less homogenous MSM populations (i.e., younger, ethnically diverse and mixed socioeconomic backgrounds) and evaluate the costs and benefits of application in practice.

EPC252
Differentiated escalating adherence support visualization for cisgender women on PrEP

R. Kofron[1], J. Blumenthal[2], S. Morris[2], C. Psaros[3], L. Burke[2], D.J. Moore[2], R.J. Landovitz[1], K.R. Amico[4]
[1]University of California, Los Angeles, Los Angeles, United States, [2]University of California, San Diego, San Diego, United States, [3]Harvard Medical School, Boston, United States, [4]University of Michigan, Ann Arbor, United States

Background: Pre-exposure prophylaxis (PrEP) use and support for HIV prevention for cisgender women remains understudied in the US. Oral PrEP adherence support strategies for cisgender women are needed.
Methods: The AEGIS study provided open-label PrEP to women at risk for HIV in California between May 2016 and April 2018. Standard adherence support for all participants included Individualized Texting for Adherence Building (iTAB), an automated daily text message and inquiry about dosing, and engaging women at each study visit in a brief discussion exploring current context and needs specific to sexual health promotion and PrEP use (integrated Next Step Counseling [iNSC]).
Dried blood spot drug concentrations were collected at weeks 4, 12, 24, 36 and 48. Concentrations suggesting less than 6-7 days dosing (<1050 fmol/punch) triggered escalated intervention(s).
The first escalation was targeted-iNSC, a version of iNSC which uses problem solving around the reported causes of the below threshold result.
A second below threshold result triggered LifeSteps for PrEP, a multi-session, theory-based adherence counseling intervention. Demographics between participants who had some improvement after escalated intervention and those who did not were evaluated with univariable Fisher's Tests and Kruskal-Wallis Tests.
Results: The Figure maps the flow the 108 women who received PrEP and had at least one follow-up visit over 48 weeks of study participation. 16 (14.8%) sustained high levels of daily PrEP use with the standard adherence support package. Only employment was associated with improvement after escalated intervention (p=0.02).

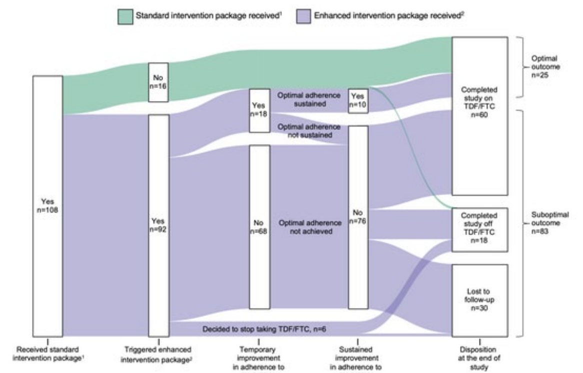

Figure. Escalating adherence support strategies and dried blood spot results.

Conclusions: While the escalated intervention approach appeared to be helpful for some participants, a large segment had drug concentrations that remained below threshold after escalation, particularly for women who were unemployed, and loss to follow-up was not uncommon. PrEP optimization for US cisgender women will likely require a robust menu of HIV prevention strategies and tailored social and structural support.

EPC253

Evaluating Black women's preferences towards sexual and reproductive health content for the mobile health app prototype Savvy HER

R. Chandler[1], D. Guillaume[2,1], N. Hernandez[3], A. Parker[4]
[1]Emory University, School of Nursing, Atlanta, United States, [2]Johns Hopkins University, School of Nursing, Baltimore, United States, [3]Morehouse School of Medicine, Atlanta, United States, [4]Georgia Institute of Technology, College of Computing, Atlanta, United States

Background: Black women in the United States experience disproportionate rates of HIV, and have the second highest rate of new HIV infections after men who have sex with men. Mobile health (mHealth) interventions can function as a valuable tool in mitigating HIV risk among Black women through providing content that is tailored towards their needs and lived experiences.

Our descriptive qualitative study explored the features that Black women desired to see within a mobile app that is currently under development, *Savvy HER*, which will focus on HIV prevention and pre-exposure prophlyaxis (PrEP) uptake for Black women.

Methods: Semi-structured in-depth interviews were conducted with n=24 Black women. Interview guide questions inquired about HIV and PrEP knowledge and awareness, sources of health information, and willingness to use a mobile app for HIV prevention. Interviews were recorded and transcribed using Otter.ai software. Data analysis employed Grounded Theory in which transcripts were coded inductively with patterns among codes being identified to categorize codes into overarching themes.

Results: Results from our qualitative study demonstrate that Black women had high acceptability of using a mobile app for sexual and reproductive health content. Participants desired content focused on various sexual and reproductive health topics that expanded beyond HIV prevention. Women stated voiced wanting to have access to accurate information on relevant health topics including family planning, contraception, and mental health. Themes pertaining to women's empowerment were also identified. Women also voiced including features that provides linkage to community resources for health and social support.

Conclusions: Black women desired content on various health topics within our proposed mHealth app that expanded beyond HIV prevention. This finding underscores the importance of using human centered design and collaborative engagement with target communities to identify end-user needs and preferences regarding the content and design of mHealth programs.

While our app prototype, *Savvy HER*, was initially developed for HIV prevention, we have now included features that were desired by Black women that promote holistic wellness (e.g.linkage to health and social resources) while ensuring Black women are adequately reflected throughout the design of *Savvy HER*.

Association between knowledge and attitudes toward methadone and the decision to initiate pre-release methadone among men living with HIV and opioid use disorder in Malaysia's Kajang prison

R.J. Bosworth[1], M.S. Chambers[1], M. Farrell[1], S.A. Kinner[2,3,4,5], R. Borschmann[2,3,6,7], D. Weatherburn[1], A.R. Bazazi[8,9,10], F.L. Altice[9,11,8]
[1]University of New South Wales, National Drug and Alcohol Research Centre, Randwick, Australia, [2]University of Melbourne, Justice Health Unit, Centre for Health Equity, Melbourne School of Population and Global Health, Melbourne, Australia, [3]Murdoch Children's Research Institute, Centre for Adolescent Health, Melbourne, Australia, [4]Griffith University, Griffith Criminology Institute, Mount Gravatt, Australia, [5]University of Queensland, Mater Research Institute, South Brisbane, Australia, [6]University of Oxford, Warneford Hospital, Department of Psychiatry, Oxford, United Kingdom, [7]The University of Melbourne, Melbourne School of Psychological Sciences, Melbourne, Australia, [8]Yale University, Department of Medicine, Section of Infectious Diseases, AIDS Program, New Haven, Connecticut, United States, [9]Yale University, School of Public Health, Department of Epidemiology of Microbial Diseases, New Haven, Connecticut, United States, [10]University of California, Department of Psychiatry, San Francisco, United States, [11]University of Malaya, Faculty of Medicine, Centre of Excellence for Research in AIDS (CERiA), Kuala Lumpur, Malaysia

Background: Strong beliefs, including misperceptions about methadone are documented among people who experience incarceration in Malaysia. We examined associations between knowledge and attitudes and the decision to initiate pre-release methadone maintenance treatment (MMT).

Methods: We used data from*Project Harapan*, a randomized (n=64) and participant choice (n=246) trial of pre-release MMT between 2010 and 2013 in Malaysia's largest prison among men living with HIV and opioid use disorder. Our analysis was restricted to participant choice, after excluding 14 men, 232 remained. Primary interest lay in relationships between responses to 14 methadone knowledge and attitude questions collected during baseline interviews and the choice to initiate or not to initiate pre-

release MMT. We conducted a latent class analysis based on responses to identify clusters of men with similar responses (chi-square tests [X^2]); examined associations between classes and socio-demographic characteristics (X^2& Kruskal Wallis tests); between classes and MMT choice (X^2); and, between responses and MMT choice (X^2).

Results: Of the participant choice sample (n=232), men were 39 years old on average, most were Malay (74%), Muslim (77.1%), reported injection drug use (94%) and few reported past MMT use (9.5%).

We uncovered four latent classes. We found differences among the groups in the proportion of men assigned to them that chose to initiate pre-release MMT.

Higher proportions of men in the two groups with lower proportions of "don't know" responses chose to initiate pre-release MMT than in the two groups with higher proportions of "don't know" responses.

We found high proportions of "don't know" responses by men assigned to each class; class 1: 17.0 %, class 2: 96.9 %, class 3: 60.3 % and class 4: 16.4 %. Pre-release MMT uptake was still quite high among men that gave many don't know responses. Overall, of the 232 men, 184 (79.3%) chose to initiate pre-release MMT, 48 (20.7%) chose not to.

Conclusions: Potential exists to increase MMT uptake by addressing uncertainty towards methadone. Prisons seeking to increase MMT uptake may consider evidence-based shared-decision aids to understand perceptions, knowledge and attitudes and address how these may challenge 'methadone as HIV prevention' efforts.

EPC255

Return to opioid use following release from incarceration: Findings from a prison-based methadone maintenance treatment program for men living with HIV and opioid use disorder in Malaysia

R.J. Bosworth[1], M.S. Chambers[1], M. Farrell[1], S.A. Kinner[2,3,4,5], D. Weatherburn[1], R. Borschmann[3,6,4,7], A.R. Bazazi[8,9,10], F.L. Altice[10,8,11]

[1]University of New South Wales, National Drug and Alcohol Research Centre, Randwick, Australia, [2]Griffith University, Griffith Criminology Institute, Mount Gravatt, Australia, [3]Murdoch Children's Research Institute, Centre for Adolescent Health, Melbourne, Australia, [4]University of Melbourne, Justice Health Unit, Centre for Health Equity, Melbourne School of Population and Global Health, Melbourne, Australia, [5]University of Queensland, Mater Research Institute, South Brisbane, Australia, [6]The University of Melbourne, Melbourne School of Psychological Sciences, Melbourne, Australia, [7]University of Oxford, Warneford Hospital, Department of Psychiatry, Oxford, United Kingdom, [8]Yale University, Department of Medicine, Section of Infectious Diseases, AIDS Program, New Haven, Connecticut, United States, [9]University of California, Department of Psychiatry, San Francisco, United States, [10]Yale University, School of Public Health, Department of Epidemiology of Microbial Diseases, New Haven, Connecticut, United States, [11]University of Malaya, Faculty of Medicine, Centre of Excellence for Research in AIDS (CERiA), Kuala Lumpur, Malaysia

Background: Return to opioid use is high following release from incarceration and is associated with poor HIV treatment outcomes and opioid-related harms. Efforts to scale-up methadone treatment as HIV prevention and reduce harms are required.

We evaluate the efficacy of pre-release methadone maintenance treatment (MMT) initiation in reducing return to opioid use post-release in Malaysia.

Methods: Individuals were enrolled in*Project Harpan*,a randomized (n=64) and participant choice (n=246) trial of pre-release MMT initiation between 2010 and 2013 in Malaysia's largest prison among men living with HIV and opioid use disorder.

After excluding 14, 296 men remained. The primary outcome was incidence of opioid use over the 12 months post-release, indicated by monthly urinalysis. We hypothesized opioid use post-release would be lower in the group initiating pre-release MMT than those not initiating.

Outcomes of urine toxicology tests for opioids were fitted to multivariable logistic regression models using generalized estimating equations after multiple imputation to test the hypothesis.

Results: Of the 296 men, most were Malay (72.3%), Muslim (76.6%), were on average 38 years old, never married (64.1%), living with hepatitis C (95.7%) and reported a history of injection drug use (91.6%). Less than 14 percent were on antiretroviral treatment, few were virally sup-

pressed (15.9%). The mean CD4+T-lymphocyte count was 451.1 (cells/mL), 17% had a CD4+T-lymphocyte count under 200 (cells/mL). Initiation of pre-release MMT was strongly associated with a decreased probability of returning an opioid-positive urine toxicology result in the first 12 months post-release, compared to individuals not initiating pre-release MMT (adjusted odds ratio 0.45, 95% CI, 0.30, 0.67).

Urine samples from individuals with equal to or greater than 4 incarceration episodes had 36 percent higher odds of testing positive for opioids than those with≤1 prior incarcerations (aOR 1.36, 95% CI, 1.04, 1.77).

Conclusions: Use of opioids in the 12 months post-release was less frequent among individuals initiating pre-release MMT. We recommend the expansion of MMT in Malaysian prisons.

Our findings suggest pre-release MMT may be an effective intervention for decreasing and interrupting the cycle ofopioid use and improving HIV prevention and treatment outcomes.

EPC256

Healthcare providers' perspectives on PrEP adherence among MSM and TGW in Peru: a qualitative study of the ImPrEP demonstration study

J.P. Jirón Sosa[1], K.A. Konda[1], C. Sandoval[1], C.F. Caceres[1]

[1]*Universidad Peruana Cayetano Heredia, Center for Interdisciplinary Studies in Sexuality, AIDS and Society, Lima, Peru*

Background: Daily Oral HIV Pre-Exposure Prophylaxis (PrEP) was implemented in Peru through the ImPrEP Study, focused on men who have sex with men (MSM) and transgender women (TGW). Healthcare providers play a significant role in the successful implementation of PrEP and their perspectives and experiences are critical to understanding PrEP adherence in these populations.

Methods: Individual in-depth interviews (IDI) were conducted with 11 healthcare providers (physicians, psychologists, midwives and peer educators) from 4 ImPrEP Study sites in Peru. Analysis explored four dimensions: PrEP acceptability among MSM/TGW, benefits of PrEP use, barriers to PrEP adherence, and current situation of health services.

Results: Healthcare providers reported that PrEP was highly acceptable among MSM/TGW, especially among participants with very active sex lives (multiple partners, condomless sex), sero-discordant couples, commercial sex workers, and those seeking an alternative HIV prevention method to condoms. Among the benefits offered by PrEP, providers stated that PrEP helps MSM/TGW reduce risk of contracting HIV while giving them greater security, confidence, and control over their sexual health. Additionally, PrEP had a liberating effect, strengthening bonds between sex partners and providing greater sexual satisfaction. Likewise, control visits helped to detect STIs in time and maintain participants' sexual health. Major barriers to PrEP adherence among MSM/TGW reported by providers included low HIV-risk perception, struggles to adhere to the daily regimen, side effects and PrEP-related stigma, followed by doubts about PrEP effectiveness, concerns about the interaction of hormone therapy and PrEP and periods of low sexual activity. Providers described several structural barriers of current services such as limited health systems capacity to provide PrEP, inadequate infrastructure, insufficient personnel, and the urgency of establishing a PrEP provision program supported by the Ministry of Health.

Conclusions: According to healthcare providers, participants with a high self-perceived HIV risk often request PrEP, which helps them reduce their risk and gives them control over their health. Daily oral regimen, low HIV-risk perception, side effects and PrEP-related stigma were described as major barriers to adherence. The health services would require changes and improvements to successfully implement PrEP within the government's public health program.

EPC257

Seroconversions monitoring in Brazil's PrEP program

I. Ornelas Pereira[1], N. Mendonça Collaço Véras[1], A.F. Kolling[1], A.C. Garcia Ferreira[1], T. Cherem Morelli[1], G.F. Mendes Pereira[1], A.R. Pati Pascom[1]

[1]*Ministry of Health of Brazil, Department of Diseases of Chronic Condition and STIs, Brasilia, Brazil*

Background: As Brazil's free-of-charge PrEP program scales-up, more individuals at increased risk of contracting HIV can benefit from this public health policy. Although PrEP has been proven effective in several studies, we aimed to analyze seroconversion in Brazil´s daily dosing PrEP program using real life data.

Methods: We analyzed the National PrEP Program Database from january 2018 to december 2021 and linked it, using unique identifiers, with the national system of Antiretroviral Therapy (ART), which registers all ART dispensation in country. We used descriptive statistics to quantify PrEP and ART dispensations and identify seroconversions during PrEP use.

Results: From 57,302 individuals seeking PrEP, we found out that 1,014 (2%) later initiated ART (median age:29, IQR 26-35). Among them, 492 (48%) were registered for PrEP, but did not initiate it and started ART instead; 481 (47%) started ART after not returning to refill PrEP pills; 34 (3%) received their first PrEP dispensation, but tested positive at the 30-day-follow-up visit, which indicates infection in the window period before PrEP; 3 (0,3%) seroconverted while in PrEP, but reported having missed 15 or more pills on the prior 30 days; 4 (0,4%) seroconverted while in PrEP and reported taking all pills. Out of these 4 cases, just one has done genotyping and no drug resistance was found.

When we analyze all 52,577 individuals who received at least one PrEP dispensation, 7 (0.01%) seroconverted (median age:36, IQR 25-46). Among those, 6 (86%) were gays/MSM and 1 (14%) was a cisgender woman; and 3 (43%) were sex workers.

Conclusions: After four years of PrEP program in Brazil, the low percentage of HIV seroconversions reinforces the effectiveness and importance of this prophylaxis and encourages the country to further expand this prevention option.

Considering that almost half of the seroconversions could be attributed to poor adherence, it is important to continue to bring attention to education, motivation and social/psychological strategies to improve adherence, but also consider the offer of new PrEP delivery models, especially for key population.

EPC258

Preferences for HIV prevention strategies among newly arrived Asian-born men who have sex with men living in Australia: a discrete choice experiment

M. Ung[1], F. Terris-Prestholt[2], M. Quaife[3], N. Medland[4], T. Phillips[5], E.P.F. Chow[6], D. Lee[6], W. Tieosapjaroen[7], L. Mao[8], S. Martin[9], B.R. Bavinton[4], S. Pan[10], J.J. Ong[6]

[1]Liverpool Hospital, Infectious Diseases, Sydney, Australia, [2]University of London, London School of Hygiene & Tropical Medicine, London, United Kingdom, [3]University of London, Faculty of Global Health and Development, London, United Kingdom, [4]The Kirby Institute, Sydney, Australia, [5]Monash University, Health Data Management and Biostatistics Unit, Melbourne, Australia, [6]Alfred Hospital, Melbourne Sexual Health Centre, Melbourne, Australia, [7]Monash University, Faculty of Medicine, Nursing and Health Sciences, Melbourne, Australia, [8]University of NSW, Centre for Social Research in Health, Sydney, Australia, [9]Canberra Health Services, Canberra Sexual Health Centre, Canberra, Australia, [10]Xi'an Jiaotong-Liverpool University, Department of Health and Environmental Sciences, Suzhou, China

Background: Overall, HIV incidence has declined in Australian-born gay, bisexual, and other men who have sex with men (MSM) but not in newly-arrived Asian-born MSM. We aimed to evaluate preferences for HIV prevention strategies among newly-arrived Asian-born MSM.

Methods: We conducted an online discrete choice experiment among MSM, not living with HIV, aged ≥18 years, born in Asia (South, East, South-East), and who arrived in Australia within the last five years. We evaluated their personal preferences for HIV prevention strategies using random parameter logit (RPL) models and estimated the relative importance for each strategy. We explored heterogeneity of preferences using latent class analysis (LCA) with interaction effects for employment status, where people sourced information about HIV and strategy used at last sex.

Results: In total, 286 participants completed the survey (1/2/2019-30/6/2021). Their mean age was 29.2 (SD6.8) years and had lived in Australia for a median of 3 years (IQR 2-4). The mean number of regular male sex partners in the last 6 months was 2.0 (SD4.0) and median was 1 (IQR 1-2).

Regarding the relative importance of strategies, men preferred PrEP as an HIV prevention strategy, followed by consistent condom use, post-exposure prophylaxis, asking their sexual partners for their latest HIV test result and insertive anal-sex.

The LCA uncovered 3 classes: 'PrEP' (52%), 'Consistent condoms' (31%), and 'No strategy' (17%). Compared to the 'No strategy' class, men in the 'PrEP' class were less likely to be a student or asked their partner for their HIV test result.

Men in the 'Consistent condoms' class were more likely to get information about HIV from online, used condoms in their last sexual encounter, and less likely to ask their partner for their HIV test result.

Conclusions: Overall, PrEP was the preferred HIV prevention strategy for this subpopulation of MSM at higher risk for HIV. Therefore, removing barriers for accessing PrEP is paramount such as more PrEP campaigns and information in language, and partnerships with education providers to disseminate PrEP information.

Focus on those in the 'No strategy' subgroup to have a strategy is also important as they would be at highest-risk of acquiring HIV.

EPC259

The positive impact of drug consumption rooms on HIV/HCV risk practices among people who inject drugs: results from the COSINUS cohort study

P. Roux[1], L. Lalanne[2], C. Donadille[1], L. Briand Madrid[1], M. Auriacombe[3], M. Jauffret-Roustide[4], Cosinus study group

[1]INSERM, SESSTIM, Marseille, France, [2]University Hospital of Strasbourg, Psychiatry/Addictology, Strasbourg, France, [3]CNRS USR 3413, SANPSY, Bordeaux, France, [4]CEMS, Paris, France

Background: The effectiveness of drug consumption rooms (DCR) for people who inject drugs (PWID) has been demonstrated in several contexts, mainly on HIV-HCV risk practices. However, none of these studies has taken into account the potential bias related to specific characteristics of the group of PWID attending DCR by comparing the exposed group to a control one.

The Cosinus cohort study conducted in France was designed to evaluate the impact of being exposed to DCR on the reduction of HIV-HCV risk practices by using a controlled cohort study.

Methods: The COSINUS cohort is a 12-month longitudinal study among 665 PWID enrolled in Bordeaux, Marseilles, Paris and Strasbourg. We used data from face-to-face interviews at enrolment, 6- and 12-month visits conducted among participants recruited in addiction care and harm

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

reduction programs in Bordeaux and Marseille and also in DCR in Strasbourg and Paris. We measured the impact of DCR exposure on HIV-HCV risk practices i.e. injecting equipment sharing (e.g., syringe, filter, spoon, water, etc.) during the previous month.

We used a two-step Heckman mixed-effects probit model, which allowed us to take into account the correlation of repeated measures and to control for the potential bias due to non-randomization between the two groups (DCR-exposed *vs.* DCR-unexposed participants).

Results: PWID exposed to DCR have 11% less HIV/HCV risk practices compared to those not exposed. After correction for the selection bias, being exposed to DCR was significantly associated with a lower risk of injection equipment sharing (adjusted coefficient (aCoeff) = -1.14; 95% confidence interval (95% CI) = [-1.91;-0.36]), after adjusting on being younger, having received food aid, using crack cocaine or free base daily, injecting daily, having harmful alcohol consumption, reporting being HCV seropositive and younger.

Conclusions: DCR that have been implemented in France have a positive impact on risk practices for infectious diseases such as HIV and HCV. This result confirms the previous studies published on the topic and provides additional strong argument to advocate for DCR implementation.

EPC260

Preventing HIV infection in pregnant women through a comprehensive antenatal care-based intervention: an implementation study in Western Uganda

S. Theuring[1], L.S. Jahn[1], A. Kengonzi[2], S. Ndugwa Kabwama[3], J. Rubaihayo[2]

[1]*Charité-Universitätsmedizin Berlin, Institute of Tropical Medicine and International Health, Berlin, Germany,* [2]*Mountains of the Moon University, School of Health Sciences, Fort Portal, Uganda,* [3]*Makerere University, School of Public Health, Kampala, Uganda*

Background: Worldwide, HIV incidence has stabilized, but isolated groups are still at high risk of infection. Pregnant women are specifically vulnerable due to biological and socio-behavioral factors. However, most endemic countries like Uganda do not specifically target HIV-negative pregnant women within prevention strategies.

The aim of our implementation study was to assess feasibility and outcomes of a comprehensive HIV prevention intervention for pregnant women in Fort Portal, Uganda.

Methods: We recruited a prospective cohort of HIV-negative antenatal care (ANC) clients in three facilities in Fort Portal. At first ANC visit, a prevention intervention was applied, including individual HIV risk counselling, referral to pre-exposure prophylaxis (PrEP) if eligible, partner counselling and testing including written invitation letters for absent partners, and reinforced repeat HIV testing after three months using reminder text messages. At the repeat test date, women were tested for HIV seroconversion. In descriptive analysis, we assessed uptake and feasibility of the measure. We analyzed predictors of post-intervention engagement in HIV risk behavior using multivariable logistic regression.

Results: Overall, 1081 women (median: 25 years, 18.6 gestational weeks) received the intervention. 81.4% were sexually active, 74.4% reported no condom use. 9.4% engaged in HIV risk behavior at baseline. 34/1081 women were eligible for PrEP services, but only two women presented there.

Among women receiving partner invitation letters, 88% delivered those; 39.6% of respective partners returned for HIV testing in ANC. The follow-up visit was attended by 848 women (78.5%); 24% of these came after text message reminder.

At follow-up, 4.9% reported HIV risk behavior, and 2/844 tested HIV-positive (pregnancy incidence rate 0.7%). HIV risk behavior despite the intervention was significantly associated with lower socioeconomic status, being a client in the rural compared to urban setting, and women and partners being less educated and lacking formal employment.

Conclusions: After receiving a comprehensive prevention intervention, this cohort showed a 0.7% incidence rate compared to pre-intervention 2.9% in the same region. The intervention was highly feasible; risk behavior three months after the intervention was halved compared to baseline. Pregnant women in rural areas and with less favorable socioeconomic conditions should be more closely targeted to prevent seroconversion during pregnancy.

EPC261

Low awareness of pre-exposure prophylaxis among female sex workers in Togo

A. Bitty-Anderson[1], A.W. Bakoubayi[2], F.A. Gbeasor-Komlanvi[3], M. Tchankoni[2], A. Sadio[2], C. Dagnra[4], P. Coffie[5], D. Ekouevi[3]

[1]*Université de Bordeaux, Public Health, Bordeaux, France,* [2]*Centre Africain de Recherche en Epidémiologie et en Santé Publique, Lomé, Togo,* [3]*Université de Lomé, Faculty of Health Sciences, Lomé, Togo,* [4]*Programme National de Lutte contre le VIH/SIDA, les hépatites virales, et les Infections Sexuellement Transmissibles, Lomé, Togo,* [5]*Université Félix Houphouet Boigny d'Abidjan, Medical Sciences, Abidjan, Cote D'Ivoire*

Background: The HIV pandemic remains a public challenge in sub-Saharan African, particularly among Female Sex Workers (FSW). Pre-exposure prophylaxis (PrEP) is an effective HIV prevention method among this high-risk group, however scarcely used in Togo. The aim of this study was to explore PrEP awareness among FSW in Togo.

Methods: A cross-sectional study was completed in June 2021 among FSW in two cities of Togo: Lomé, the capital city in the South and Kara in the North. A snowball sam-

pling method was used and initial seeds were identified in collaboration with local FSW non-governmental organizations. After consent, a standardized questionnaire was administered by trained research staff.

Results: A total of 447 (300 in Lomé) FSW participated in this study. Median age was 30 (interquartile range [24 - 38]), and 48.8% (n=218) had a secondary school education or higher. Only 8 (1.8%) were aware of PrEP. After explanation on what PrEP is, 88.5% (n=309) expressed their interest and intention in using PrEP if available.

If on PrEP, 12.1% and 47.7% reported they would be willing to engage in condom less sex with clients and partners, respectively. Nearly half (47.4%) were unsure whether PrEP could fully fulfill their HIV prevention needs, and 24.7%, (n=43) of those who believed PrEP could fully fulfill their HIV prevention needs indicated that they would absolutely not use condoms with their clients if on PrEP (p<0.001).

A third of FSW (33.8%) indicated that they would find it difficult and very difficult to take PrEP every day without missing a dose, and among them 43.7% (n=66) indicated not feeling capable to take PrEP every day without missing a dose.

About one in two (n=223; 49.9%) FSW indicated they would prefer obtaining PrEP at the pharmacy, and only 10.3% (n=46) would prefer access through FSW community-based organizations and peer-educators. More than half (52.8% (n=236) indicated that they would be willing to pay for PrEP if given the option.

Conclusions: .Despite low awareness, FSW were interested in PrEP for HIV prevention. However, for a successful implementation, long-acting PrEP, non-stigmatizing access to PrEP and steady behavioral prevention should imperatively be considered.

EPC262

Human Immunodeficiency Virus prophylaxis use by female sex workers during COVID-19 lockdown in Uyo, Nigeria

U. Omo-Emmanuel[1], K. Ochei[2], D. Udah[3], F. Jegede[4], M. Akhigbe[5]

[1]United States Agency for International Development (USAID), Integrated Service Delivery, Abuja, Nigeria, [2]USAID Sustaining Technical and Analytic Resources, Nigeria, Abuja, Nigeria, [3]John Snow Incorporated, Abuja, Abuja, Nigeria, [4]Family Health International, Abuja, Nigeria, [5]Heartland Alliance LGTE Nigeria, Uyo, Nigeria

Background: Human Immunodeficiency Virus (HIV) is a sexually transmitted infection of public health priority. Sex work is an important driver of HIV transmission making female sex workers (FSWs) a vulnerable group at high risk of HIV infection. The outbreak of Coronavirus disease 2019 (COVID-19) in Nigeria led to lockdown on 30th March 2020. As a result, there was treatment interruption and limited access to HIV prevention services such as Pre- and Post-Exposure Prophylaxis (PrEP and PEP) among FSWs. This study assessed the sexual practices and PrEP and PEP use among FSWs in Uyo, Nigeria during COVID-19 lockdown.

Methods: A cross-sectional survey was carried out by interviewing a total 344 HIV-negative female sex workers from June to August 2020 to collect data on PrEP and PEP use with a questionnaire. Participants were selected using systematic random sampling.

Results: The mean age of the respondents was 29.06 ± 5.20. Majority of the respondents were within the age range of 25-34 years (68.6%), unmarried (88.7%), and had duration of sex work of ≤5years (74.4%) with about half (41.9%) having at least post-secondary education.

Current PrEP and PEP use as at the time of the survey was 16.8% and 20% respectively, despite 23% condom non-use among the respondents and 47.4% of them engaging in unprotected sex with incentives from clients. Among those who were using PEP, reasons for use were client did not want to use condom (47.3%), respondents chose not to use a condom (21.1%), condom burst (21.1%) and coerced sex (10.5%). Similarly, the major reason for PrEP use was unprotected sex with clients who gave incentives. 34% of the respondents reported using solutions to cleanse self after sex as the reason for not taking PEP despite exposure while 25.0% didn't know where to get the drug. Furthermore, 30.9% reported starting PEP and not completing the 4 weeks of medications.

Conclusions: PrEP and PEP use among FSWs was poor despite unprotected sex and condom burst associated with their activities. There is a need for more education on the usefulness of PrEP and PEP in HIV prevention among FSWs to promote the use of them.

EPC263

Exploring retention in PrEP care in high-risk HIV negative patients in a Miami community health center

A. Ichite[1,2], V. Mills[2], K. Villalba[3], M. Jean-Gilles[1], A. Saxena[1], R. Rosenberg[1], J. Devieux[1]

[1]Florida International University, Health Promotion & Disease Prevention, Miami, United States, [2]Care 4 U Community Health Center, Miami, United States, [3]University of Central Florida, Population Health Science, Orlando, United States

Background: Black people account for roughly 40% of persons in need of PrEP for HIV prevention, but are six times less likely than Whites to be prescribed PrEP. Community Health Centers (CHCs) play a key role in reducing HIV disparities by helping underserved populations gain access to quality free or subsidized healthcare. Despite removing barriers to PrEP access like prescription cost and availability, retention in care remains low in Black populations. Using data from a Miami CHC, we examined gender differences in retention in PrEP care and explored factors that may predict retention.

Author Index

Methods: This retrospective study reviewed de-identified clinical and demographic data from the health records of patients enrolled in the CHC's PrEP program between September 2018 and January 2019. Retention in care was defined as the number of on time follow-up (F/U) visits attended in the 1st year of enrollment.

Four visits (one every 3 months) from the date of enrollment were considered 100% retention. Using SPSS, descriptive statistics were calculated for all patients, differences in means and proportions calculated using t-tests and chi-square tests respectively, and regression analysis used to identify predictors of retention.

Results: Of the 230 men (n=98) and women (n=132) in the sample, 19.6 % achieved 100% retention in care. 64% attended their 1st F/U visit at 3 months, 47.8% at 6 months, and 34.8% at 9 months. Average F/U time was 3.66 months between enrollment and visit one.

The more visits attended, the more likely patients were to be on time for their next visit. No gender differences in risk behaviors were observed. 48% reported transactional sex as a risk behavior. Strongest predictors for retention were being female, being 40 or older, and self-reporting transactional or condomless sex.

Conclusions: We found low retention in PrEP care amongst Black at-risk patients. Future interventions for PrEP retention should take gender differences into account, since barriers and motivators may be different, and incorporate multilevel approaches addressing complex social and structural drivers of HIV to promote continuation in populations with risky behaviors and a myriad of unaddressed needs that interfere with their capacity/willingness to continue with PrEP and required maintenance appointments.

EPC264

Chemsex, PrEP use and adherence to PrEP among gay, bisexual and other men who have sex with men (GBMSM) in Taiwan

H.-J. Wu[1], S.W.-W. Ku[2,3], C.-W. Li[4], A.-C. Chung[5], N.-Y. Ko[5,6], C. Strong[7]

[1]Kirby Institute, UNSW, Sydney, Australia, [2]Taipei City Hospital Renai Branch, Division of Infectious Diseases, Department of Medicine, Taipei, Taiwan, Province of China, [3]HIV Education And Research Taiwan (HEART) Association, Taipei, Taiwan, Province of China, [4]National Cheng Kung University, Center for Infection Control and Department of Internal Medicine, National Cheng Kung University Hospital, College of Medicine, Tainan, Taiwan, Province of China, [5]Taiwan Love and Hope Association, Kaohsiung, Taiwan, Province of China, [6]National Cheng Kung University, Department of Nursing, National Cheng Kung University Hospital, College of Medicine, Tainan, Taiwan, Province of China, [7]National Cheng Kung University, Department of Public Health, College of Medicine, Tainan, Taiwan, Province of China

Background: Limited studies have examined the prevalence, types and role of chemsex in relation to biomedical prevention methods (i.e. pre-exposure prophylaxis, PrEP). This study aims to improve our understanding of the evolving chemsex practices among GBMSM seeking for sexual health services and further examine PrEP uptake and adherence to PrEP in relation to chemsex practice.

Methods: We used data from a multi-center, prospective cohort study conducted at hospital-based clinics in Taiwan between 2018 and 2019. Chemsex was defined as sex under the influence of MDMA, ketamine, GHB/GBL, methamphetamine or mephedrone at least once in the past 12 months. Adherence to PrEP was defined as a correct intake of PrEP for the most recent anal intercourse in the past month. Correct intake of PrEP was considered as:

1. Taking two pills on day X (i.e. the day having sex) or the day X-1, and at least one pill on the day X, X+1 and X+2 for event-driven regimen,
2. At least one pill every day for five days for daily regimen.

Logistic regression model was used to evaluate PrEP uptake and adherence in relation to chemsex.

Results: Among 935 MSM enrolled in the analysis, 111 (11.9%) reported engaged with chemsex. Compared to non-chemsex group, higher proportion of chemsex group were HIV positive (9.0% vs 2.8%, p=0.003), were versatile in condomless anal sex (60.4% vs. 26.5%, p <0.001), had sexually transmitted infections (63.1% vs. 34.8%, p <0.001), had higher number of sexual partners (>5, 48.6% vs. 22.0%, p<0.001).

Chemsex was significantly associated with PrEP uptake experience after controlling for cofounding factors (57.7% of PrEP use in chemsex group vs. 41.5% in non-chemsex group; aOR=1.81, *p*<.05). Among 344 MSM on PrEP, 45 (13.1%) were engaged in chemsex. Level of PrEP adherence was similar comparing chemsex to non-chemsex (83.5% vs. 83.4%).

Conclusions: GBMSM who engaged in chemsex are more likely to use PrEP. Further, chemsex is not a barrier to PrEP adherence. We urged to continue the effort to promote biomedical prevention methods in GBMSM who engaged in chemsex and to incorporate situated and interdisciplinary care for GBMSM who engaged in chemsex.

EPC265

Health insurance and provider access among young MSM in the US: baseline results from the COMPARE Study

A. Liu[1,2], E. Vittinghoff[2], J. Hill-Rorie[3], K. Coleman[1], H. Scott[1,2], K. Mayer[3,4,5], S. Buchbinder[1,2], R. Muench[6], L. Ackah-Toffey[7], J. Mitchell[8], L. Hightow-Weidman[8], K. Biello[9,3], iTech ATN 143 Team

[1]*San Francisco Department of Public Health, Bridge HIV, San Francisco, United States,* [2]*University of California, San Francisco, United States,* [3]*The Fenway Institute, Boston, United States,* [4]*Harvard Medical School, Boston, United States,* [5]*Beth Israel Deaconess Medical Center, Boston, United States,* [6]*Ruth Rothstein CORE Center, Chicago, United States,* [7]*Emory University, Atlanta, United States,* [8]*University of North Carolina, Chapel Hill, United States,* [9]*Brown University, School of Public Health, Providence, United States*

Background: Young men who have sex with men (YMSM) have among the highest HIV incidence and lowest uptake of HIV testing and pre-exposure prophylaxis (PrEP) in the US. Health insurance can greatly impact PrEP access, and youth on parental insurance face unique challenges when accessing prevention services. We characterized health insurance type and provider access in a multisite Adolescent Trials Network (ATN) study.

Methods: The COMPARE Study (ATN 143) enrolled HIV-uninfected YMSM aged 15-29 across 9 US sites into a randomized trial evaluating mobile apps to increase HIV/STI testing and PrEP uptake. At enrollment, participants completed an online survey assessing demographics, sexual behaviors, insurance status, and experience with HIV/STI testing and PrEP.

Results: From October 2019-November 2021, 384 YMSM enrolled in the study. Median age was 22, 17% were Black, 18% Latinx, and 51% White. Overall, 61% were currently in school, 69% were employed, 43% reported low income, and 46% were completely out to their immediate family regarding their sexual identity; 81% reported recent anal sex, 71% had ever tested for HIV, and 63% tested for an STI. While 95% had heard of PrEP, 15% had ever taken PrEP. The majority of youth were on their parent/guardian's health insurance (52%), 36% had their own insurance, and 12% were uninsured.

Among the insured, 83% had private insurance and 16% were publicly insured. Most participants primarily received healthcare from a private physician/HMO (56%) or public health/community clinic (19%), and 19% reported having difficulty getting healthcare in the past year. Being uninsured was associated with Black or Latinx race/ethnicity, lower income, residing in a non-Medicaid expansion state, and reporting difficulty getting healthcare (all $p<0.05$).

Compared with those on their own insurance, parentally-insured YMSM were more likely to be under 25, white, and less likely to have tested for HIV/STIs, talked with a provider about PrEP, or taken PrEP (all $p<0.05$).

Conclusions: The majority of YMSM in this cohort were on their parent's insurance, which was associated with lower engagement in HIV/STI testing and PrEP. Strategies to assist parentally-insured YMSM and those who are uninsured navigate prevention services are critical to address HIV disparities among youth.

EPC266

Gender based violence among Female Persons who Inject Drugs (FPWIDs) and Female Sex Workers (FSWs) – Implication on HIV epidemic control in Nigeria

O. Tewobola Olabosinde[1], T. Alamu[1], G. Emmanuel[1], P. Umoh[1], A. Adeyemi[2], N. Ogbonna[1]

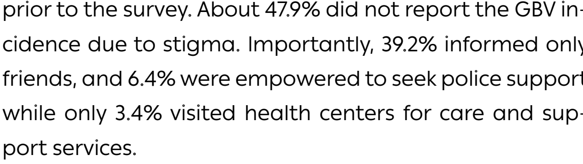
[1]*Heartland Alliance Nigeria, Program, Abuja, Nigeria,* [2]*Consultant, Program, Abuja, Nigeria*

Background: The Female Persons Who Injects Drugs (FPWIDs) and Female Sex Workers (FSWs) are highly affected by HIV in Nigeria due to their behavior and drug-use. HIV prevalence among Brothel Based FSWs was 19.4%, Non-Brothel Based was 8.6%, and PWID was 7.0% compared to the national prevalence of 1.3%. Key Populations (KPs) constitute about 1% of adult population in Nigeria but contribute about 23% of new HIV infections in Nigeria.

FSW and FPWID belong to the Key population community and are frequently exposed to Gender Based Violence (GBV) which makes them more vulnerable to HIV. Interventions targeting GBV prevention for these populations are limited. This study assessed the vulnerability of these populations to HIV.

Methods: A baseline study on KP subgroup was conducted using a mixed method approach (qualitative and quantitative), questionnaires, interviews and focus group discussions to determine GBV prevalence and associated information. A total of 424 respondents were reached (200 FPWIDs and 224 FSWs) across 20 LGAs in Benue and Lagos, Nigeria.

Results: The mean age was 27.1±7.1years with age range of 15-58years. About 225 (53.1%) respondents completed secondary education while 52(12.3%) completed tertiary education. Majority 324(76.4%) of the respondents daily income were less than a dollar. GBV prevalence among the respondents was 234(55.2%) six months preceding the survey, while 183 (43.2%) reported no GBV experienced. However, findings showed 127 of 234 (63.5%) FPWIDs and 107 of 234 (47.8%) FSWs experienced GBV in last 6 months



prior to the survey. About 47.9% did not report the GBV incidence due to stigma. Importantly, 39.2% informed only friends, and 6.4% were empowered to seek police support while only 3.4% visited health centers for care and support services.
Conclusions: The study shows high burden of GBV among FPWIDs and FSWs, which could increase their vulnerability to HIV. Unfortunately, actions taken by some of the survivors are not adequate to manage the GBV issues. There is therefore an urgent need to integrate gender responsive post GBV interventions in all HIV prevention and treatment programs specifically for KPs to reduce their vulnerability to HIV.

EPC267

Perspectives on ethical issues around the use of smartphone apps for HIV prevention among men who have sex with men in Malaysia

A. Khati[1], A. Rosen[1], J. Luces[2], J. Wickersham[3], I. Azwa[4], M.A. Ab Halim[5], R. Shrestha[1,3]
[1]University of Connecticut, Allied Health Sciences, Storrs, United States, [2]University of the Philippines, Allied Medical Professions, Manila, Philippines, the, [3]Yale University, Internal Medicine, New Haven, United States, [4]University of Malaya, Department of Medicine, Kuala Lumpur, Malaysia, [5]University of Malaya, Centre of Excellence for Research in AIDS (CERiA), Kuala Lumpur, Malaysia

Background: The use of smartphone apps can improve the HIV prevention cascade for key populations such as men who have sex with men (MSM). In Malaysia, where stigma and discrimination toward MSM are high, app-based strategies have the potential to open new frontiers for HIV prevention efforts. However, little guidance is available to inform researchers about ethical concerns unique to the development and implementation of app-based HIV prevention programs.
Methods: We conducted online focus group discussions (FGDs) with 23 MSM between August and September 2021. Using in-depth semi-structured interviews, participants were asked about their perceived risks, benefits, and ethical issues associated with using mobile apps for HIV prevention. Each session was digitally recorded and transcribed. Transcripts were inductively coded using Dedoose software and analyzed to identify and interpret emerging themes.
Results: Overall, participants indicated a preference for using app-based strategies for HIV prevention efforts. Emerging themes on benefits related to app use for HIV prevention included convenience, anonymity (ability to remain anonymous while seeking care), less-stigmatizing (able to avoid the burden and stigma of visiting an HIV clinic in person), readily accessible multimedia resources (e.g., text, graphics, videos), and self-management portals (e.g., medication adherence, appointment reminders).
Prominent concerns raised by participants included privacy and confidentiality concerns, issues around personal health data storage and management, and fear of the Malaysian government accessing data.
Conclusions: The findings from this study indicate that app-based strategies for HIV prevention efforts are acceptable among Malaysian MSM. The results further highlighted the role of ethical concerns and the associated risks and benefits related to the use of app-based HIV prevention programs.
Given the ever-evolving nature of such technological platforms and the complex ethical-legal landscape, such platforms must be safe and secure to ensure widespread public trust and uptake.

EPC268

HIV treatment optimism moderates the relationship between sexual risk behaviours and HIV risk perceptions among urban Canadian HIV-negative gay, bisexual and other men who have sex with men

P.M. Luz[1], H. Apelian[2], G. Lambert[3], M. Dvorakova[2], D. Grace[4], N. Lachowsky[5], T. Hart[6], D. Moore[7], S. Skakoon-Sparling[6], J. Cox[8]
[1]National Institute of Infectious Disease Evandro Chagas, Oswaldo Cruz Foundation, Rio de Janeiro, Brazil, [2]Research Institute of the McGill University Health Centre, Montreal, Canada, [3]Direction Régionale de Santé Publique de Montréal, CIUSSS Centre-Sud-de-l'Ile-de-Montréal, Montreal, Canada, [4]Dalla Lana School of Public Health, University of Toronto, Toronto, Canada, [5]School of Public, Health & Social Policy, University of Victoria, Victoria, Canada, [6]Ryerson University, Department of Psychology, Toronto, Canada, [7]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [8]Biostatistics & Occupational Health, McGill University, Department of Epidemiology, Montreal, Canada

Background: Studies suggest that HIV treatment and prevention advances have led to greater treatment optimism and consequently increased high-risk sexual behaviour. Some gay, bisexual, and other men who have sex with men (GBM) engaging in high-risk sexual behaviour do not perceive themselves at risk of acquiring HIV.
We evaluate whether treatment optimism moderates this relationship.
Methods: Engage is a prospective three-city Canadian study; sexually-active GBM aged 16+ were recruited using respondent-driven-sampling (RDS). Baseline(02/2017-06/2018) questionnaire data from HIV-negative/unknown GBM in Montréal were analysed. 'High-risk' sexual behaviour was defined as a high-risk event (episode of condomless anal sex with a casual partner where PrEP was not used or a partner with detectable/unknown viral load) or anal sex with >5 men, in past six months; "low-risk" was defined as no high-risk event and anal sex with ≤5 men.

Self-perceived HIV-risk was assessed using the question: "How would you assess your current risk of getting HIV?" Responses dichotomized to "no-risk"(very unlikely/unlikely) and "at-risk" (somewhat likely/likely/very likely).
The moderator was HIV treatment optimism-skepticism (TOSS), a 12-item scale (e.g., "A person with undetectable viral load cannot pass on the virus"); higher scores=greater optimism. Logistic regression (adjusted for age, ethnicity, sexual orientation, education, income, transactional sex, main partner, chemsex, and HIV testing) was used, including an interaction term to explore TOSS scores (z-standardized) as a potential moderator. All analyses used RDS-II weights.
Results: Engage-Montréal enrolled 938 self-reported HIV-negative/unknown participants. Mean age was 35.4 years, 40% (n=448) were categorized "high-risk"; among them, 28% (112) perceived themselves "at-risk". "High-risk" sexual behaviour was significantly associated with perceived HIV risk (adjusted Odds Ratio=2.08, 95%CI=1.51-2.88). TOSS moderated the relationship (p<0.001): for GBM reporting "high-risk", higher TOSS scores were associated with greater perceived HIV risk while for "low-risk" GBM, higher TOSS scores were associated with lower perceived HIV risk.
Conclusions: Only a quarter of GBM engaging in high-risk behaviour perceived themselves at risk of HIV. Our findings suggest that participants with higher TOSS scores better aligned their risk perception to their sexual behaviour.
Promoting awareness around advances related to HIV prevention and treatment is important for appropriate risk assessment and for increased engagement in prevention interventions.

EPC269

Only 34% sex work hotspots are covered by HIV prevention services: programmatic mapping approach in 8 region of Ukraine

O. Kovtun[1]
[1]ICF "Alliance for Public Health", Monitoring and Evaluation Department, Kyiv, Ukraine

Background: Sex workers (SW) continue to be the hard-reach group for HIV-service projects. According to the 2021 integrated bio-behavioral survey among SWs in Ukraine, only 40.7% of them are clients of non-governmental organizations that provide HIV-related services, and 62.8% have been tested for HIV and received results in the last year. The programmatic mapping approach allows optimizing the work of HIV prevention and testing projects for SWs.
Methods: We used the programmatic mapping approach in two steps known as Level 1 (L1) and Level 2 (L2). During L1, information about location of the hotspots, characteristics of these hotspots, and SWs at them was collected from key informants (KI), and an exhaustive list of hotspots was created. During Level 2 (L2), all identified hotspots were visited and validated their active status, and interviews were conducted with KI from the SW's community to confirm and clarify information from L1.
This study was conducted in March-July 2021 in 8 regions of Ukraine, and its results were analyzed and visualized using QGIS.
Results: 1212 KI of 10 different types were interviewed at L1, and 1966 KI were interviewed at L2. 2581 hotspots of 13 different types were identified, and 82% of them (2118) were active. 43.2% of hotspots were apartments, 11.7% were virtual (websites) and 11.1% were street-based (eg parks, squares).
97 of 2118 hotspots were operated by male SWs (560 people), 20 were trans* people (81 people), and 175 were SW-PWID (352 people). Only 1/3 of hotspots (720) confirmed that HIV-prevention services were provided there, and using mobile vans at 400 hotspots. HIV services were not always working at the hotspots where HIV-positive SWs were.
The total number of SWs estimated at the 8 regions stood at 7866 (3883-13537). Their minimum age was 14 years, maximum was 60 y.o. Typologies of hotspots, coverage with the prevention, characteristics of SWs, and the estimated number vary depending on the region.
Conclusions: The programmatic mapping approach helps to determine the size of SWs and their locations in regions. The results of the study will be used to optimize and plan outreach routes for HIV projects among SWs in Ukraine.

EPC270

Willingness to use Pre-exposure Prophylaxis (PrEP) for HIV Prevention among Women Who Inject Drugs in Lagos, Nigeria

M. Onigbogi[1], O. Onigbogi[2], O. Ojo[3]
[1]The University of Texas Health Science at Houston School of Public Health, Epidemiology, Human Genetics and Environmental Sciences, Stafford, United States, [2]University of Lagos, Department of Community Health, Lagos, Nigeria, [3]Federal Medical Center, Department of Community Health, Abeokuta, Nigeria

Background: People who inject drugs (PWID) are at a higher risk for HIV infection because of the dual risk from injection and sexual behaviors, including transactional sexand forced sex. Pre-Exposure Prophylaxis (PrEP) has been proven to be effective in preventing HIV. We, therefore, sought to determine the knowledge of, uptake, and willingness to take PrEP among Women Who Inject Drugs (WWID) in Lagos State, Nigeria.
Methods: Methods: The study had a descriptive, cross-sectional design with 422 participants selected using a purposive sampling method. Questionnaires were used to elicit feedback on knowledge and use of PrEP by participants and their willingness to use PrEP if it was available.

The inclusion criteria included HIV seronegativity and self-report of substance abuse within 3 months prior to the study. Data were analyzed using Epi Info 7 software. Descriptive statistics, Chi-square, and multivariable logistic regression were used in the analysis and the level of significance was at p<0.05.

Results: Only thirty-three participants (7.8%) had good knowledge of PrEP with 8 of them (1.9%) reporting that they had ever used PrEP. A total of 358 participants (84.8%) reported a willingness to take PrEP if it was available.

Substances commonly ingested by participants included stimulants (33.6%), cocaine/crack (30.6%), heroin (19.9%), opiates (5.0%), methadone (4.7%), and sedatives (2.6%). Perceived barriers to using PrEP included probable side effects (43.4%), accessibility to the product (34.1%), frequency of use (10.2%), cost (6.6%), others (5.7%). Increased knowledge of PrEP was associated with secondary school or higher level of education compared to those with lower education (AOR:7.63 95%C, 2.59-22.45).

Willingness to use PrEP was associated with religion, tribe, and health provider. WWID who were Muslims had a higher willingness to use PrEP compared to Christians (AOR: 1.43 95% CI, 0.30-0.92).

Conclusions: Most of the participants indicated a willingness to use PrEP despite their poor knowledge of it. It is important to design programs that can improve the knowledge of PrEP so as to reduce the risk of HIV infection in this vulnerable population. There is a need to consider the correlates of willingness to use PrEP in designing interventions for this group.

EPC271

Medication-assisted treatment in Ukraine must be tailored to the needs of the large populationof people who inject drugs who are skeptical about the program

R. Kulchynska[1], Y. Sazonova[1], N. Podolchak[1], R. Keating[1], I. Ivanchuk[2], S. Salnikov[2], S. Ohorodnik[2], E.J. Barzilay[1]

[1]*CDC-Ukraine, Overseas Strategy & Management Branch, Division of Global HIV & TB, Centers for Disease Control and Prevention, Kyiv, Ukraine,* [2]*Public Health Center of the MOH of Ukraine, Kyiv, Ukraine*

Background: Medication-assisted treatment (MAT) effectively reduces health risks, and improves the wellbeing of people who inject drugs (PWID). Ukraine's HIV epidemic is concentrated among PWID, so previous prevention efforts have focused on expanding MAT coverage to PWID who use opioids. According to the national strategic plans, Ukraine intends to increase current MAT coverage to almost 31,000 PWID by the end of 2023. Such ambitious plans require significant efforts at both structural and individual levels.

To better understand how to increase MAT service coverage in Ukraine, we examined existing bio-behavioral surveillance data to assess factors associated with PWID willingness to start MAT.

Methods: We performed an analysis of the 2020 bio-behavioral surveillance (BBS) of PWID in Ukraine. Restricting our sample to those PWID who use opioid drugs (n=3,861), we assessed MAT willingness among three groups:

1. Those having experience with MAT (current or former clients),
2. Those naïve to MAT but willing to be enrolled, and;
3. Those having no intention to enroll in MAT (skeptics).

We ran additional regression analyses among MAT skeptics to identify correlates of MAT skepticism in comparison with the experienced group.

Results: An estimated 24% of PWID had experience with MAT, 25% were willing to be enrolled in it, and 51% of PWID were MAT skeptics. Prevalences of MAT skepticism varied by geographical areas, from 37% to 73%. The highest proportion of skeptics were observed in Kriviy Rih, Odesa, Dnipro and Mariupol.

Additionally, MAT skepticism was associated with younger age (below 34 years, AOR 1.43 [1.00-2.03]), higher income levels, AOR 2.37 [1.54-3.64], being married, AOR 1.29 [1.02-1.63], using home-made opioids, AOR 2.13 [1.49-3.03], no prior incarceration, AOR 0.53 [0.41-0.67], HIV negative status, AOR 1.75 [1.34-2.27], and lower chances of receiving social services/being NGO client, AOR 0.16 [0.13-0.21].

Conclusions: To expand MAT, Ukraine must reach a large population of PWID, many of whom are skeptical about MAT. The profiles of skeptics we have identified could be used to improve communication campaigns.

Additional in-depth research is needed to better understand current barriers to MAT for this group, and develop effective communication strategies and program adaptations.

EPC272

Impact of primary care and health care encounters for HIV testing among men who have sex with men in Puerto Rico

C. Rodriguez-Diaz[1], D. Mehta[1], K. Joshi[1], M. Martinez-Lozano[2], S. Malave-Rivera[2]

[1]*George Washington University, Milken Institute School of Public Health, Washington, United States,* [2]*University of Puerto Rico, School of Public Health, San Juan, Puerto Rico*

Background: HIV prevention strategies have evolved, and primary healthcare plays a vital role in integrating HIV screening and prevention services. However, there is limited evidence on access to primary care in increasing HIV testing among men who have sex with men (MSM). We also lack an understanding of how healthcare encounters facilitate preventive services. In this study, we explored the role of having primary care providers (PCPs) in HIV prevention practices, including HIV testing and the disclosure of sexual orientation and sexual practices among MSM in Puerto Rico (PR).

Methods: We conducted a cross-sectional online survey with n=256 MSM in PR. Participants were recruited via social media with the support of community-based orga-

nizations serving these populations. Descriptive statistics and binary logistic regressions were used to answer the research questions.

Results: The mean age of participants was 31 years and lived in non-urban areas (59%). Most participants have tested for HIV at least once during their lifetime (93%), and, of those, 42% tested in primary healthcare settings. Those with a PCP (59.2%) tested for HIV more often than those without a PCP (56% vs. 36%; p=0.04). Most participants have never been asked by their PCP about their sexual orientation (70%) or sexual practices (54%), and most have not disclosed this information to their PCP. Having a PCP was not statistically associated with disclosing or being asked about sexual orientation and sexual practices.

After controlling for confounding variables, participants with a PCP were 2.7 times more likely (95%CI=1.02,7.08) to have tested for HIV in their lifetime when compared to those who did not have a PCP.

Conclusions: Increasing access to PCPs is essential in enhancing HIV testing among MSM in PR and an excellent opportunity to provide other HIV prevention services.

However, although access to a PCP yields an increase in HIV testing, providers are not explicitly asking their patients about their sexual orientation or sexual practices. Comprehensive primary care and HIV prevention interventions should facilitate affirmative and inclusive services to populations made socially vulnerable.

EPC273

Perspectives of federal prison inmates and institution staff on a unique HIV harm reduction service

L. Leonard[1,2]

[1]*University of Ottawa, School of Epidemiology and Public Health, Ottawa, Canada,* [2]*Ottawa Hospital Research Institute, Clinical Epidemiology Program, Ottawa, Canada*

Background: Responding to ongoing HIV transmission among inmates evidenced by seroconversion data and unacceptable incidence of non-fatal overdose events, Correctional Service Canada (CSC) implemented Canada's first and, to date, only Overdose Prevention Service (OPS) at a medium-security Institution for male offenders. Operational June 2019, in supervised personal cells inmates access sterile injection and drug preparation equipment for use with their own drugs.

Process evaluation data are presented in this paper - acceptability of the service from the perspectives of inmates, feasibility from the perspectives of correctional officers and program staff.

Methods: At three months post-implementation, confidential anonymous interviews following informed consent conducted with inmates with varying OPS experience to assess acceptability and with Correctional Officers and other program staff to assess feasibility. All interviews took place in confidential locations, grounded theory applied to analyze responses.

Results: *Acceptability.* Availability of supervised location away from cells and ranges seen as the prime benefit, *"It's a safe place. It's supervised. It's not in the cells, not in the units."* At the individual level, OPS participants stressed importance of sterile injection equipment distribution to reduce needle sharing, "*I no longer have to trust that someone else's needle is clean." "I don't use a dirty rig no more – a jail rig."*

Feasibility. Initial negative perspectives of correctional and security staff: "*Our job is to keep drugs out. This is backward thinking."* changed over time*:* "*I've changed my attitude, I'm not so against it."*

Similarly, early safety concerns regarding needle-stick assaults dissipated due to non-occurrence. Health Services staff saw OPS as a unique opportunity for supportive prevention counselling, "*It's a safe way to talk about drug use. We're here. It's safe. We are here to help with this."*

Conclusions: These process data - one component of a comprehensive evaluation - document significant beneficial outcomes for inmates and eventual successful adoption by Institution staff.

Recommendations shared for service development included comprehensive preparation and ongoing training for institution staff, increased OPS hours, and availability of safer snorting equipment. CSC is currently responding to these and other recommendations prior to increased pan-Canadian implementation.

Sexuality, gender and prevention technologies (including condoms, treatment as prevention, medical male circumcision, pre-exposure prophylaxis)

EPC274

"You never know with one's husband, so this is important": Preliminary hypothetical acceptability responses to the Dapivirine Vaginal Ring for HIV prevention among Latina community clinic attendees

E. Gollub[1], E. Finver[2], C. Raposo[3]

[1]*Pace University, Health Science Program, College of Health Professions, Pleasantville, United States,* [2]*CUNY Graduate School of Public Health and Health Policy, Epidemiology and Biostatistics, New York, United States,* [3]*Open Door Family Medical Center, Mamaroneck, United States*

Background: The Dapivirine Vaginal Ring (developer, International Partnership for Microbicides) is the first discreet, long-acting product shown to reduce risk of HIV infection in women. The ring has received a positive scientific opinion by the European Medicines Agency, and is WHO prequalified. Data on US women are limited. We report initial, interim results on the first 90 women enrolled in a hypothetical acceptability study.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Methods: Women (>=18 years) were recruited from the waiting room of a community clinic serving a predominantly Latina population by a bilingual research assistant. Participants underwent a brief informational session, handled a placebo ring, then completed a survey via audio computer-assisted self-interview (Spanish or English). Participants received $25 gift cards.

Results: Mean age was 37 years. Most participants (67%) opted for the Spanish survey (SPS). One third (34%) had no high school diploma; 43% had some college education.91% reported a main partner; 18% had a casual partner; 74% had children; 78% reported some prior (male) condom use. 20% (main) and 33% (casual) felt at risk for HIV from a partner. 58% had prior tampon use.

Overall, 53% reported wanting to try the ring when available, including 62% of SPS participants and 37% English survey participants (p<0.001); 30% SPS participants responded "don't know/unsure".

Overall, more than half reported concerns about ring safety, comfort and ease of use, but these were not associated with a lack of desire to try the ring when available. SPS respondents reported more concerns about partner discovery of the ring, ring getting stuck, and ring "falling out of the vagina". Prior tampon use predicted less concern that the ring would "fall out" (p=0.03).

Overall, the majority of participants liked the following ring attributes: constant internal risk reduction and having to worry less (94%), not having to take pills every day for HIV prevention (98%), being able to control insertion and removal themselves (94%).

Conclusions: Considerable interest was shown for the new product, especially among women preferring Spanish survey language, with areas identified to be addressed in educational messaging and counseling for successful uptake. Prior tampon use did not generally predict greater overall hypothetical acceptability.

EPC275
Which are the most valued pre-exposure prophylaxis (PrEP) attributes? A discrete choice experiment among men who have sex with men (MSM) and transgender women (TW) in Peru

O.A. Elorreaga[1], K.A. Konda[1], K.E. Campos[1], G.M. Calvo[1], T.S. Torres[2], C.F. Caceres[1], for the ImPrEP Study Group
[1]Universidad Peruana Cayetano Heredia, Centro de Investigación Interdisciplinaria en Sexualidad, SIDA y Sociedad, Lima, Peru, [2]Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz (INI-Fiocruz), Rio de Janeiro, Brazil

Background: There is potential demand for PrEP in Peru; however, little is known about preferences towards various potential ways to take PrEP or the importance of various PrEP attributes. Our research focused on which attributes most influence the choice of PrEP modalities among MSM/TW. We also assessed how participants' preferences vary by recruitment strategy and population.

Methods: We applied a discrete choice experiment in three mutually exclusive groups:
1. PrEP recipients;
2. Sexually transmitted infections (STI) clinic attendees; and,
3. Social Media outreach. Inclusion criteria:
MSM or TW, age>=18 years-old, self-reporting a non-HIV positive status, and who provided informed consent. PrEP attributes assessed were: route of administration, frequency of taking PrEP, healthcare provider, HIV testing frequency, side effects, and efficacy. Each participant was presented 12 option pairs with mixed attribute levels and had to choose one option per pair.

Results: From June to October 2021 we recruited 2931 participants (91.5% MSM; 8.5% TW), with mean age=29.0y [SD=9.0]; 56.6% completed tertiary education; 46.8% earned US$232 or less. In general, efficacy [27.6%, 95%CI 27.0-28.2], and frequency of taking PrEP [21.2%, 95%CI 20.8-21.7] were the most important attributes (Panel A), with the social media group placing the highest importance on efficacy [32.0%, 95%CI 31.1-32.9] (Panel B). STI clinic attendees and the social media groups were more concerned about potential side effects, while the current PrEP recipients placed the greatest importance on frequency of taking PrEP [26.7%, 95%CI 25.6-27.7] (Panel B).

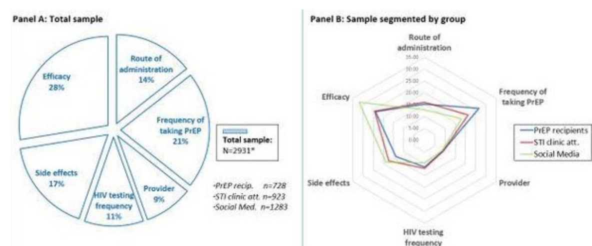


Figure 1. Ranking of most important PrEP attributes in the whole sample and segmented by field work source.

Conclusions: Overall, attributes such as efficacy and frequency of taking PrEP were the most important attributes across the recruitment strategies; however, current PrEP recipients placed more weight on frequency than the other groups. Prior knowledge and previous PrEP experience influenced how attributes were considered.

Our data may be helpful for future PrEP scale-up strategies, anticipating potential users' concerns, and learning from current users.

EPC276

Perspectives from sex venue management towards occupational HIV Pre-Exposure Prophylaxis (PrEP) in Bangkok and Pattaya, Thailand

T. Chemnasiri[1,2], K. Kamkong[1,2], S. Janyam[3], D. Linjongrat[4], S.H.H. Mon[5], A. Wirtz[5], A. Hickey[1,2], C. Beyrer[5]

[1]U.S. Centers for Disease Control and Prevention, Division of HIV Prevention, Atlanta, United States, [2]Thailand Ministry of Public Health-U.S. Centers for Disease Control and Prevention Collaboration, Nonthaburi, Thailand, [3]Service Workers in Group Foundation, Bangkok, Thailand, [4]Rainbow Sky Association of Thailand, Bangkok, Thailand, [5]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

Background: Bangkok and Pattaya are Thai cities with globally known sex venues (brothels, beer bars, gogo bars, and massage parlors). We aimed to fill a gap in knowledge about venue management attitudes towards HIV pre-exposure prophylaxis (PrEP) through qualitative interviews among venue management.

Methods: We interviewed 24 venue managers using key-informant interviewing from July 2016-July 2018 in Bangkok and Pattaya, Thailand. Participants were Thai, aged >=20, and worked for a sex work venue for >=12 months. Interviews focused on HIV/STI screening and treatment, HIV prevention knowledge and practices, occupational PrEP acceptability and support, challenges and needs, and policy suggestions.

Results: Participants were a median age of 42 years (range 21-52), were employed full-time (91.7%), reported completed bachelor's degree or higher (37.5%), and self-identified as transgender (62.5%). Venue management were aware of PrEP but had difficulty distinguishing it from post-exposure prophylaxis (PEP). Most managers expressed high interest in occupational PrEP for sex venue workers. Reasons for support included the high-risk nature of sex work, low condom negotiation power during group sex and chemsex, and scrutinization of condoms as a means for policing sex work in Thailand.

Concerns encompassed PrEP adherence (capacity to take daily doses, interference with substance use), social harms (HIV treatment stigma), and sex work-related risk compensation (condomless sex, increased sexual partners, misuse of PrEP as a rate negotiation tool). Venue managers who had previously taken PrEP expressed concerns about long-term side effects due to their own past negative experiences with PrEP (e.g. acute reactions/side-effects to medications).

Overall, venue management believed PrEP could increase sex workers' confidence in occupational safety and personal motivations for safe sex practices. Managers recommended that PrEP rollout targeting venue-based sex workers prioritize access by optimizing locations and procedures for initiating and managing PrEP that are convenient, uncomplicated, and minimally time-consuming.

Conclusions: While sex venue management in Bangkok and Pattaya are generally aware of PrEP, targeted education (particularly addressing long-term safety concerns, misinformation, and stigma) could facilitate institutional support for PrEP use among venue management.

Efficient PrEP implementation with sex venues may depend on enhancing coordination between health departments and other municipal authorities, communities, and sex venue management.

EPC277

Awareness and use of Undetectable=Untransmittable (U=U) among gay, bisexual, and other men who have sex with men in five Asian countries: results of the Asia Pacific MSM internet survey

B. Bavinton[1], A. Hill[2], N. Amos[2], S.H. Lim[3], T. Guadamuz[4], N. Kaneko[5], M. Holt[6], A. Bourne[2]

[1]University of New South Wales, Kirby Institute, Sydney, Australia, [2]La Trobe University, Australian Research Centre in Sex, Health and Society, Melbourne, Australia, [3]University of Malaya, Kuala Lumpur, Malaysia, [4]Mahidol University, Bangkok, Thailand, [5]Nagoya City University, Nagoya, Japan, [6]University of New South Wales, Centre for Social Research in Health, Sydney, Australia

Background: The global Undetectable=Untransmittable (U=U) campaign informs people that a person living with HIV who is on antiretroviral therapy (ART) with undetectable viral load (UVL) cannot sexually transmit HIV.

However, the extent of U=U awareness among gay, bisexual, and other men who have sex with men (GBM) in many Asian countries is unclear.

Methods: An online cross-sectional survey targeting GBM in Indonesia, Japan, Malaysia, Thailand, and Vietnam was conducted from May 2020–January 2021. Factors independently associated with U=U awareness were determined by multivariable logistic regression, stratified by HIV status.

Results: We recruited 15,872 participants (Indonesia = 1,342; Japan = 7,452; Malaysia = 849; Thailand = 1,566; Vietnam = 4,663). Overall, 6.8% were HIV-positive, 46.2% HIV-negative, and 47.0% of unknown-status. Overall, 35.9% were aware of U = U, 44.8% had never heard of it prior to the survey, and 19.3% were not sure.

U = U awareness varied by country (Indonesia = 27.6%; Japan = 41.1%; Malaysia = 39.3%; Thailand = 33.4%; Vietnam = 30.2%; $p<0.001$) and by HIV status (HIV-positive = 75.5%; HIV-negative = 43.8%; unknown-status = 22.4%; $p<0.001$).

Among HIV-positive men, factors independently associated with U=U awareness included: university education ($p = 0.014$); reporting any condomless anal intercourse (CLAI; $p = 0.004$); currently being on ART ($p<0.001$); having UVL at last test ($p<0.001$); and having fewer experiences of sexuality-related stigma ($p = 0.002$). Among non-HIV-positive men, U=U awareness was associated with: being older ($p=0.002$); being "out" to more people ($p<0.001$);

university education (p = 0.003); identifying as gay (p = 0.009); reporting sex with >10 male partners in the previous year (p = 0.001); having an HIV test in the previous year (p<0.001); and currently taking PrEP (p<0.001).

Of 4,707 men reporting CLAI with a regular partner in the previous 12 months, 30.4% had used UVL to prevent HIV transmission (HIV-positive men = 75.2%; non-HIV-positive men=25.1%; p<0.001). Among 1,797 men reporting CLAI with casual partners, 22.8% reported using UVL to prevent transmission (HIV-positive men = 70.2%; HIV-negative men = 17.2%; p<0.001).

Conclusions: Two-thirds of GBM were not aware that U=U and one-quarter of HIV-positive men lacked this awareness. While a large proportion of HIV-positive men used UVL to prevent transmission when having CLAI, this was uncommon among non-HIV-positive men.

Such a situation significantly challenges the ability of GBM to utilise proven safer-sex options and diminishes opportunities to disrupt pervasive stigma experienced by people living with HIV.

EPC278

"You tell him, 'Baby, I am protecting myself'": Women's agency and constraint in relationships, and the potential for PrEP use in the context of stigma in South Africa

A. Harrison[1], S. Bergam[2], N. Bhengu[3], L. Miller[4], T. Exner[5], N. Tesfay[3], S. Magutshwa[3], S. Khumalo[3], C. Dolezal[5], J. Hanass-Hancock[3], S. Hoffman[6]

[1]Brown University School of Public Heath, Department of Behavioral and Social Sciences, Providence, United States, [2]University of KwaZulu Natal, Paediatrics, Umbilo, South Africa, [3]South African Medical Research Council, Gender and Health Research Unit, Durban, South Africa, [4]Columbia University, ICAP, Mailman School of Public Health, New York, United States, [5]NYS Psychiatric Institute, HIV Center for Clinical and Behavioral Studies, New York, United States, [6]Mailman School of Public Health, Columbia University, Department of Epidemiology, New York, United States

Background: Daily oral pre-exposure prophylaxis (PrEP) offers effective HIV prevention. In South Africa, PrEP is publicly available, but use among young women remains low.

This study explores women's willingness to consider using PrEP for HIV prevention in the context of HIV- and sexuality-related stigma and gendered relationship dynamics, in Durban, KwaZulu-Natal, South Africa.

Methods: As formative qualitative research prior to developing a gender-informed intervention, Masibambane, to introduce PrEP to young, urban, educated women, we conducted six focus group (FG) discussions with 46 women ages 18-25 years and individual interviews with eight FG participants. Women not using PrEP were recruited from clinic and community settings using a criterion-based snowball sampling technique. Qualitative data were coded and analyzed thematically, using a team-based consensus approach for final coding, analytical decisions, and data interpretation.

Results: Women clearly understood the benefits of PrEP, focusing on their right to protect themselves. Their thoughts about future PrEP use were challenged by social stigmas related to HIV and female sexuality, but motivated by a desire for health promotion and sexual empowerment.

Women feared that daily PrEP pills would be confused with anti-retroviral treatment, creating HIV stigma, and that PrEP pills and related clinic visits would "out" them to their communities as sexually active. Women were realistic about potential reactions of male partners if the women opted to use PrEP, including disapproval, loss of trust, loss of the relationship, and violence.

Some women advocated for covert use of PrEP whereas others argued for disclosure, proposing various approaches to presenting PrEP to their partners. Women repeatedly suggested that both partners use PrEP.

They sought to avoid discussions about trust and partners' possible infidelities, and instead focused on preserving or building the relationship through PrEP use.

Conclusions: Women offered diverse narratives on agency and constraint in relation to choosing PrEP for HIV prevention. Women's pronounced concerns about HIV stigma, negative community perceptions of young women's sexual activity, and relationship challenges speak to the need for tailored interventions to bolster women's confidence, sense of empowerment, communication, and decision-making skills for successful adoption of PrEP.

EPC279

In vivo pharmacokinetics and safety in mice for ultra-long-acting injectable, biodegradable, and removeable in-situ forming implant with cabotegravir for HIV prevention

I. Young[1], R. Shrivastava[2], P. Maturavongsadit[2], A. Prasher[2], M. Cottrell[3], A. Schauer[3], S. Montgomery[4], A. Kashuba[3], R. Benhabbour[2]

[1]University of North Carolina at Chapel Hill, Eshleman School of Pharmacy - Division of Pharmacoengineering and Molecular Pharmaceutics, Chapel Hill, United States, [2]University of North Carolina at Chapel Hill, Biomedical Engineering, Chapel Hill, United States, [3]University of North Carolina at Chapel Hill, Eshelman School of Pharmacy - Division of Pharmacotherapy and Experimental Therapeutics, Chapel Hill, United States, [4]University of North Carolina at Chapel Hill, Pathology and Lab Medicine, Chapel Hill, United States

Background: Globally, 1.5 million new HIV infections occurred in 2020. Daily oral HIV PrEP, while effective, can have low patient adherence. Monthly injectables are not removeable and their pharmacokinetic (PK) tail can lead to drug resistance.

Thus, we propose to develop an ultra-long-acting, injectable, removable, and biodegradable in-situ forming implant (ISFI) with cabotegravir (CAB) for HIV prevention.

Methods: A 90-day PK and 30-day safety study was conducted in female BALB/c mice (n=6/time point) with the CAB ISFI formulation (50 µL subcutaneous injection). Plasma samples were collected longitudinally to quantify CAB, TNF-α and IL-6 concentrations.

At day 3, 7 and 30, the depot and surrounding tissue were excised for H&E staining to assess local inflammation. At day 90, depots were removed to quantify residual CAB, evaluate polymer degradation with gel permeation chromatography, and depot microstructure with scanning electron microscopy.

Results: In vivo plasma concentrations of CAB were above its 4X PA-IC90 for 90 days, demonstrated zero-order release kinetics *(Fig. 1A)*, and showed low concentrations of TNF-α and IL-6 in plasma with mild/moderate local inflammation *(Fig. 1B/C/E)*. Depots retrieved 90-days post-administration showed no fibrotic tissue *(Fig. 1D)* and reached ~47% polymer degradation and contained ~73% of residual CAB.

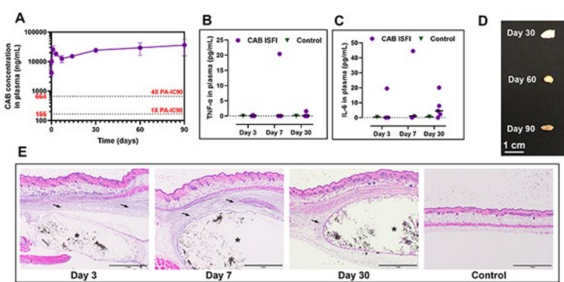

Figure 1. In vivo PK and safety of CAB ISFI in female BALB/c mice. (A) CAB concentration in plasma over 90 days. Dashed lines represent 1X and 4X PA-IC90. (B) Individual TNF-α levels and (C) IL-6 levels in plasma over 30 days. (D) Image of depots removed after 30, 60, 90 days post-injection. (E) Hematoxylin and eosin (H&E) stained images of depots and surrounding tissue day 3, 7 and 30 post-injection compared to no injection control. Asterisks represent ISFI and arrows represent infiltrated immune cells.

Conclusions: Our results demonstrated sustained CAB release kinetics in mice for 90 days with plasma levels well above the 4X PA-IC90 in a well-tolerated and safe formulation.

EPC280

Examining PrEP cascade engagement in a statewide sample of transgender, nonbinary, and gender diverse adults in the United States

D. Gerke[1], J. Call[1], S. Kattari[2], A. Lacombe-Duncan[3], B. Misolek[4]

[1]University of Denver, Graduate School of Social Work, Denver, United States, [2]University of Michigan, School of Social Work & Department of Women's and Gender Studies, Ann Arbor, United States, [3]University of Michigan, School of Social Work, Ann Arbor, United States, [4]Transcend the Binary, Ferndale, United States

Background: Although transgender/gender diverse (TGD) individuals are at increased risk for HIV, few studies have examined engagement of TGD individuals with different gender identities (e.g., transmasculine, transfeminine, nonbinary) across the PrEP cascade.

There is particularly little knowledge regarding PrEP engagement among transmasculine and nonbinary individuals.

Accordingly, this study examined engagement in the PrEP cascade among a statewide sample of transfeminine, transmasculine, and nonbinary individuals and tested for significant differences in engagement by gender.

Methods: Data come from the Michigan Trans Health Survey (*N*=659), a community-based participatory research project. Data were collected using a computerized self-report survey.

We used frequencies to examine engagement in the PrEP cascade (i.e. education, referral, prescription, use) and Pearson chi-squares to determine significant differences in engagement by gender.

Results: The sample included all participants who qualified for PrEP due to reporting anal or vaginal sex (*n*=317). A majority of participants were White (78.39%).

Participants also identified as Black/African American (6.45%), Latinx/Chicanx/Hispanic (4.84%), Asian/Pacific Islander (2.90%), Multiracial (5.81%), or other (1.61%) and were an average age of 27.67 years (SD=8.47).

Of those who qualified for PrEP, 64 (20.19%) received information about PrEP from their healthcare provider, 17 (5.36%) received a referral to PrEP, seven (2.21%) visited a provider who could prescribe PrEP, and five (1.58%) received a PrEP prescription and began taking PrEP.

Of those five, three planned to continue PrEP use into the foreseeable future. Chi-square results indicated a significant difference by gender in who received information about PrEP from their health providers (χ^2 (1, N=317) = 11.34, *p*=.01).

A significantly greater proportion of transfeminine participants (40.91%) and those who reported multiple/other genders (48.39%) received PrEP information than their transmasculine (22.09%) and nonbinary (13.95%) peers.

We were unable to detect additional significant gender differences due to small numbers of participants who engaged further in the PrEP cascade.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Conclusions: A substantial number of PrEP-eligible TGD individuals reported not receiving information about PrEP from healthcare providers, and even fewer engaged further in the PrEP cascade.

Provider education on sexual health for TGD individuals is needed to increase PrEP engagement in this population, especially for transmasculine and nonbinary individuals.

EPC281

Designing the next generation intravaginal ring for prevention of HIV and unplanned pregnancy: what do potential users' perceptions have to do with it?

C. Golin[1], E. Millar[2], E. Ferguson[1], J. Mishra[1], E. Schenck[1], R. Janusziewicz[3], K. Guthrie[4], S.R. Benhabbour[3,5]

[1]*University of North Carolina at Chapel Hill, Medicine and Health Behavior, Chapel Hill, United States,* [2]*University of North Carolina at Chapel Hill, Carolina Population Center, Chapel Hill, United States,* [3]*University of North Carolina at Chapel Hill's Eschelman School of Pharmacy, Division of Pharmacoengineering and Molecular Pharmaceutics, Chapel Hill, United States,* [4]*Brown University School of Medicine, Psychiatry & Human Behavior, Providence, United States,* [5]*North Carolina State University and The University of North Carolina at Chapel Hill, Joint Department of Biomedical Engineering, Raleigh, United States*

Background: Intravaginal rings (IVRs), woman-controlled devices for delivering medications for contraceptive and/or HIV prophylaxis, must be used consistently to be effective. Informing IVR design with women's input on potential IVR features can promote product uptake and use, particularly when elicited early in product development.

Methods: In 2020-2021, using virtual focus groups (VFGs) and in-person in-depth interviews (IDIs), we elicited potential users' sensory perceptions and experiences to iteratively inform the design of a novel 3D-printed IVR, which enables engineers to readily modify designs in response to input.

Women from a state-wide health system aged 18-45 years, who were Black, non-Hispanic white, or Latina from urban and rural areas of North Carolina participated. They were shown prototypes of varying designs and colors. In nine VFGs we assessed reactions to visual aspects of IVR prototypes and to modifications derived from VFG data and concurrent safety/efficacy animal data.

We then interviewed 25 women in person to assess their perceptions of both visual AND tactile features of the modified prototypes. VFGs and IDIs were audiotaped, transcribed, and independently coded by two researchers and summarized/organized into matrices by key areas.

Results: IVR characteristics generally perceived as important were: texture, hue, size, comfort, and hygiene. Overall, smoother surfaces and lighter hues (e.g., lavender, light grey) were preferred ("calming", "more approachable", enabling one to "see what was on it" for cleanliness), but color preferences were not paramount. Women felt smaller rings would enhance comfort.

Some women perceived designs with small holes as unhygienic, potentially increasing risk of infections. In in-person IDIs, on initial visualization, prototypes were perceived as "chunky", "thick", "big and wide," suggesting uncomfortableness, but upon handling, women found IVRs were "more soft and malleable" than they initially perceived.

For many women the perceived comfort advantages that the holes afforded outweighed the women's hygiene concerns.

Conclusions: Women's views of HIV prevention devices varied, providing useful information in product design. IVR pliability was perceived to govern comfort and was a critical consideration for women.

EPC282

Reimagining 'discontinuation' of pre-exposure prophylaxis (PrEP) as part of an ongoing PrEP journey for gay and bisexual men

S.P. Philpot[1], C. Chan[1], B. Haire[1], D. Murphy[1], D. Fraser[1], A. Grulich[1], B.R. Bavinton[1]

[1]*UNSW Sydney, Kirby Institute, Kensington, Australia*

Background: The focus on the risks associated with discontinuation of pre-exposure prophylaxis (PrEP) among gay and bisexual men (GBM) masks nuances regarding changing PrEP use and neglects GBM's HIV risk behaviour during periods off PrEP. The concept of ‚prevention-effective adherence' describes the alignment of ongoing HIV risk and PrEP persistence.

Methods: We explored GBM's patterns of PrEP use and sexual behaviour. We conducted semi-structured interviews with 40 GBM in Australia recruited from a previous PrEP clinical trial. Eligibility required that participants had changed their PrEP use.

Results: Median age was 39 and 24 had university education. All 40 participants commenced PrEP with daily dosing, with considerable diversity in PrEP use over time (Figure 1).

At *any* point in their PrEP journey, 34 had discontinued, voluntarily suspended (during temporary periods of anticipated absent sex), or involuntarily suspended (due to depleted PrEP supply while travelling or mental health issues) at least once. During periods off PrEP, 22 of these 34 did not have condomless anal intercourse (CLAI).

However, 12 had CLAI after discontinuing or suspending, among whom condoms were unviable and assumptions were sometimes made about a partner's HIV, PrEP, or viral load status without prior discussion.

Among those who had CLAI after discontinuation, two had CLAI once, which prompted recommencement of PrEP, and six had CLAI on multiple but dispersed occasions, but reported they did not see themselves at sufficient risk to warrant recommencement.

Figure 1.

Conclusions: The complexity of GBM's PrEP use demonstrates that discontinuation may only form one part of a broader PrEP journey, and does not necessarily increase HIV risk when considering changes made to sexual behaviour.

Service delivery models and health promotion should address this complexity by encouraging non-condom based HIV prevention during periods off PrEP and supporting GBM in recognising changing risk and recommencing PrEP when appropriate.

EPC283

Who prefers what? Correlates of preferences for next-generation HIV prevention products among a national U.S. sample of young MSM

K. Biello[1,2], P. Valente[1], D. Teixeira da Silva[3], W. Lin[3], R. Drab[3], L. Hightow-Weidman[4], K. Mayer[2,5]

[1]Brown University School of Public Health, Providence, United States, [2]Fenway Health, Boston, United States, [3]University of Pennsylvania, Philadelphia, United States, [4]University of North Carolina, Chapel Hill, Chapel Hill, United States, [5]Beth Israel Deaconess Medical Center/ Harvard Medical School, Boston, United States

Background: Young men who have sex with men (YMSM) in the United States remain at high HIV acquisition risk. Pre-exposure prophylaxis (PrEP) has been available for nearly a decade; yet only ~15% of young people with clinical indications have a PrEP prescription.

Next-generation PrEP modalities may address some challenges of daily oral PrEP. However, preferences for these products are unknown.

Methods: From October 2020-June 2021, we conducted a national online survey of 737 cisgender, HIV uninfected YMSM (age 15-24 years) (ATN141a: NextChoices). After reviewing PrEP product descriptions (daily oral pills, event-driven oral pills, event-driven rectal douches, bimonthly intramuscular injections, bimonthly intravenous bnAb infusions, yearly subcutaneous implants), participants were asked to rank them from 1 (most preferred) to 6 (least preferred). Exploded logit models were estimated to examine the association between ranked preferences of PrEP modalities and sample characteristics.

Results: Participants' mean age was 21 years (SD=2.3); 19% identified as Black, 24% as Latino. Twenty-eight percent had ever used daily oral PrEP; 19% were currently taking it. Across six PrEP modalities, daily oral PrEP had the highest preference ranking, followed by event-driven oral (OR=0.89, p=.058), injectable (OR=0.83, p=.005), implant (OR=0.48, p<.0001), bnAb (OR=0.38, p<.0001), and rectal douches (OR=0.24, p<.0001).

There were differences by age, insurance status, sexual behavior, PrEP use history, HIV and STI testing history, and STI diagnoses (p<0.05). Participants selected reason(s) for choosing their top-ranked product: ease of use for those who chose daily oral (99%) and daily event-driven (98.5%); feel more protected against HIV for those who chose injectable (95.4%) and implants (100%); not worry about remembering to take it for those who chose bnAbs (93.8%); and being able to stop taking it when they want for those who chose rectal douche (90.9%).

Conclusions: Next-generation modalities were less likely to be preferred over daily oral PrEP; however, a substantial minority did prefer the next-generation modalities, and there were differences in the magnitude by sociodemographic and behavioral characteristics.

Given the low uptake of daily oral PrEP, having a menu of products may increase PrEP uptake overall, but it is essential that end-users' preferences for and concerns about PrEP products are understood and addressed.

What is the added value of incorporating pleasure in sexual health interventions? A systematic review and meta-analysis

A. Philpott[1], M. Zaneva[2], A. Singh[3], I. Askew[4], G. Larsson[5], L. Gonsalves[6]
[1]The Pleasure Project, Shaftesbury, United Kingdom, [2]University of Oxford, Oxford, United Kingdom, [3]The Pleasure Project, Delhi, India, [4]UNDP-UNFPA-UNICEF-WHO-World Bank Special Programme of Research, Development and Research Training in Human Reproduction (HRP), WHO, Department of Sexual and Reproductive Health and Research, Nairobi, Kenya, [5]The Case for Her, Stockholm, Sweden, [6]UNDP-UNFPA-UNICEF-WHO-World Bank Special Programme of Research, Development and Research Training in Human Reproduction (HRP), World Health Organization, Department of Sexual and Reproductive Health and Research, Geneva, Switzerland

Background: Despite billions of dollars invested into Sexual and Reproductive Health and Rights (SRHR) and the significant burden of disease of AIDS, the effect of incorporating sexual pleasure, a key driver of why people have sex, in sexual health interventions is currently unclear. We conducted a systematic review and meta-analysis to answer the question 'Do SRHR interventions which incorporate sexual pleasure improve relevant health outcomes (as compared with 'usual' SRHR interventions)?
To our knowledge, this is the first systematic review of interventions incorporating pleasure beyond condom eroticization. Our systematic review and meta-analysis provide evidence for the effectiveness of different interventions incorporating pleasure for a variety of outcomes in the context of sexual health.
Methods: We followed PRISMA guidelines in carrying out this systematic review and meta-analysis. We searched 7 databases for relevant articles published between 1 January 2005-1 June 2020 and conducted secondary search strategies. We adopted an expansive approach and included randomized controlled trials and quasi-experimental studies with both pre and post-intervention measures and a control group published in peer-reviewed journals. For our meta-analysis we accepted only standard SRHR control or matched groups with a similar SRHR intervention.
We considered various outcomes including behavioral measures (use of condoms, prevention services, risky behavior etc), attitudes and knowledge (about contraception use, STI/HIV incidence etc).
Results: We identified 33 unique interventions that incorporate pleasure. All included interventions targeted HIV/STI risk reduction. We find that the majority of interventions targeted populations that authors classified as high-risk. We were able to meta-analyze 8 studies reporting condom use as an outcome and found an overall moderate, positive, and significant effect of Cohen's d = 0·37. Full results here.

Conclusions: Incorporating sexual pleasure within SRHR interventions can improve sexual health outcomes. Our meta-analysis provides evidence about the positive impact of pleasure-incorporating interventions on condom use which has direct implications for reductions in HIV and STIs. Qualitatively, we find evidence that pleasure can have positive effects across different informational and knowledge-based attitudes.
Taking all the available evidence into account, we recommend that agencies responsible for sexual and reproductive health consider incorporating sexual pleasure considerations for effective interventions.

EPC285
Disclosure practices among PrEP adopters in the eThekwini district, South Africa

J. Basdav[1], F. Haffejee[1], P. Reddy[2]
[1]Durban University of Technology, Basic Medical Sciences, Durban, South Africa, [2]Durban University of Technology, Community Health Studies, Durban, South Africa

Background: South Africa is described as an HIV epicentre where young girls and women are disproportionately affected. In 2021, the HIV prevalence was recorded at 13.7%. The intervention of pre-exposure prophylaxis (PrEP) as a daily HIV prevention pill may assist by combating potential seroconversions. PrEP is known as a self-controlled measure particularly among women which is synonymous with covert use.
The aim of this study was to determine disclosure practices among PrEP adopters in the province of KwaZulu-Natal, South Africa.
Methods: A qualitative study was conducted at two primary healthcare clinics in the eThekwini district during November and December 2021. Non-probability sampling was used to purposively select PrEP users (n=15) aged 18 and older with minimum PrEP use of 6 months and identifying either as a current or ex-user. Thematic analysis was used to identify themes and sub-themes.
Results: All participants were Black African aged 30.4 ±8.13. Majority were female (86.7%), employed full-time (46.7%) with PrEP duration ranging from 7-31 months. Over two-thirds (73.3%) disclosed their PrEP use to their sexual partner and family members. Over 50% told their friends about their medication use and few admitted this to their work colleagues.
Most revealed this directly, however, few recalled how their PrEP use was discovered accidentally by their sexual partner. Despite this unexpected turn of events, their sexual partner was initially shocked by this revelation but later came to an understanding.
None of the participants were subjected to anger and/or violence by their sexual partner when disclosing their PrEP use. Interestingly, minimal stigma levels were identified by ones' family and social networks upon disclosure. Few males within ones' family and social networks came

to know about their medication intake. Additionally, some recommended PrEP to their sexual, family, social and work contacts while others began using PrEP due to their disclosure and reasoning for initiation. When recommending PrEP, the suggestion was framed based on their network's personal circumstance at that point in time.

Conclusions: This study highlights how disclosure was received without prejudice and recommending PrEP use among their contacts. Furthermore, PrEP adopters increased both awareness and uptake levels.

Access to harm reduction interventions

EPC286

Characterizing history of opioid agonist therapy uptake among people who inject drugs in Iran: findings from a national bio-behavioral surveillance survey in 2020

F. Mehrabi[1], S. Mehmandoost[1], A. Mirzazadeh[2], A. Noroozi[3], F. Tavakoli[1], H. Mirzaei[1], M. Khezri[1], G. Mousavian[1], N. Ghalekhani[1], P. Afsar Kazerooni[4], M. Shokoohi[5], F. Navaiian[6], Z. Farajzadeh[7], H. Sharifi[1], M. Karamouzian[8]

[1]HIV/STI Surveillance Research Center, and WHO Collaborating Center for HIV Surveillance, Kerman, Iran, Islamic Republic of, [2]University of California, Department of Epidemiology and Biostatistics,, San Francisco, United States, [3]Iranian National Center for Addiction Studies (INCAS), Tehran University of Medical Sciences (TUMS), Tehran, Iran, Islamic Republic of, [4]Shiraz HIV/AIDS Research Center, Shiraz University of Medical Sciences, Shiraz, Iran, Islamic Republic of, [5]Dalla Lana School of Public Health, University of Toronto, Toronto, Canada, [6]HIV Expert of Deputy of Health, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of, [7]Ahvaz Jundishapour University of Medical Sciences, Ahwaz, Iran, Islamic Republic of, [8]Brown School of Public Health, Brown University, Rhode Island, United States

Background: Opioid agonist therapy (OAT) is an effective harm reduction intervention that helps reduce opioid withdrawal and cravings, injection drug use, and all-cause mortality among people who inject drugs (PWID). Iran has the largest OAT program in the Eastern Mediterranean region, but our understanding of barriers to OAT uptake is limited. We aimed to characterize Iranian PWID who had never received OAT and examine the associated barriers.

Methods: In the 2019-2020 national bio-behavioral surveillance survey in Iran, a respondent-driven sample of 2,684 PWID (i.e., history of last-year injection drug use) were recruited from 11 large and geographically dispersed cities. Outcome of interest was no lifetime uptake of OAT medications (i.e., prescribed methadone, buprenorphine, or opium tincture maintenance therapy).

We measured the association of sociodemographic and behavioral variables with no history of OAT uptake using multivariable logistic regression models. People who had never received OAT were asked for the underlying reasons/barriers which were categorized into primary themes.

Results: Lifetime prevalence of no history of OAT uptake among PWID was 31.3% (95% confidence interval (CI): 29.5, 33.1). In the multivariable analysis, younger age (adjusted odds ratio [aOR]: 0.99; 0.98, 0.99), ≥ high school education (aOR: 1.41; 1.17, 1.71), being married compared to divorced (aOR: 1.28; 1.01, 1.61), never been married compared to divorced (aOR: 1.46; 1.16, 1.83), no history of prior incarceration (aOR: 1.48; 1.22, 1.79), and length of injecting career of 2-5 years compared to more than five years (aOR: 1.42; 1.03, 1.95) were significantly and positively associated with never receipt of OAT.

Individual-level barriers (e.g., having a hard time, too many failures in the previous attempts to quit drugs, mental problems), financial barriers (e.g., unaffordable cost of OAT services), and system-related barriers (e.g., service availability interfering with working hours, long distances to OAT services, unrealistic treatment-related expectations from staff, stigma and rejection from healthcare providers) were the main barriers to obtaining the OAT.

Conclusions: About one-third of PWID in this national study in Iran had never received OAT in their lifetime. PWID continue to face preventable barriers to obtaining OAT, which calls for revisiting how OAT is provided across the country.

EPC287

Factors associated with preference of "take-away dose" among Opioid Substitution Therapy clients in Nepal

P. Shakya[1], D. Sherpa[1], K. Dhakal[1], A. Pun[1], R. Bhattarai[1], K. Kishore[1]

[1]Save the Children, Global Fund, Kathmandu, Nepal

Background: Opioid Substitution Therapy (OST) is a crucial harm reduction component of HIV program for people who inject drugs. Despite being the first South Asian country to start OST, low retention rate (21%) has always been a major challenge of OST program in Nepal. During COVID lockdown period, Nepal successfully implemented "Take-away OST dose" which accelerated the advocacy for take-away dose provision for stable clients during normal times also.

However, little is known about client's perception between "take-away dose" and "daily site visit". Thus, we examined the socio-economic factors associated with choice of "take-away dose" or "daily site visit" among OST clients in Nepal.

Methods: We conducted a cross-sectional study among 852 currently enrolled OST clients in all 12 OST sites in Nepal. We collected data during September 2021 through online self-administered questionnaire.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

We measured socio-demographic variables, OST duration, distance to OST site, commuting habit, clients' choice between "take-away dose" or "daily site visit". We used multivariable logistic regression model to analyze the data.

Results: Out of 852 participants, 4% were female. The mean age was 33.8 years (SD 8.0). Half of the participants had higher school education or above. Around 51% participants were employed. The mean OST duration was 27.7 months (SD 33.3). Around 21% and 18% of participants travel daily 6-10 kms and more than 10 kms respectively to visit OST site. Around 64% participants use motorbike to commute daily to OST site. Around 78% participants prefer "take-away dose" than "daily site visit".

Participants who travel daily for more than 10 kms and those who travel 6-10 kms daily were respectively 5.6 times (AOR= 5.65, 95% CI 2.80-11.39) and 1.8 times (AOR= 1.82, 95% CI 1.16-2.86) more likely to prefer "take away dose" than those who travel less than 5 kms daily.

Conclusions: Daily long commuting distance to the OST site is strongly associated with clients' preference of take-away OST dose. Such evidence is important to advocate for take-away OST dose in Nepal and thus improving the access and retention rate of the clients in the OST program.

EPC288

Partnering with the Ministry of Justice (MOJ) to launch and scale Ukraine's first-ever medication-assisted treatment (MAT) as part of comprehensive HIV prevention services for prisoners with opioid dependency

S. Leontieva[1], T. Gaborets[1], K. Gamazina[1], S. Vasyliev[2], T. Dergach[2], I. Khaniukov[3]

[1]*PATH, Ukraine Country Program, Kyiv, Ukraine,* [2]*Ministry of Justice of Ukraine, Center of Health Care, Kyiv, Ukraine,* [3]*Global Fund and Serving Life Projects Implementation Group, Kyiv, Ukraine*

Background: HIV prevalence in prisons in Ukraine is 8.9% (2019), and 90% of prisoners incarcerated for drug crimes continue using drugs while in prison. Access to harm reduction services in prison settings is critical to prevent HIV transmission while addressing substance use disorders. However, no drug-related harm reduction programs existed in Ukrainian prisons before 2019. The USAID/PATH Serving Life project partnered with the MOJ to launch and scale the first MAT pilot in prisons.

Description: Serving Life and the MOJ undertook the following steps to pilot MAT:

1. Advocated to integrate MAT into the comprehensive care package in penal settings;
2. Developed standard operating procedures to guide MAT program enrollment, provision of psychosocial support, and MAT adherence counseling by project-supported social workers, offering of HIV testing as part of MAT services, and linkage to civil-sector MAT programs for prisoners being released;
3. Created a medical advisory board and multidisciplinary care team to manage medical and social services for MAT clients;
4. Established a MAT room at pilot sites equipped with required commodities. MAT was first piloted in Bucha Prison Colony #85 (male prison) in 2019, and in four additional prisons (male and female) in 2021.

Lessons learned: Among the 144 prisoners enrolled in MAT from December 2019 through December 2021, 123 (85%) are continuing therapy. As of December 31, 2021, 100 prisoners received daily MAT in prisons. Procedures established to transition MAT clients to civil-sector MAT programs upon release were effective, with 23 former prisoners linked to community-based MAT services. No overdoses have been reported. Prisoners are reporting health benefits of MAT, and no longer buy illegal drugs or share injecting equipment, decreasing HIV and viral hepatitis risk.

Conclusions/Next steps: Providing MAT services in Ukrainian prison settings is feasible and acceptable. As part of a comprehensive HIV prevention package, MAT enabled prisoners to decrease HIV risk and improve health outcomes. Close partnership with the MOJ was critical to obtaining political will to launch MAT. Serving Life and the MOJ plan to open MAT sites in three additional prisons in 2022; and the MOJ plans to scale MAT at all penal settings in 2023.

EPC289

The first study of psychoactive substance use and drug checking practices among participants of electronic dance music Events in Ukraine

V. Kushakov[1], G. Sergiienko[1], V. Dvoryak[1]

[1]*Alliance for Public Health, Kyiv, Ukraine*

Background: The study explored psychoactive substance (PAS) use associated with electronic dance music (EDM) culture in Ukraine; examined the uptake, relevance and utility of drug checking and its influence on harm reduction behaviour in order to inform the development of harm reduction interventions.

Methods: Between May and October 2021 we conducted a cross-sectional survey of attendees of 12 EDM festivals of varying sizes and genres in Kyiv, Ukraine. The survey conducted in conjunction with harm reduction intervention focused on PAS use, associated risks and the experience of drug checking. The final analytic sample included 1307 participants who reported consumption of PAS excluding tobacco, alcohol and cannabis.Trends in drug checking were analysed based on cross-sectional surveys of a major festival in 2018, 2019, and 2021.

Results: The mean age of participants was 24.4. Slightly over a half were male. 76% self-identified as heterosexual, 3% homosexual, and 16.6% bisexual. 37.7% experienced overdose symptoms in the past 12 months, most common related to mental health: anxiety/paranoia/panic attacks (19%) and confusion/changes in mental state (15%).

MDMA, amphetamine, LSD, cocaine, ketamine, psilocybin were most prevalent followed by methamphetamine, synthetic cathinones, 2C-B and GHB/GBL.

Between 2018 and 2021 the proportion of participants who report to have ever tested PAS increased from 2% to 26%. The odds of consuming the tested substance were about 2.5 times lower (p = 0.008) in case of unexpected drug checking results compared to situations when testing confirmed the intended substance.

Cluster analysis identified three distinct clusters of study participants with specific risk factors that may require tailored harm reduction responses. E.g., experience of overdose symptoms may be correlated with age, gender, and substance use history. The risk of overdose significantly increased among people who report using synthetic cathinones.

Conclusions: In addition to influencing harm reduction behaviour drug checking can be instrumental in engaging and creating rapport with recreational PAS users thus allowing to implement HIV prevention and harm reduction interventions in this underserved population.

Further interventions in this group should address mental health challenges. Emergence of synthetic cathinones on the Ukrainian drug scene calls for interventions to prevent transition to injecting and transmission of HIV.

EPC290

Digitally facilitated harm reduction intervention for experimenting and recreational users of psychoactive substances in Ukraine serves 1437 unique clients in 7 months

G. Sergienko[1], V. Kushakov[1]

[1]*Alliance for Public Health, Kyiv, Ukraine*

Background: Young recreational users of psychoactive substances (PAS) in Ukraine are an underserved population facing significant risks associated with PAS use and related sexual behaviours. The intervention aims to prevent HIV transmission and reduce harms in this population.

The objectives included engagement of the target population, studying the risks and needs, and home delivery of HIV prevention and harm reduction commodities.

Description: The intervention employed online survey marketed through relevant social media as outreach instrument. People who reported using PAS (excluding cannabis, alcohol or tobacco) were directed to harm reduction information resources and offered home delivery of the PartyBox – a harm reduction kit containing condoms, lube, HIV self-test, safer sniffing kits, vitamins and drug checking tests. 1437 unique individuals from all geographic regions of Ukraine received PartyBoxes between June and December 2021, 49% women, 51% men, 61% aged 18-24, 28% - 25-34, 6% - 14-17, and 5% - 35-44. 26.4% reported non-heterosexual orientation. 90% never administered PAS by injecting.

Lessons learned: Targeted marketing, modern design, appropriate language, alignment with current trends in the target population and highly demanded information and services have allowed to engage a large group of young recreational PAS users. The intervention confirmed the demand for HIV prevention, testing and harm reduction (including drug checking) services in this population and the role of peers in further promotion of services.

Collected data on the profiles and risks indicated high prevalence of overdose symptoms; psycho-emotional problems (41% of participants), problems with relationships (20%), health (20%), work or school (12%) and law enforcement (9%); use of PAS to modify sexual experiences, and low condom use. Participants prioritised drug checking kits (82%), condoms (75%), lube (73%), sniffing straws and cards (61%), STI testing (51%) and HIV testing (50%).

Conclusions/Next steps: Online operational studies can be utilised as outreach tools tailored to specific underserved populations. HIV prevention and testing services are in high demand among recreational PAS users.

The established link with the target population and high demand for information and services allows for further efforts to prevent transitions to injecting, HIV transmission associated with sexualised drug use and to address the identified mental health challenges.

EPC291

South to south learning between Uganda and Kenya to scale up access to Medically Assisted Therapy services for people who inject drugs

M. Mensah[1], L. Lunika[2], M. Mugambi[3], P. Mudioppe[4], D. Byamukama[5], J. Musimbi[1], K. Skosana[2], K. Mangold[2], P. Bhatacharjee[1,6]

[1]*Partners of Health and Development in Africa, Nairobi, Kenya,* [2]*Genesis Analytics (Pvt) Ltd, Johannesburg, South Africa,* [3]*National AIDS and STI Control Programme (NASCOP), Nairobi, Kenya,* [4]*Ministry of Health, Kampala, Uganda,* [5]*Uganda AIDS Commission, Kampala, Uganda,* [6]*University of Manitoba, Manitoba, Canada*

Background: The South-South Learning Network (SSLN) is an HIV prevention learning initiative that supports the Global HIV Prevention Coalition to strengthen national HIV programmes through shared learning and problemsolving across 10 African countries, including Uganda and Kenya. The SSLN facilitates meaningful engagements across countries through deliberately constructed webinars and workshops, mentoring and capacity-building, technical support, documentation and dissemination of best practices.

Description: Uganda's Medically Assisted Therapy (MAT) program started in September 2020 with initiation of a MAT center within Butabika National Referral Hospital to enroll 200 clients. Community consultation identified long distances to the center and suboptimal demand generation activities as key barriers to access and uptake of MAT.

Uganda Ministry of Health approached the SSLN to facilitate a process of peer to peer learning with Kenya which has a scaled MAT programme. The SSLN conceptualized and facilitated a virtual country-to-country mentoring programme. Kenya selected facilitators from facility and community programmes to lead the interactive sessions covering topics including:

a. Establishing multiple MAT sites;

b. Establishing mobile van MAT services;

c. Demand generation by strengethening community outreach with PWID;

d. Microplanning at site and population level; and,

e. Action planning.

Five 2-hour sessions were conducted biweekly from October to December 2021. Each session was attended by more than 25 participants from the two countries representing national, facility and community level service providers and implementers.

Lessons learned: Joint country to country problem solving, which is actively facilitated by a learning network can lead to structured learning and application. Involving facilitators and participants that have different technical capacities in the mentorship sessions encourage practical deliberations. Concluding mentoring sessions with action plans provide countries with an agenda to apply the learnigs in their own context.

Conclusions/Next steps: Uganda plans to adapt strategies including:

a. Targeted demand generation through peers using microplanning tools;

b. Providing more comprehensive services in MAT clinics;

c. Adopting mobile van for MAT dispensing reaching difficult to reach population; and,

d. Initiate livelihood programmes for MAT clients to make MAT more accessible.

EPC292

ChemSex risk management: a global sexual health approach through a single entry point of care in Hospital St Louis' Infectious Diseases Unit in Paris

I. Bichard[1], E. Laussat[1], B. Loze[1], A. Aslan[1], J.-M. Molina[1]

[1]*Saint-Louis Hospital (AP-HP), Department of Infectious and Tropical Diseases, Paris, France*

Background: ChemSex involves between 15% and 50% of men who have sex with men (MSM, on PrEP or HIV positive). This practice corresponds to the use of psychoactive substances to increase the intensity and duration of sexual intercourse and is associated with an increased risk of sexually transmitted infections, psychiatric diseases and sexual dysfunctions.

ChemSex harm reduction (HR) consultations have been implemented since September 2019 in the Infectious Diseases Department of Hospital Saint-Louis to integrate a sexual healthcare management that is cross-cutting and available in a single location to facilitate patient care.

Description: Physicians of this department are trained to identify and refer patients for HR. Specialized caregivers conduct harm reduction interviews with ChemSex users wishing to change their practices.

At each consultation, the professional and the patient set an objective for the HR, and a personalized action plan is established, specifically to help manage cravings. The means of action are re-assessed every consultation and new objectives are established. The patient is sent to the referring physician, psychiatrist or sexologist in case of co-morbidity.

Lessons learned: Between September 2019 and December 2021, 633 HR consultations were carried out in the unit for 172 MSM patients (average age 41 years). 77% of patients carried on to at least one consultation.

A survey was conducted in December 2021 assessing the behaviors and comorbidities of the consultants. 96 patients responded, 28% of whom practiced ChemSex several times a week.

96% of the respondents regularly used cathinones, 67% GHB. 60% of the patients had a sexual dysfunction before the practice of ChemSex, 41% of whom declared a sexual addiction and 32% an erectile dysfunction.

83% of the respondents felt that the harm reduction consultations had reduced the risks associated with their use of psychoactive products and 84% would "definitely" recommend the consultation to someone in the same situation as them.

Conclusions/Next steps: Patients encourage us to continue our integrative sexual health approach by expressing a major benefit and interest in these ChemSex consultations within a familiar and unique point of care, and underlined the need for more systematic sexual counseling to prevent ChemSex use.

EPC293

Outcomes of neonates born to mothers on opioid substitution therapy (OST) with Methadone in Kenya

J.A. Omwoha[1], A. Laving[2], R. Nduati[2]

[1]*Ministry of Health, Government of Kenya, Nairobi, Kenya,*
[2]*University of Nairobi, Department of Pediatrics and Child Health, Nairobi, Kenya*

Background: Use of heroin during pregnancy has been associated with high incidence of prematurity, low birth weight, neonatal abstinence syndrome (NAS) and neonatal mortality. A study was conducted to determine the clinical outcomes of neonates born to mothers on Opioid Substitution Therapy (OST) in Kenya.

Methods: A retrospective cohort study was carried out on mothers on opioid substitution therapy (OST) with methadone and their neonates born in the period 1st January 2015 to 31st December 2019 from six of the largest Medication assisted treatment (MAT) clinics in Kenya. Mother/infant data was extracted from the patient files using a

standard data collection tool, entered into a Microsoft Excel spreadsheet, cleaned and transferred to STATA version 11.2 for analysis. Proportions were used as estimates of the prevalence of LBW, NAS and neonatal mortality. Logistic regression analysis was conducted in order to test the factors associated with these three outcomes.
Results: A total of 81 mother infant pairs were included in the study.The median age of the mothers was 31 years, 95.1% had some formal education and 80.3% were unemployed. All the women were heroin users on OST, and in addition 87.7% and 65 (80.3%) reported cannabis and tobacco use respectively. The mothers had been on OST for a median 20 months (range: 1-60) and were receiving a median of 90mg of methadone (range 0-245mg) just before delivery.
Overall 39.7 of the babies were low birth weight (LBW) and median birthweight was 2550g. Independent predictors of LBW were maternal history of heroin IVDU Adjusted odds ratio (AOR) =5.7 (95% CI 1.7,18.9) p=0.004) and AOR=37.05 (95% CI 3.8,361.8) p=0.002] for heroin used during pregnancy.
Overall 35% of neonates developed NAS. Maternal use of benzodiazepine was associated with a significantly reduced risk of NAS use, AOR=0.31 [95%CI 0.10-0.97) p=0.045].
Overall 8.7% of the babies died.Risk of neonatal death was significantly reduced by methadone use AOR=0.97[(95% 0.95, 1.0) p=0.031] and increased by cocaine use AOR =12.85 [(95% 2.0,82.4) p=0.007].
Conclusions: The neonatal outcomes of neonates born to mothers on OST was poor, There is need for better interventions, education and emphasis on management of mothers and neonates in this population.

EPC294

First harm reduction intervention among MSM who use Psychoactive Substances (PAS) to modify their sexual experiences (practice Chemsex) in Ukraine

V. Kushakov[1], G. Sergienko[1]
[1]*Alliance for Public Health, Kyiv, Ukraine*

Background: Following initial explorations of chemsex phenomenon in Ukraine the Alliance for Public Health launched outreach and services to MSM who practice chemsex in Kyiv and Odesa. The intervention aimed to verify the feasibility of and demand for HIV and harm reduction services in this population, and to study the initial group of clients to inform further development of services.
Description: In June - December 2021 trained outreach workers through online and offline channels recruited the initial group of 572 people who reported using PAS before or during sex in order to change their sexual experience. 53% of clients were aged 25-34, 24% - 18-24, 20% - 35-44, and 2% - 45-54. Expected effects from chemsex included increased pleasure, new sensations/experience, arousal, reduced inhibitions, improved/prolonged sex, empathy with the partner, muscle relaxation, overcoming physical discomfort and fear. 565 people agreed to obtain unique identification codes that facilitate further access to services. 10% reported ever *injecting* PAS and 1.8% having done so within the last 30 days. Last anal sex condom use was 61%, and 32% reported having 10 or more casual sex partners in the last 12 months. 439 participants ordered HIV testing. 13 tested positive and initiated ART.
Participants received harm reduction, sexual health and PrEP counselling and referrals. 450 people received PartyBoxes - harm reduction kits containing condoms, lube, HIV self-test, cards and straws for safer intranasal use, vitamins and drug checking tests.
Lessons learned: Chemsex is prevalent among MSM in Ukraine with the main substances used being MDMA, amphetamine, GHB/GBL, cocaine, mephedrone and other synthetic cathinones, LSD, ketamine and methamphetamine. Friendly and creatively branded harm reduction services are in high demand among people who practice chemsex.
Participants highly prioritised drug checking (82%), lube (82%), condoms (77%), safer sniffing tools (57%), STI (56%) and HIV (52%) testing and harm reduction counselling (24%). 37% expressed their willingness to receive PrEP.
Conclusions/Next steps: The programme verified demand for HIV prevention, harm reduction and sexual health services among MSM who practice chemsex in Ukraine.
Further scaleup of such interventions is advisable and likely to contribute to HIV prevention and care in this population.

EPC295

Remotely support the chemsexers: the french experience of association AIDES

B. Fred[1], A. Beaucamp[2], E. Bodoignet[2], L. Passalaqua[2], V. Labrouve[2], J. Situ[2]
[1]*Paris 08 - AIDES, Pantin, France,* [2]*AIDES, Pantin, France*

Background: Men who have sex with men (MSM) who use psychoactive products in a sexual context (chemsexers) may live in rural areas, order psychoactive substances online and recruit partners on dating apps. Moreover it is difficult for chemsexers to find friendly and trained interlocutors, to tell their HIV status, to describe their practices. Therefore, they may be very far from care.
Furthermore, the restrictions resulting from the Covid epidemic in France, mental health and addiction professionals, especially community health workers, have warned about the worsening situation for many of them. They have observed an increase in psychoactive substance use and chemsex practices as well as an increase in the number of first-time consumers.
Description: To meet to the needs of these chemsexers who are isolated or far from care, AIDES developed a national remote assistance offer in 2017 based on sexual

prevention, harm reduction, self-assistance and referral to care. This assistance is provided through a Facebook page and WhatsApp. Thus, this offer managed by about fifteen activists covers the whole of France.

For dealing with the reduction of interventions with the public within the context of Covid, AIDES has reinforced this assistance by organizing self-support groups by videoconference and individual interview proposals on WhatsApp.

Lessons learned: Of 1201 active members in the Facebook support group, 90% are MSM and 58% are between 25 and 44 years old. The main requests include the need for support and medical guidance, information about harm reduction, expression of loneliness. On WhatsApp, 88% of 258 interviews in 2021 concerned chemsex. Callers were 44% from Paris region.

This system has become a forum for discussion and essential services for those who have stopped using healthcare centers. Satisfaction criteria include the quality of the information provided, the appropriateness of the support and especially the possibility of communicating with people who are not sexual partners.

Conclusions/Next steps: This remote offer, which has been reinforced according to the sanitary context, responds to unmet needs. This offer was useful during the Covid crisis thus AIDES decided to sustain the online support group and the possibility of online interviews although the Covid-19 epidemic is in decline.

Optimizing vertical transmission prevention programmes

EPC296

A prospective analysis of PrEP adherence and depressive symptoms among Kenyan women who initiated PrEP during pregnancy and postpartum

A. Larsen[1], J. Kinuthia[2], M. Marwa[3], J. Dettinger[4], L. Gomez[4], J. Stern[4], F. Abuna[3], B. Odhiambo[3], N. Mwongeli[2], P. Omondi[2], J. Baeten[1], J. Pintye[5], G. John-Stewart[4]

[1]University of Washington, Department of Epidemiology, Seattle, United States, [2]Kenyatta National Hospital, Nairobi, Kenya, [3]University of Nairobi, Nairobi, Kenya, [4]University of Washington, Department of Global Health, Seattle, United States, [5]University of Washington, School of Nursing, Department of Biobehavioral Nursing and Health Informatics, Seattle, United States

Background: Prior studies report suboptimal adherence among depressed PrEP users, yet few data exist on psychosocial factors associated with PrEP adherence among pregnant and postpartum women.

Methods: We prospectively analyzed data from the PrIMA Study (NCT03070600) among participants who initiated PrEP during pregnancy or postpartum to identify psychosocial correlates of adherence. Depressive symptoms were assessed serially (pregnancy, 6 weeks, 9 months postpartum) using the Center for Epidemiologic Studies Depression scale (moderate-to-severe depressive symptoms [MSD]=scores≥10).

Optimal PrEP adherence (self-reporting no missed PrEP pills in the last 30 days) was evaluated monthly in pregnancy; 6 weeks, 14 weeks, 6 months, 9 months postpartum. Correlates of PrEP adherence were identified using generalized estimating equation models, clustered by participant, adjusted for age, parity, education, partner HIV status, pregnancy status.

Results: Among 715 women who initiated PrEP, median age was 25 years (IQR:21-30), median gestational age at PrEP initiation was 29 weeks (IQR:24-33), 88% were married, and 19% had a partner living with HIV. Over a third (36%) of women reported MSD during pregnancy; of those 36% reported MSD in postpartum. Perinatal MSD was associated with having a partner of unknown HIV status, ≥4 lifetime sexual partners, intimate partner violence (IPV), and low social support ($p<0.05$). Among 3856 PrEP follow-up visits, 47% had optimal PrEP adherence which was 60% higher during pregnancy compared to postpartum (adjusted relative risk [aRR]:1.5, 95%CI:1.4-1.6, $p<0.001$).

Women >24 years were more likely to adhere to PrEP compared to younger women (aRR:1.2, 95%CI:1.0-1.3, $p=0.008$). PrEP adherence was 60% higher among women with partners living with HIV compared to women with partners of unknown HIV status or presumed HIV-negative (aRR:1.6, 95%CI:1.4-1.7, $p<0.001$). MSD in the past 6 months was not associated with PrEP adherence (aRR:1.02, 95%CI:0.93-1.14, $p=0.643$). Marital status, IPV, and social support were not associated with PrEP adherence.

Conclusions: Among perinatal women who initiated PrEP, self-reported adherence was higher in pregnancy than postpartum, among older women, and those with partners living with HIV.

In contrast to studies of non-pregnant women, PrEP adherence was not associated with depression. Our findings suggest that the impact of psychosocial barriers to PrEP adherence may be attenuated among perinatal populations.

EPC297
I=I (U=U) is good news

E. El Hage[1], M. Comegna[1], M. Comegna[2]
[1]*Once Trece Foundation, Caracas, Venezuela, Bolivarian Republic of,* [2]*Once Trece Foundation / Hospital Vargas de Caracas, Caracas, Venezuela, Bolivarian Republic of*

Background: In 2016 Prevention Access Campaign launched the global campaign U=U (undetectable = untransmissible). Once Trece Foundation designed the campaign i=i, the acronym for U=U in Spanish for the Venezuelan public. Although several years have passed since then and U=U is a verifiable fact, millions of people, do not know the advantages of these 3 characters.
In a voluntary and confidential survey of 200 patients living with HIV at the infectious disease department of the Vargas Hospital in Caracas, 47% said they did not know the meaning of i=i (U=U) and 36.6% believed that even under treatment people could continue to transmit HIV. When the campaign was explained, 97.62% said it was good news and 100% assured that making this public would end the stigma and discrimination of PLWHA.
Description: The campaign designing an easily recognizable logo. Some materials were distributed, 1000 flyers, 500 posters for ARV pharmacies, 800 T-shirts, 600 bags, 13 videos, 13 podcasts , 2 mobile clinics labeled with the message, 1 massive concert for World AIDS Day.
The material was distributed in communities carrying the i=i message. Several journalists, including international channels, used the T-Shirts to report on HIV-AIDS.
Doctors in other countries, including DR, Colombia and Argentina requested shipments of T-shirts and material to carry the campaigns outside Venezuela. On World AIDS Day, a massive concert with the National Orchestra System reached an audience of more than 4,500 people, including ambassadors from several countries and officials from UN offices and other AIDS NGOs from Venezuela and the world. Both musicians and singers wore i=i t-shirts during the concert.
Lessons learned: Talking about HIV-AIDS almost always generates rejection from the general population, which is not yet prepared to face realities without stigmatization. One way to reach people is through everyday life: clothes, music, shows. Societies prepared to stop discrimination could be better off in a future of equality.
Conclusions/Next steps: Campaigns like these will make it possible to bring the end of discrimination and stigma closer. Achieving the 95, 95, 95, 95, goal in Venezuela is a difficult task but, this kind of initiatives bring closer the possibilities to reach the goal.

EPC298
Accelerated declines in HIV incidence and flattening prevalence trends with scale-up of combination HIV prevention in a Ugandan adult population cohort, 1989-2021

I. Kasamba[1], J. Mugisha[1], R. Makanga[1], A. Abaasa[1], J. Seeley[2], P. Kaleebu[1], R. Newton[1], E. Ruzagira[1]
[1]*MRC/UVRI and LSHTM Uganda Research Unit, Entebbe, Uganda,* [2]*London School of Hygiene & Tropical Medicine, London, United Kingdom*

Background: The long-term evolution of the HIV response and its impact on HIV infection can offer insights for optimizing HIV interventions. In a population-based longitudinal study conducted over 30 years, we explain annual changes in HIV incidence, prevalence, and all-cause mortality in the context of a changing HIV response in rural Uganda.
Methods: Between 1989 and 2021, participants were repeatedly tested for HIV, and longitudinal data were collected on sexual behavior, circumcision, and residency status (in-migration, out-migration, death). People living with HIV (PLHIV) have reported on knowing their HIV status, starting antiretroviral therapy (ART), and their viral load data obtained.
While calculating HIV incidence, the seroconversion date was randomly imputed between each participant's last negative and first positive tests using a uniform distribution. These imputations were repeated 30 times to account for random error, and Rubin's rules were used to obtain age, sex, and calendar period-specific estimates.
To explain HIV incidence and prevalence trends, data were also examined for outcomes that might reflect the national HIV policy and practice in the study area. Analysis was restricted to participants aged ≥15 years.
Results: Participants (n=20,959) contributed 176,659 person-years and 669 seroconversions. In both men and women, HIV incidence initially declined slowly until the early 2000s, subsequently increasing after the introduction of ART in 2004, but there have been accelerated declines since 2011. Between 2015 and 2021, all age-specific incidences remained higher in women than men except in older adults (55 years and older) in whom incidence was similar.
Overall HIV prevalence initially declined from 8.0% in 1989/90 to 5.8% in 2002, then steadily increased until 2015 where it has since flattened at about 9.8%. More recently, male circumcision was scaled-up, virtually all participants were initiated on ART once diagnosed, more than 91% were virally suppressed, but a considerable proportion of PLHIV have unknown HIV status (18.4% in men, 13.6% in women).
Conclusions: HIV prevention and testing-and-treatment programmes must be concurrently scaled-up to accelerate population-level declines in HIV spread. The expansion of male circumcision in this study further accelerated declines in HIV incidence among men, but gaps exist in reaching PLHIV with unknown status.

Adherence to HIV treatment and prevention among a young Black and Latinx sexual minority men and transgender women cohort in the United States: PUSH study 2017-2021

N. Galai[1,2], A. Wirtz[1], D. Celentano[1], C. Beyrer[1], R. Arrington-Sanders[3]
[1]Johns Hopkins Bloomberg School of Public Health, Epidemiology, Baltimore, United States, [2]University of Haifa, Statistics, Haifa, Israel, [3]Johns Hopkins, Medicine, Baltimore, United States

Background: Adherence to HIV and prevention care is a critical target for status-neutral HIV prevention efforts. Rates of PrEP adherence have been lower among younger Black and Latinx sexual minority men and transgender women in the United States. This analysis sought to identify which key factors may undermine adherence in care in a vulnerable population of youth.

Methods: Young (aged 18-24) Black and Latinx sexual minority men and transgender women participating in randomized trials to evaluate an intervention to increase HIV care and prevention were followed for up to 18 months in the PUSH study in Eastern US. Adherence was defined as no missed doses in the last week for those at risk for HIV who reported being on daily, oral PrEP (N=117) and no missed doses in the last 4 days for those living with HIV who reported being on ART (N=33).

Logistic GEE regression models with stepwise covariate selection were used to obtain adjusted odds ratios (AOR) for medication adherence, adjusting for baseline factors (e.g., age, race/ethnicity, gender and sexual identity, history of unstable housing and transactional sex) and time-dependent substance use (grouped by common patterns of reported substances).

Results: Overall adherence rate was 47.5%. Only 11.2% reported no substance use while 67.4% used both alcohol and cannabis with or without tobacco. Over 176 person-visits, there were no statistically significant difference in adherence related to HIV status, age, unstable housing, or COVID time period since March 2020.

Minority gender identity (transgender, queer, questioning, non-conforming, other) was associated with lower adherence (AOR=0.24, p=0.015).

Poly substance use in the prior 3 months was associated with lower adherence: Combined alcohol and cannabis use (AOR=0.21, p=0.008), combined alcohol, cannabis and tobacco use (AOR=0.14, p=0.001) and use of alcohol or cannabis combined with other drugs (amphetamines, opioids, cocaine, inhalant, sedatives, hallucinogens) (AOR=0.31, p=0.065).

Conclusions: Efforts to improve adherence to HIV treatment and prevention need to address concomitant drug use among young Black and Latinx sexual and gender minority youth. Additional barriers to adherence among gender diverse youth will also need to be better understood to overcome and achieve optimal HIV outcomes.

Prevention of vertical transmission

EPC300

Determining the viral load threshold for initiating neonatal combination antiretroviral therapy prophylaxis in HIV exposed newborns

J. Brochon[1], T. Lee[2], J. Singer[2], J. Brophy[3], M.E. Metras[1], J. Coumeau[4], A. Tse-Chang[5], D. Money[6], I. Boucoiran[1], L.J. Sauve[6], A. Bitnun[7], F. Kakkar[1]
[1]CHU Sainte Justine, Université de Montréal, Montréal, Canada, [2]CIHR Canadian HIV Clinical Trials Network, Vancouver, Canada, [3]Children's Hospital of Eastern Ontario, University of Ottawa, Ottawa, Canada, [4]IWK Health Centre, Dalhousie University, Halifax, Canada, [5]Stollery Children's Hospital, Edmonton, Canada, [6]Women's Hospital and Health Centre of British Columbia, University of British Columbia, Vancouver, Canada, [7]Hospital for Sick Children, University of Toronto, Toronto, Canada

Background: Neonatal combination antiretroviral (cART) prophylaxis is recommended in situations at high-risk of vertical transmission, however, the maternal viral load threshold at time of delivery (dVL) for which neonatal cART is warranted is not clear. The objective of this study was to describe cART use and risk of vertical transmission at low levels of dVL.

Methods: Data were analyzed from mother-infant pairs (MIPs) in the Canadian Perinatal HIV Surveillance Program between 1997-2020, collected annually from 22 perinatal HIV centers in Canada. Infants were categorized as high-risk (dVL ≥1000c/ml, or maternal cART <4 weeks prior to delivery), medium-risk (dVL detectable and <1000c/ml, and maternal cART ≥4 weeks prior to delivery), and low-risk (dVL undetectable, and maternal cART ≥4 weeks prior to delivery). Neonatal ART regimens and HIV transmission risk was compared between groups.

Results: A total of 4743 MIPs were included; overall, 1.8% of newborns received no prophylaxis, 70.4% received monotherapy, 14.5% a dual-combination regimen, and 13.3% cART. The most commonly prescribed cART regimens were zidovudine (ZDV)/lamivudine (3TC)/nelfinavir (NFV) (6.5%), followed by AZT/3TC/nevirapine (NVP) (5.6%), and AZT/3TC/NVP/NFV (0.5%). Raltegravir based cART was used in only 0.3% of infants. A total of 2891 MIPS were categorized into risk categories (incomplete data for n=1854); 65.1 % were categorized low risk, 6.8% medium-risk, and 28.1% high-risk. An equal proportion of high and medium-risk infants received cART (25.7% *vs.* 26.6%). There were 55 HIV transmissions events; this included 49 (6.2%) of those in the high-risk, 1 (0.5%) in the medium-risk, and 5 (0.3%) in the low-risk category (p<0.001).

Among those prescribed cART, transmission occurred among 12.6% of infants in the high-risk group, 2.1% of those in the medium risk group, and 4.8% of those in the low-risk group. There were no transmissions among infants receiving single, dual or no ART in both low and medium-risk groups.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Conclusions: While cART was equally prescribed in both high and medium-risk situations, the benefits in the medium-risk group with low level detectable viremia are not clear. These data suggest that efforts may be better directed towards ensuring access to cART in high-risk situations, and limiting cART exposure in others.

EPC301

Broadly neutralizing antibodies - A new hope for elimination of vertical transmission of HIV

U. Persaud[1], A. Martin[1], M. McCluskey[1], M. Keane[2], S. Malhotra[2], C. Dugdale[3], A. Ciaranello[3], S. Torres-Rueda[4], F. Terris-Prestholt[5], E. Sparrow[6], K. Kripke[7], J. Mukherjee[8], V. Chakrapani[9], V. Muturi-Kioi[10], Y.W. Machira[10], K. Chapman[2], M. Hamilton[7], S.u. Hadi[8], D. Sok[2], A. Lima[1], M. Barnhart[1], L. Ghazaryan[1]
[1]U.S. Agency for International Development, Washington D.C., United States, [2]IAVI, New York, United States, [3]Massachusetts General Hospital, Boston, United States, [4]London School of Hygiene and Tropical Medicine, London, United Kingdom, [5]The Joint United Nations Programme on HIV/AIDS, Geneva, Switzerland, [6]World Health Organization, Geneva, United Kingdom, [7]Avenir Health, Takoma Park, United States, [8]IAVI, New Dehli, India, [9]Centre for Sexuality and Health Research and Policy, Chennai, India, [10]IAVI, Nairobi, Kenya

Background: Progress in preventing vertical transmission of HIV has stagnated. In 2020, there were 150,000 new HIV infections among children globally. The majority of new infections occurred through vertical transmission and fell dramatically short of the Joint United Nations Programme on HIV/AIDS (UNAIDS) 2020 targets.
Preliminary research indicates that broadly neutralizing antibodies (bNAbs) are potentially promising tools for prevention of vertical transmission of HIV.
Description: In partnership with other global health organizations and implementing partners, USAID supported activities related to research, development, and preparation for future implementation of bNAbs in low- and middle-income countries (LMICs) (Table 1).
Given the recent advances in the safety, tolerability, and pharmacokinetic characteristics of bNAbs, a strategic priority is to contribute evidence-based information on how bNAbs might be optimally positioned to contribute to the elimination of vertical transmission in LMICs.
Lessons learned: The analysis indicates that several complementary streams of work must be implemented to overcome bottlenecks in advancing bNAbs for prevention of vertical transmission. A robust business case, user-informed target product profile, and clear access strategy built upon learnings from these activities will be needed early in clinical development.
The inclusion of applications of bNAbs to reduce vertical transmission in the broader preferred product characteristic (PPC) of bNAbs for prevention has provided initial momentum for mobilizing the global health community to actively explore the potential of bNAb-based prevention products to reduce new vertical transmissions in LMICs.

Activity	Key Partners Involved	Brief Description/Main Purpose
Health Economic Research Strategy	• IAVI • London School of Hygiene and Tropical Medicine (LSHTM) • UNAIDS	Identify gaps in evidence and propose a priority agenda for health economic and modeling studies for biomedical HIV prevention over the next decade to inform critical decision-making junctures along the pathway from early development through implementation.
Cost-effectiveness of bNAbs for HIV Prophylaxis for All Infants Born in High-burden Settings	• Massachusetts General Hospital • IAVI	Evaluate the clinical impact and cost-effectiveness of bNAbs for infant HIV prophylaxis in Côte d'Ivoire, South Africa, and Zimbabwe.
Demand Forecasting	• Avenir Health • IAVI	Define the potential market for bNAbs for infant prophylaxis to inform clinical development strategy, commercial investment decisions, eventual implementation planning, and estimate manufacturing scale and costs.
Expert Consultations on the bNAb Use to Prevent Vertical Transmission	• IAVI • Individual stakeholders	Understand critical considerations, potential barriers, and enablers through expert consultations and two workshops to discuss strategies for the rapid development, access, adoption, and effective implementation of bNAbs for infant HIV prophylaxis.
World Health Organization (WHO) Preferred Product Characteristics (PPC) for bNAbs for HIV Prevention	• WHO • IAVI	Define preferred attributes for bNAbs including for the prevention of vertical transmission to inform product development; Lay the groundwork for policy recommendations & WHO pre-qualification; Increase the understanding of the potential role of bNAbs for HIV prevention in the global agenda.
Access Plan	• IAVI	Define a strategy to ensure the affordability, availability, differentiated value proposition, and integration into health delivery systems of future bNAb products, to pave the way for accelerated access, including for infant prophylaxis indications.
Acceptability Studies	• IAVI • Y.R. Gaitonde Centre for AIDS Research and Education • Centre for Sexuality and Health Research and Policy • Humsafar Trust • Final Mile	Understand the perspectives of potential end-users, service providers, and policy makers on the acceptability and feasibility of bNAbs as HIV prevention products among populations of interest in India, as a starting point, and then expand studies to other locations.

Table 1. Evidence informing decision-making around bNAbs for prevention of HIV vertical transmission in LMICs.

Conclusions/Next steps: Willing partners within the global health community should continue prioritizing strategic activities to inform consideration of bNAbs as a potentially integral tool to reduce vertical transmission and to understand the feasibility of bNAb implementation in LMICs.
The goal of the historic four-decade-long journey to end the global HIV epidemic and eliminate vertical transmission will be reached only when we have a range of safe and effective prevention methods and have achieved comprehensive implementation of these methods worldwide.

EPC302

Predictors of HIV transmission at two months among HIV exposed infants in twenty four States of India

V. Deshmukh[1], S. Rajan[2], B.S. Kushwaha[2], M. Manihani[2], S. Gitika[3], P. Suthar[4], A. Pradhan[5], R. Verma[6], M. Chugh[1], N. Purohit[7], S. Shrivastava[8], H. Kaur[9], V. Basavarajachar[10], K. Muthuselvan[11], L. Ramakrishnan[11], S. Kumar[11], S.S. Raghavan[1]

[1]Solidarity and Action Against The HIV Infection in India (SAATHII), Delhi, India, [2]National AIDS Control Organization, Delhi, India, [3]Solidarity and Action Against The HIV Infection in India (SAATHII), Mumbai, India, [4]Gujarat State Network of People living with HIV/AIDS (GSNP+), Ahmedabad, India, [5]Solidarity and Action Against The HIV Infection in India (SAATHII), Hyderabad, India, [6]Solidarity and Action Against The HIV Infection in India (SAATHII), Jaipur, India, [7]Solidarity and Action Against The HIV Infection in India (SAATHII), Kolkata, India, [8]LEPRA, Bhopal, India, [9]National Coalition of People Living with HIV in India (NCPI+), Chandigarh, India, [10]Swami Vivekananda Youth Movement, Bengaluru, India, [11]Solidarity and Action Against The HIV Infection in India (SAATHII), Chennai, India

Background: In India, 20,958 HIV+ pregnant women are estimated to be giving birth annually. Though the country has made significant progress in scaling up PMTCT interventions, there is limited data on the efficacy of these interventions.

The objective of this analysis is to assess the factors associated with antenatal, intrapartum and postpartum transmission among 11,827 HIV Exposed Infants (HEI) served by the National EMTCT program between 2018-2020 in 24 states of India.

Description: Routine program data of 11,827 mother-infant pairs from the GFATM funded Svetana program is used for this analysis. Logistic regression analysis was conducted using SPSS21. Mean age of women was 25 years and CD4 was 438 Cells/mm^3, 50% were Primigravida, 11% presented during labor and postpartum periods and 38% of the partners were HIV negative. Around 58% of the HIV+ women received >24 weeks of ART during pregnancy, 20% received 12-23 weeks, 15% below 11 weeks and 7% received no antenatal ART.

In addition, 71% of them underwent Normal Delivery and 29% Caesarean Delivery, 77% of them opted for exclusive breastfeeding and 99% of HEI received ARV prophylaxis. Antenatal ART regimens included 95% TLE, and infant ARV prophylaxis included 97% NVP and 3% AZT.

Lessons learned: Around 1.5% of the babies (173/11,827) tested positive at two months. Risk factors associated with HIV transmission were; no ARV prophylaxis to baby [aOR = 8.1, 95% CI (1.3- 50.0)], maternal CD4 count <200 [aOR = 3.3, 95% CI (1.8-5.8)] and 200 to 500 [aOR=2.2, 95% CI (1.4-3.4)], no antenatal ART [aOR = 2.3, 95% CI (1.2-4.2)], enrolment during the postnatal period [aOR = 2.2, 95% CI (1.1-4.2)], normal delivery [aOR = 1.8, 95% CI (1.2-2.9)], and antenatal ART duration of <4 weeks [aOR=1.8, 95% CI(1.0-3.5)]. Age and education of the mother, spouse HIV status, and birth weight of the baby were not significantly associated with HIV transmission whereas second pregnancy order [aOR = 0.61, 95% CI (0.39-0.96)] was found to be a protective factor.

Conclusions/Next steps: Early identification and initiation of ART and improving maternal CD4 during pregnancy, infant ARV prophylaxis for all HEI and planned C-Section can further reduce vertical transmission at two months in India.

EPC303

Preventing mother-to-child transmissionin Botswana: a health system strengthening approach

G. Gokatweng[1], C. Baumhart[2], O. Phuthego[1], N.H. Blanco[2], R. Marima[1]

[1]Bummhi, HIV, Gaborone, Botswana, [2]Center for International Health, Education, and Biosecurity (Ciheb), University of Maryland School of Medicine, HIV, Baltimore, United States

Background: The Government of Botswana made a strong commitment to achieve HIV epidemic control and eliminate mother-to-child transmission (MTCT). In April 2015, the Botswana University of Maryland School of Medicine Health Initiative (Bummhi) received PEPFAR funding for the Botswana Partnership for Advanced Clinical Education (BPACE) Project. BPACE provided technical assistance to the Ministry of Health and Wellness on HIV care and treatment and consolidated efforts for achieving epidemic control, including support for preventing mother-to-child transmission (PMTCT).

A bundle of strategies were implemented, including increased testing of pregnant women and use of triple prophylaxis. This paper describes PMTCT program successes over the 5-year BPACE project.

Methods: Bummhi conducted a retrospective analysis of the BPACE PMCTC programmatic data collected between October 2015 and July 2020. The analysis focused on 13 high-HIV burden districts in eastern Botswana, where BUMMHI implemented an HIV care and treatment program. The evaluation included all women and babies who received care in the 22 facilities that were continuously supported by Bummhi. Data was collected from paper-based ANC, baby testing, and HTS registers. Data Clerks then captured the data into Bummhi's Health Information Software (DHIS-2) system. The evaluation focused on PEPFAR-reported indicators

Results: By 2020, the number of women registered for antenatal care (ANC) more than doubled to 25,315 and the proportion of women with known HIV status increase to99% (p=0.015).The proportion of known HIV-positive clients remained steady through the years (15% to 16%, p=0.108), while the proportion of newly positive clients

decreased (9% to 3%, p<0.001). Among women who were HIV-positive, the proportion on ART increased from 74% to 99% (p<0.001). Additionally, as part of the early infant diagnosis activities, 4,637 newborns were tested for HIV (866 by 6 weeks, 3,050 by 2 months, and 3,955 by 1 year).

Conclusions: Despite Botswana being one of the countries with the highest HIV prevalence, the country has made exceptional progress in reducing MTCT. The implementation of the targeted PMTCT program along with EID services increased the number of pregnant women accessing ANC and HIV services. Engagement with these services increased the number of newborns being tested and linked to HIV services.

EPC304

Role of disclosure, stigma, discrimination on ART adherence among people living with HIV in sub-Saharan Africa: a qualitative systematic review

O. Ojeh[1], P. Nwaokoro[2], O. Toyo[1], U. Akpan[1], E. Nwanja[1], I. Elechi[1], K.-A. Ukpong[1]

[1]Achieving Health Nigeria Initiative, Uyo, Nigeria, [2]Family Health International 360, Uyo, Nigeria

Background: Adherence to antiretroviral therapy (ART) is key in achieving viral suppression and better health outcomes among people living with HIV (PLHIV). Non-adherence has been linked with several factors including disclosure, stigma, and discrimination in resource-limited settings. However, this relationship has not been properly investigated in Sub-Saharan Africa.

This study aims to systematically examine the evidence on stigma and disclosure and its effect on adherence to ART among PLHIV.

Methods: Thematic analysis of qualitative studies that reported findings on the role of disclosure, stigma, and discrimination on ART adherence among PLHIV in sub-Saharan Africa was explored. Six electronic databases - PubMed, CINAHL, Health Source: Nursing/Academic Edition and MEDLINE via EBSCO, Cochrane Central Register of controlled trials (Central), and PsychINFO were searched for related articles, including published, unpublished, and grey literature. Relevant abstracts were listed.

Any study conducted among PLHIV in sub-Saharan Africa that reported on the role of disclosure, stigma and discrimination on ART adherence was included for review. Data were extracted, quality assessment was conducted and the findings were synthesized using thematic synthesis.

Results: The database search yielded 341 initial results. After eliminating duplicates and screening the titles and abstracts, 30 journal articles were listed. However, only six qualitative studies met the inclusion criteria for this review. These studies were conducted in South Africa, Ethiopia, Kenya, and Tanzania. The thematic synthesis identified 3 major third order themes that centered around various levels of personal, interpersonal, and structural elements of stigma, discrimination, and disclosure and their role in ART adherence among PLHIVs. The review found that stereotypes around HIV necessitate concealment and undermine adherence. Non-disclosure and maintaining secrecy were highlighted as a means to protect one's reputation. Concerns around stigma, discrimination, and abandonment limited disclosure.

Those who disclosed reported feeling a sense of freedom from a guilty conscience. Many participants found that disclosure helped them adhere to their treatment and appointments.

Conclusions: Disclosure improves adherence and reduces the fear of stigma and discrimination among PLHIVs. Programs should implement interventions that increase clients' willingness to disclose their HIV status to their partners.

EPC305

Impact of Option B+ combination antiretroviral therapy on mother-to-child transmission of HIV-1, maternal and infant mortality rates; a 24-month prospective follow-up study at a primary healthcare clinic in Harare, Zimbabwe

L.S. Zijenah[1], T. Bandason[2], W. Bara[3], M.M. Chipiti[1]

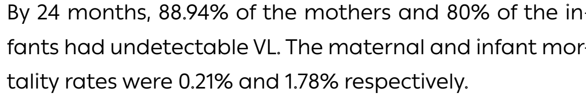
[1]University of Zimbabwe Faculty of Medicine and Health Sciences, Immunology, Harare, Zimbabwe, [2]Biomedical Research and Training Institute, Statistics, Harare, Zimbabwe, [3]Ministry of Health and Child Wellfare, Harare City Health, Harare, Zimbabwe

Background: In 2013, the World Health Organization recommended lifelong combination antiretroviral therapy (cART) for, treatment of maternal HIV disease and prevention of mother-to-child transmission of HIV (MTCT), dubbed Option B+.

We conducted a 24-month prospective follow-up study, at a primary healthcare clinic in Harare, Zimbabwe, to determine the MTCT rate, the contributions of intrauterine (IU), intrapartum (IP), and postpartum (PP) to MTCT , maternal and infant virologic responses to cART, as well as maternal and infant mortality rates in the era of Option B$^+$ cART.

Methods: Plasma for virus load (VL) quantitation was obtained from 475 mothers enrolled into the study. VL was quantified at enrolment and every 6 months thereafter up to 24 months using the Cepheid GeneXpert HIV-1 Quantitative test. Dried blood spots were collected from 453 infants at birth, 4-6 weeks, 3 months and every 3 months thereafter up to 24 months. HIV-1 infant diagnosis was conducted using the Cepheid GeneXpert HIV-1 Qualitative test. Absolute, cumulative MTCT rates and mortality rate were calculated.

Results: Seven mothers (1.55%) transmitted HIV-1 infection to their infants by 24 months. Four infants (0.88%; 95% CI, 0.26%-2.33%), 1 infant (0.22%; (95% CI, 0%-1.4%) and 2 infants 0.44%; 95% CI, 0.01%-1.7%) were infected IU, IP and PP respectively.



By 24 months, 88.94% of the mothers and 80% of the infants had undetectable VL. The maternal and infant mortality rates were 0.21% and 1.78% respectively.

Conclusions: In the first 24 months of life, IU transmission is the major route of MTCT. The cumulative MTCT rate of 1.55%, low maternal and infant mortality rates of 0.21% and 1.78% respectively contribute to growing evidence that Option B+cART not only drastically reduce MTCT but also maternal and infant mortality.

Innovative behavioural prevention interventions

EPC306
Engaging parents to create an enabling environment for young people's PrEP use: developing and field testing a new tool to supplement family strengthening programs

R. Dayton[1], M. Garcia[2], J. Arney[2], D. Chikoka[3], M. Kiruki[4], D. Nhamo[5], T. Mamvuto[5]
[1]FHI 360, HIV Division, Durham, United States, [2]FHI 360, Durham, United States, [3]Zimbabwe Health Interventions, Harare, Zimbabwe, [4]LVCT, Nairobi, Kenya, [5]Pangaea Zimbabwe AIDS Trust, Harare, Zimbabwe

Background: An incredible tool for HIV prevention — pre-exposure prophylaxis (PrEP) — continues to be underutilized among adolescent girls and young women (AGYW). AGYW's uptake and continuation of oral PrEP are affected by parental support, particularly if they still live with their parents. AGYW, implementers, parents, and researchers have all called for more parental involvement in PrEP programs, so that parents understand and can support their daughters' effective PrEP use.

Description: The USAID- and PEPFAR-supported CHOICE consortium developed a module to facilitate parental involvement: *Engaging Parents to Create an Enabling Environment for Young People's PrEP Use.* The module was informed by dialogues—with AGYW, parents participating in family strengthening programs, and program facilitators—and field tested in Kenya and Zimbabwe.

It can be paired with and leverages the *HIV Prevention Ambassador Training Package*, which is designed for young people. *Engaging Parents* contains seven activities — to be delivered together as one session in a larger curriculum-based family strengthening program — that introduce oral PrEP and the PrEP ring, counter common misconceptions, support parents to speak to their AGYW about PrEP, and encourage parents to reduce PrEP stigma from other adults.

Lessons learned: During dialogues, parents, facilitators, and AGYW shared priority topics (Figure 1) that were then integrated into the session. In field tests with 147 parents and 57 family strengthening program facilitators, pre- and post-tests showed that PrEP knowledge doubled: average knowledge scores rose from 33% to 68%. In addition, there was a dramatic increase in parents saying they would support their children's PrEP use, from 40% to 60%. Qualitative feedback suggested that participants would also share information with other adults in their social networks.

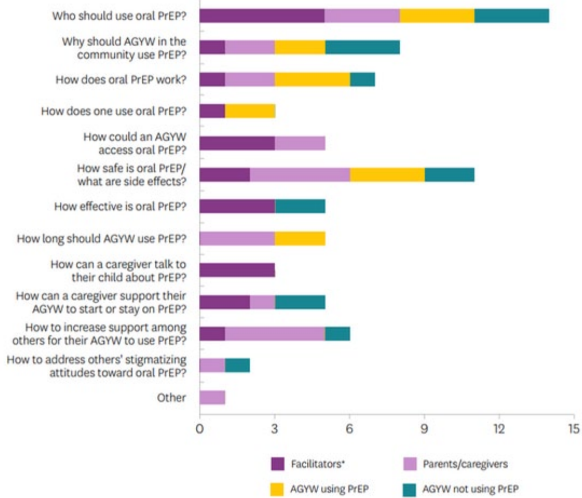


Figure 1. Topics identified as priorities for session inclusion in dialogues with facilitators, parents and AGYW.
** Unit of measurement is number of dialogues. Facilitator dialogue data reflects individual interviews in Zimbabwe and group discussions in Kenya. All other dialogues occurred with groups.*

Conclusions/Next steps: Parents can be an invaluable resource in making PrEP an accessible reality for AGYW. *Engaging Parents'* contributors are currently partnering with AGYW HIV programming across Africa to scale up the module.

EPC307
Refining POSSIBLE: a multicomponent intervention to increase HIV risk perceptions and PrEP initiation among Black Sexual Minority Men

D. Dangerfield II[1], J. Anderson[2], C. Wylie[1], R. Arrington-Sanders[3], R. Bluthenthal[4], C. Beyrer[5], J. Farley[1]
[1]Johns Hopkins School of Nursing, Baltimore, United States, [2]University of Tennessee Health Science Center, College of Nursing, Memphis, United States, [3]Johns Hopkins School of Medicine, Baltimore, United States, [4]Keck School of Medicine of the University of Southern California, Preventive Medicine, Los Angeles, United States, [5]Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

Background: Increased HIV pre-exposure prophylaxis (PrEP) initiation is urgently needed to substantially decrease the incidence among U.S. Black sexual minority men (BSMM). However, BSMM are less likely than other groups to accept a clinician's recommendation to initiate PrEP, and adherence remains suboptimal. Peers and smartphone apps are popular HIV prevention intervention mechanisms that are typically used independently. This study refined a multicomponent intervention using

a peer change agent (PCA) and a smartphone app called PrEPme to increase HIV risk perceptions (HRP) and PrEP willingness for referral among BSMM.

Methods: Data were obtained from 12 focus groups and one in-depth interview among BSMM from Baltimore, MD, between October 2019 and May 2020 (*N*=39).

Participants were eligible based upon the following criteria: self-identifying as a Black or African-American man, being ≥18 years of age, self-reporting being HIV-negative, having oral or anal intercourse with at least one male partner in the previous six months, and residing in Baltimore. Focus groups were stratified by age: 18-24, 25-34, and 35 and older. Facilitators probed on attitudes towards PrEPme, working with a PCA in the intervention, and preferences for PCA characteristics.

Data analysis consisted of reflexive debriefing among the facilitators and thematic analysis using an adapted pile sorting approach.

Results: Most participants self-identified as homosexual, gay, or same gender-loving (68%), were employed (69%), single (66%), and interested in using the app to self-monitor sexual risk behaviors (68.4%). Across all age groups, participants had low HRP despite disclosing high-risk behaviors. They also suggested that using the app to self-monitor sexual behaviors could trigger internalized stigma by increasing their consciousness of HIV risk behaviors. The PCA was highly accepted and endorsed as an interventionist. Participants also expressed that an acceptable PCA should be a "possible self" who was using PrEP to inspire BSMM and reduce concerns regarding efficacy and side effects.

Conclusions: The PrEPme app and its self-monitoring sexual health functionality was acceptable despite participants endorsing that monitoring their sexual health might increase internalized stigma. A PCA is an important part of the healthcare team for BSMM. Increasing HIV risk perception and PrEP implementation using multi-component strategies requires further research.

EPC308

Partner notification for persons diagnosed with HIV/STIs in community pharmacies in Uganda: lessons learned for future HIV/STI control interventions

A. Onzia Aketoko[1], R. Parkes-Ratanshi[1], Y. Manabe[2], M. Hamill[2], E. Laker[1], A. Kiragga[1]

[1]*Makerere University, Infectious Diseases Institute, College of Health Sciences, Research, Kampala, Uganda,* [2]*Johns Hopkins University, Medicine/Microbiology, Baltimore, United States*

Background: After effective treatment, persons diagnosed with a sexually transmitted infections (STIs) are encouraged to modify behaviour and notify partners. Partner notification for testing and treatment is a challenge in resource-limited settings (RLS) due to factors including fear of blame, relationship breakup, lack of STI knowledge and poor communication skill. This ultimately leads to failure of treatment, reinfection and a vicious cycle of STI spread among sexual networks in communities.

Description: A project that aims to assess feasibility of community pharmacies/drug stores for HIV/STI testing in Uganda is collecting blood and urogenital samples from symptomatic and asymptomatic persons seeking across the counter treatments for different ailments including STI-like symptoms. Samples are tested using point of care (POC) diagnostics for *Neisseria gonorrhoeae* (NG), *Chlamydia trachomatis* (CT), *Trichomonas vaginalis* (TV), Syphilis and HIV.

HIV/STI positive participants receive treatment, and are randomised to either standard of care (SOC) arm where they receive an HIV/STI information leaflet and partner notification slip ;or the assisted partner notification (APN) arm using Call 4 life (C4L) arm where they receive automated phone calls and a partner notification slip both aimed at prompting and encouraging partner notification (PN). They are then followed up in person and using automated phone calls on days 30 and 90 post-enrollment to ascertain treatment completion,partner notification and symptom resolution.

Lessons learned: 200 participants have been recruited for this study.47(23.5%) had at least one STI with 23 randomised to the C4L arm and 24 to the SOC arm. PN was at 15(65%) and 11(45%) for C4L and SOC respectively. PN was especially poor (15%) among asymptomatic participants who has been diagnosed with an STI as compared to symptomatic ones (36.7%).

Follow-up visits on days 30 and 90 showed overall poor partner testing and treatment rates (16%). 46.8% of participants reported they had no intention of notifying their partners citing various reasons.

Conclusions/Next steps: PN was low in this population many of whom reported risky sexual behaviour although treatment completion rate and follow-up visits was high for index participants across both arms. Innovative ways to incentivize PN especially among asymptomatic persons like the Call 4 life system are necessary in future HIV/STI control interventions.

EPC309

Real-time monitoring andjust-in-time interventionfor adherence to pre-exposure prophylaxis among men who have sex with men in China: a multicentre RCT study

X. Jin[1], J. Xu[2]

[1]*AIDS Healthcare Foundation, Beijing, China,* [2]*China Medical University, Shenyang, China*

Background: PrEP has been demonstrated to be effective to prevent transmission of HIV infection, although medication adherence remains a challenge.

Methods: A multicentre RCT study was conducted at four hospital-based clinics in four cities of China from September 2019 to December 2020. 422 MSM PrEP users were

randomized to electronic monitors intervention (n=247) or control (n=195). The intervention participants were provided with real-time monitoring equipment that triggers twice just-in-time SMS (Short Messaging Service) medication reminders to PrEP users every half an hour when a scheduled dosage is missed and followed with just-in-time SMS medication reminders to clinicians half an hour when there is no supplement after the second just-in-time SMS reminder.

Clinicians will initiate individualised telephone intervention as soon as possible upon receipt of the just-in-time SMS missed dose alert. The control participants only received generic weekly SMS reminders. Trial outcomes to be measured by adherence (tenofovir plasma levels) at 3 and 6 months.

Results: 516 MSM were screened to recruit 442 participants. Median age was 31 years old, 81.7% had completed college, 52.5% were single, and 70.6% had a monthly income less than 1,200 USD. Plasma tenofovir levels were significantly higher in the intervention group in both daily and ED MSM PrEP users using mixed linear model analysis.

By 3 months, the intervention daily group continued to have drug levels consistent with TDF/FTC use was 86.4% (81.4%-90.2%), while the comparison group was only 71.8% (64.0%-78.5%) had similar levels (p=0.0006); the intervention ED group continued to have drug levels consistent with TDF/FTC use was 80.8% (72.8%-86.8%), while the comparison group was only 64.4% (55.1%-72.6%) had similar levels (p=0.006).

By 6 months, the intervention daily group continued to have drug levels consistent with TDF/FTC use was 85.8% (81.9%-89.0%), while the comparison group was only 70.9% (64.9%-76.2%) had similar levels (p<0.0001); the intervention ED group continued to have drug levels consistent with TDF/FTC use was 80.5% (74.0%-85.7%), while the comparison group was only 68.0% (60.1%-74.9%) had similar levels (p=0.010).

Conclusions: A real-time monitoring and just-in-time intervention system could be utilized for improving adherence of daily and ED PrEP users, and thus effectiveness of PrEP application.

EPC310
Prevention of HIV among convicts

M. Bondarenko[1]
[1]Charitable Organization "Light of Hope", Public Health Department, Poltava, Ukraine

Background: The COVID-19 pandemic has made adjustments to progress in tackling the HIV / AIDS epidemic. Convicted and imprisoned citizens felt this most acutely. This situation complicates the access of prisoners and convicts in penitentiaries, including HIV-positive, viral hepatitis and tuberculosis patients, to health care provided by NGOs. This, in turn, makes it difficult for health professionals to motivate HIV diagnosis, adhere to treatment for ART and hepatitis, and engage HIV-positive clients in index testing. Based on this, it was important to ensure continuity in the provision of health services for quality social support to clients in the prevention and treatment of HIV, TB, viral hepatitis.

Description: We were able to ensure unimpeded access to preventive services by introducing the position of a social worker in the medical staff of the State Institution "Poltava Penitentiary Institution (№23). As part of the preparatory process, an analysis of regulations and barriers to changes in the staffing of the Poltava City Medical Unit № 23 were made.

Then we advocated for changes in the staffing of the Poltava City Medical Unit № 23, prepared a draft regulation on the establishment of a multidisciplinary team, held a series of working meetings. After the introduction of a social worker, we continue to provide mentoring support to the institution.

Lessons learned: The covid pandemic has made it clear that it is time to look for alternative and innovative ways to prevent HIV in penitentiaries in particular. The introduction of a social worker has made it possible to ensure unhindered access to prevention services for the target group.

Conclusions/Next steps: this case can be an example for the whole of Ukraine. To date, we have a proven algorithm for the introduction of a social worker in the staff, proven efficiency, economic feasibility and seek to spread this successful experience to other regions.

EPC311
A systematic review of technology-based interventions promoting sexual health outcomes of adolescents and young people (10–24 years) in sub-Saharan Africa

T. Nyoni[1], S. Mwima[2], M. Okumu[3]
[1]University of Toronto, Factor-Inwentash Faculty of Social Work, Toronto, Canada, [2]University of Illinois, Urbana-Champaign, School of Social Work, Urbana, United States, [3]University of Illinois, Urbana-Champaign, School of Social Work, Urbana, IL, United States

Background: Technology-based interventions could address the growing sexual health needs of adolescents/young people in sub-Saharan Africa – a region disproportionately affected by HIV. However, no known systematic review has examined the effectiveness and methodological rigor of these interventions. Therefore, this review addressed:

1. What is the most common delivery strategy?
2. What are the most common sexual health-related outcomes evaluated in these interventions?
3. What is the methodological rigor of technology-based intervention studies?
4. Are technology-based interventions effective, and for which outcomes?

Methods: A systematic search of 9 databases was conducted to identify peer-reviewed articles on intervention studies that were:
1. Conducted in SSA,
2. Quantitative evaluations of technology-based interventions to promote sexual health, and;
3. Focused on or included AYPs between ages 10-24, and
4. Reported sexual outcomes.

The methodological rigor of the studies was evaluated using the Methodological Quality Rating Scale (MQRS). A median split of MQRS scores established high versus medium-to-low-rigor studies. Data extracted from studies included study design, sample description, delivery strategy, interventions components, sexual health outcomes, and results.

Results: Of the nine intervention studies included, intervention delivery strategy included: SMS (n=4), internet/computer-based (n=3) and game-based learning (n=2). Despite different delivery strategies, all the interventions (n=9) provided sexual health information and knowledge.

Measured sexual health outcomes included sexual health knowledge (n=7), condom use (n=4) and abstinence (n=4), and HIV testing (n=1). The MQRS results indicated that methodological rigor was high for most studies (n=5), with a median score of 13 on a 22-point scale.

The major methodological strengths of the studies were the use of RCT study design (n=7), discussing the reliability and validity of measures (n=9), and a longer follow-up duration than the intervention(n=8). Methodological weaknesses included follow-up assessments of >12 months (n=8), delivering only one intervention component (n=8), and conducting interventions in a single site (n=7). Overall, most interventions (n=7) significantly improved levels of sexual health knowledge among adolescents/young people.

Conclusions: Our findings support the effectiveness of digital technology-based interventions in improving sexual health knowledge. There is a need for multi-component technology-based interventions that go beyond cognitive change to address contextual drivers of HIV.

Structural HIV prevention interventions

EPC312
Food security reduces multiple HIV infection risks for adolescent mothers and non-mothers in South Africa

L. Cluver[1,2], W. Rudgard[1], E. Toska[3], M. Orkin[4], M. Ibrahim[1], N. Langwenya[1], C. Kuo[5], N. Xaba[6], K. Roehm[6], M. Smith[7], S. Bernardini[7], G. Giordana[6], M. Mumma[6], J. Kingori[6], R. Yates[1], L. Sherr[8]
[1]University of Oxford, Department of Social Policy and Intervention, Oxford, United Kingdom, [2]University of Cape Town, Department of Psychiatry and Mental Health, Cape Town, South Africa, [3]University of Cape Town, Department of Psychiatry and Mental Health and Centre for Social Science Research, Cape Town, South Africa, [4]University of the Witwatersrand, Medical Research Council Development Pathways to Health Research Unit, School of Clinical Medicine, Johannesburg, South Africa, [5]Brown University, Providence, Department of Behavioral and Social Sciences, School of Public Health, Rhode Island, United States, [6]UN World Food Programme Regional Bureau for Southern Africa, Johannesburg, South Africa, [7]UN World Food Programme, Johannesburg, South Africa, [8]University College London, London, United Kingdom

Background: Adolescent mothers in Southern Africa experience high HIV seroconversion and transmission. We need to identify whether poverty is driving these risks, to develop effective responses.

Methods: A cross-sectional study of1712 adolescent girls (11-25 years) in South Africa's Eastern Cape Province in 2018-19. We measured HIV risk behaviours: multiple sexual partners, transactional sex, age-disparate sex, unprotected sex, sex on substances, alcohol, and school non-enrolment; household food security, and covariates. Analyses used generalised estimating equations with a logit link, and adjusted probability differences.

Results: 46% ofadolescent girls were living with HIV (mean age 17.51 years, SD: 2.54), 61% were adolescent mothers. Compared to non-mothers, adolescent mothers had lower alcohol use (AOR: 0.47, CIs:0.29-0.75), but higher multiple sexual partners (AOR: 1.93, CIs:1.36-2.74), age-disparate sex (AOR: 3.26, CIs:2.13-4.99), unprotected sex (AOR: 8.19, CIs:6.03-11.12), school non-enrolment (AOR: 3.07, Cis:2.21-4.26), and sex on substances (AOR: 1.89, CIs:1.11-3.23). Household food security was highly protective for both groups (Figure 1).

Amongst non-mothers, household food security was associated with less multiple sexual partners (AOR: 0.45, CIs:0.26-0.78), transactional sex (AOR: 0.32, CIs:0.12-0.81), and school non-enrolment (AOR: 0.6, CIs:0.37-0.99). Amongst adolescent mothers, household food security was associated with less transactional sex (AOR: 0.17, CIs:0.1-0.28), age-disparate sex (AOR: 0.66, Cis:0.47-0.92), school non-enrolment (AOR: 0.57, CIs:0.41-0.79), sex on substances (AOR: 0.51, CIs:0.32-0.82), and alcohol use (AOR: 0.45, CIs:0.25-0.76).

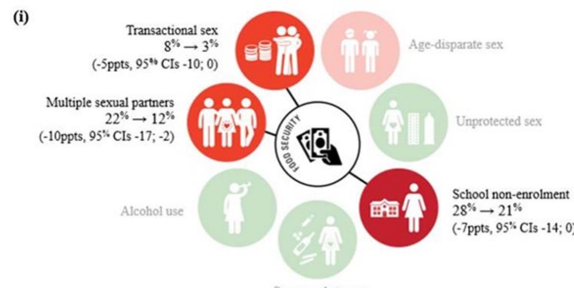
Author Index



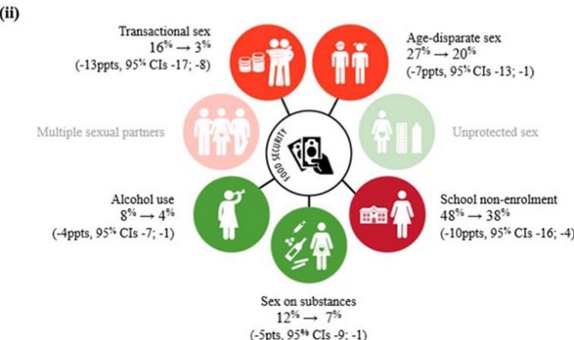


Figure 1: Reductions in HIV-infection and transmission risks for i) adolescent non-mothers and ii) adolescent mothers.

Conclusions: Adolescent motherhood exacerbates vulnerabilities to HIV-infection and transmission. Leveraging social protection to increase access to sufficient food is likely to reduce HIV-risk pathways for adolescent girls and young women, with most numerous impacts for adolescent mothers.

Other new HIV prevention tools

EPC313

Potential end-user and community-level perspectives on new biomedical HIV prevention methods in Zimbabwe

F.M. Simmonds[1], T. Mamvuto[1], D. Nhamo[1], E. Gwavava[1], J. Murungu[1], I. Mahaka[1], S. Napier[2], K. Williams[2]

[1]Pangaea Zimbabwe AIDS Trust, Harare, Zimbabwe, [2]FHI 360, Durham, United States

Background: Zimbabwe is considering new biomedical HIV prevention methods, such as the dapivirine vaginal ring (PrEP Ring) and injectable cabotegravir (CAB-LA), to increase client choice. We spoke with potential end-users and community influencers to gain a better understanding of their needs and concerns about these methods and to inform introduction and rollout efforts using lessons from experiences with oral PrEP.

Description: We conducted 7 group conversations with 71 purposively selected participants who provided verbal consent. Participants included 51 potential end-users (adolescent girls and young women (AGYW), adult women, and female sex workers and 20 community influencers (parents of AGYW, village health workers, and religious and political leaders). Thirty-seven of the potential end-users were current or former oral PrEP users. Detailed notes and audio recordings of the conversations were summarized using Microsoft Excel with common themes identified by participant type.

Lessons learned: Both potential end-users and community influencers thought women would use the ring and CAB-LA because they are discreet, long-acting, and do not require daily adherence. They also cited concerns about the ring, including its relatively lower efficacy, discomfort with a vaginally inserted product, and the possibility of it being felt or dislodged during sex, resulting in involuntary disclosure.

Nine end-users reported stopping oral PrEP due to stock-outs, negative attitudes from health care providers, COVID-19 restrictions and related clinic closures. Helpful strategies for effective oral PrEP use cited by potential end-users included:

Programmatic area	Strategy
Client follow-up	• Routine/periodic follow up by health care providers and lay cadres • Reminders such as phone calls or texts from providers • Support from peers and family (including PrEP champions)
Commodity supply	• Uninterrupted commodity supply
Service delivery (in the context of COVID-19 restrictions and related clinic closures)	• Community based service delivery models including outreach services or home visits for drug delivery.

Table.

Potential end-users preferred integrated PrEP and FP services with synchronized clinic visits for both services. AGYW mentioned non-traditional delivery channels, such as retail shops and key population-friendly spaces (e.g., youth drop-in centres), as potential options to access PrEP services.

Conclusions/Next steps: Potential end-users and community influencers in Zimbabwe expressed desire for expanded PrEP service delivery channels and communication highlighting the benefits of new prevention products. Provision of clear messages addressing community and potential end-user concerns on the products will help optimize uptake and effective use. Leveraging strategies for effective oral PrEP use will be key to successful implementation of new biomedical methods.

EPC314

Considerations for the delivery of new biomedical HIV prevention methods: Zimbabwe healthcare provider perspectives

T. Mamvuto[1], F.M. Simmonds[1], D. Nhamo[1], E. Gwavava[1], J. Murungu[1], I. Mahaka[1], S. Napier[2], K. Williams[2]
[1]*Pangaea Zimbabwe AIDS Trust, Harare, Zimbabwe,* [2]*FHI 360, Durham, United States*

Background: Women in Zimbabwe continue to be disproportionately affected by HIV despite available prevention methods, including oral pre-exposure prophylaxis (PrEP). Expanded method choice has the potential to increase the overall uptake of PrEP, especially among adolescent girls and young women. As Zimbabwe considers adopting emerging PrEP methods such as the dapivirine vaginal ring (the ring) and injectable cabotegravir (CAB-LA), effective service delivery strategies need to be considered. We gathered perspectives from healthcare providers (HCPs) on implementation considerations that should be addressed to effectively deliver multiple biomedical HIV prevention methods in Zimbabwe.

Description: We conducted 20 in-person conversations with HCPs (12 oral PrEP and 8 family planning [FP] providers) using thematic discussion guides. The 20 HCPs were drawn from public, private, and church-based facilities, and pharmacies. Detailed notes and audio recordings of the conversations were consolidated into a Microsoft Excel table. Commonly occurring themes by HCP type were identified.

Lessons learned: All HCPs welcomed new PrEP methods because they expand options for clients and will likely increase uptake. Public sector providers were worried about the potential of increased workloads given current staffing shortages. Public providers suggested removing user fees and establishing user support groups for improved service uptake and continuity. Providers came up with implementation considerations around counseling, service integration, tools and support materials to aid implementation. Their suggestions are highlighted in the table below:

Implementation consideration	Main issues with some suggestions for improvement
Counseling	• PrEP providers mentioned that counseling around varying user requirements for multiple methods would be time-consuming. • FP providers reported familiarization with counseling on multiple FP methods as well as FP products with varied efficacy.
Service Integration	• All providers, particularly those from pharmacies and church-based facilities, welcomed integration of FP and HIV prevention services. • FP providers anticipated challenges with clients who opt to receive CAB-LA and the two-month contraceptive injections and suggested the synchronization of visits to reduce client burden. • Oral PrEP providers in larger public and private facilities suggested PrEP be offered across multiple departments to improve client flow and efficiency of service delivery.
Tools and support Materials	• Both PrEP and FP providers desired additional training on new products and follow-up systems, samples of products for demonstrations during counseling, and educational materials such as posters and pamphlets to support client decision-making.

Table.

Conclusions/Next steps: HCPs who participated in our conversations expressed a need for trainings, tools, and support materials to provide comprehensive counseling on multiple PrEP methods.
Ensuring adequate HCPs, particularly in public health facilities, will ensure effective service delivery of multiple PrEP methods. PrEP and FP services need to be integrated and delivered across multiple access points whilst ensuring the synchronization of visits for FP and PrEP products.

EPC315

Obstacles to using event-driven (2-1-1) PrEP: exploring the role of reported barriers on PrEP dosing choice in a national US sample

P. Botti Carneiro[1], V. Patel[2], C. Grov[1]
[1]*CUNY School of Public Health, New York, United States,* [2]*Albert Einstein College of Medicine, New York, United States*

Background: The CDC has released, inclusive of event-driven PrEP, or PrEP-211 – an effective dosing regimen, untested in US populations, outside of small trials. While individuals in the US may choose to use their daily PrEP prescription*on-demand*, this use is considered off-label in the US.
With the rollout of new dosing regimens of PrEP, it is imperative that we understand how current off-label users may make choices about their dosing regimen.

Methods: Our sample includes current PrEP users (n=875) from the US—both daily users and those who reported 211 use.
We conducted a bivariate analysis of individuals who regimen choice (daily vs 211), including demographic, provider dosing recommendation, and reported barriers experienced since initiation.
We built univariate and adjusted logistic models predicting how self-reported barriers predicted PrEP-211 choice among individuals who self-selected into PrEP-211 (i.e., chose 211 despite medical provider recommendation for daily).

Results: Our overall sample had 875 PrEP users, about 10% (*n*=89) were following 211 dosing. PrEP-211 users were more concentrated in the northeast (27% vs. 15.4% daily users) and selected this PrEP dosing regardless of their provider recommendation for daily PrEP (62% PrEP 211 vs. 99.6% daily users).
Additionally, PrEP-211 users were significantly more likely to report experiencing side effects and adherence issues (See Table 1).
Table 2 provides our univariate and adjusted regression models predicting choice of PrEP-211 among users whose providers recommended daily PrEP (*n*=838, PrEP 211=6.5%).
Among self-selection PrEP-211 users reporting adherence issues, the odds of PrEP-211 choice were 2 times that of choosing daily PrEP (aOR=2.14 95%CI 1.18-3.92).

Table 2. Logistic regression models predicting odds of PrEP 211 choice among self-selection participants who reported barriers since initiation (n = 838 PrEP 211 = 55 or 6.5%)

Models	OR	95% CI	aOR*	95% CI
Model 1 and 1a: Side effects	1.60	0.86 - 2.95	1.48	0.59 - 3.68
Model 2 and 2a: Adherence	2.16	1.20 - 3.86	2.14	1.18 - 3.92
Model 3 and 3a: Paying for PrEP	1.5	0.57 - 3.93	1.63	0.61 - 4.36
Model 4 and 4a: Following-up and receiving care	1.81	0.69 - 4.72	1.84	0.68 - 4.94
Model 5 and 5a: Health insurance issues	1.85	0.84 - 4.08	1.78	0.79 - 4.00

*Adjusted models are controlled for age groups, gender, geographic location and race/ethnicity

Conclusions: Our study shows that, for participants who reported any adherence issue since initiation, PrEP-211 dosing choice was significantly more likely than daily dosing. This was done despite a provider recommendation, which shows that considering the patient feedback is key to an effective rollout of new PrEP regimens.

EPC316
A qualitative inquiry on potential barriers to provision and use of the PrEP ring in Kenya

M.M. Kiruki[1], P. Jeckonia[2], J. Mugambi[2], H. Burke[3], A. Cole[4], M. Garcia[4]

[1]LVCT Health, Research and Strategic Information, Nairobi, Kenya, [2]LVCT Health, HIV Prevention, Nairobi, Kenya, [3]Family Health International 360, Reproductive, Maternal, Newborn, and Child Health (RMNCH), Durham, United States, [4]Family Health International 360, HIV Prevention Programs, Durham, United States

Background: Although Kenya has made great strides in controlling the HIV epidemic among some populations, women and key populations such as female sex workers (FSWs) continue to be disproportionately affected. New long-acting HIV prevention methods in the pipeline, such as the dapivirine vaginal ring (PrEP ring), may help reach these key communities. LVCT Health engaged stakeholders to understand potential barriers to the provision and use of the PrEP ring.

Description: From May to July 2021, we held one-on-one and group dialogues with HIV prevention service clients (18 young women aged 18-29 years and 17 FSWs aged 21-42 years) and 22 HIV and Family Planning (FP) healthcare providers (HCPs) selected from LVCT Health programs or affiliated public facilities in the Nairobi and Lake regions. Conversations were audio-recorded and thematic analysis was conducted using a two-step rapid analysis process.

Lessons learned: Young women and FSWs described misconceptions about the PrEP ring, including worries that it may fall out, get stuck, or disappear into the body. Young women predicted difficulties in self-insertion and removal of the ring and wondered whether use during sexual intercourse could be discreet. FSWs and HCPs were concerned about the ring's lower efficacy compared to that of oral PrEP. HIV prevention providers were also worried that some women may face challenges practicing good hygiene during insertion and may get infections as a result. FP health providers expressed misconceptions, including that the PrEP ring should be contraindicated for women with multiple sexual partners to reduce the risk of recurrent sexually transmitted infections. They also had misconceptions about side effects, fearing that ring use would cause a long-term increase in vaginal discharge, which would negatively affect the sexual activities health of users.

Conclusions/Next steps: PrEP ring education efforts in Kenya should proactively address multiple reported misconceptions and incorporate product demonstrations of this important addition to the HIV prevention methods basket. Early education of HCPs on the new method and training in practical counseling skills will be key to community understanding and acceptance of the PrEP ring and will enable providers to support users to make informed choices based on their needs and lifestyles.

EPC317
Attitudes and Beliefs regarding an HIV preventive vaccine among sexual and gender minorities in Brazil

T.S. Torres[1], P.M. Luz[1], S.P. Giozza[2], I. Brito[2], C. Pimenta[2], B. Grinsztejn[1], V.G. Veloso[1]

[1]Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz, Rio de Janeiro, Brazil, [2]Ministério da Saúde do Brasil, Brasilia, Brazil

Background: Brazilians have a long-term history of high acceptability of vaccines including, more recently, COVID-19 vaccine. However, fake news, science mistrust, and conspiracy beliefs have emerged globally in recent years, including in Brazil. We explored attitudes and beliefs regarding HIV prevention vaccines among Brazilian sexual and gender minorities (SGM).

Methods: Cross-sectional online survey (July-August 2021) among SGM aged ≥18 years, self-reported HIV negative/unknown status, living in Brazil, and recruited on Grindr, Hornet and Facebook/Instagram. We administered six scales related to HIV knowledge, vaccine-related issues (confidence, conspiracy beliefs, altruism, and social concern), and risk compensation.

We used a 4-point Likert scale to assess willingness to use an HIV preventive vaccine with the question: "Would you use a vaccine to prevent HIV?". Response options were dichotomized: yes = "highly likely" and no = all other re-

	Willingness to use HIV preventive vaccine			
	Total N=3422	Yes N=2634	No N=798	p-value
HIV knowledge scale (12-items; total score rage:0-12; mean, standard deviation)	11.1 (1.2)	11.2 (1.1)	10.9 (1.4)	<.001
Vaccine confidence Index (yes; n, %)				
1-Overall, I think vaccines are important for adults to have.	3359 (97.9)	2589 (98.3)	770 (96.5)	0.002
2-Overall, I think vaccines are safe.	3315 (96.6)	2581 (98.0)	734 (92.0)	<.001
3-Overall, I think vaccines are effective.	3342 (97.4)	2592 (98.4)	750 (94.0)	<.001
4-Vaccines are compatible with my religious beliefs.	3133 (91.3)	2440 (92.6)	693 (86.8)	<.001
Vaccine conspiracy beliefs (scores range 1-7 per item; mean, standard deviation)				
1-Vaccine safety data is often fabricated.	1.8 (1.3)	1.6 (1.2)	2.3 (1.5)	<.001
2-Immunizing children is harmful and this fact is covered up.	1.5 (0.9)	1.4 (0.8)	1.8 (1.1)	<.001
3-Pharmaceutical companies cover up the dangers of vaccines.	2.2 (1.5)	2.0 (1.4)	2.7 (1.6)	<.001
4-People are deceived about vaccine efficacy.	1.9 (1.3)	1.7 (1.2)	2.4 (1.5)	<.001
5-Vaccine efficacy data is often fabricated.	1.7 (1.1)	1.5 (0.9)	2.1 (1.3)	<.001
6-People are deceived about vaccine safety.	1.8 (1.2)	1.6 (1.1)	2.3 (1.4)	<.001
7-The government is trying to cover up the link between vaccines and autism.	1.9 (1.3)	1.8 (1.2)	2.4 (1.5)	<.001
Total Composite Mean Score (standard deviation)	1.8 (1.0)	1.7 (0.9)	2.3 (1.2)	<.001
Vaccine Altruism (scores range 1-4 per item; mean, standard deviation)				
1-I would get an HIV vaccine even if I thought the vaccine might not protect me 100% against HIV infection.	3.3 (1.0)	3.5 (0.9)	2.6 (1.0)	<.001
2-I would get an HIV vaccine that would prevent me from being able to infect other people with HIV, even if the vaccine might not protect me against HIV.	3.1 (1.0)	3.3 (1.0)	2.6 (1.0)	<.001
3- I would be one of the first people to get an HIV vaccine.	3.2 (1.0)	3.4 (0.9)	2.5 (0.9)	<.001
4- My willingness to get an HIV vaccine is important for the good of all people.	3.5 (0.9)	3.7 (0.7)	2.9 (1.0)	<.001
Total Composite Mean Score (standard deviation)	3.3 (0.8)	3.5 (0.7)	2.6 (0.8)	<.001
Vaccine Social Concern (scores range 1-4 per item; mean, standard deviation)				
1- I would be concerned about how my family might react to my getting an HIV vaccine.	3.2 (0.9)	3.3 (0.9)	2.9 (0.9)	<.001
2-I would be concerned about how my sexual partner or partners might react to my getting an HIV vaccine.	3.3 (0.9)	3.4 (0.8)	3.0 (0.9)	<.001
3-I would be concerned about confidentiality (others finding out) if I received an HIV vaccine.	3.1 (1.0)	3.2 (1.0)	2.8 (0.9)	<.001
4-I would be concerned that getting an HIV vaccine would affect my ability to get health insurance.	3.0 (1.0)	3.1 (1.0)	2.7 (0.9)	<.001
5-I would be concerned that getting an HIV vaccine would lead to discrimination against me.	3.2 (0.9)	3.3 (0.9)	2.8 (0.9)	<.001
6-It concerns me that if I were to get an HIV vaccine, the HIV antibody test might show me as being HIV- positive.	2.5 (1.0)	2.6 (1.0)	2.2 (0.9)	<.001
Total Composite Mean Score (standard deviation)	3.1 (0.7)	3.2 (0.7)	2.7 (0.6)	<.001
Risk compensation (scores range 1-4 per item; mean, standard deviation)				
1-Getting an AIDS vaccine means you can have sex without using condoms.	3.4 (0.7)	3.4 (0.7)	3.2 (0.7)	<.001
2-An AIDS vaccine will make safer sex less important.	3.2 (0.8)	3.3 (0.8)	3.1 (0.8)	<.001
3-If I get an AIDS vaccine, I would be more likely to have sex without using a condom.	2.8 (0.9)	2.8 (0.9)	2.8 (0.8)	0.45
4-HIV/AIDS will no longer be a threat when there is an AIDS vaccine.	2.6 (0.9)	2.6 (0.9)	2.6 (0.8)	0.91
5-Everyone who gets an AIDS vaccine will be protected against HIV/AIDS.	2.4 (0.8)	2.4 (0.8)	2.5 (0.7)	<.001
Total Composite Mean Score (standard deviation)	2.9 (0.6)	2.9 (0.6)	2.8 (0.5)	0.022

EPC317 Table.

sponses. We compared scales scores and participant's characteristics according to the willingness to use HIV prevention vaccine (yes vs. no) using chi-square or t-tests, as applicable.

Results: Among 3432 SGM included, median age was 33 years [IQR:27-41], 455 (13.3%) aged 18-24 years, 3351 (97.6%) cisgender men, 1270 (37.0%) Black/Mixed-Black, 2407(70.1%) >secondary education, 2314(67.4%) from Southeast region, and 1477(45.2%) were Christian. Most (2774; 80.8%) reported awareness of HIV vaccines under research. A total of 2634(77.0%) reported willingness to use HIV preventive vaccine. Most respondents reported confidence in vaccines with higher scores among those willing to use an HIV prevention vaccine (Table).

Higher scores for HIV Knowledge, vaccine altruism, vaccine social concern, and risk compensation scales were observed among those willing to use it vs. not. Scores for vaccine conspiracy beliefs items were low overall, but lower among those willing to use an HIV prevention vaccine.

Conclusions: SGM showed positive attitudes and beliefs regarding an HIV prevention vaccine. Willingness to use HIV prevention vaccine was very high considering that no HIV vaccine is currently available. Continuous educational campaigns are essential to avoid mistrust in vaccines.

EPC318

Acceptability of broadly neutralizing antibodies (bNAbs) for HIV prevention: a qualitative investigation among Adolescent Girls and Young Women (AGYW) in India

V.S. Mahendra[1], R. Nelson[1], M. Shunmugam[1], S Alwin[1], J. Mukherjee[2], P. Aggarwal[2], S. ul Hadi[2], V. Chakrapani[1]
[1]*Centre for Sexuality and Health Research and Policy (C-SHaRP), Chennai, India,* [2]*IAVI, New Delhi, India*

Background: Broadly neutralizing monoclonal antibodies (bNAbs) have fuelled optimism for a new HIV prevention product. We conducted a qualitative study among a vulnerable and potential end-user population – adolescent girls and young women (AGYW) – to understand their preferences for product attributes and contextual/behavioral factors that might influence the uptake of bNAbs.

Methods: In 2021, an exploratory qualitative study (6 focus groups and 9 in-depth interviews) was conducted among AGYW in three Indian metro cities. Data were explored using framework analysis, guided by the Theoretical Framework of Acceptability.

Results: Participants' (n=46) mean age was 21 years; the majority had completed higher-secondary education, and two-thirds were single. None had heard of bNAbs pri-

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

or to this study; however, once explained, many expressed interest in using it. While most AGYW considered bNAbs as appropriate for sex workers, they also felt it could benefit at-risk AGYW from contracting HIV. Key preferred product attributes included high efficacy (>90%), low cost, no side-effects, quarterly administration of intramuscular injections (on the arm by a healthcare provider).

Some expressed concerns about administering bNAbs injection during pregnancy and early infancy, fearing that it could harm the fetus and infant. Most preferred government hospitals to receive bNAbs as they thought it would be free there.

However, given the lack of freedom of mobility for AGYW, some preferred obtaining bNAbs from nearby private clinics or NGOs. Most single women feared that their character would be questioned for seeking HIV prevention products.

To avoid negative consequences, most single AGYW opined that they would not disclose their decision to take bNAbs to their family/partners; however, married women wanted to inform their husbands to avoid relationship discord.

Conclusions: To facilitate uptake of bNAbs among AGYW, as part of combination HIV prevention, it is essential to provide comprehensive and accurate information about efficacy, safety (especially for fetus/infants), and mode and site of administration.

At the social-structural level, engagement with the families of AGYW and communities is essential to challenge existing social norms on women's sexual life and reduce HIV-related stigma, which in turn can facilitate uptake of bNAbs among at-risk AGYW.

EPC319

Lactobacillus spp interaction with neat and formulated Griffithsin, a candidate for topical HIV prevention

O.E. Asowata[1], P. Barnable[1], M. Aravantinou[1], T. Bonnaire[1], H. Ahmed[1], B.R. O'Keefe[2], J.A.F. Romero[1,3], N. Teleshova[1]

[1]*Center for Biomedical Research, Population Council, New York, United States,* [2]*National Cancer Institute, Molecular Targets Program, Center for Cancer Research, and Natural Products Branch, Developmental Therapeutics Program, Division of Cancer Treatment and Diagnosis, Frederick, United States,* [3]*The City University of New York, Science Department, Borough of Manhattan Community College, New York, United States*

Background: The Population Council is developing Griffithsin (GRFT), a non-antiretroviral lectin with outstanding anti-HIV activity, as topical PrEP for on-demand use or sustained delivery. Phase 1 trial of GRFT formulated in a carrageenan vaginal gel demonstrated that the gel was safe and GRFT released in vaginal fluids was active against HIV. Previous studies reported high GRFT binding in cervico-vaginal fluids from women with *Lactobacillus*-predominant flora, which could reduce GRFT availability and impact activity. Here we evaluated (i) effect of neat and formulated GRFT on *Lactobacillus* viability and (ii) effect of *Lactobacillus* on GRFT concentrations and anti-HIV activity.

Methods: *L. jensenii* and *L. crispatus* were exposed to neat GRFT for 30 minutes and 24 hours and to diluted gels (starting at 1:100 dilution) for 30 minutes at 37°C and 5% CO_2. The viability of *Lactobacillus spp* was determined based on colony-forming unit (CFU) using methodology that allows to detect 1 Log10 decrease in CFU. GRFT concentrations after incubation with *L. jensenii* were quantified using UPLC-MS. Anti-HIV-1_{BaL} activity of GRFT following incubation with *L. jensenii and L. crispatus* was tested in TZM-bl cells.

Results: GRFT at 100 ng/ml did not decrease the viability of *L. jensenii* and *L. crispatus*. Similarly, incubation with diluted GRFT/carrageenan gels did not decrease *L. jensenii* viability. Although incubation with *L. jensenii* led to only limited decrease in GRFT concentrations, anti-HIV activity of GRFT in the presence of *L. jensenii* and *L. crispatus* supernatants was almost completely blocked ($p<0.05$).

Conclusions: Our data indicate that *Lactobacillus* impacts GRFT activity without significantly changing GRFT concentrations. Lack of GRFT and GRFT/carrageenan gel toxicity in *Lactobacillus spp* confirms the safety of this lectin. These data support further development of GRFT-containing formulations for topical PrEP and emphasize the need to study interactions between microbiota and GRFT.

EPC320

Identification of viral mutations that confer cross resistance to VRC01 antibody in HIV-1 subtype C viruses

A.Z. Mbadu[1], P. Cohen[2], B. Lambson[2], C.A. Magaret[3], P.B. Gilbert[3], C. Williamson[4], L. Morris[2,5], P.L. Moore[2,5], H.T. Mufhandu[1]

[1]*North West University, Department of Microbiology, Faculty of Natural and Agricultural Sciences, Mmabatho, South Africa,* [2]*National Institute for Communicable Diseases (NICD), Division of the National Health Laboratory Service, Centre for HIV and STI, Johannesburg, South Africa,* [3]*Fred Hutchinson Cancer Research Center, Vaccine and Infectious Disease Division and Statistical Center for HIV/AIDS Research and Prevention, Seattle, United States,* [4]*University of Cape Town, Division of Medical Virology, Faculty of Health Sciences, Observatory, South Africa,* [5]*University of the Witwatersrand, Faculty of Health Sciences, Parktown, South Africa*

Background: Human immunodeficiency virus (HIV-1) subtype C remains the cause of most of the new HIV infections worldwide. South Africa being the most burdened region, is one of the participating countries in the Antibody Mediated Prevention (AMP) studies investigating broadly

neutralizing antibody (bNAb) VRC01 for HIV prevention. However, the use of this bNAb is hindered by emerging resistant mutations that cause neutralization escape.
Methods: The study focused on the features that are known by experimental evidence and machine learning predictions to contribute to VRC01 binding. The study included seven HIV-1 subtype C envelope sequences from breakthrough infections during VRC01 therapy, from which seven putative escape mutations were identified (D99, K279, E279, E455, W456, T471, and Q471) by analyzing them using information from HIV LANL database.
The role of the identified sites was investigated by reverting them to sensitive residues by site-directed mutagenesis. All wildtypes and their respective mutant pseudoviruses were assessed for neutralization sensitivity towards VRC01 antibody and other related CD4 binding site (CD4bs) bNAbs (VRC07-523LS and 3BNC117) with the use of the TZM-bl neutralization assay.
Results: Four envelopes in which we introduced a single mutation (H0902_K279D, V0217_E279D, V1298_E455T, and V1255_D99N) became sensitive to VRC01 and 3BNC117 compared to their respective wildtypes. They were also sensitive towards VRC07-523LS except for H0902_K279D. Interestingly the single mutant, V1298_E455T was completely sensitive to VRC01 although predicted by machine learning (Q455) to cause resistance.
However, H1798 envelope with the same mutation (E455T) remained resistant. Similarly, single mutation (V1255_D99N) caused partial sensitivity to VRC01, while mutant V1298_D99N was resistant. Neutralization escape for each mutant may be mediated by a different pathway and dependent upon the gp160 background sequence.
Conclusions: The V1298_455 mutation warrants further investigation as this is the first report on E455T to show VRC01 sensitivity in HIV-1 subtype C isolates.
Overall, our data supports the concept that some HIV-1 subtype C isolates change critical CD4 binding features to escape VRC01, some causing cross-resistance to other CD4 binding antibodies. The data also promote continued efforts of characterizing VRC01 resistant sites in preparation for future passive immunity trials that include CD4bs antibodies.

Measuring and enhancing retention and adherence in HIV prevention programmes

EPC321

Retention of clients on daily oral HIV pre-exposure prophylaxis in Vietnam

H. Nguyen[1], H. Dang[1], V. Nguyen[1], T.V. Nguyen[1], H. Phan[2], N. Nguyen[3], T. Vuong[1], R. Coley[1]
[1]FHI 360, Hanoi, Viet Nam, [2]Viet Nam Authority for HIV/AIDS Control, Hanoi, Viet Nam, [3]United States Agency for International Development, Health, Hanoi, Viet Nam

Background: Vietnam launched HIV pre-exposure prophylaxis (PrEP) in 2017 to prevent HIV acquisition among high-risk populations. Daily and event-driven PrEP are only effective when used in alignment with clinical guidelines. As most clients in Vietnam are on daily PrEP, they need to adhere to a daily pill. However, analysis of PrEP retention data is limited.
We aimed to evaluate PrEP retention among daily PrEP clients in Ho Chi Minh City, Tay Ninh, and Tien Giang provinces.
Methods: Retention among all new and existing PrEP clients was assessed between October 2020 and September 2021. Kaplan-Meier was used to analyze time from PrEP enrollment to discontinuation stratified by sex, province, age group, and key or priority population. Multivariable Cox regression was used to estimate a hazard ratio (HR) and associations between PrEP retention and other covariates.
Results: Between October 2020 and September 2021, there were 791 clients in the Meeting Targets and Maintaining Epidemic Control (EpiC) PrEP program in three provinces: Tien Giang (326, 41.2%), Tay Ninh (282, 35.7%), and Ho Chi Minh City (183, 23.1%). Most clients were male (665, 84.1%). Men who have sex with men were the largest group of clients (539, 68.1%), followed by negative partners in serodiscordant couples (228, 28.8%). The most common reasons for discontinuation were loss to follow-up (259, 51.9%) and transfers (123, 24.7%).
Median retention was 120 days. Retention rates at three, six, and 12 months were 67.0%, 30.3%, and 8.3%, respectively. Female clients were retained longer than male clients (HR=0.6, $p<0.005$), regardless of population group. In the multivariable model, younger age was associated with PrEP discontinuation, and male clients from Tay Ninh province tended to have higher PrEP discontinuation rates than those from Tien Giang (HR=0.5, $p<0.001$) and Ho Chi Minh City (HR = 0.4, $p<0.001$).
Conclusions: More effort is needed to understand the underlying reasons for discontinuation, especially among males from different provinces and age groups. Targeted interventions designed for men and younger individuals, and tailored to provincial contexts, are needed to address barriers to PrEP retention.

EPC322

Acceptability of an mHealth intervention to promote the use of pre-exposure prophylaxis among individuals at increased risk of HIV. The case of the *Jichunge* smartphone app in Dar es Salaam, Tanzania

C. Mbotwa[1,2], M. Kazaura[1], K. Moen[3], W. Mauka[4,5], M. Leshabari[4], E. Meta[4], E.J. Mmbaga[3,1]
[1]*Muhimbili University of Health and Allied Sciences, Epidemiology and Biostatistics, Dar es Salaam, Tanzania, The United Republic of,* [2]*University of Dar es Salaam, Mbeya College of Health and Allied Sciences, Mbeya, Tanzania, The United Republic of,* [3]*University of Oslo, Department of Community Medicine and Global Health, Oslo, Norway,* [4]*Muhimbili University of Health and Allied Sciences, Behavioural Sciences, Dar es Salaam, Tanzania, The United Republic of,* [5]*Ministry of Health, National Blood Transfusion Service, Dar es Salaam, Tanzania, The United Republic of*

Background: Reducing HIV infection rates among at-risk populations is more likely to contribute to achieving the 2030 goal of ending the epidemic.Countries in sub-Saharan Africa, including Tanzania, have started rolling out pre-exposure prophylaxis (PrEP), but adherence to the daily pills poses a challenge. Evidence indicates that mHealth is a promising solution for promoting uptake, retention, and adherence to PrEP. However, evaluation data of its implementation in Africa settings are scarce. This study aimed at assessing acceptability and initial use of mHealth in promoting PrEP use among female sex workers (FSW) and men who have sex with men (MSM) in Dar es Salaam, Tanzania.

Methods: FSW and MSM residing in Dar es Salaam who owned smartphones and were eligible for PrEP were recruited using respondent-driven sampling and provided with the Jichunge, a smartphone-based application designed to promote adherence to PrEP and retention in PrEP services. The app offers users information about HIV and PrEP, reminds them to take their daily pill, allows them to consult a doctor and peer educators, and includes an online forum where may engage in discussions with other PrEP users.

Results: A total of 885 participants (470 FSW and 415 MSM) with a median age of 26 and 21 years, respectively, were recruited. Most (559; 63.2%) opened the app and registered pill-taking (523; 59.1%) at least once. About a third of the participants accessed the app's PrEP and HIV editorial contents (348; 39.3%) and participated in the discussion forum (277; 31.3%). A total of 172(19.4%) consulted a doctor or peer educator via the app. FSW were significantly more likely than MSM to open the app (FSW:74%; MSM: 50.8%; p<0.001), register daily pill use (FSW:71.7%; MSM: 44.8%; p<0.001), access editorial contents (FSW:47.0%; MSM: 30.6%; p<0.001), and engage in the discussion forum (FSW:34.3%; MSM: 27.9%; p=0.044). Online consultation was not statistically significant different between the two populations (FSW:20.1%; MSM: 18.1%; p=0.336).

Conclusions: The use of different services of Jichunge was significantly high. This suggests that mHealth is acceptable and can be a valuable platform to promote the use of PrEP and other services among HIV at-risk populations in Tanzania.

EPC323

"I was scared dating... who would take me with my status?" Living with HIV in the UTT era in Johannesburg, South Africa

T. Sineke[1], D.D. Onoya[1], I. Mokhele[1], R. Cele[1], S. Sharma[2], S. Sigasa[1], M. Dukashe[3], L. Hansrod[4], R. Inglis[4], R. King[5], D.J. Bor[1,2]
[1]*Health Economics and Epidemiology Research Office, Department of Internal Medicine, School of Clinical Medicine, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa,* [2]*Boston University School of Public Health, Department of Global Health, Boston, Massachusetts, United States,* [3]*HIV Survivors and Partners Network, Pretoria, South Africa,* [4]*Jive Media Africa, Pietermaritzburg, South Africa,* [5]*University of California, Institute for Global Health Sciences, California, United States*

Background: South Africa rolled out Universal Test-and-Treat (UTT) in 2016, extending treatment eligibility to all people living with HIV (PLHIV). We sought to understand how the experience of living with HIV may have changed as the HIV epidemic matured in South Africa, particularly under the expanded treatment access in the UTT era.

Methods: As part of an ongoing randomized controlled trial, in May 2021 we conducted in-depth interviews (N = 27) with adult (≥18 years) PLHIV referred by HIV counsellors at three peri-urban primary healthcare clinics. We also conducted three focus group discussions (N = 27) with PLHIV recruited by snowball sampling through civil society organisations in Johannesburg, South Africa. Interviews and focus group discussions were audio-recorded, transcribed verbatim, translated to English, and analysed thematically.

Results: Participants reported less fear of death and ill health as antiretroviral therapy (ART) was easily and widely accessible. However, they reported feeling guilt and shame about HIV as a sexually transmitted disease. The mode of HIV transmission also elicited some expectation of stigma and judgement as some participants attributed their HIV status to their own reckless behaviour. Others expressed anger and blamed their partner for their status, leading to strong motivation to not become transmitters themselves.

However, most participants lacked knowledge about treatment-as-prevention and feared transmitting HIV to others even after starting ART. ART adherence behaviour was motivated by their own health and a sense of responsibility to be present for loved ones. Despite the normalization of HIV as a chronic condition, the fear of re-

jection by potential partners in response to status disclosure persists. Fear of disclosure was also a barrier to ART adherence, as some PLHIV reported hiding or not taking their medication in front of other people. They considered whether to risk rejection, avoid relationships, or avoid disclosure and felt they had limited options.

Conclusions: Despite normalization of HIV, stigma persists in the domain of sexual partnerships related to the perception that PLHIV are likely to transmit HIV. Disseminating information on treatment-as-prevention could reduce the psychological burdens of HIV including self/internalized stigma, encourage disclosure, and remove barriers to HIV testing and treatment adherence.

EPC324

Geographic disparities in HIV PrEP pharmacy reversals, a novel observational data indicator of PrEP non-adherence

L.T. Dean[1], H.-Y. Chang[2], R. Dawit[1], W.C. Goedel[3], S. Bakre[1], P.A. Chan[4], J.A. Doshi[5], A.S. Nunn[6]

[1]*Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States,* [2]*Johns Hopkins Bloomberg School of Public Health, Department of Health Policy & Management, Baltimore, United States,* [3]*Brown University School of Public Health, Department of Epidemiology, Providence, United States,* [4]*Brown University, Department of Medicine, Providence, United States,* [5]*University of Pennsylvania, Perelman School of Medicine, Philadelphia, United States,* [6]*Brown University, Department of Behavioral and Social Sciences, Providence, United States*

Background: HIV PrEP adherence is suboptimal in many populations across the world, affecting the impact of this efficacious prevention intervention. Furthermore, common measures of PrEP adherence in observational studies are often expensive, infeasible, or burdensome to collect. We recently introduced PrEP reversals, or when patients fail to pick up PrEP prescriptions, as a novel national population-based measure of HIV PrEP non-adherence, and showed their association with HIV rates. In the current study, we assess reversal and abandonment across four geographic characteristics.

Methods: We used a national claims database covering up to 75% of all HIV PrEP claims across the United States (2015 to 2019). After using a multi-step process to identify new PrEP claims, we calculated the percentage of patients with an HIV PrEP insurer-approved index prescription claim that was reversed (patient did not pick it up and pharmacy withdrew the claim) or abandoned (reversed and still not picked up after 12 months), across ZIP codes classified by: US Census region; Rural-Urban Community Area Codes; low (≤10th percentile) or high (>10th percentile) Area Deprivation Index; and 2019 Ending the HIV Epidemic (EHE) jurisdiction, a US policy initiative targeting areas with high or rising HIV rates.

Results: Across 42,796 newly-prescribed PrEP patients, reversals were significantly (p≤0.001) higher among patients in the Midwest and South (21%) than the Northeast and West (18%); rural (27%) than urban (19%); high deprivation ZIPs (20%) than low (17%); and non-EHE (23%) than EHE (17%) ZIPs (Figure 1). Results for abandonment showed similar patterns.

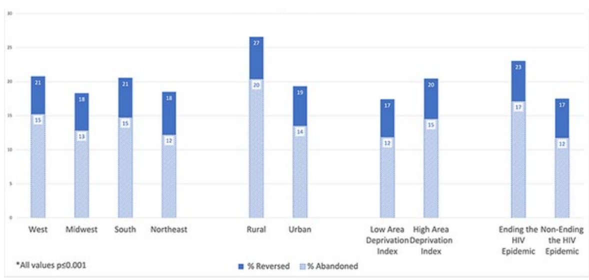

*Figure 1. Geographic disparities in the percentage of PrEP reversals and abandonments in the US population 2016-2019**

Conclusions: The geography of reversals quantifies where PrEP is likely not to make it into the homes of new patients and informs where to invest resources to prevent them. Our results establish baseline values for tracking reversal trends over time or in response to HIV prevention initiatives, and offer a metric for international PrEP surveillance.

EPC325

Putting 2+1+1 into practice: MSM PrEP users' knowledge about safely starting and stopping PrEP in Belgium

A. Rotsaert[1], T. Reyniers[1], J. Vanhamel[1], E. Van Landeghem[2], T. Vanbaelen[3], H. Van Mieghem[2], C. Nöstlinger[2], M. Laga[2], B. Vuylsteke[2]

[1]*Institute of Tropical Medicine, Department of Public Health, Antwerp, Belgium,* [2]*Institute of Tropical Medicine, Department of Public health, Antwerp, Belgium,* [3]*Institute of Tropical Medicine, Department of Clinical sciences, Antwerp, Belgium*

Background: Achieving prevention-effective adherence to pre-exposure prophylaxis (PrEP) requires aligning PrEP use with actual risk-taking, which may change according to intra-, inter-personal and contextual variables. Men who have sex with men (MSM) can safely start and stop PrEP use by respecting the 2+1+1 rule, which entails two pills before having sex and two pill-days after the last sexual act before stopping.

The study's objective was to assess MSM PrEP users' self-perceived and actual knowledge to safely start and stop with 2+1+1 oral PrEP in Belgium.

Methods: We analyzed data from an online survey among 206 MSM PrEP users being male at birth in Belgium (September 2020 – June 2021). We asked: "How do you assess your own knowledge about starting and stopping PrEP safely?" to asses self-perceived knowledge. Actual knowledge was evaluated through two hypothetical scenarios,

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

respectively safely starting and stopping. Participants who failed to answer both safe-start-and-stop scenarios correctly were classified as PrEP users with 'insufficient knowledge'. Using bivariate logistic regression we examined associations between sociodemographic and sexual behavioral factors, PrEP use, and insufficient knowledge on safely starting and stopping PrEP.

Results: The majority of the participants (85.0%) perceived their knowledge of safely starting and stopping with PrEP as 'very good'. The proportion correctly indicating how to safely start was 82.0%, whereas 73.3% for safely stopping. Overall, 128 (62.1%) correctly indicated how to safely start and stop. PrEP users who had stopped PrEP use [OR=2.54, 95%CI (1.04-6.20)] or who had been taking daily PrEP [OR=2.13, 95%CI (1.15-3.99)] in the last 3 months were more likely to have insufficient knowledge on safely starting and stopping compared with on-demand PrEP users.

Those not considering their knowledge as 'very good' were also more likely to have insufficient knowledge on safely starting and stopping [OR=2.27, 95%CI (1.05-4.98)].

Conclusions: Although self-perceived knowledge was high, an important proportion failed to correctly answer two hypothetical scenarios on safely starting and stopping PrEP. Emphasis on adherence counselling, including safely starting and stopping is needed, regardless of the PrEP regimen used as MSM PrEP users may experience alternating periods of use and may switch between PrEP regimens.

EPC326

Association of patient Out-of-Pocket costs with HIV Pre-Exposure Prophylaxis (PrEP) pharmacy reversals, a novel measure of PrEP non-adherence, and abandonments

L.T. Dean[1], A.S. Nunn[2], H.-Y. Chang[3], W.C. Goedel[4], S. Bakre[1], P.A. Chan[5], J.A. Doshi[6]

[1]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [2]Brown University, Department of Behavioral and Social Sciences, Providence, United States, [3]Johns Hopkins Bloomberg School of Public Health, Department of Health Policy & Management, Baltimore, United States, [4]Brown University School of Public Health, Department of Epidemiology, Providence, United States, [5]Brown University, Department of Medicine, Providence, United States, [6]University of Pennsylvania, Perelman School of Medicine, Philadelphia, United States

Background: Out-of-pocket (OOP) costs can be a key barrier for patients to use HIV PrEP. Our prior study introduced PrEP prescription reversals, or when patients fail to pick up PrEP from the pharmacy, as a novel measure of PrEP non-adherence. HIV cases were three times higher among patients who never picked up their prescription (reversed and abandoned) compared to patients who picked it up. In this study, we examined the association of OOP costs with PrEP reversals and abandonment.

Methods: We analyzed claims from a national database with up to 75% of all HIV PrEP claims in theUS (2015-2019). After using a multi-step process to identify new PrEP claims, we examined whether individuals reversed (i.e. patient did not pick up insurance-approved prescription and pharmacy withdrew the claim) or abandoned (not picked up within 365 days) their initial PrEP prescription. Multivariable regressions estimated the odds of reversal and abandonment associated with varying PrEP OOP cost relative to $0 OOP cost.

Results: About 24% of the sample (N=66,819) faced no OOP costs; the remainder faced OOP costs ranging from $>0-10 (35%) to >$500 (8%). While the overall reversal and abandonment rates were 19% and 13%, respectively, rates were higher in greater OOP cost categories, abandonment was lowest (5.5%) when OOP was $0, but double (11%) with OOP $>0-10, and 44% with OOP >$500.

These patterns remained after controlling for sociodemographic, insurance, and clinical factors: with over double the odds of abandonment with OOP $>0-10 and 18 times the odds with OOP >$500, compared with $0 (Figure 1).

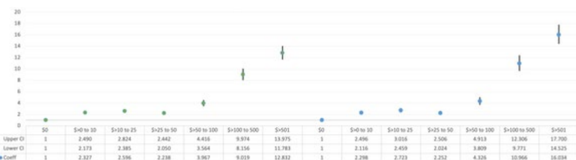

Figure 1. Adjusted odds of reversed and abandoned HIV PrEP prescriptions in the US 2015-2019 by patient out-of-pocket cost.

Conclusions: Even a small OOP cost of ≤$10 was associated with double the odds that a patient will abandon their first PrEP prescription. These results, combined with our prior study, highlight the importance of eliminating PrEP OOP costs to achieve the goal of ending the HIV epidemic.

EPC327

Understanding and addressing barriers to pre-exposure prophylaxis (PrEP) continuation among vulnerable adolescent girls and young women in Namibia

E. Ernest[1], T. Gwande[1], A. Mwinyi[1], S. Kelbert[2], T. Ventimiglia[3], E. Kuhlik[3], K. Thura Tun[3], M. Manyando[4]

[1]Jhpiego, Rundu, Namibia, [2]Jhpiego, Baltimore, United States, [3]Pact, Washington, United States, [4]USAID, Windhoek, Namibia

Background: Understanding the barriers to PrEP continuation is essential to designing programs that meet clients' needs. There is limited information about the factors hindering PrEP continuation among adolescent girls and young women (AGYW) in Namibia despite a low continuation rate (29%) at a one-month follow-up.

This study examines reasons for and outcomes of PrEP discontinuation among AGYW receiving DREAMS services under ACHIEVE, a USAID/PEPFAR-funded project in northern Namibia.

Methods: The retrospective analysis included programmatic data for AGYW aged 15-24 years from April–to September 2021 who missed follow-up appointments and/or discontinued PrEP in four semi-urban health facilities in Rundu district. Nurses and PrEP ambassadors are responsible for contacting PrEP clients by phone after missing one-month follow-up PrEP appointments. Results are recorded on a standardized client tracing form.

During the study period, 1,010 clients newly started PrEP; of those, 614 (61%) missed the one-month follow-up visit, with 376 (age-disaggregated: 138 [15-19 years] and 238 [20-24 years]) followed up. Descriptive analysis was used to present the results.

Results: Sixty percent (225) of 376 AGYW responded, while 15% (55) were not reachable or the phone number was wrong, and 25% (96) refused to respond. Of the 225 respondents, 75 were aged 15-19 and 150 were 20-24 years. The distribution of responses by primary reason for missing appointments was: PrEP no longer needed, 24% (55); forgot the appointment date, 20% (46); traveled away from home, 20% (46); felt unwell after taking PrEP, 13% (29); lack of money to support transport to a facility, 6% (13); lack of food, 5% (12); unclear PrEP instructions, 4% (8); and lack of family/community support, 3% (7). Variation of results by age was not statistically significant.

After clients were contacted, ACHIEVE continued strengthening the provision of PrEP education and counseling. As a result, 27% (60) of the 225 AGYW restarted PrEP, 68% (152) stopped using PrEP though still at risk, and 6% (13) considered themselves no longer at HIV risk.

Conclusions: Understanding the reasons for the discontinuation of PrEP is critical to designing/improving programs to meet clients' needs and to continue addressing HIV risk among vulnerable AGYW.

EPC328

Linking PLHIV lost to follow-up back to care in 5 regions of the Russian Federation

A. Banshchikova[1], J. Godunova[1], N. Ustyuzhanina[2]

[1]Association of Patients and Professionals, Helping People with HIV, Viral Hepatitis and other Socially Significant Diseases 'E.V.A.', Saint Petersburg, Russian Federation, [2]Autonomous Non-Profit Organization 'Rehabilitation Centre of Socio-Psychological Assistance for Chemically Dependent People by Natalia Ustyuzhanina Generation', Tyumen, Russian Federation

Background: According to data from the Russian Federation governmental analytics center, the budget for HIV prevention for the year 2020 was insignificant. Consequently, tertiary prevention, that is aimed at improving the quality of PLHIV lives, is deteriorating.

Therefore it is crucial to implement projects directed at retaining PLWH in systems of care provision. In 2020-2023, the E.V.A. Association is implementing a project to initiate/restart LTFU PLHIV on ART with local non-profit organizations in 5 regions of Russia. The main project goal is to find 6,392 PLWH, who are lost to follow-up at AIDS Centers, make contact with 3,388 (53%) of them and retain 3,049 (90%) PLWH in systems of care.

Description: The project focuses on searching for patients lost to follow-up for more than 28 days; documenting their status, including those who have died or relocated; and providing them with motivational counseling, peer navigation and escorting services to initiate or resume ART, as well as retention counselling.

The key groups include people who use drugs, sex workers, men who have sex with men, people who have been incarcerated, migrants, youth (10-24), and pregnant women.

Lessons learned: In implementing the first year of field work from November 2020 through November 2021, regional differences were noted in accompaning LTFU PLWH. The regions where the "Green Corridor" works well show great results in project clients starting/restarting ART. The Green corridor is a system which includes peer navigation, out of order appointments and accelerated clinical examination.

There are also other factors which impact accompaniment and retention of LTFU PLWH. For example, training of medical workers, social and psychological support, mutual support groups, motivational kits, assistance with transport, and ART home delivery. An analysis of regional reports and expert visits confirms the importance of these practices.

Conclusions/Next steps: The "Green Corridor", training of medical workers, social and psychological support, mutual support groups, motivational kits, assistance with transport, and ART home delivery allow for more patients with HIV, who have dropped treatment at the AIDS Center, to be retained in systems of care. It is important to develop similar practices in other regions of Russia.

EPC329

Improving viral load testing uptake for HIV infected cohort on antiretroviral therapy (ART) at a rural setting: lessons learnt from Neno district, Malawi

J.C. Suffrin[1], L. Thengo[1], M.B. Aron[1], B.L. Mwagomba Matanje[1], C. Kachimanga[1], W. Khoviwa[1], B. Moir[1], C. Kanyenda[1], E. Ndarama[2], J. Matope[2], F. Phiri[2], A. Phiri[1], B. Mailosi[1], F. Valetta[1], M. Charles[1], H. Chinkhata[1], F. Phiri[2], J. Kalua[2], E. Connolly[1,3,4]

[1]Partners In Health, Neno, Malawi, [2]Ministry of Health, Neno, Malawi, [3]University of Cincinnati, Division of Pediatrics, Cincinnati, United States, [4]Cincinnati Children's Hospital Medical Center, Division of Hospital Medicine, Cincinnati, United States

Background: To achieve the goal of ending the HIV pandemic by 2030, virological monitoring for HIV suppression is required. Despite recommendation of regular viral load (VL) monitoring, viral load testing uptake still stands to

be a challenge in many resource-limited settings such as Neno District in rural Malawi. We implemented a quality improvement project to increase uptake of viral load testing in a large HIV cohort in 2019.

Methods: A Plan-Do-Study-Act (PDSA) model of quality improvement was used with a goal of 50% improvement in the proportion of HIV patients with an up to date viral load per national guidelines. A root-cause analysis was done through observation using a fishbone graph. A multidisciplinary group approach was utilized to identify bottlenecks of staff non-compliance to the VL testing schedule, Electronic Medical Record (EMR) system failure on reminders of VL, and lack of feedback system on rejected blood samples.

We implemented 3 PDSA cycles between April 2019 and August 2019 with a process-centered approach that identified suitable interventions including:

1. Orienting staff team on new VL flow process and protocol;
2. Re-writing of the logic for generating patient appointment and VL reminder lists in EMR system; and,
3. Introducing a new VL rejection flow process that emphasized sample re-collection if the initial sample was rejected to ensure VL completion.

Results: Prior to the intervention in April 2019, an open cohort of 8210 patients was active eligible for VL testing. However, only 2216 (27.72%) had an up to date VL per national guidelines. After three PDSA cycles in August 2019, the proportion of patients with current VL test increased to 81.20%, representing a statistically significant increase of VL testing uptake (P<0.01).

Conclusions: VL testing uptake in Neno district significantly improved by >50% using a PDSA quality improvement approach in a multidisciplinary approach and thus greater information on virologic suppression and treatment needs of HIV patients. Similar process-based strategies could be used in other rural settings to address quality care challenges in large HIV cohorts.

EPC330

Comparison of adherence measurement tools used in a pre-exposure prophylaxis demonstration study men who have sex with men in China

X. Jin[1], J. Zhang[2], J. Xu[2]
[1]AIDS Healthcare Foundation, Beijing, China, [2]China Medical University, Shenyang, China

Background: Measuring adherence to PrEP remains challenging. Blood drug concentration measurement are reported to be more accurate than other traditional adherence measurements (self-reports, pill counts), but cannot be suitable in resource-limited countries. We aimed to measure PrEP adherence by real-time electronic monitoring and compare with traditional adherence measurements to determine if this new measure is reliable and correlate well with blood drug concentration adherence measurement.

Methods: We recruited 422 MSM PrEP users from four cities of China from September 2019 to December 2020. Plasma TFV concentrations were analyzed in samples collected at baseline and months 3, 6 visits. Self-reported adherence was captured at baseline and months 3, 6 visits by questionnaire by asking participants to report the number of missed pills within the past three months. For pill count, medications were refilled quarterly, and participants were asked to bring in their medication bottles at each follow-up visit. Using Kappa coefficient to compare the adherence measured by real-time electronic monitoring, self-report, pill count, and plasma TFV concentrations.

Results: Of 422 participants, 96.6% completed 6-month follow up. For daily PrEP users, the adherence data from all visits was 93.7% for real-time electronic monitoring, 98.0% for self-report, 91.8% for pill count, while the proportion of TFV concentration have drug levels consistent with TDF/FTC use (adherence no less than 90%) was 78.4%. For ED PrEP users, the adherence data from all visits was 85.7% for real-time electronic monitoring, 98.8% for self-report, 86.8% for pill count, while the proportion of TFV concentration have drug levels consistent with TDF/FTC use (adherence no less than 90%) was 76.5%.

Adherence measured by real-time electronic monitoring was in greater consistence with TFV concentrations (Kappa coefficient=0.68) than self-report (Kappa coefficient=0.08) and pill count (Kappa coefficient=0.19). The cost of average adherence measurement by real-time electronic monitoring (162 USD) was less than half of TFV concentrations (384 USD), while higher than pill count (66 USD) and self-report (49 USD).

Conclusions: Real-time electronic monitoring of adherence measurement could be an alternative inexpensive and accurate approaches to monitor PrEP adherence. It reflects the daily PrEP uptake and can trigger just-in-time interventions before adherence has lapsed for several months.

EPC331

Accuracy of PrEP adherence measures among adolescents men who have sex with men and transgender women in Brazil

D. Zeballos[1], F. Soares[1], L. Magno[2], M. Eustorgio[3], L. Amorim[1], I. Dourado[1], The PrEP1519 Brazil Study Group
[1]Federal University of Bahia, Collective Health Institute, Salvador, Brazil, [2]State University of Bahia, Salvador, Brazil, [3]Federal University of Bahia, Institute of Mathematics and Statistics, Salvador, Brazil

Background: Adherence is fundamental to PrEP effectiveness. Direct measures of adherence are expensive and not sustainable in most PrEP services. Therefore, an indirect measure is a feasible alternative.

The aim of this analysis was to assess the concordance of indirect measures for PrEP adherence comparing them with a direct measure.

Methods: PrEP1519 is a daily PrEP demonstration cohort study among adolescent men who have sex with men (aMSM) and transgender women (aTGW) aged 15-19 years. Indirect measures such as medication possession ratio (MPR), pill-count, and self-report were compared to tenofovir diphosphate (TFV-DP) concentrations in dried blood spot (DBS).

Participants receiving pills of FTC/TDF, had DBS collected and stored at each study visit, were asked to return their PrEP bottles and to recall PrEP use in the last 30 days. A sample of DBS from aMSM, DBS from all seroconverters, and all aTGW were sent for quantification of TFV-DP concentrations.

The accuracy of each indirect measure was assessed using Areas under (AUC) the receiver operating characteristics (ROC) curves for protective TFV-DP levels ≥800fmol/punch equivalent to 4 doses per week or above. Sensitivity (SE), specificity (SP), and predictive values positive (PPV) and negative (NPV) were assessed for the best cutoff points identified by Youden index.

Results: DBS data from 188 participants were included. Coincidental data for indirect measures were: MPR (N=185), pill-count (N= 68) and self-report (N= 174). The AUC was 0.55 (95%CI: 0.47–0.53) for MPR, AUC = 0.67 (95%CI: 0.54–0.80) for pill count, and AUC = 0.72 (95%CI: 0.65–0.80) for self-report. The best cut-off point was 0.90 for MPR with 80.3% SE, 40.4% SP, 25.4% PPV and 51.6% NPV; for pill count was 92.7% with 72.7% SE, 62.9% SP, 29.0% PPV and 35.1% NPV and 83.3% for self-report with 91.8% SE, 46.5% SP, 11.3% PPV and 44.6% NPV.

Conclusions: Pill count and self-report were able to discriminate adolescents with protective levels of TFV-DP. In addition, self-report adherence showed the best performance, and it is feasible and sustainable to be implemented in PrEP services for adolescents.

EPC332

Utilization of oral pre-exposure prophylaxis (PrEP) after FTC/TAF approval in the United States

R. Elion[1], J. Gruber[2], J. Radtchenko[3], M. Dunbar[2], K. Mayer[4], G. Huhn[5], K. Mounzer[6]

[1]George Washington University School of Medicine, Washington, DC, United States, [2]Gilead Sciences, Foster City, United States, [3]Trio Health, Louisville, United States, [4]Fenway Health, The Fenway Institute, Boston, United States, [5]The Ruth M. Rothstein Core Center, Rush University Medical Center, Chicago, United States, [6]School of Medicine at the University of Pennsylvania, Philadelphia Fight Community Health Centers, Philadelphia, United States

Background: Two oral medications are approved for PrEP in the US: emtricitabine/tenofovir disoproxil fumarate and tenofovir alafenamide (FTC/TDF, FTC/TAF). This study describes socio-demographic and clinical characteristics of individuals new to PrEP after the approval of FTC/TAF in the US (October 2019) to better understand PrEP prescription and dispense patterns in clinical practice.

Methods: EMR and dispensing data from Trio Health HIV Research Network (10/2019-11/2021) were used for the study. Included: HIV-negative adults prescribed or dispensed oral PrEP (≥1-month supply) with ≥3 months follow-up. Excluded: indications of HBV or PEP.

Comorbidities, socio-demographic and clinical characteristics for PrEP-naïve participants were compared among those prescribed and (separately) those dispensed FTC/TAF vs FTC/TDF (t-test, chi-square) at the same facilities.

Results: In the prescription cohort (N=2213), most individuals were prescribed FTC/TAF (1821 [82%] vs. FTC/TDF 392 [18%]). A similar distribution was observed for the dispense cohort (N=1794; FTC/TAF 1551 [86%]; FTC/TDF 243 [14%]).In both cohorts, most participants had commercial insurance and FTC/TAF individuals were more likely to be white and male. In the prescription cohort, high-risk behavior and clinical characteristics, including BMI and renal function (eGFR mL/min/1.73m²), were similar for FTC/TAF and FTC/TDF among those with available data [Table].

Individuals dispensed FTC/TAF were more likely to be overweight at baseline (39% vs. 29%; p=.019), with high-risk behavior (75% vs. 63%, p<.001), age >50 (16% vs. 11%, p=.041), and less likely to be age ≤25 (13% vs 18%, p=.018).

Baseline characteristics n (%);	Prescription cohort (n=2213)		Dispense cohort (n=1794)	
mean (std)	FTC/TDF n=392	FTC/TAF n=1821	FTC/TDF n=243	FTC/TAF n=1551
Male Gender	257 (66)	1312 (72)*	124 (51)	1024 (66)#
White Race	190 (48)	1020 (56)†	108 (44)	928 (60)#
Commercial Insurance	264 (67)	1173 (64)	116 (48)	949 (61)#
Age[1]: 18-25 years	61 (16)	326 (18)	44 (18)	195 (13)*
Age[1]: 51+ years	49 (13)	245 (13)	26 (11)	244 (16)*
High-risk Behavior[2]	279 (71)	1372 (75)	154 (63)	1156 (75)#
eGFR (<90 mL/min/1.73²)[3]	257 (74)	1105 (73)	133 (75)	892 (70)
Mean BMI (kg/m²)[4]	27.6 (9.4)	26.9 (7.3)	27.9 (11.1)	27.2 (9.3)

*p<0.05; †p<0.01; #p<0.001 FTC/TDF vs FTC/TAF.
[1]Age category 26-50 years: no differences between FTC/TDF and FTC/TAF.
[2]High-risk behavior: ICD-10 codes for high-risk sexual behavior and exposure to cummunicable diseases.
[3]eGFR = estimated glomerular filtration rate; eGFR values available for 84% (1865) of those prescribed and 81% (1457) of dispensed.
[4]BMI = body mass index; BMI values available for 69% (1567) of prescribed and 71% (1237) of disensed.

Table. Characteristics of individuals prescribed and dispensed PrEP after october 2019.

Conclusions: This retrospective observational study among adults initiating PrEP after FTC/TAF approval showed most new PrEP users were prescribed and dispensed FTC/TAF.

While differences were observed in socio-demographic characteristics between regimens and across cohorts, evidence suggests that individual safety risk factors (e.g., age and renal function) may not factor into prescribing decisions.

Barriers and facilitators to daily, oral pre-exposure prophylaxis (PrEP) use among pregnant adolescent girls and young women (AGYW) in Cape Town, South Africa: A qualitative study

S. Haribhai[1], N. Mashele[2], L.-G. Bekker[3], P. Gorbach[4], T.J. Coates[5], L. Myer[2], D.L. Joseph Davey[4,2]

[1]Demond Tutu Health Foundation, University of Cape Town, South Africa, Demond Tutu Health Foundation/ International AIDS Vaccine Initiative Fellowship, Cape Town, South Africa, [2]University of Cape Town, Division of Epidemiology and Biostatistics, School of Public Health and Family Medicine, Cape Town, South Africa, [3]University of Cape Town, The Desmond Tutu HIV Centre, Cape Town, South Africa, [4]University of California Los Angeles, Department of Epidemiology, Fielding School of Public Health, Los Angeles, United States, [5]University of California Los Angeles, David Geffen School of Medicine, Los Angeles, United States

Background:
Over half of HIV infections globally occur among cisgender women. High HIV incidence among adolescent girls and young women (AGYW) persists during pregnancy and postpartum, and there is evidence that HIV acquisition risk increases by >2-fold during pregnancy and the postpartum period. Rates of unintended pregnancy are disproportionately high among South African AGYW. Research on facilitators and barriers to pre-exposure prophylaxis (PrEP) use among pregnant AGYW is scarce.
Our study aims to evaluate barriers and facilitators to daily, oral PrEP continuation and self-reported adherence among pregnant AGYW in Cape Town, South Africa.
Methods: We purposively enrolled pregnant AGYW (age 16-25 years) from an ongoing cohort study at a busy antenatal clinic between July and September 2020. Trained peers conducted in-depth interviews among pregnant and postpartum AGYW who had initiated PrEP during antenatal care. We purposively recruited participants who continued on PrEP and reported *high adherence* (≥25 days in past 30 days and no missed pick-ups) or *PrEP discontinuation and low adherence* (reporting missing >5 days in last 30 days or missed pick-up). We organized findings thematically and iteratively coded these (using*Nvivo*-v.1.5) with reference to an adapted conceptual framework by Ickovic and Meisler (1997).
Results: We interviewed n=18 pregnant or postpartum AGYW (median age=23 years). Facilitators of PrEP continuation/adherence included: strong desire to protect themselves and their infant against HIV acquisition; risk perception including partners' sexual risk-taking behaviour; social support by family (mother), partner and friends; autonomy of daily, oral PrEP that does not require partner cooperation or buy-in.
Common barriers included: fear of stigma (that they were taking ART and may be seropositive); lack of widespread access to PrEP; limited social support (especially from family); socioeconomic hardship; and the experience of side effects (e.g., nausea) which may overlap with common, pregnancy-related symptomatology.
Conclusions: Oral PrEP needs to be integrated into antenatal care at scale and targeted to at-risk pregnant and postpartum AGYW. Counseling and interventions to improve disclosure and family-/partner support may improve PrEP continuation and adherence. More research is needed on long-acting PrEP such as injectables and vaginal rings which may be effective at improving PrEP adherence in this population.

Key population-led prevention programmes (from reach, recruit, test, treat, prevent and retain)

Quantifying delay in HIV program contact among young female sex workers in Mombasa, Kenya: a time-to-event analysis

K.C. Yiu[1], H. Ma[1], L. Wang[1], G. Manguro[2], P. Gichangi[2,3,4], H. Musyoki[5], P. Bhattacharjee[6], S. Kaosa[7], J. Kioko[7], S. Isac[6,8], J. Blanchard[6], M. Becker[6], S. Mishra[1,9]

[1]Unity Health Toronto, MAP Centre for Urban Health Solutions, St. Michael's Hospital, Toronto, Canada, [2]International Centre for Reproductive Health, Mombasa, Kenya, [3]Technical University of Mombasa, Mombasa, Kenya, [4]Ghent University, Department of Public Health and Primary Care, Ghent, Belgium, [5]National AIDS & STI Control Program, Nairobi, Kenya, [6]University of Manitoba, Institute for Global Public Health, Department of Community Health Sciences, Rady Faculty of Health Sciences, Winnipeg, Canada, [7]Partners for Health and Development in Africa, Nairobi, Kenya, [8]India Health Action Trust, New Delhi, India, [9]University of Toronto, Division of Infectious Diseases, Department of Medicine, Toronto, Canada

Background: Evidence suggests early HIV acquisition risks before or at start of sex work. Until 2018, there were no HIV programs designed for young women who sell sex (YSW) in Kenya.
Methods: We used data from the 2015 *Transitions* Study, a cross-sectional survey of sexually active cis-women aged 14-24 years frequenting sex work venues in Mombasa, Kenya. We transformed cross-sectional data into a virtual cohort using the timing of self-reported events relative to the survey date and estimated the time from self-identifying as sex worker to first contact with an HIV prevention program for sex workers (program contact gap).
We used age-adjusted Cox proportional hazard regression models to identify determinants associated with initial program contact rate(higher rate means shorter contact gap). We estimated the population-level person-years of program contact gap among YSW in Mombasa

using the study sample's estimated contact gap, extrapolating based on published estimates of the YSW population size in Mombasa.

Results: Among 392 YSW, the program contact rate was 0.52 per 100 person-months (95% confidence interval (CI):0.38, 0.68) and median contact gap was 12 months (interquartile range: 2,24). In Mombasa, there was an estimated 11,532 person-years of sex work not reached by programs (estimated population-level contact gap for YSW). Older age at time of first negotiation in exchange for sex (age-adjusted hazard ratio (aHR): 1.2[95%CI:1.0,1.5]) was associated with a higher program contact rate (shorter contact gap) (Figure).

Among variables on perceptions of sex work, the only factor associated with a shorter contact gap was related to the ease/difficulty of earning money through sex work.

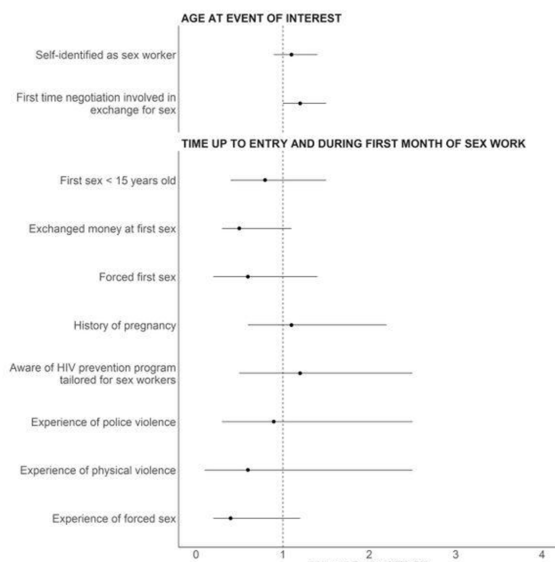

Figure. Forest plot of age-adjusted hazard ratios by determinants on contact gap.
Figure depicts association between determinants and time from self-identifying as a sex worker to first contact by HIV prevention program designed for sex workers (program contact gap).
Hazard ratios are adjusted for current age. A larger hazard ratio means a shorter contact gap.

Conclusions: There exists a large gap between the start of sex work and HIV program contact. Findings signal the need for services to reach YSW before or immediately after self-identifying as a sex worker. Data on start of sex work and program contact allow programs to monitor the local population-level contact gap as a key performance indicator.

Demand creation for HIV testing

EPC335

HIV testing strategies, types of tests, and uptake by men who have sex with men and transgender women: a systematic review and meta-analysis

L. Magno[1], M. Pereira[2], C. Tianeze de Castro[2], T. Aranha Rossi[1], L. Mirella Galvão Azevedo[3], I. Dourado[2]
[1]*Universidade do Estado da Bahia, Departamento de Ciências da Vida, Salvador, Brazil,* [2]*Universidade Federal da Bahia, Instituto de Saúde Coletiva, Salvador, Brazil,* [3]*Universidade Federal do Oeste da Bahia, Escola de Medicina, Barreiras, Brazil*

Background: Men who have sex with men (MSM) and transgender women (TGW) still face several barriers to HIV testing. The aim was to investigate the effectiveness of testing strategies (community- and facility-based testing) and types of HIV tests (standard laboratory, rapid, self, and multiple test combinations) to reach MSM and TGW, and barriers to testing.

Methods: A systematic review and meta-analysis was performed according to the PRISMA and registered in the PROSPERO. Several databases were searched between June-July/2020. Observational, intervention, and mixed studies that implemented HIV testing strategies for MSM and TGW were included.

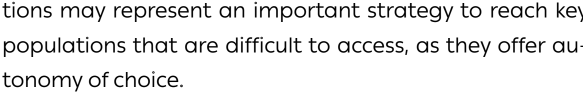
The outcomes analyzed were HIV infection prevalence, new HIV diagnosis detection, and HIV testing uptake. The prevalence and respective confidence intervals(95%CI) were calculated using a random-effects model.

Results: A total of 6,820 references were selected, and 263 were included in the review. Most studies included in this research were from high-income countries. Most the studies used the community or the internet as strategies for demand creation. Standard laboratory test had the highest uptake for MSM (100.0%, 95%CI 99.3–100.0) and multiple test combinations for TGW (100.0%, 95%CI98.6–100.0). The testing strategy with the highest uptake was facility-based for MSM (96.4%,95% CI 96.2–96.7) and TGW (100.0%,95%CI 98.6–100.0).

Facility-based testing strategy showed a high HIV infection prevalence and new HIV diagnosis detection for the MSM (7.7%,95%CI 7.5–8.0; 6.9%,95%CI 6.7–7.2, respectively) and TGW groups (20.4%,95%CI 15.7–25.8; 20.4%, 95%CI 15.7–25.8, respectively). Standard laboratory test showed the highest HIV infection prevalence among MSM (14.3%,95%CI 13.3–15.3) and multiple test combinations among TGW (14.7%,95%CI 12.3–17.3).

Urine test detected the highest rate of new HIV diagnosis detection for MSM (7.1%,95%CI 6.0–8.3) and multiple test combinations for TGW (14.7%,95%CI 12.3–17.3).Psychosocial and structural factors, such as stigma, and fear of positive test results, were the main barriers to HIV testing.

Conclusions: Facility-based testing and standard laboratory test stood out, but the study draws attention to the need for strategy diversification. Multiple test combina-



tions may represent an important strategy to reach key populations that are difficult to access, as they offer autonomy of choice.

Facility-based HIV testing strategies

EPC336

Prospective health setting evaluation of two Point of care Tests for Syphilis and HIV (PoSH Study) for the diagnosis and treatment of syphilis during an infectious syphilis outbreak in Canada

A. Singh[1], N. Ives[2], J. Gratrix[2], L. Ferron[2], L. Hale Balla[3], M. Crawford[2], K. Dong[4], G. Meyer[2], P. Smyczek[2], S. Rourke[5], K. Fonseca[6]

[1]University of Alberta, Medicine/Infectious Diseases, Edmonton, Canada, [2]Alberta Health Services, Edmonton, Canada, [3]Saddle Lake Cree Nation, SaddleLake, Canada, [4]University of Alberta, Edmonton, Canada, [5]University of Toronto, Toronto, Canada, [6]Alberta Precision Laboratories, Calgary, Canada

Background: Alberta (Canada) declared an outbreak of infectious syphilis in 2019 with approximately 20% of cases receiving same day testing and treatment.

We sought to evaluate the performance of two investigational dual point of care tests (POCT) for syphilis and HIV and to determine if POCT could shorten the time to syphilis treatment and facilitate linkage to HIV care.

Methods: Participants undergoing testing for syphilis and HIV were offered POCT from fingerprick whole blood specimens with the INSTI Multiplex HIV-1/2 Syphilis Ab test (bioLytical Laboratories, Richmond, BC) and the Multiplo Rapid TP/HIV test (MedMira, Halifax, NS).

Parallel testing was done using standard laboratory algorithms. POCT results were compared to standard test results from serum specimens, including two indeterminate HIV POCT results which were considered a preliminary positive. Linkages to care for non medically urgent positive HIV POCT results were made after serological confirmation.

Results: Of 1193 participants, 56.8% male (n=678), 43.0% female (n=513), and 0.2% trans (n=2) with a median age of 32.1 years (IQR 26.1-38.1). 1020 tests were conducted in a correctional facility, 64 at an STI clinic, 60 in a First Nations community and 49 in two inner city emergency departments. The HIV prevalence was 1.5% and the syphilis EIA reactive prevalence was 36.0%.

The sensitivity, specificity, positive and negative predictive values (PPV and NPV) of the tests are summarized below:

Two indeterminate HIV POCT were confirmed positive on serologic testing. Of 194 new syphilis cases, 89.6% (n=174) were infectious and 142 (81.6%) of these cases were tested and treated on the same day. Four new HIV positive cases were diagnosed; all were linked to care.

Test	Sensitivity (%)	Specificity (%)	PPV (%)	NPV (%)
INSTI Multiplex HIV1/2 Syphilis Ab				
HIV	100	99.8	90	100
Syphilis (RPR < 8 dils)	52.5	99.7	98.3	87.7
Syphilis (RPR ≥ 8 dils)	97.5	99.7	99.0	99.3
Multiplo Rapid TP/HIV				
HIV	100	99.6	81.8	100
Syphilis (RPR < 8 dils)	70.7	99.7	98.6	92.6
Syphilis (RPR ≥ 8 dils)	98.4	99.4	97.9	99.6

Table.

Conclusions: Both POCT for HIV and syphilis (especially with RPR ≥ 8 dilutions) performed well in health settings using fingerstick whole blood specimens. POCT have the potential to aid in the testing and reduce the time to treatment of infectious syphilis.

EPC337

Associations between service readiness and PMTCT cascade effectiveness: a 2018 cross-sectional analysis from Manica province, Mozambique

A. Dinis[1,2], O. Augusto[1,3], K. Ásbjörnsdóttir[4], J. Crocker[1], C. Inguane[1], S. Gimbel[5], I. Ramiro[6,7], K. Sherr[1]

[1]University of Washington, Global Health, Seattle, United States, [2]Ministry of Health of Mozambique, Maputo, Mozambique, [3]Eduardo Mondlane University, Maputo, Mozambique, [4]University of Iceland, Center of Public Health Sciences, Reykjavík, Iceland, [5]University of Washington, Department of Child, Family and Population Health Nursing, Seattle, United States, [6]Health Alliance International, Maputo, Mozambique, [7]Comité para Saúde de Moçambique, Maputo, Mozambique

Background: Despite high coverage of maternal and child health services in Mozambique, prevention of mother-to-child transmission of HIV (PMTCT) cascade outcomes remain sub-optimal. Delivery effectiveness is modified by health system preparedness, and identifying modifiable factors that impact quality of care and service uptake can inform strategies to improve PMTCT programs effectiveness.

We estimated associations between facility-level modifiable health system readiness measures and HIV testing implementation and outcomes: early infant diagnosis (polymerase chain reaction (PCR) before 8 weeks of life), ever PCR (before or after 8 weeks), and positive PCR test result.

Methods: A 2018 cross-sectional, facility-level study was conducted in a sample of 36 health facilities in 12 districts in Manica province, central Mozambique, as part of a baseline assessment for the SAIA-SCALE trial (NCT03425136). Data on HIV testing outcomes among 3,427 exposed infants were abstracted from at-risk child service registries. Nine health system readiness items were included in the analysis.

Logistic regression were developed to estimate associations between readiness measures and pediatric HIV testing outcomes. Odds ratios and 95% confidence intervals are reported.

Results: Forty-eight percent of HIV-exposed infants had a PCR test within 8 weeks of life, 69% ever had a PCR test, and 6% tested positive. Staffing levels, gloves stockout and distance to the reference laboratory were positively associated with early PCR (OR =1.36[1.19,1.54], OR=1.73[1.24, 2.40] and OR=1.12[1.07, 1.16], respectively) and ever PCR (OR=1.35[1.18,1.54], OR=1.80[1.26, 2.58] and OR=1.13[1.09,1.19], respectively). Catchment area size and multiple NGOs supporting PMTCT services were associated with early PCR testing (OR=1.47 [1.19; 1.81] and OR=0.54 [0.30, 0.97], respectively).

Facility type, stockout of prophylactic antiretroviral, the existence of quality improvement program and mothers' support groups in the health facility were not associate with PCR testing. No associations with positive HIV result were found.

Conclusions: Salient modifiable factors associated with HIV testing for exposed infants include staffing levels, distance to the reference laboratory, catchment area size, NGO support and stockout of essential commodities. Strategies should target these factors to improve PMTCT performance, particularly at small and rural facilities.

EPC338

Use of an electronic adult HIV screening tool and HIV self-testing for improved targeted HIV testing in Zimbabwe

K.C. Takarinda[1], E. Dhodho[1], P. Chimberengwa[1], S. Page-Mtongwiza[1], K. Webb[1,2], A. Sibanda[1], T. Mhlanga[1], P.K. Kambamura[1], T. Bepe[1], T.T. Chinyanga[1]

[1]*Organization for Public Health Interventions & Development, Harare, Zimbabwe,* [2]*London School of Hygiene and Tropical Medicine, London, United Kingdom*

Background: In the quest to identify the narrowing gap of undiagnosed people living with HIV (PLHIV), HIV testing in Zimbabwe has increased by 43% from 2011-2019 but with decreasing testing yields ranging from 20% to 5%. This necessitated adoption of HIV screening tools for better targeting of high-risk clients.

In this project, an electronic HIV screening tool was piloted to identify clients aged ≥15 years old at high-risk of HIV in outpatient/inpatient departments (OPD/IPD) for HIV testing at high-volume public health facilities in Zimbabwe.

Description: The tool was a custom-made application uploaded on electronic tablets and designed with a decision support logic to decline or offer HIV self-testing (HIVST) and subsequent rapid HIV-testing to those with a "yes" for at least one of 17 questions assessing:

i. Behavioural HIV-risk exposures,

ii. Tuberculosis symptoms or no previous exposure to HIV testing or within the past 12 months.

Those with STI symptoms (genital rash, sores, or discharge) in the past year were immediately eligible for rapid HIV-testing.

Lessons learned: Between 01 July 2021-31 December 2022, 12,455 patients were screened across 66 health facilities in the OPD/IPD of whom 8,109 (65%) were females with a median age of 30 years (IQR, 22-40). Of these, 1,947 (15.6%) had never been HIV-tested whilst 9,510 (75.8%) reported a previous HIV-negative result. Of 11,457 assessed for HIV-risk behaviours/symptoms, 1,270 (11%) were eligible for direct rapid HIV-testing, 1,245 (98%) were tested resulting in 15.7% being HIV-positive. Of the 11,090 eligible for HIVST, 73.9% received an HIVST with 8% being reactive of whom 95.4% were HIV-positive.

Compared to the July-December 2020 period for same facilities, rapid HIV tests conducted in OPD/IPD decreased by 92% from 21,177 to 1,765 and overall HIV testing yield improved from 11.1% to 39%.

Conclusions/Next steps: An electronic screening tool assists health care workers to consistently and systematically determine and document eligibility of clients for HIV testing.

Wider adoption of the electronic adult screening tool coupled with HIVST will not only reduce numbers HIV tested and improve HIV-positivity yield but also enhance accurate decision-making in determining eligibility for HIV screening and testing.

EPC339

Safe index testing as a high yielding HIV case identification strategy, the successful implementation by Oljabet Health Center, Laikipia, Kenya

O. Osoti[1], D. Wandina[2], D. Juma[3], J. Kibet[4], N. Osinde[5], A. Gwada[1], J. Kamande[6], G. Mochama[7], D. Mogeni[8], W. Opudo[5], P. Kamau[9]

[1]*Goldstar Kenya, Monitoring and Evaluation, Nairobi, Kenya,* [2]*Goldstar Kenya, HIV Prevention, Nairobi, Kenya,* [3]*Deloitte, Data Management, Nakuru, Kenya,* [4]*FHI 360, Pharmacy and Supply Chain, Nairobi, Kenya,* [5]*Goldstar Kenya, HIV Care and Treatment, Nairobi, Kenya,* [6]*Laikipia County Department of Health, Health, Nyahururu, Kenya,* [7]*Laikipia County Department of Health, Health, Nanyuki, Kenya,* [8]*Laikipia Health Services, Health, Oljabet, Kenya,* [9]*Goldstar Kenya, Program Management, Nairobi, Kenya*

Background: Globally, an estimated 38 million people are living with HIV, and nearly one in five are unaware of their HIV status. WHO introduced safe index and partner notification testing strategy centred on obtaining a list of contacts sharing HIV risk with HIV-positive clients. USAID funded projects (Afya Nyota ya Bonde and USAID Tujenge Jamii) in partnership with Laikipia County have supported the implementation of safe index testing through the Surge initiative from 2019. Oljabet Health Center worked further to develop and adopt context-specific strategies to integrate index testing in service delivery.

Methods: Facility data review sessions were used to track and adopt short learning loops, identifying strategies that worked for scaling up. A multipronged approach where elicitation of sexual contacts from consenting clients was adopted. It involved clinicians, nurses, HTS Service providers, mentor mothers, community link personnel or adolescent champions. This depended on which provider the client had forged a better personal relationship and who the client was most comfortable engaging in the subject of their sexual contacts. Cultural barriers around age and gender on discussions surrounding sex and sexual contacts were taken into consideration.

Results: We included data on index testing for Oljabet Health Center from 2019 to 2021. In the year 2020 the facility after adopting the context-specific strategies for safe index testing realized a 46% contribution of positives from index testing and a 27% positive yield up from 0% in 2019. The improved performance based on the strategies was sustained in 2021 where the facility registered 40% positive contribution from index testing and a yield of 31%. The facility contributed to 9% of the index testing and 21% of the positives identified through index testing for Laikipia County by the end of the financial year 2021.

Conclusions: The implementation of safe index testing is a high impact intervention for HIV case identification. The modality is high yielding and should be rolled out in all the health facilities.

Facilities should implement adaptive learning by continuously evaluating processes to identify and adopt safe index testing strategies that are context-specific based on client needs, cultural beliefs and responsive existing systemic and cultural barriers.

Community-based HIV testing strategies

EPC340

Urban Mobile Testing in key population as a strategy to reduce the HIV diagnostic gap in Lima, Peru

R. Errea[1], E. Gonzales Monzo[1], L. Picoaga Romero[2], M. Alegre Tuesta[2], M.A. Tovar Huamani[3], L. Lecca[4], L.Z. Llanos[5]

[1]Socios en Salud Sucursal Peru (Partners in Health - Peru), Community Health Program, Lima, Peru, [2]Ministry of Health of Peru, Directorates of Integrated Health Networks of Lima North - Health Strategy for the Prevention and Control of STIs, HIV/AIDS and Hepatitis, Lima, Peru, [3]Socios en Salud Sucursal Peru (Partners in Health - Peru), Medical Direction, Lima, Peru, [4]Socios en Salud Sucursal Peru (Partners in Health - Peru), Executive Directorate, Lima, Peru, [5]Ministry of Health of Peru, Directorates of Integrated Health Networks of Lima North - General Direction, Lima, Peru

Background: In Peru, 30% of people living with HIV are unaware of their diagnosis. The HIV epidemic in Peru is concentrated in Lima (58%), in men who have sex with men (MSM, 10%), transgender women (TW, 30%) and sex workers (SW, 1-2%). To reduce the HIV diagnostic gap, the non-profit organization Socios En Salud (SES), together with the Northern Lima Health Directorate of the Ministry of Health, reimplemented a mobile strategy to screen key populations (MSM, TW and SW) in urban areas of Lima.

Description: The regular strategy screens the general population (key and non-key) that arrives at the STD and HIV/AIDS Referral Centers (CERSH), while the mobile strategy (*Urban Mobile Testing - UMT*) screens key population that is invited to screening points on designated dates, where 1 nurse and 2 peer counselors carry out free HIV screening. MSM and TW are recruited through a dating mobile application, while SW are recruited outside of where they work. Five to ten BMU are performed per month, avoiding repeating screening points. Individuals with positive results are linked to the CERSH for treatment initiation.

Lessons learned:

	UMT		CERSH	
	Individuals screened (key population)	Reactivity	Individuals screened (general population)	Reactivity
May	51	7.80%	196	2.55%
June	71	5.63%	226	2.65%
July	46	10.80%	140	5.00%
August	109	11.90%	57	3.51%
September	92	18.18%	136	8.09%
October	97	10.30%	150	7.33%
Total	466	10.70%	905	4.64%

Table. Comparison of number of individuals screened and percentage of reactivity in the UMT versus CERSH between May-October 2021.

Since June, flyers with information of all the dates and points of testing of the month were shared with participants. Since September, condoms were given free to participants. Both events could explain the increases in positive cases since then.

Conclusions/Next steps: The UMT obtains double the percentage of reactivity compared to the regular strategy. UMT is an efficient strategy to reduce the gap in HIV diagnosis in Peru.

EPC341

Maintenance of HIV voluntary counseling and testing service during the COVID-19 pandemic: an Internet-based primary health care network in Guangzhou, China

Y. Gu[1], Y. Luo[1], C. Hao[2], Y. Lu[3], G. Meng[3], L. Sun[3], L. Zhang[1], Y. Cai[1], Z. Han[1]

[1]Guangzhou Center for Disease Control and Prevention, Guangzhou, China, [2]Sun Yat-sen University, Guangzhou, China, [3]Lingnan Partners Community Support Center, Guangzhou, China

Background: In Guangzhou, China, center for disease control and prevention (CDC) of city and district level and the primary health care institution (PHCI) of community level constitute the VCT network. Previously, people knew less about the VCT provided by PHCIs and preferred to acquire VCT at CDCs. Since COVID-19 spread over the world, CDCs in China took the responsibility to combat the pandemic, which compelled the service hour for VCT to be cut. Hence we tried to maintain the VCT service in this circumstance, through an Internet-based PHCI network.

Description: Based on WeChat (a Chinese social application like WhatsApp) Mini-Program Framework, we developed an online VCT service applet named "ChaBei" which can be used on WeChat without installing additionally. "ChaBei" provides consultation function for people to communicate with experts online and appointment function for accessing VCT service offline.

After internal testing within 12 CDCs in 2018, we began to promote "ChaBei" to PHCIs since 2019. As VCT sites on "ChaBei" increased from 108 (2019) to 149 (2020) to 166 (2021), this Internet-based network has covered the entire 11 districts of Guangzhou City.

Lessons learned: For 2019, 87.9% of the total 10528 online appointments on "ChaBei" were seeking for VCT at CDCs. In 2020, due to the impact of COVID-19, the amount of online appointments (6438) was 38.8% lower than 2019. But the proportion of appointments to PHCIs has increased from 12.1% to 39.3%. Despite the VCT service hour of CDCs were further shortened in 2021, the online appointments made on "ChaBei" still had an 27.1% growth. Among, we found the reason may be that the appointments for VCT at PHCIs contributed 51.1% to the total amount (8180).

Conclusions/Next steps: Internet-based VCT model is a promising solution to bind the PHCIs together as a network. Especially under the circumstance like COVID-19, it provides a great opportunity to promote the utilization of VCT at PHCIs, and to maintain the VCT service of the city by the joint efforts of all PHCIs. Further, this model can be utilized well in many cities and helps to develop a nationwide network for people to connect to VCT service more conveniently.

EPC342

Periodic HIV Index Case Testing: a worthwhile approach to reach "the unreached" in the journey to epidemic control

K. Mwanda[1], M. Chikuba-Mcleod[2], M. Musonda[3], S. Habbanti[1], D. Chilenga[1], I. Siluka[1], L. Mashapi[1], T. Kapinda[1]

[1]John Snow Incorporation/USAID DISCOVER-Health, Clinical Care, Lusaka, Zambia, [2]John Snow Incorporation/USAID DISCOVER-Health, Management, Lusaka, Zambia, [3]USAID - Zambia Mission, Health Office, Lusaka, Zambia

Background: With over 90% of people living with HIV (PLHIV) already diagnosed in Zambia (MoH-ZAMPHIA, 2018), it has become increasingly difficult to reach the people that remain untested and undiagnosed. The JSI implemented USAID DISCOVER-Health project embarked on a robust initiative to identify potentially untested PLHIV.

Description: Between July and August 2021, USAID DISCOVER-Health project offered index case testing to clients that were already on treatment and had initially undergone index case testing, but have since found new sexual partners. Trained psychosocial counselors provided a brief counselling session that aimed at eliciting the new sexual partners. The partners were then approached and offered HIV counselling and testing in a professional manner either with the help of the index clients or as part of a community level door-to-door HIV testing program.

Lessons learned: Through engaging with 503 (196 males and 307 females) clients that were on treatment from 0-18 months, 572 sexual partners (223 males and 349 females) were elicited.

523 (91.4%) accepted speaking to a counsellor. Of these313 (59.8%) were testedand 210 (40.2%) knew their status, but had not disclosed it to the indexed partner.

Of those tested, 55 (17.6%) were positive. Of the positives, 22 (40%) were male, while 33 (60%) were female. The largest proportion of the positives, 31 (70.9%), were elicited from partners that were on treatment for 13-18 months. While the least, 6 (10.9%), came from those on treatment for 0-6 months, and those on treatment for 7-12 months accounted for 18 (32.7%).

Conclusions/Next steps: Though recipients of index services already on ART will not necessarily transmit HIV to their new partners once they are on treatment and virally suppressed, they remain an important link to the unreached people living with HIV that are not yet diagnosed. This applies especially to those that are on treatment for a longer period, deeming periodic HIV index case testing a worthwhile strategy to finding those that are yet to be

reached. In areas where saturation is evident, the Project has included periodic index case testing among its case identification strategies.

EPC343
A case study: index case tracing and testing of male partners and children in Angola

N. Kwendeni[1], K. Grubb[1], S. Ellis[1], S. Zondo[1], I. Kuleba[2], A.M. Mbule[1], L. Makhupula[1], K. Schmitz[1]
[1]*mothers2mothers, Programmes and Technical Support, Cape Town, South Africa,* [2]*mothers2mothers, Programmes, Luanda, Angola*

Background: In Angola, m2m uses the community tracing and testing approach to reach male partners and biological children of HIV-positive pregnant and breastfeeding women (PBFW) enrolled into the facility program. Lay healthcare cadres, known as Mentor Mothers are trained and accredited to conduct rapid HIV testing in the community.
As health facilities, index clients, who are HIV-positive PBFW are identified and enrolled, and consent is obtained to trace their male partners and biological children under the age of 15 years.
Methods: We conducted a descriptive analysis of data collected from two sites in Angola from January 2020-June 2021. The data included services provided by Mentor Mothers, which was collected using a mobile health application. The sample, consisted of male partners and biological children aged below 15years of HIV positive antenatal and postnatal women registered at health facility level.
Results: Out of 2, 978 women enrolled at facility, 97% consented to index case tracing and testing. 2,976 male partners were named and traced in the community. Out of the 55% of the men contacted, 151 men (9%) were found to be HIV positive and 99% of these men were linked to ART. 55% of the 6,624 children elicited from PBFW and new mothers were traced in their communities, 4% yielded an HIV positive result and 94% of these were linked to care and initiated on ART.

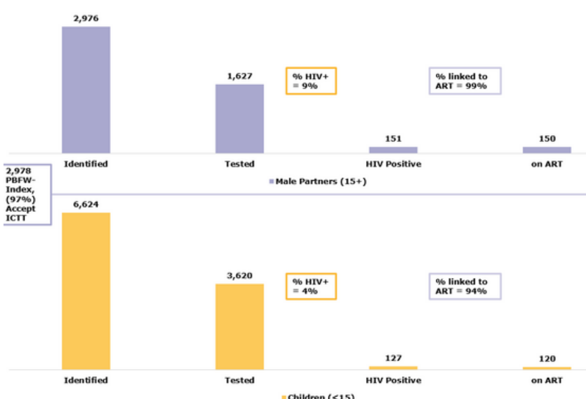


Figure 1. m2m's performance along the HIV case tracing and testing cascade in Angola.

Conclusions: The 9% positivity rate among male partners tested is considerably higher than Angola's **1.9%** HIV prevalence rate, as published by UNAIDS 2019. Children linked to care and initiated on ART, slightly below the 95% treatment target. m2m's performance against the UNAIDS 95-95-95 goals remains high even when implementation of the community-based HIV testing strategy was challenged by the pandemic

EPC344
Implementing Scottish community-led HIVST in the era of COVID-19 (June 2021-2022)

A. Hudson[1], L. Clarke[1], M. Greenshields[1]
[1]*HIV Scotland, Glasgow, United Kingdom*

Background: Widespread availability of HIV self-testing (HIVST) has the potential to overcome disparities in access to and uptake of HIV testing, particularly among key and minoritised groups. Because of the severe disruption of COVID-19 impacted upon sexual health and blood borne virus services (SHBBVs) in Scotland, and in light of advantages of HIVST and reinvigorated policy priorities reflected in zero new HIV Transmissions by 2030, HIV Scotland – funded through Gilead Sciences – developed an online platform for ordering HIVST kits.
Description: HIV Scotland has provided free HIVST since March 2020 in which tests are procured through a dedicated website (HIVTest.scot) and delivered discreetly to everyone in Scotland. This presentation focuses on the period since relaunch and rebrand (June 2021 to June 2022). The service rebrand improved efficiency in ordering process, number of 'contact points' with the end user, enhanced health promotion and had a greater emphasis on follow-up. These efforts were framed within a HIVST service which reflected an Amazon-like e-commerce platform with a dedicated marketing campaign.
Lessons learned: HIV Scotland distributed 4358 HIVST kits with the majority being ordered by males (n = 2747, 63%). A growing number of service users self-identify as female (n = 1131, 26%) and the remaining identified as non-binary (n = 69, 2%) and trans (n = 27, <0.5%). Across this period, 4 provisional positive results have been recorded and support offered. We identified a highly acceptable, engaged click-through journey of the HIVST service. By making changes in the service platform design, as well as a dedicated – diverse- advertising campaign, we expanded the potential reach to potential service users which has been documented in the growing demographic diversity from those who order a HIVST.
Conclusions/Next steps: Community-led HIVST has the potential to increase HIV testing access for a range of demographics and minoritsed groups by circumventing clinic-based structural barriers. Given promising findings from the relaunch, we have received increased funding to strengthen the advertising campaign for HIVST and endeavour to compare future uptakes on a cyclical basis. We

are also exploring opportunities to integrate HCV tests in the postal service to those with further SHBB needs across Scotland.

Peer-led HIV testing strategies

EPC345

Social network strategy: an innovative approach to reach hard-to-reach people who inject drugs in northeast states in India

B. George[1], P. Goswami[2], K. Perry[3]
[1]FHI 360, India Country Office, New Delhi, India, [2]Independent Consultant, New Delhi, India, [3]FHI 360, APRO, Bangkok, Thailand

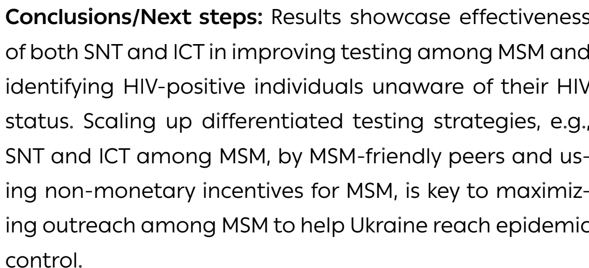
Background: India has a concentrated HIV epidemic, with an estimated 2.3 million people living with HIV (0.22% adult prevalence). Key populations (KPs) are disproportionately affected, with HIV prevalence among people who inject drugs (PWID) at 6.26%. High HIV prevalence in northeast states of Mizoram (2.3%), Nagaland (1.45%), and Manipur (1.18%) is driven by injecting drug-use behavior.
Under the PEPFAR/CDC-supported Project Sunrise, FHI 360 implemented social network strategy (SNS), an innovative approach to provide HIV prevention, testing, and treatment services to hard-to-reach PWID in these three states from June 2019 to March 2020.
Description: Community-based organizations (CBOs) hired peers as seed participants and used a chain-referral recruitment strategy and social network connections to reach, test, link, and treat hard-to-reach PWID in six sites in the three states.
Using 139 initial seed participants (14 HIV positive, 125 HIV negative), 3,495 PWID, injecting and sexual partners were recruited and tested for HIV. SNS participant characteristics included predominantly male (95%); young (44% less than 25 years); unmarried (59%); completed basic school (56%); and unemployed (55%).
Three hundred (8.6%) tested HIV positive, of whom 208 (69%) were initiated on antiretroviral therapy. Nine hundred thirty (29%) HIV negative participants were linked to harm reduction programs. Twenty-one (7%) of the 300 HIV-positive clients were females.
Nearly half (n=311) of the new HIV-positive PWID were identified in Aizawl, Mizoram, with a 19% case-finding rate.
Lessons learned: SNS can strengthen CBO networks' ability to penetrate hard-to-reach networks using minimal additional human resources. Early community involvement with SNS processes was critical to the strategy's effectiveness, including the discussion of incentives.
Robust referral networks including network size, syringe services, and injection environment improved identification of undiagnosed PWID. Enrolment of spouse and sexual partners through SNS was challenging.
Conclusions/Next steps: SNS implementation effectively reached unreached populations and provided communities with increased access to HIV services. Based on the results of SNS implementation, National AIDS Control Organization included SNS in expanded outreach interventions to reach new KP individuals. Such network-based referral strategies, including both SNS and index testing services, should be scaled up and integrated to increase case finding to accelerate progress toward achieving the UNAIDS 95-95-95 goals.

EPC346

Advancing peer-driven social network testing (SNT) and index testing to maximize reach of HIV testing services (HTS) among men who have sex with men (MSM) and their contacts in Ukraine

S. Leontieva[1], T. Gaborets[1], N. Roman[1], K. Gamazina[1]
[1]PATH, Ukraine Country Program, Kyiv, Ukraine

Background: Ukraine's HIV epidemic is concentrated among key populations, with a prevalence of 7.5% among MSM, highlighting a need for additional strategies to more efficiently reach MSM and their contacts. The USAID/PATH Serving Life project introduced SNT and expanded index testing to improve access to HIV testing and linkage services among MSM and their contacts across nine oblasts.
Description: Under the project's SNT approach, trained community workers (peer case finders and social workers) offered HTS to MSM through multiple outlets (e.g, MSM-friendly counseling rooms; hotspot outreach; and virtually through gay dating apps). Community workers counseled MSM on HTS; provided assisted or unassisted HIV self-testing, based on client preference; and offered non-monetary incentives (premium dating app subscriptions; telephone credits; high-quality lubricants) for testing. They followed up with clients to confirm self-test results and link those with reactive results for confirmatory diagnosis and treatment, or PrEP for HIV-negative clients at substantial risk. Community workers also offered HTS to eligible partners and biological children of HIV-positive MSM (current and new) via index testing, with referrals to follow-on services. We analyzed program data from October 2020 to September 2021 for both approaches.
Lessons learned: Among the 5,136 MSM tested through SNT, 127 were newly diagnosed HIV positive (2.5% yield) among whom 120 (95%) were initiated on treatment. 160 (61%) HIV-positive MSM accepted index testing and provided 490 contacts of whom 441 (90%) accepted HTS, with 56 confirmed HIV positive (12.7% yield) and 55 (98%) initiated on treatment. While more people were tested and diagnosed HIV-positive through SNT, the testing yield was more than five times higher under index testing—both approaches were critical to reach overall results. Both models had high linkage to treatment rates, and clients appreciated service delivery by MSM-friendly community workers and the various options provided.



Conclusions/Next steps: Results showcase effectiveness of both SNT and ICT in improving testing among MSM and identifying HIV-positive individuals unaware of their HIV status. Scaling up differentiated testing strategies, e.g., SNT and ICT among MSM, by MSM-friendly peers and using non-monetary incentives for MSM, is key to maximizing outreach among MSM to help Ukraine reach epidemic control.

EPC347

Towards HIV epidemic control: Social Network Strategy as a testing modality to reach underserved key populations for HIV testing and prevention services

L.K. Mwango[1], B. Lindsay[2], P. Olowski[3], T. Khauso[3], B. Musonda[4], S.L. Malupande[1], E. Fundulu[1], H. Kabombo[1], C. Nzangwa[1], J. Sikanyika[3], H. Sakala[1], R. Sheneberger[3,2], L. Hachaambwa[2,1], C.W. Claassen[3,2]

[1]Ciheb Zambia, Lusaka, Zambia, [2]Center for International Health, Education, and Biosecurity, University of Maryland School of Medicine, Lusaka, Zambia, [3]Maryland Global Initiative Corporation, Lusaka, Zambia, [4]Ministry of Health, Lusaka, Zambia

Background: Moving towards HIV epidemic control in Zambia requires innovative approaches to reach the remaining people living with HIV. Social network strategy (SNS) is an incentive-based testing modality which assumes that people in the same social network share similar HIV risks. Through the CIRKUITS project, we used SNS to identify underserved key populations (KPs) in the rural Eastern Province of Zambia.

Description: To implement SNS, we set up safe spaces in the community and conducted SNS and KP sensitivity trainings for 45 peer promoters, nurses, and community liaison officers. Peer promoters identified recruiters from KP communities, including female sex workers (FSWs), men who have sex with men (MSM), and transgender (TG) persons. Each recruiter was given five coupons to distribute to network members.

Upon presentation of the coupon at the safe space, KPs received health education, risk screening, and health services based on their risk profile, including antiretroviral treatment (ART) or HIV pre-exposure prophylaxis (PrEP). Upon coupon redemption clients received an incentive of 20 kwacha (~1.50 USD).

Lessons learned: From October to December 2021, 73 recruiters distributed 323 coupons and 137 (78%) were redeemed, as follows: 49 FSW distributed 243 coupons (104, 98% redeemed), 19 MSM distributed 60 coupons (24, 53% redeemed), and 5 TG distributed 20 coupons (9, 45% redeemed).

Of the redeemed coupons, 132 (96%) accessed HIV testing. Of these 28 (21%) tested HIV positive: 26/105 (25%) FSW, 2/19 (11%) MSM, and 0/8 (0%) TG, with all 28 (100%) linked to ART. Furthermore, 104 (79%) tested negative with 73 (70%) KPs accessing PrEP: 59 FSWs, 10 MSM, and 4 TG.

SNS identified KPs not accessing testing via traditional modalities. FSW recruiters had minimal challenges in inviting their network members to access health services. However, only half of the coupons distributed among MSM and TG were redeemed.

Conclusions/Next steps: In Zambia, SNS was highly successful at identifying PLHIV among FSWs, moderately so for MSM, and did not identify TG. Including KP community members in providing HIV testing services via community safe spaces helped identify underserved KPs who had not yet accessed HIV testing. Linkage to ART and PrEP was high for clients identified via SNS.

EPC348

Enhanced peer outreach approach increases HIV case finding among female sex workers and men who have sex with men in Dar Es Salaam, Tanzania

C. Mbise[1], A. Mwakibete[1], B. Ogwang[1], J. Ng'weshemi[1], I. Mauya[1], M. Ngailo[1], D. Boyee[1], E. Thobias[2], M. Mkesso[3], M. Abnoor[4], N. Njuguna[5], U. Kategile[6]

[1]FHI 360, EpiC, Dar es Salaam, Tanzania, The United Republic of, [2]Mapambano Ya Kifua Kikuu Na Ukimwi (MUKIKUTE), EpiC, Dar es Salaam, Tanzania, The United Republic of, [3]Asasi ya Uwezeshaji Tanzania (ASUTA), EpiC, Dar es Salaam, Tanzania, The United Republic of, [4]Partners for Health Services and Research Foundation (PHSRF), EpiC, Dar es Salaam, Tanzania, The United Republic of, [5]FHI 360, LINKAGES, Nairobi, Kenya, [6]USAID, Dar es Salaam, Tanzania, The United Republic of

Background: In Tanzania, key populations (KPs) are disproportionately affected by HIV with prevalence among female sex workers (FSWs) and men who have sex with men (MSM) estimated at 26% and 25% respectively. Despite community outreach for HIV testing services, higher-risk KP individuals remain hidden due to stigmatization, discrimination, and criminalization. The USAID- and PEPFAR-funded EpiC project implemented the enhanced peer outreach approach (EPOA) to improve HIV case identification among FSWs and MSM in Dar Es Salaam, Tanzania.

Description: Peer-led coupon network mobilization was implemented in an urban region of Dar Es Salaam. Twenty Peer Educators (PEs) were trained to identify hard-to-reach KP members and invite them to access HIV testing services (HTS) using a coupon promotion. Ten Health Care Providers (HCPs) were trained to screen clients accessing HTS and select those with higher-risk peer networks to become peer mobilizers (PMs). PMs were given coupons to distribute to their risk networks and invite them to receive comprehensive HIV services. Each PE and PM was given five coupons and provided with monetary incentives for each one returned. Weekly network analysis was done to identify PEs and PMs with productive networks for continued coupon distribution. We compare case identification rates from EPOA and traditional mobile testing, used Chi-squared test to determine if the difference is statistically significant.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Lessons learned: EpiC distributed 1,893 coupons (1,325 FSWs and 568 MSM) between July 2020 and September 2021; 1,590 (84%) individuals returned with coupons. Of those, 100% were offered and accepted HIV testing. HIV case finding rate was 14.3% (169/1,179) among FSW tested through EPOA and 6.5% (1,257/19,411) through traditional mobile testing. Among MSM, case finding rate was 16.1% (66/411) through EPOA and 10.4% (534/5,126) through traditional mobile testing. The odds of testing positive were 2.4 times higher among FSW in EPOA compared to traditional mobile testing (2.42 Odds ratio, 2.03-2.89 95%CI), and 1.6 times higher among MSM tested through EPOA (1.65 Odds ratio, 1.23-2.18 95%CI).

Conclusions/Next steps: EPOA is effective in identifying high-risk FSWs and MSM, especially those who are difficult to reach through traditional methods. EPOA provides a viable option in settings where case finding has proven to be a challenge.

EPC349

"Lesotho's eMTCT Detectives": mentor mothers' tireless work towards HIV epidemic control through m2m's comprehensive PMTCT services

H. Mandali[1], M. Mohloai[1], M. Nyapisi[1], M. Mosoeu[1], N. Kwendeni[2], L. Makhupula[2], A.M. Mbule[2], S. Ellis[2], K. Grubb[2], J. Mirembe[3], T. Sonkwele[4]
[1]mothers2mothers, Programmes, Maseru, Lesotho, [2]mothers2mothers, Programmes and Technical support, Cape Town, South Africa, [3]PEPFAR/USAID, Maseru, Lesotho, [4]PEPFAR/USAID, Johannesburg, South Africa

Background: m2m's peer-led integrated service platform employs HIV positive women as 'Mentor Mothers' to deliver innovative and proactive approaches for uptake of PMTCT cascade services. With funding from USAID/the President's Emergency Plan for AIDS Relief (PEPFAR), m2m is working closely with the Lesotho Ministry of Health (MOH) to improve the lives of pregnant and breastfeeding women (PBFW) and their families.

From January - March 2019 as part of the comprehensive PMTCT services package, Mentor Mothers accelerated their support in linking or access of PBFW and HIV-exposed infants (HEIs) to HIV testing services.

Methods: The data sampled included data from July 2018 to June 2021, an analysis of uptake of PMTCT services among HIV-positive PBFW and HEIs (aged 0-2 years) from a sample of 31 sites was performed.

The evaluated indicators include rates of HIV infections to exposed infants by measuring the MTCT rates, early infant diagnosis (EID) services uptake, and outcome test.

Results: Rates of MTCT among this sample ranged from 0% - 3.3%, with a final rate reported at 1.7% in April – June 2021. The positive trends can be appreciated starting from the first quarter of FY19 when m2m started to implement a comprehensive PMTCT program, which increase in EID testing within two months and documentation of the outcomes of the HIV Exposed Infants.

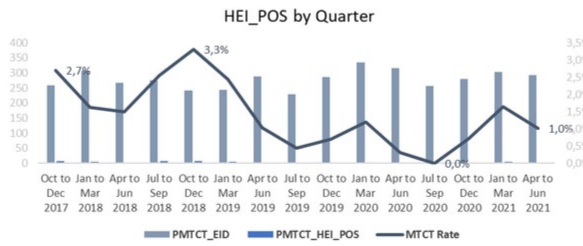


Figure. HEI_POS by quarter.

Conclusions: The results highlight the importance of having competent mentor mothers in achieving lower rates of mother to children transmission, and increase access to early infants' diagnosis services. The scaling up of the comprehensive model resulted in increasing EID contributing to the general positive desired results across the country.

Our findings underscore the important work of Mentor Mothers ('eMTCT detectives') in reaching every possible client who may potentially benefit from comprehensive PMTCT services.

HIV testing with virtual and/or digital support

EPC350

Going Online: pilot of a complementary virtual approach to engage key populations and other hard-to-reach people with HIV services

S. Cooper[1], G. Kamanga[1], S. Noriega Minichiello[2], C.K. Kerbay[1], R. Lyimo[1], D. Darrow de Mora[3], N. Fousa Clement[1]
[1]FHI 360, Monrovia, Liberia, [2]FHI 360, North Carolina, United States, [3]FHI 360, Washington DC, United States

Background: The PEPFAR- and USAID-funded Meeting Targets and Maintaining Epidemic Control (EpiC) project, led by FHI 360 in Liberia, is piloting Going Online (GO), a complementary approach to maximize reach and provide a comprehensive package of HIV services to key populations (KPs) and other hard-to-reach people. GO is primarily intended to increase reach to unreached individuals, engage them using online platforms, and connect them to HIV services.

Description: EpiC Liberia used an app called QuickRes developed by FHI 360 to manage clinic appointments and complete the cascade of HIV services. EpiC identified and trained two community peer outreach workers (OWs), as well as "elite" outreach workers (elite OWs). The latter are professional health workers recruited for their skill and rapport with clients. Peer educators assisted clients with taking an online risk assessment that helped the client decide which services they needed. The app then walked clients through the booking process, helping them identify the nearest of seven PEPFAR-supported facilities where they could receive HIV services.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Lessons learned: We launched QuickRes on July 19, 2021, and have reporting through December 8, 2021. EpiC successfully reached and booked 311 clients (236 KP clients booked by peer OWs, and 75 general population clients booked by elite OWs). All 311 clients (100%) arrived at the facilities, and 30 clients who rebooked for antiretroviral therapy (ART) refilled successfully, for a total of 341. Overall, 62 clients (18%) tested positive, and all were initiated on ART; this is the highest case-finding rate within the subsets of case-finding strategies for EpiC Liberia. The HIV case finding from KP clients booked through community OWs was 21.6% (51/236). The HIV case finding from elite OWs was 14.7% (11/75). Ordinary outreach testing in the project had a case-finding rate of 11% during the reporting period.

Conclusions/Next steps: Using peer OWs improved reach among key population individuals, who are more likely to be positive. There are ongoing efforts to document and scale up best practices from the pilot as we strive to replicate results in other areas of Liberia.

EPC351

National HIV Testing Week: an effective tool for increasing HIV testing at scale in key populations during and beyond COVID-19

C.A. Kifetew[1], A. Sparrowhawk[1], K. Neate[2], T. Mukiwa[1], D. Edwardes[1], M. Brady, Dr[1], I. Green[1]

[1]Terrence Higgins Trust, London, United Kingdom, [2]Office for Health Improvement and Disparities, Department of Health and Social Care, London, United Kingdom

Background: National HIV Testing Week (NHTW) is an annual campaign devised by Terrence Higgins Trust, delivered by HIV Prevention England, and funded by the UK government's Office for Health Improvement and Disparities. NHTW aims to increase HIV testing amongst key populations.

Description: The campaign ran in five cycles from 2016 to 2021, targeted gay and bisexual men and people of Black African ethnicity (BA) in England, and focused on "real people telling real stories" to encourage HIV testing.

A multi-modal approach was used to reach populations at scale:

- User-testing and coproducing campaign imagery, themes and messaging with key populations
- social marketing using digital, press, outdoor and influencer-led channels to generate HIV self-sampling kit (HSS) online orders
- physical community-based outreach and testing
- engaging healthcare professionals to promote testing.

Lessons learned: Findings: From 2016, NHTW led to over 112,000 people testing through HSS and community-based HIV testing. More than a quarter tested for the first time. 77% of all those tested were from key populations, and the overall reactivity rate was 0.85%.

During COVID-19 (2020-21), NHTW maintained high levels of engagement and over 30,000 HIV tests were ordered online. However, a lower proportion of BA people ordered tests compared to previous years.

Due to lockdowns, in-person community and clinic-based testing was curtailed. However, the introduction of a digital community engagement model ensured that some grassroots outreach was maintained.

	Average per year pre-COVID-19 (2016-20)	COVID-19 year (2020-21)
Media promotion		
Numbers reached*	137,131,415	177,475,200
Numbers engaged**	80,662	91,092
Tests ordered^	18,608	30,613
Community outreach		
Numbers engaged	7,141	3,557
Numbers tested	1,761	514
*Through all media channels. **Click-through rates. ^Test availability was determined by funding		

Table.

Conclusions/Next steps: NHTW is a high-impact campaign which increased HIV testing at national scale for key populations, including during COVID-19 constrained situations.

There was an increase in HSS during NHTW 2020-21. While this may indicate increased acceptability of HSS, it could mask issues for those BA people who did not access HSS kits ordered online.

It is essential to ensure that equitable access for key populations is prioritised for both face-to-face and online HIV testing services.

EPC352

SelfCare's Cat and Pao: the use of community-led automated virtual assistance and peer support in an unassisted HIV self-testing program in Metro Manila, Philippines

J.D. Rosadiño[1,2], J.L. Dinglasan[1], R. Pagtakhan[1], M. Briñes[1], E. Baja[3], J.O. Corciega[1], P.V. Junio[1], R. Domingo[1], R. Briñes[1], J.M. Maynes[1], C.E. Gray[1], P. Gumabao[1]

[1]LoveYourself, Inc., Mandaluyong City, Philippines, the, [2]University of the Philippines - Open University, Faculty of Management and Development Studies, Los Baños, Philippines, the, [3]University of the Philippines - Manila, National Institutes of Health, Manila, Philippines, the

Background: Ease of access is one factor in getting tested for HIV. Community quarantines caused by the COVID-19 pandemic limited this access further. An automated virtual assistance system was developed and used to provide assistance to maintain the unassisted nature of HIV blood-based self-testing in the Philippines. This was initiated by the community-based organization LoveYourself under the program SelfCare.

Description: This entire virtual assistance system was developed and implemented built-in into Facebook Messenger, which was used because of its familiarity, being

the most-used online messaging platform in the country. In order to access the service, clients just need to send a message to the SelfCare Facebook page. To organize all information collected from the clients, the conversation flow was divided into five parts: expression of interest, qualification, delivery, guided self-testing, and post-testing.

This assisted the clients in ordering the self-testing kits, guiding them on how to use the kits (via instructional videos), reporting their HIV test results, submitting feedback, and guiding them to HIV combination prevention strategies (PrEP if HIV non-reactive, linkage to confirmatory testing and same-day ART if HIV-reactive).

Conversations were made more interactive by creating Cat (an online version of Miss Universe 2018 Catriona Gray, in English) and Pao (an online version of Paolo Gumabao, one of the actors in a popular Filipino HIV-themed film Mga Batang Poz, in Filipino). After reporting the result, peer counselors are on standby to answer questions and other concerns.

Lessons learned: Out of 1,292 individuals who reported their test results through this system, 106 participants reported a reactive result (8.20% reactivity). 60% of those HIV reactive were successfully linked to HIV treatment. The design made data gathering and report generation easier on the implementers' part by viewing a created message database. This also paved the way for online peer volunteers to assist clients who tested reactive for linkage to confirmatory testing.

Conclusions/Next steps: Using alternative platforms like SelfCare enabled a platform to provide care and support virtually. This mechanism can guide implementers to use innovations in order to provide assistance and support to key populations, especially during this time.

EPC353

Home HIV testing with virtual assistance Ppomotes linkage to care

L. Fidelak[1], D.M. Dery[1], K. Adams[1], B. Brown[1]

[1]*Access Health Louisiana, New Orleans, United States*

Background: During 2020, many clinicians at Access Health Louisiana (AHL), a Federally Qualified Health Center with clinics across southeast Louisiana, provided care via tele-health, limiting the availability of in-person HIV screening. In response, with funding from the Bureau of Primary Health Care, AHL introduced a free, virtually-assisted home HIV testing program for residents of southeast Louisiana.

Description: Prospective patients may request tests through an online survey or by calling or emailing the home HIV testing team. Once the request is received, the Home HIV Testing Coordinator contacts the patient via phone and completes a limited registration, requiring only a name, phone number and address for kit delivery, and schedules the patient for their virtual appointment. During the appointment, the Coordinator provides counseling, assists the patient with interpreting test results, and links the patients to care depending on outcomes. Patients are contacted again three months after their virtual appointment for follow-up testing.

Lessons learned: From December 2020 to December 2021, AHL received 84 test requests. Of these, 37 were registered as patients and delivered a test kit. 31 patients, or 84%, completed virtual appointments, and 1 patient tested independently. Seventy-two percent of participants identified as female, while the remaining 28% identified as male. 15 patients provided responses for race/ethnicity, with 53% identifying as Black/African American, 40% as White, and 7% as Asian. Patients ranged from ages 18 to 53, with an average age of 32 years. 11 patients disclosed sexual orientation, with 18% identifying as lesbian, gay or homosexual and 82% identifying as straight or heterosexual. Of the patients who completed a virtual appointment, 32% were linked to care at AHL. Limitations on this data include sample size and reported sexual orientation and race/ethnicity.

Conclusions/Next steps: Home HIV testing programs can effectively supplement in-person screening, especially when coupled with virtual assistance. This format allows for increased accessibility and privacy, while still providing the necessary support and linkage to care, as evidenced by the 32% of patients linked from this program.

The next phase of this project will incorporate additional screenings, such as STIs and HCV, and expand to other regions in the state.

HIV self-testing

EPC354
HIV self-testing programming acceptability among injured persons seeking emergency care in Nairobi, Kenya

A. Aluisio[1], S. Bergam[2,1], J. Sugut[3], J. Kinuthia[4], R. Bosire[5], E. Ochola[4], B. Ngila[4], D. Ojuka[6], A. Lee[1], A. Maingi[7], K. Guthrie[8], T. Liu[9], M. Mugambi[10], D. Katz[11], C. Farquhar[11,12,13], M. Mello[1]
[1]Alpert Medical School of Brown University, Department of Emergency Medicine, Providence, United States, [2]University of KwaZulu Natal, Paediatrics, Umbilo, South Africa, [3]Kenyatta National Hospital, Department of Accident and Emergency, Nairobi, Kenya, [4]Kenyatta National Hospital, Department of Research & Programs, Nairobi, Kenya, [5]Kenya Medical Research Institute, Center for Public Health Research, Nairobi, Kenya, [6]University of Nairobi Faculty of Health Sciences, Department of Surgery, Nairobi, Kenya, [7]Kenyatta National Hospital, Department of Dermatology, Nairobi, Kenya, [8]Alpert Medical School of Brown University, Department of Psychiatry and Human Behavior, Providence, United States, [9]Brown University School of Public Health, Department of Biostatistics, Center for Statistical Sciences, Providence, United States, [10]Ministry of Health, Nairobi, Kenya, [11]University of Washington, Department of Global Health, Seattle, United States, [12]University of Washington, Department of Epidemiology, Seattle, United States, [13]University of Washington, Department of Medicine, Seattle, United States

Background: ED-based HIV self-testing (HIVST) is an innovative approach to deliver HIV testing services (HTS) to populations that may not engage through standard pathways, and that could increase identification of PLHIV. However, patient acceptability for ED-based HIVST is unknown.
Methods: A prospective cohort of adult injured persons seeking emergency care was enrolled during March-May 2021 at Kenyatta National Hospital (KNH) in Nairobi, Kenya. Demographic, information and data from eleven Likert items with five-point response ranges were collected. The Likert items encompassed Likert scale domains for ED-HIVST programs of: general acceptability (Domain 1), personal acceptability (Domain 2) and acceptability to distribute to social/sexual networks (Domain 3). Ordinal regression was performed yielding adjusted odds ratios (aOR) with associated 95% confidence intervals (CI).
Results: Of 600 participants, 88.7% were male and the median age was 29 years. Approximately half (55.0%) had a primary care providers (PCP) and 86.2% had prior HIV testing. Across all Likert items, the majority of participants reported the highest level of agreement (range 55.7%-71.8%).
Adjusted analysis found that those <25 years of age had a greater odds of favorable response for general acceptability as comparted to those >25 years (aOR=1.67, 95% CI: 1.36-2.08, p<0.001), as did those with prior HIV testing versus those without (aOR=1.68, 95% CI: 1.27-2.21, p<0.001) (Domain 1). For Domain 2 pertaining to personal acceptability, those with a PCP had greater odds of favorable response than those without (aOR=3.31, 95% CI: 2.72-4.03, p<0.001) as did those with prior HIV testing (aOR=1.83, 95% CI: 1.41-2.38, p<0.001).
In assessment of acceptability to distribute to social/sexual networks for use (Domain 3) having a PCP had greater odds of favorable response (aOR=2.42, 95% CI: 2.01-2.92, p<0.001) as did those with prior HIV testing (aOR=1.79, 95% CI: 1.38-2.33, p<0.001).
Conclusions: Among the population studied, ED-HIVST programming was highly acceptable. Those with previous HIV testing had significantly greater acceptability across all domains, as did younger persons for general acceptability and having a PCP for personal acceptability and acceptability to distribute to social/sexual networks.
These data provide a foundation to inform development of strategies to implement effective ED-HIVST programming in Kenya.

EPC355
A qualitative analysis of male partner engagement in HIV care

J. Boyer[1], M. Wyatt[2], B. Kamusiime[3], V. Kasiita[3], G. Nalukwago[3], A. Nalumansi[3], C. Twesige[3], A. Nakyanzi[3], F. Naddunga[3], P. Ssendiwala[3], E. Pisarski[2], A. Mujugira[3], C. Celum[1], N. Ware[2]
[1]University of Washington, Global Health, Seattle, United States, [2]Harvard Medical School, Boston, United States, [3]Infectious Disease Institute, Kampala, Uganda

Background: Low HIV testing rates among male partners of pregnant women living with HIV is a key challenge to prevention of mother-to-child transmission (PMTCT) programs in sub-Saharan Africa. Understanding facilitators of and barriers to male engagement in antenatal care is critical for optimizing the benefits of PMTCT.
Methods: The Obumu study was a randomized trial to evaluate secondary distribution of HIV self-test kits (HIVST) by 500 pregnant women living with HIV in Uganda on the uptake of HIV testing and subsequent linkage to HIV prevention (PrEP) or treatment (ART) by their male partners.
Men who attended the clinic after receiving an HIVST or invitation for HIV testing from their pregnant partner were enrolled (N=212).
A purposefully-selected subset of 45 men took part in qualitative interviews exploring experiences of HIV testing, study participation, relationships, and linkage to care. Qualitative data were coded and inductively analyzed to identify themes representing men's motivations for attending clinic and testing for HIV.
Results: Four key themes that explain men's decisions to attend clinic and test for HIV emerged from the qualitative data:

1. *Role fulfillment:* Some men felt it was their responsibility as a husband and father to know more about their health status so they could remain healthy and continue to take care of their family;
2. *Reciprocity:* Others felt respected and cared for by their partners and wished to reciprocate their support;
3. *Valuing stability:* Male partners also wanted to avoid conflict at home, thus preserving their relationships; and,
4. *Trust:* Men were reassured by counseling from lay male healthcare workers, giving them more confidence to overcome initial concerns about testing.

Receipt of an HIVST or invitation letter did not appear to be a main driver of decisions to attend clinic. Overall, a sense of trust, support, and duty within relationships facilitated clinic attendance and HIV testing among male partners.

Conclusions: Relationship dynamics and counselor support are important factors in encouraging men to attend antenatal clinics and test for HIV. Tailoring HIV testing strategies and messages to address the role of relationships may enhance male partner engagement in care, thus improving PMTCT outcomes.

EPC356

Improving ART initiation among men who use HIV self-testing in Malawi: a qualitative study

J. Hubbard[1,2], M. Mphande[2], K. Phiri[2], K. Balakasi[2], R.M. Hoffman[1], J. Daniels[3], A. Choko[4], T.J. Coates[5], K. Dovel[1,2]
[1]*University of California Los Angeles (UCLA), David Geffen School of Medicine - Division of Infectious Diseases, Los Angeles, United States,* [2]*Partners in Hope Medical Center, Implementation Science Department, Lilongwe, Malawi,* [3]*Arizona State University, Edson College of Nursing and Health Innovation, Phoenix, United States,* [4]*Malawi–Liverpool–Wellcome Trust, Clinical Research Programme, Blantyre, Malawi,* [5]*University of California Global Health Institute, San Francisco, United States*

Background: HIV self-testing (HIVST) increases HIV testing uptake among men; however, linkage to antiretroviral therapy (ART) among HIVST users can be low. We qualitatively examined barriers to linkage to care and ART initiation for men who used HIVST, and their preferences for innovative strategies to improve treatment engagement following self-testing.

Methods: Semi-structured in-depth interviews were conducted with men (≥15 years) in Malawi who tested HIV-positive using HIVST between 2018-2020, and their female partners (≥15 years) who distributed HIVST kits to men. Medical records from seven facilities were used to identify respondents.

We included men who received HIVST from a health facility (primary distribution) and those who received HIVST from female sexual partners (secondary distribution). Interviews were conducted in the community and were audio-recorded, translated and transcribed, and analyzed using constant comparison methods in Atlas.ti v.8.4, comparing themes by men who received HIVST through primary versus secondary distribution strategies. Data were collected between 2019-2020.

Results: Twenty-seven respondents were interviewed: 16 respondents in male/female dyads, eight men without a female partner, and three women who represented men who were unreachable. Among the 19 men represented, seven received HIVST through primary distribution and 12 through secondary distribution. Six men never initiated ART (all secondary HIVST distribution users).

Barriers to ART initiation centered on the absence of health care workers at the time of diagnosis and included lack of external motivation that pushed men to link to care (men had to motivate themselves) and lack of counseling before and after testing (leaving ART-related fears and misconceptions unaddressed) – the latter was especially true within secondary HIVST distribution.

Desired interventions were similar across primary/secondary HIVST distribution and included ongoing peer mentorship for normalizing treatment adherence, male-tailored counseling (focused on how HIV treatment can support men's role as financial providers, maintaining a strong physical body, and ensuring a promising future for their children), outside-facility HIV treatment for convenience and privacy, and help understanding how to navigate ART clinics.

Conclusions: Male HIVST users face unique challenges to ART initiation, especially those receiving HIVST through secondary distribution. Male-tailored interventions are desired by men and may help overcome barriers to care.

EPC357

National surveillance of home-based HIV testing among Australian gay and bisexual men, 2018-2020: uptake after commercial availability of HIV self-tests

Y. Zhang[1], M. Holt[2], C. Chan[1], T.L. Applegate[1], B.R. Bavinton[1], T.R. Broady[2], P. Keen[1], L.P.L. Wulandari[1], L. Mao[2], H. McManus[1], N.A. Medland[1], G. Presatge[1], V. Wiseman[1,3], R.J. Guy[1]
[1]*Kirby Institute, UNSW, Sydney, Australia,* [2]*Centre for Social Research in Health, UNSW, Sydney, Australia,* [3]*London School of Hygiene and Tropical Medicine, Department of Global Health and Development, London, United Kingdom*

Background: HIV self-testing allows people to collect samples and test themselves at home, addressing known barriers to facility-based testing. Despite strong evidence about its benefits, HIV self-testing became commercially available in Australia in a restricted way (online only) at the end of 2018.

We aimed to measure the uptake of home HIV testing among Australian gay and bisexual men (GBM) between 2018-2020 and among subgroups where there are known gaps in the frequency of HIV testing.

Methods: Data were analysed from the Australian Gay Community Periodic Surveys (repeated behavioural surveillance of GBM at venues, events and online). We used Poisson regression models to assess trends in-home HIV testing among non-HIV positive GBM between 2018 and 2020 and multivariable logistic regression to assess factors associated with home versus facility-based testing.

Results: Overall, 24,214 non-HIV-positive GBM completed surveys in 2018-2020. The use of home HIV testing was low, but slightly increased during 2018-2020 (from 0.3% to 0.8%, RR=1.54, 95%CI=1.23-1.92, p-trend<0.001).Testing at home was more likely among non-HIV-positive GBM who were born overseas and recently arrived in Australia (OR=4.71, 95%CI=2.59-8.56), at higher risk of HIV (OR=2.17,95%CI=1.15-4.09), infrequent HIV testers (OR=2.09, 95%CI=1.18-3.72), and was less likely among GBM who had not been diagnosed with a sexually transmitted infection in the last year (OR=0.41,95%CI=0.18-0.94).

Conclusions: The uptake of HIV home testing by GBM after its commercial availability in Australia remains extremely low, but a small increase occurred in 2020 during COVID-19 lockdowns. The greater use of home testing in priority groups such as infrequent testers, recent migrants, and men at higher risk of HIV was encouraging.

Compared to HIV home testing, COVID-19 rapid antigen in Australia has been quickly made available in various distribution channels, such as clinics, pharmacies, and supermarkets. Learning from the COVID rapid antigen test kit distribution in Australia, there is an urgent need for policy and practice changes to make kits affordable and accessible to cater for different population needs.

EPC358

Accuracy of the home-based rapid HIV urine antibody test and the preference among men who have sex with men: a discrete choice experiment study

C. Zhang[1], Y. Gu[2], Y. Lu[3], C. Hao[1,4], Y. Hao[1,4]

[1]Sun Yat-Sen University, Department of Medical Statistics, School of Public Health, Guangzhou, China, [2]Guangzhou Center for Disease Control and Prevention, AIDS Control and Prevention, Guangzhou, China, [3]Kangyuan Community Support Center, Yuexiu District, Guangzhou, China, [4]Sun Yat-Sen University, Sun Yat-Sen Global Health Institute, Guangzhou, China

Background: This study was to evaluate the accuracy of self-administered rapid HIV urine antibody test among men who have sex with men (MSM) in China. A discrete choice experiment (DCE) was applied to elicit their preferences for different attributes of home-based rapid HIV test.

Methods: We compared the self-administered rapid HIV urine test with HIV venous blood test in terms of sensitivity and specificity. In the DCE, four attributes were identified: type of test (finger prick vs urine sample), instruction on how to conduct the test (regular instruction vs instructional video), the interpretation of test result (by themselves vs by clinic staff) and cost of the test (free, 3USD, 7.5USD, 12USD). Each participant was asked to choose between two alternatives that comprised four attributes across 8 choice sets (Table 1 is an example of a choice set).

	Test A	Test B
Type of test	Finger prick	Urine sample
Instruction on how to conduct the test	Regular instruction	Instructional video
The interpretation of test result	By yourself	By clinic staff
Cost of the test	Free	3USD
Which test would you prefer?	□	□

Table 1. An example of a choice set

Results: A total of 1096 participants provided venous blood samples for HIV-testing, of whom 4.65% (51) were HIV positive. The sensitivity of the urine test was 80.4% performed by participants themselves, with 100.0% specificity. Our results identified significant preference heterogeneity for all attributes (Table 2). Finger prick sample (β=0.41, P< 0.01), using regular instructions (β=0.18, P<0.01), interpreting test result by themselves (β=0.13, P=0.04) and lower cost (β=-0.02, P<0.01) were preferred.

Attributes		β	95%CI	P
Type of test				
	Finger prick vs urine sample (control)	0.41	(0.32, 0.50)	<0.01
Instruction on how to conduct the test				
	Regular instruction vs instructional video (control)	0.18	(0.08, 0.29)	<0.01
The interpretation of test result				
	By themselves vs by clinic staff (control)	0.13	(0.01, 0.26)	0.04
Cost of the test		-0.02	(-0.021, -0.017)	<0.01

Table 2 DCE parameter estimation (N=964)

Conclusions: The accuracy of the self-administered rapid urine test was unfavorable. It suggests the rapid urine test might need to be further validated. Another possibility would be to standardize or health professionals guide the testing process and interpretation of the test results, similar as demands of the DCE results showed.

EPC359

The role of oral HIV self-testing in ending the HIV epidemic: lessons learned from Bhutan

L. Khandu[1], C. Dolkar[1], D. Tshering[1], J. Thinley[1], K.D. Tshering[2], J. Norbu[2], T. Dendup[2], T. Gyeltshen[3], T. Tobgay[4]

[1]National HIV, AIDS and STIs Control Program, Department of Public Health, Thimphu, Bhutan, [2]Save the Children Bhutan, Thimphu, Bhutan, [3]Pride Bhutan, Thimphu, Bhutan, [4]Institute of Health Partners, Thimphu, Bhutan

Background: Bhutan envisions ending HIV epidemics by 2030. One of the major bottlenecks of achieving this vision is the testing gap. Since the detection of the first case in 1993, a total of 795 cases were diagnosed till November 2021, 599 of them are currently alive and 580 on ART. However, UNAIDS modelling predicts a total of 1300 cases resulting in a detection gap of 39%. HIV Self Testing (HIVST) was used and found to be an effective approach to test the hidden key populations (KPS) in many countries to make early diagnoses, linkage to treatment, and prevent transmission. Therefore, a demonstration project to see the feasibility of uptake and delivery models of HIVST by the KPs was initiated.

Description: We present lessons learned from the HIVST demonstration project implemented in five identified epidemiological zones of Thimphu-Paro, Phuntsholing, Gelephu, Samdrup Jongkhar, Wangdue-Punakha from August-November 2021. The cross-sectional mixed methods study protocol was approved by the Research Ethics Board of Health.

The identified laymen from KPs were trained on HIV Counseling and Testing to conduct HIVST for the first time. A total of 438 (233-MSM, 62-TG and 143-FSW) KPs were tested using rapid oral HIVST. Several methods like social media, dating apps, telephonic contacts, meetings in person and peer-driven methods were used to network and initiate the contacts.

Lessons learned: All of the respondents preferred to be contacted for delivery of HIVST for self-testing, follow-up on test results and HIV education program. About 98.6% (432/438) accepted the HIVST while 1.4% didn't accept. Around 70.7% preferred assisted self-testing and 22.6% preferred unassisted self-testing while the remaining 6.7% preferred blood-based testing through VCT centres indicating the preference of saliva over blood as a sample of choice for HIVST.

Conclusions/Next steps: The demonstration project found that HIVST can be implemented in Bhutan as one of the new testing strategies to reach the hidden KPs. Following this demonstration project, MoH will scale up HIVST throughout the country as a part of community-based testing services for KPs. We posit that HIVST will play a critical role in meeting the 95-100-95 national targets to end the AIDS epidemic by 2030.

EPC360

Evaluating effect modification by HIV testing history to understand the mechanisms behind the impact of announcing HIV self-testing availability in a clinic system in Kenya

E. Kelvin[1], M. Romo[1], G. George[2], J. Mantell[3], E. Mwai[4], S. Kinyanjui[4], E. Nyaga[4], J. Odhiambo[4], K. Govender[2]

[1]CUNY Graduate School of Public Health and Health Policy, City University of New York, Epidemiology and Biostatistics, New York, United States, [2]University of KwaZulu-Natal, Health Economics and HIV and AIDS Research Division, Durban, South Africa, [3]Columbia University, HIV Center for Clinical and Behavioral Studies, Gender, Sexuality and Health Area, New York, United States, [4]North Star Alliance, Nairobi, Kenya

Background: In sub-Saharan Africa, truckers and female sex workers (FSW) have high HIV risk and face challenges accessing HIV testing. Adding HIV self-testing (HIVST) to standard of care (SOC) programs increases testing rates. However, the underlying mechanism is not fully understood. HIVST may decrease barriers (inconvenient clinic hours, confidentiality concerns) and we would thus expect a greater impact among those not accessing SOC testing (barriers prevented previous testing).

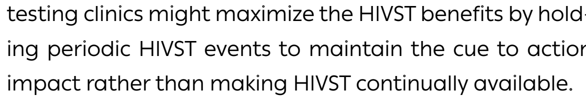
As a new biomedical technology, HIVST may also be a cue to action (the novelty of a new product motivates people to try it), in which case we might expect the impact to be similar by testing history.

Methods: We used data from two randomized controlled trials evaluating the announcement of HIVST via text-message to male truckers (n=2260) and FSWs (n=2196) in Kenya. Log binomial regression was used to estimate the risk ratio (RR) for testing ≤2 months post-announcement in the intervention versus SOC overall and by having tested in the past 12-months (12m-tested) and we assessed interaction between the intervention and 12m-tested. We also estimated risk differences (RD) per 100 and tested additive interaction using linear binomial regression.

Results: We found no evidence that 12m-testing modified the HIVST impact. Among truckers, those in the intervention were 3.1 times more likely to test than the SOC (p<0.001).Although testing was slightly higher among those not 12m-tested (RR=3.5, p=0.001 versus RR=2.7, p=0.020), the interaction was not significant (p=0.683).

Among FSWs, results were similar (unstratified RR=2.6, p<0.001; 12m-tested: RR=2.7, p<0.001; not 12m-tested: RR=2.5, p<0.001; interaction p=0.795). We also did not find significant interaction on the additive scale (truckers: unstratified RD=2.8, p<0.001; 12m-tested RD=3.8, p=0.037; not 12m-tested RD=2.5, p=0.003; interaction p=0.496. FSWs: unstratified RD=9.7, p<0.001; 12m-tested RD=10.7, p<0.001, not 12m-tested RD=9.1, p<0.001; interaction p=0.615).

Conclusions: The impact of HIVST was not modified significantly by 12m-tested among truckers and FSWs on the multiplicative or additive scale. Announcing the availability of HIVST likely served primarily as a cue to action and



testing clinics might maximize the HIVST benefits by holding periodic HIVST events to maintain the cue to action impact rather than making HIVST continually available.

EPC361

Introduction of oral-based HIV self-testing in Ukraine through the national-scale HealthLink Project: distribution strategies and key results

O. Vlasiuk[1], D. Shevchuk[1], L. Gavrysh[1]

[1]CO ,100%LIFE', Kyiv, Ukraine

Background: Before 2019, OraQuick HIV self-tests were not legally registered in Ukraine and therefore not allowed for official distribution. CO "100%LIFE", the largest patient-led organization in Ukraine, initiated the registration process and was the first to introduce oral-based HIVST in testing programs.

In particular, the distribution of OraQuick HIVST kits became a priority intervention for the HealthLink Project that aims at increasing the overall number of people who know their HIV status in Ukraine.

Description: Between 2019 and 2021, HealthLink distributed kits through community-based strategies, including primary and secondary distribution by social workers at 27 NGOs, online orders at two websites, and distribution via 10 vending machines. The geography of the intervention included all Ukrainian regions.

Considering the context of Ukrainian epidemic, intervention was targeted at hard-to-reach KP representatives, primarily MSM, as well as adult heterosexual men with risk behavior.

The overall aim was to reach persons with high risk of HIV who refuse from testing at traditional settings like NGOs or HCFs. All tests were distributed with contact information for follow-up calls and additional counseling.

Lessons learned: Out of all distributed kits in FY2021 (n=21035), 74% were received by men, 26% by women. Men outnumbered women across all distribution strategies, but in case of vending machines the difference was the smallest. The percentage of KP representatives varied by the distribution strategy, but MSM were the most covered group (56% of all kits were provided to MSM), followed by GP with reported risk behavior (39%).

Online strategies and vending machines were not popular among PWIDs, and they were mostly reached by NGO workers at community sites.

In total, 4% of tests were received by PWIDs, and 5% of all tests were taken by PLHIV for further secondary distribution. In total, 86 persons who obtained self-testing kit were later retested positive at project sites.

Conclusions/Next steps: Program results provided valuable insights for all future projects aiming to reach the ‚first 95' in Ukraine. Healthlink significantly contributed to generating demand for home-based HIV testing and provided evidence that oral-based HIVST has huge potential for reaching undiagnosed populations in Ukraine, primarily among men and MSM.

EPC362

Estimating the impact of HIV self-testing on HIV testing services, diagnoses, and treatment initiation at the population-level with routine data: the example of the ATLAS program in Côte d'Ivoire

A. Simo Fotso[1], C. Johnson[2], A. Vautier[3], K.B. Kouamé[4], P.M. Diop[5], R. Silhol[6], M. Maheu-Giroux[7], M.-C. Boily[6], N. Rouveau[8], C. Doumenc-Aïdara[5], R. Baggaley[2], E. Ehui[4], J. Larmarange[8], ATLAS team

[1]IRD, Centre Population & Développement, Université de Paris, Inserm URL 1244, 75006, France, [2]WHO, Geneva, Switzerland, [3]Solidarité Thérapeutique et Initiatives pour la Santé, Solthis, Dakar, Senegal, [4]Programme National de Lutte contre le Sida, Abidjan, Cote D'Ivoire, [5]Solidarité Thérapeutique et Initiatives pour la Santé, Dakar, Senegal, [6]Imperial College London, Medical Research Council Centre for Global Infectious Disease Analysis, School of Public Health, London, United Kingdom, [7]McGill University, Department of Epidemiology and Biostatistics, School of Population and Global Health, Montreal, Canada, [8]IRD, Centre Population & Développement, Université de Paris, Inserm URL 1244, Paris, France

Background: HIV self-testing (HIVST) is a critical testing approach particularly for reaching those at HIV risk who are hesitant or unable to access existing services. While the discreet and flexible nature of HIVST is appealing to users, these features can limit the ability for programmes to monitor and estimate the population-level impacts of HIVST implementation. This study triangulates publicly available routine programme data from Côte d'Ivoire in order estimate the effects of HIVST distribution on access to testing, conventional testing (self-testing excluded), HIV diagnoses, and antiretroviral treatment (ART) initiations.

Methods: We used quarterly programmatic data (Q3-2019 to Q1-2021) from ATLAS, a project that aims to promote and implement network-based HIVST distribution in West Africa, in addition to routine HIV testing services program data obtained from the PEPFAR dashboard. We performed ecological time series regression using linear mixed-models.

Results: Between Q3-2019 and Q1-2021, 99,353 HIVST kits were distributed by ATLAS in 78 health districts included in the analysis. The results (Table 1) show a negative but non-significant effect of the number of ATLAS HIVST on the volume of conventional tests (-190), suggesting the possibility of a slight substitution effect. Despite this, the beneficial effect on access to testing is significant: for each 1000 HIVST distributed via ATLAS, 390 to 590 additional HIV tests were performed if 60% to 80% of HIVST are used . The effect of HIVST on HIV diagnosis was significant and positive, with 8 additional diagnoses per 1,000 HIVST distributed. No effect of HIVST was observed on ART initiations.

Outcome variables	Effect for 1000 HIVST distributed by ATLAS	95% CI	p-value
HIV testing (utilisation rate of HIVST of 80%)	+590	356 to 821	<0·001
HIV testing (utilisation rate of HIVST of 60%)	+390	160 to 625	<0·001
Conventional testing	-190	-427 to 38	0·10
HIV diagnosis	+8	0 to 15	0·044
ART initiations	-2	-8 to 5	0·66
[1]CI = Confidence Interval. ART = antiretroviral treatment.			

Table 1: Linear effect of number of HIVST distributed via ATLAS on access to HIV testing, on 'conventional' testing, HIV diagnosis and ART initiation, in 78 health districts monitored by PEPFAR in Côte d'Ivoire (Q3-2019 to Q1-2021), adjusted by quarter year and region.

Conclusions: Our study provides a standard methodology for estimating the population-level impact of HIVST that can be used across countries. It shows that HIVST distribution was associated with increased access to HIV testing and diagnosis in Côte d'Ivoire. Wide-scale adoption of this method will improve HIVST data quality and inform evidence-based programming.

EPC363

HIV self-testing to increase combination prevention demand among men who have sex with men (MSM) and transgender women (TGW): a randomized clinical trial and sub-study of the ImPrEP project

K. Konda[1], B. Hoagland[2], K. Campos[1], N. Fernandes[2], G. Calvo[1], C. Pimenta[3], M. Benedetti[2], T.S. Torres[2], C. Rocha[2], J.R. Grangeiro[2], E. Bastos[2], S. Nazer[2], R. Ismerio[2], M.T.L. de Vasconcellos[2], L.A.B. Camacho[4], C. Palombo[5], C.F. Caceres[1], B. Grinzstejn[2], V.G. Veloso[2], for the ImPrEP study
[1]Universidad Peruana Cayetano Heredia, Centro de Investigación Interdisciplinaria en Sexualidad, Salud, y SIDA, Lima, Peru, [2]Instituto Nacional de Infectologia Evandro Chagas, Fundação Oswaldo Cruz (INI-Fiocruz), Rio de Janeiro, Brazil, [3]Brazilian Ministry of Health, Departmento de Doenças de Condições Crônicas e Infecções Sexualmente Transmissiveis, Rio de Janeiro, Brazil, [4]Escola Nacional de Saúde Pública Sergio Arouca, Fundação Oswaldo Cruz (ENSP/Fiocruz), Rio de Janeiro, Brazil, [5]Hospital Municipal Carlos Tortelly, Rio de Janeiro, Brazil

Background: HIV self-testing (HIVST) is highly accurate and recommended by WHO to increase HIV testing. This study evaluated the feasibility and effectiveness of HIVST secondary distribution by PrEP users to increase demand for HIV combination prevention among MSM/TGW.
Methods: This randomized controlled trial enrolled MSM and TGW using PrEP for at least six months from the ImPrEP demonstration study at two sites in Rio de Janeiro, Brazil, and three sites in Lima, Peru. Participants were 1:1 randomized to receive 5 HIVST+vouchers (to be distributed together) or 5 vouchers (control arm) and were instructed to distribute them to their MSM/TGW network. All participants randomized to HIVST+Vouchers were trained on the HIVST. All vouchers invited individuals for combination HIV prevention services at study sites, including HIV testing, PrEP, TasP, and PEP. Each voucher contained a barcode allowing the linkage of participant who distributed the test to the recruited individual attending the site. Chi-square testing was used to compare the recruitment yield by arms stratified by country.
Results: From July/2019 to January/2021, Brazil invited 705 participants and enrolled 418 (59%), while in Peru, 325 were invited and 276 (85%) were enrolled; randomization resulted in balanced groups. Recruitment yield was slightly higher in the voucher-only group in Brazil (p=0.069), whereas in Peru recruitment yield was much higher among voucher-only holders (p<0.001).

	HIVST + Voucher			Voucher Only			
	# Successfully recruited	# HIVST + Vouchers distributed	% Successfully recruited participants	# Successfully recruited	# Vouchers distributed	% Successfully recruited participants	Chi-2 p-value
Brazil	68	747	9.1	87	724	12.0	0.069
Peru	62	518	12.0	104	475	21.9	<0.001

Among the 135 recruited in Brazil, 14 (10%) were identified as HIV-positive (9 via HIVST arm) and 73 (54%) were enrolled in PrEP. Among the 177 recruited in Peru, 20 (11%) were identified as HIV-positive (8 via HIVST arm), and 137 (77%) were enrolled in PrEP. All individuals identified as HIV-positive started antiretroviral treatment.
Conclusions: Both arms successfully recruited MSM/TGW for HIV combined prevention consultation. In Peru the voucher-only arm was more successful at recruiting individuals to health services. HIVST may have contributed to awareness of HIV status among MSM and TGW in the community, although not possible to quantify. Individuals with HIVST negative result may deem additional HIV services unnecessary, despite PrEP availability at all sites.

EPC364

HIV self-testing to reach African American and Latino MSM in Alameda County (California)

S. Gibson[1], L. Hinojosa[1], N. Murgai[1], J. Hecht[2]
[1]Alameda County Health Care Services Agency, Alameda County Public Health Department, San Leandro, United States, [2]Building Healthy Online Communities, Richmond, United States

Background: The Centers for Disease Control and Prevention (CDC) recommends that people at higher risk of acquiring HIV should test for HIV annually. For African-American (AA) and Latino MSM, HIV-related stigma, discrimination, and homophobia are barriers to accessing HIV testing. The COVID-19 pandemic significantly disrupted HIV prevention and testing activities. In April 2020, the CDC issued guidance encouraging programs expe-

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

riencing a disruption to consider the use of self-testing. Research demonstrates self-testing effectively increases testing among MSM, including those previously not tested. Self-testing increases access to testing for populations who have not sought testing for reasons cited previously. Building Healthy Online Communities and NASTAD began offering HIV self-testing through TakeMeHome in March 2020. Alameda County Public Health Department (ACPHD) joined the program in September 2020.

Description: ACPHD implemented self-testing to increase access to HIV testing for priority populations, including AA and Latino MSM, specifically focusing on younger MSM. Self-test kits are available to Alameda County (AC) residents 18 or older who report not having tested for HIV in 12-months or longer. Kits are shipped directly to the requestor with instructions on collecting the oral-fluid specimen and interpreting results. Local referral resources are provided. Kits are promoted on gay dating apps and other social media. ACPHD partnered with local organizations and neighboring health departments to promote self-testing.

Lessons learned: Between September 2020 and September 2021, 226 kits were distributed. 84% were ordered by males. Of these, 42% were ordered by AA or Latinos compared to 19% by Whites. Compared to published national self-testing data, ACPHD reached higher percentages of non-white participants (68% vs. 44%) and those 35 or younger (75% vs. 69%); in AC 39% of kits were ordered by people 24 and younger. More AC testers (42%) report not testing previously compared to the national data (36%). A higher percent of AC participants (42%) reported no previous test. Of those testing previously, 58% report not testing in the last year.

Conclusions/Next steps: HIV self-testing successfully reaches MSM of color, including younger MSM. ACPHD will expand self-testing to include HIV dried bloodspot, multisite gonorrhea and Chlamydia, and syphilis.

EPC365

Facilitators and barriers to HIV self-testing among female sex workers in Bulawayo Province, 2021

M.K. Moyo[1], E. Chikaka[1], F. Sibanda[2], E. Sibanda[2], E. Mugomeri[1]

[1]Africa University, Faculty of Health Sciences, Mutare, Zimbabwe, [2]City of Bulawayo, Health Services, Bulawayo, Zimbabwe

Background: Understanding the factors that facilitate and obstruct utilization of HIV self-testing among female sex workers will assist in demand-creation for HIV testing services in Bulawayo Province. This study presents the facilitators and barriers to HIV self-testing among female sex workers in Bulawayo Province, Zimbabwe.

Methods: An unmatched case-control study involving 66(37.3%) cases and 111(62.7%) controls was carried out from 31.08.2021 to 01.12.2021 at Bulawayo Province in Zimbabwe. Convenience sampling was used to select participants which were interviewed using a structured interviewer-administered questionnaire. Univariate analysis and forward-stepwise logistic regression were used to predict uptake of HIV self-testing within the past three months, with the model adjusting for age and employment status.

Results: The mean age of the respondents was 27.8 years (SD 5.76). The following factors emerged significant from the univariate analysis; private hospital space (OR 4.9, 95% CI 2.5-9.4, p<0.001), perceived seriousness of HIV infection (OR 3.3, 95% CI 1.7-6.2, p<0.001), access to peer support (OR 3.3, 95% CI 1.7-6.2, p<0.001), employment status (OR 3.3, 95% CI 1.0-5.3, p<0.006), recent illness (OR 2.9, 95% CI 1.5-5.5, p<0.001), having been treated for a sexually transmitted infection (STI) (OR 2.0, 95% CI 1.0-3.7, p<0.027), knowledge of were to get tested (OR 2.0, 95% CI 1.1-3.8, p<0.030), access to HIV information (OR 0.5, 95% CI 0.3-0.9, p<0.001) and delays in turnaround time (OR 0.4, 95% CI 0.2-0.7, p<0.001).

Findings from the multivariate logistic regression revealed that perceptions that hospitals were a private space (aOR 4.4, 95% CI 2.5-9.4, p<0.001), perception of the seriousness of an HIV infection (aOR 2.7, 95% CI 1.3-5.9, p<0.01), having peer support to do an HIV test (aOR 2.3, 95% CI 1.0-5.3, p<0.001) and delays in turnaround time (aOR 0.3, 95% CI 0.1-0.6, p<0.001) were significantly associated with using HIV self-testing.

Conclusions: Strategies to improve uptake of HIV testing by female sex workers in Bulawayo Province should consider these factors, particularly the need to improve peer support and awareness of HIV. The emergent barriers of waiting time and privacy signify the need to rollout the HIV self-testing model without delay.

EPC366

Acceptability and feasibility of HIV self-testing among street adolescents in Togo in 2021

A.J. Sadio[1], F.A. Gbeasor-Komlanvi[2], R.Y. Konu[1], M.K. Tchankoni[1], W.I.C. Zida-Compaore[1], G.K. Azialey[3], H.R. Kouanfack[1], A.P. Amenyah-Ehlan[4], A. Dagnra[5], D.K. Ekouevi[2]

[1]African Center for Research in Epidemiology and Public Health (CARESP), Scientific Department, Lome, Togo, [2]University of Lomé, Faculty of Health Sciences, Department of Public Health, Lomé, Togo, [3]FHI 360, Endind AIDS in West Africa Project, Lomé, Togo, [4]University of Lomé, Faculty of Health Sciences, Department of Fondamental Sciences, Laboratory of Molecular Biology and Immunology, Lomé, Togo, [5]Ministry of Health, Public Hygiene and Universal Access to Health Care, National Program for the Fight against HIV/AIDS, Viral Hepatitis and Sexually Transmitted Infections, Lomé, Togo

Background: HIV self-testing is a complementary testing strategy especially for populations with limited access to health care facilities such as street adolescents. The aim of this study was to assess the acceptability and feasibility of HIV self-testing among street adolescents in Togo.

Methods: A cross-sectional study was carried out in July 2021, in Lomé (capital city of Togo). Adolescents of both sexes, living in the street at least three months, aged 13 to 19 years were included. A face-to-face questionnaire was administered to document their knowledge and practices on sexual and reproductive health (SRH). A blood sample was taken for HIV testing according to national strategies. In addition, a self-test (OraQuick®) was used.
We defined Acceptability as the proportion of participants who completed the self-test and Feasibility was the proportion of street adolescents who took the test and reported valid self-test results.
Results: A total of 307 street adolescents of median age 15 years, interquartile range (IQR) [14-17], of which 5.2% (n=16) were female were included in this study. Nearly 7 in 10 street adolescents (69.5%) were sexually active, of whom 71.2% (n=221) reported not using a condom during their last sexual intercourse. A history of HIV testing was reported by 16.6% (n=51) of street adolescents. HIV prevalence was estimated at 1.0% (n=4), 95% confidence interval (95% CI) [0.3-3.1]. The self-test was offered to 171 street adolescents. Acceptability was 91.9% (157/171), 95%CI [86.5-95.3] and feasibility was 97.5% (153/157), 95%CI [93.2-99.2]. The results of the self-test were correctly read by 96.8% of street adolescents.
Conclusions: Self-testing is acceptable and feasible among street adolescents in Lomé. The implementation of the self-test, particularly through advanced listening centers, could help improve access to screening services and allow rapid care for street adolescents.

Designing an intervention to support HIV self-testing among women engaged in sex work and drug use in Kazakhstan

O. Cordingley[1], T. McCrimmon[2], M. Darisheva[3], V. Frye[4], B. West[1], A. Terlikbayeva[3], S. Primbetova[3], N. Zholnerova[5], E. Grigochuk[6], A. Kuskulov[1], L. Gilbert[1], N. El-Bassel[1]
[1]*Columbia University, School of Social Work, New York, United States,* [2]*Columbia University, Mailman School of Public Health, New York, United States,* [3]*Global Health Research Center of Central Asia (GHRCCA), Almaty, Kazakhstan,* [4]*City College of New York (CUNY), School of Medicine, New York, United States,* [5]*Amelia, Public Association, Taldykorgan, Kazakhstan,* [6]*Sau Bolashak, Public Association, Union of Leaders, Almaty, Kazakhstan*

Background: In Kazakhstan, women who exchange sex and use drugs (WESUD) are at increased risk of HIV infection, yet face barriers to consistent testing. HIV self-testing (HST) is one promising method to facilitate more consistent testing, and has been shown to be acceptable and effective among WESUD in other regions. To inform the expansion of HST access for WESUD in Kazakhstan, we evaluated their preferences for HST access, use and training and developed an intervention to increase uptake of HST and encourage consistent or frequent HIV testing.
Methods: We conducted 30 in-depth interviews and 4 focus groups with 48 WESUD in two Kazakhstani cities, Almaty and Taldykorgan. Participants were recruited through snowball sampling at two local, trusted NGOs serving WESUD. We utilized the framework method for pragmatic analysis of data and intervention mapping methods to develop an intervention and HST programming.
Results: WESUD have high interest in HST due to HIV stigma experienced through other HIV testing settings. Four implications for HST programming emerged:
1. Training and HST kit access that is responsive and adaptive to WESUD needs (training in-person and virtually at multiple locations, access to HST at a variety of locations);
2. Social support and stigma (learning with social network members, interest in training fellow sex workers, impact of HIV and intersectional stigma on uptake of HIV testing);
3. Linkage to care/referrals (concerns around confirmatory HIV testing, need for services like legal aid, gynecologists, and psychologists);
4. Potential negative impacts of HST (depression, suicidal ideation and attempts in response to positive results, client and intimate partner violence, loss of work/livelihood).
Based on these results, we designed a 4-session intervention to support HST, linkage to HIV care (if positive) and prevention (if negative) by addressing awareness, access, outcome expectancies, stigma, negative outcomes, and social support.
Conclusions: A HST training and support program for women who exchange sex work and use drugs in Kazakhstan must reflect the needs and preferences of this key population. Also needed are structural, community and institutional interventions to reduce both potential negative consequences of and thus barriers to testing, such as social stigmatization, exclusion and loss of material resources.

EPC368
Availability and accessibility of HIV self-tests and self-sample kits at community pharmacies in the Netherlands

E. Op de Coul[1], C. Kandil[1], T. Heijman[2], H. Bos[3], M. Teichert[4], R. Finkelflügel[5], J. Hugtenburg[6]
[1]*National Institute for Public Health and the Environment (RIVM), Centre for Infectious Disease Control, Bilthoven, Netherlands, the,* [2]*Public Health Service of Amsterdam, Amsterdam, Netherlands, the,* [3]*STI Aids Netherlands, Amsterdam, Netherlands, the,* [4]*Royal Dutch Pharmacists Association (KNMP), the Hague, Netherlands, the,* [5]*Dutch Association of People with HIV, Amsterdam, Netherlands, the,* [6]*Amsterdam University Medical Center, location VU, Amsterdam, Netherlands, the*

Background: In 2016 the WHO declared HIV self-testing and self-sampling an effective and safe test option that can reduce testing barriers. Supporting the use of HIV self-tests and self-sampling kits (HIV-ST/SS) is not included in the Dutch national HIV policy, but HIV self-tests are

available for purchase at Dutch community pharmacies since 2019. We investigated the availability and accessibility of HIV-ST/SS in community pharmacies and factors associated with the HIV-ST/SS offer.

Methods: A survey by email among all Dutch community pharmacies (n=1,987) was conducted in April-June 2021 through the Royal Dutch Pharmacists Association (KNMP). Pharmacy/pharmacist characteristics associated with the HIV-ST/SS offer were explored by logistic regression analysis. Experiences of pharmacists with the HIV-ST/SS offer were descriptively analyzed. Last, we analyzed pharmacy HIV-ST/SS dispensing data (2019-2021) from the Foundation for Pharmaceutical Statistics (SFK database).

Results: In total, 465 pharmacists completed the questionnaire; covering an estimated 20.0-23.4% of all Dutch community pharmacies. Of the responding pharmacists, 6.2% (29/465) offered HIV-ST/SS. The majority (78.6%) sold only small numbers per year: 0-20 tests, 13.8% sold 20-40 tests, and 3.4% >40 tests. In total, pharmacies sold an estimated 370 HIV-ST/SS per year. The SFK database showed similar results: an average of 355 HIV-ST/SS dispensations per year between 2019-2021.

Pharmacies that offer HIV-ST/SS were less often located in moderately urbanized to rural neighborhoods (OR 0.35, 95%CI 0.16-0.77 versus highly urbanized), and less often located in low-to-medium SES neighborhoods (OR 0.40, 95%CI 0.18-0.88 versus high SES). Important reasons for not offering HIV-ST/SS by pharmacists were no or little demand (69.3%), and not being familiar with HIV-ST/SS (17.4%). Of the pharmacists, 52% provided information about testing to clients who buy a test. Options to improve the test offer, reported by pharmacists, were giving advice to test buyers (72.4%), placing the tests visible on the counter (51.7%), and advertisement (37.9%).

Conclusions: HIV-ST/SS have limited practical availability in Dutch community pharmacies since its introduction in 2019, especially in lower urbanized and lower SES areas. Pharmacists see opportunities to improve the test offer. Further research is needed to explore how to expand access to HIV-ST/SS through community pharmacies in the Netherlands.

EPC369

Launching oral-based HIV self-testing (HIVST) in Sri Lanka through the COVID-19 pandemic

S. Herath[1], R. Hettiarachchi[2], I. Hodges-Mameletzis[3], L. Gunasekara[4], I. Wijesinghe[5], S. Elayan[5], N. Fernandopulle[6], N. Nanayakkara[6]

[1]National STD/AIDS Control Program, Key Populations Programs, Global Fund HIV Project Implementing Unit, Colombo, Sri Lanka, [2]National STD/AIDS Control Program, Directorate, Colombo, Sri Lanka, [3]National STD/AIDS Control Program, Sri Lanka, International Consultant, HIV Self-Test Implementation, Geneva, Switzerland, [4]Asia Lanka Social Development Co-Operation, Community Based Program for Drug Use, Kalutara, Sri Lanka, [5]National STD/AIDS Control Program, Community Based Program for Drug Use, Colombo, Sri Lanka, [6]Family Planning Association, Global Fund HIV Project Implementing Unit, Colombo, Sri Lanka

Background: HIV testing services are compromised due to COVID -19 pandemic. Availability of HIV self-testing (HIVST) may help to increase awareness of HIV infection for people who would not otherwise get an HIV test. Oral HIVST kits distribution was piloted to expand HIV testing access, in the context of COVID-19.

Description: Ten thousand (10,000) Oral kits were secured by the National STD/AIDS Control Program (NSACP) for distribution starting in December 01.2020, through cycles of COVID-19 waves. Kits were distributed through many entry points, the network of community-based organizations (CBOs), public Sexually Transmitted Diseases (STD) clinics, web-based portal (www.know4sure.lk), social media posts, and a hotline that was established for clients to order a free kit. User demographic information was collected upon distribution of a kit to a client.

Reporting client's self-test result was encouraged, but not mandatory. Following distribution, staff or peers supported clients to access for services for PrEP, STI testing & ART services.

Lessons learned: As of December 31, 2021 a total of 7996/10000 (80%) HIVST kits were distributed to 32 sites across Sri Lanka, of which 16 were CBOs (5275 kits), 11 were government STD clinics (2475 kits) throughout Sri Lanka. Of the distributed kits, nearly 3500 individuals reported their results. A total of 17 self-tests were reactive, of which 14 reactive cases were reported through CBOs, one reactive reported through government STD clinic and two were reported by ordering through social media and hotline system. Of these reactive individuals 14 were confirmed being positive and linked to ART services. HIVST was useful in identifying individuals who are not accessing routine public STD clinics for HIV testing, and CBOs were particularly well placed to pivot and support clients seeking HIVST kits.

Conclusions/Next steps: This is the first pilot in Sri Lanka that showcases HIVST is well accepted by individuals through a variety of outlets for distribution. Based on our

findings, HIVST is an effective way to reach key populations who have never tested for HIV. An additional 10,000 kits have been secured and additional models of distribution, including pharmacies, are being explored. More in-depth analysis is underway in order to inform national scale-up.

EPC370

Feasibility of OraQuick HIV self-test in people who inject drugs, men who have sex with men, female sex workers, and transgenders in Iran: a national study

Y. Moradi[1], G. Moradi[1], M.M. Gouya[2], N. Izadi[3], H. Namdari[4], K. Tayeri[4], O. Zamani[5], N. Ghalekhani[5]

[1]Kurdistan University of Medical Sciences, Epidemiology, Sanandaj, Iran, Islamic Republic of, [2]Center for Communicable Disease, Tehran, Iran, Islamic Republic of, [3]Shahid Beheshti University of Medical Sciences, Epidemiology, Tehran, Iran, Islamic Republic of, [4]HIV/AIDS Control Office, Center for Communicable Disease, Tehran, Iran, Islamic Republic of, [5]HIV/STI Surveillance Research Center, and WHO Collaborating Center for HIV Surveillance, Kerman, Iran, Islamic Republic of

Background: This study was designed to evaluate the feasibility (percentage of satisfaction and acceptance) of using the OraQuick HIV self-test (OraQuick HIVST) in PWIDs and the development and availability of this test in the populations of MSM, FSWs, and TGs in more parts of Iran.
Methods: This study was a cross-sectional study that was conducted in November 2021, at 23 centers from 8 provinces in Iran including Tehran, Alborz, Iranshahr, Yasuj, Kurdistan, Mazandaran, Hamedan, and Lorestan.
The study population was included high-risk groups of MSM, FSWs, and TGs in order to develop the use of OraQuick HIVST and access PWIDs for evaluating the test feasibility.
The sampling method in this study was convenience sampling and the test distribution methods were facility-based, home-based HIV testing and counseling (HTC).
Results: In total, the participants in the present study were 1384 PWIDs and 1563 MSM, FSWs, and TGs. Overall, the test result was reactive in 21 patients (1.52%) of the PWIDs participating in the study.
Approximately, 97% of the participants stated that they had no problem with the confidentiality of information when preparing or performing the test (satisfaction). In general, the average feasibility based on 5 assessment questions in this group was equal to 6.25 out of 7.
The acceptance of using HIV self-tests in injecting drug users was 100%. Of the total groups of MSM, FSWs, and TGs, 1059 people (67.75%) were FSWs, 258 (16.51%) were MSM, 83 (5.31%) were TGs and the rest were sexual partners.
The test result was reactive in 15 participants (0.96%), of whom 3 were FSWs, 2 were partners of FSWs, 7 were MSM, 1 was a partner of MSM, and 2 were TGs.
Conclusions: The results of the present study showed that the OraQuick HIVST in the high-risk populations of Iran, including MSM, FSWs, TGs, and PWIDs, had very high acceptability. Therefore, according to these results, this type of test can be used in these high-risk populations for access to the hidden community of these populations, early and appropriate identification of key HIV-infected people, and proper implementation of screening, care, and treatment programs related to HIV.

EPC371

Tailoring HIVST to local communities can improve uptake: lessons learned from a virtual HIV self-testing intervention in India

R. Pollard[1], S. Okram[2], J. Thakker[1], A. Singh[1], J. Bell[1], A. McFall[3], M. Taduri[2], V. Gupta[2], J. Patil[2], S. Ghosh[2], A. Enugu[1], A. Reddy[1], S. Mehta[3], S. Solomon[1]

[1]The Johns Hopkins University School of Medicine, Baltimore, United States, [2]YR Gaitonde Center for AIDS Research and Education, Chennai, India, [3]The Johns Hopkins Bloomberg School of Public Health, Baltimore, United States

Background: To achieve UNAIDS 95-95-95 targets in India, innovative strategies are needed to increase uptake of HIV testing among unreached groups. HIV self-testing (HIVST) offers a promising way to reach new clients and overcome barriers to in-person testing.
Description: A web-based platform for HIVST was launched in June 2021. Virtual counsellors contacted clients across 28 Indian states and territories on dating apps and social media platforms and directed interested clients to HIVST via home delivery or pick up at a community site. Linkage to confirmatory testing, ART, or PrEP was provided as needed. Descriptive statistics were used to characterize outcomes. We conducted in-depth interviews over the phone from Dec 2021-Jan 2022 with clients who ordered HIVST kits. Respondents were purposively sampled by region, gender, age, kit retrieval method, and HIVST result. Transcripts were analyzed using deductive thematic analysis.
Lessons learned: Between June 30, 2021-Jan 21, 2022, 2,610 total clients ordered an HIVST kit and 2,185 received one. Among them, 2,018 (92%) uploaded results, 93 (5%) screened positive, and 31 (33%) were linked to confirmatory testing. 25 (81%) were confirmed positive and 25 (100%) initiated ART. We interviewed 20 of these clients aged 19-45years (75% men, 5% women, 20% transgender women), 18 of whom screened negative and 2 screened positive. Clients said they were interested in HIVST because they could test privately, get results quickly, and avoid stigmatizing experiences at facilities. Clients appreciated the option of home delivery, confidential packaging, and picture/video instructions showing how to complete the kit. Clients shared that virtual counselor support and patience was instrumental in guiding and motivating them

to complete HIVST, and for those who screened positive, pursue confirmatory testing. Reported barriers included a lack of local languages on the website and kit instructions, and lack of messaging from trusted sources on the accuracy of HIVST. Clients felt strongly that HIVST should be promoted widely to general as well as key populations.
Conclusions/Next steps: HIVST reaches populations who remain unreached with existing HIV testing approaches. Tailoring HIVST strategies to incorporate local languages and counseling options can help build trust among communities and further improve uptake of HIVST.

EPC372

A comprehensive population-based approach to HIV testing, including nominal, anonymous and directed HIV self-testing

A. Kroch[1,2,3], J. Liu[3], V. Tran[3,4], K. English[5], A. Musten[1], S. Colyer[1,1], P. O'Byrne[6]
[1]Ontario HIV Treatment Network, Toronto, Canada, [2]University of Toronto School of Public Health, Clinical Public Health, Toronto, Canada, [3]Public Health Ontario, Toronto, Canada, [4]University of Toronto, Laboratory Medicine and Pathobiology, Toronto, Canada, [5]Ontario Ministry of Health, Toronto, Canada, [6]University of Ottawa, Ottawa, Canada

Background: Ontario's HIV testing strategy has long included population targeted nominal and anonymous testing for gay, bisexual or other men who have sex with men, people who use injection drugs, African, Caribbean and Black people, and Indigenous Peoples. To incorporate self-testing in a comprehensive strategy, and to increase access to HIV testing during the COVID-19 pandemic, Ontario implemented a free HIV self-testing program targeted to key populations, where participants register and complete a self-assessment online (www.GetaKit.ca). Participants receive kits by mail, report their results in a secure portal, and are linked to care and resources.
Methods: Nearly all HIV testing in Ontario is conducted at the Public Health Ontario's laboratory, and HIV testing is monitored by demographics and risk factors. In preparation for self testing licensure in Canada, GetaKit launched July 20, 2020 in Ottawa, Canada with special access; licensure was approved in Nov 2020, and the program expanded across Ontario April 1, 2021.
Results: The pandemic had a profound impact on HIV testing, (2019: 677,254 tests; 2020: 500,517 tests). Anonymous testing was particularly impacted (2019: 16,478 tests; 2020: 5,309 tests). When HIV risk factors were known, the percent of tests within target populations increased (2019: 25%, 2020: 27%). The positivity rate was unchanged at 0.01% for all testing, and increased in anonymous tests (2019: 0.47%, 2020: 0.81%). GetaKit sent 1,748 tests from July 2020 to Dec 2021, with a test result report rate of 64% (1,111/1,748). In preliminary analysis, ~70% of testers reported risk and demographic factors of targeted populations. There were 8 confirmed positive tests, with a test positivity of 0.46% (8/1,748) overall, and 0.72% (8/1,111) for all reported results.
Conclusions: HIV self-testing is a critical component of a comprehensive testing program. During the pandemic, self-testing provided a needed resource for people at risk for HIV. As clinic access improves with the pandemic, and self-testing is more widely available, the demographics and positivity rates of GetaKit participants must be monitored. The high positivity rates for both anonymous testing and self-testing during the pandemic indicate that those programs are well targeted to those populations at greatest risk of HIV.

EPC373

HIVST among children, adolescents and pregnant and breastfeeding women: implementation results and enablers for scale-up

C. Nwafor[1], N. Otubu[1], A. Muhammad-Mujtaba[1], O. Adewole[1], M. Obioma[1], F. Lufadeju[1], J. Drakes[2], L. Simao[2], S. Dowling[2], K. Suggu[2], O. Wiwa[1]
[1]Clinton Health Access Initiative, HIV Access Program, Abuja, Nigeria, [2]Clinton Health Access Initiative, Global HIV Access Program, Boston, United States

Background: In 2020, ART coverage was 44% for children and 45% for pregnant women living with HIV in Nigeria. Since 2016, WHO has recommended HIV self-testing (HIVST) for under-reached populations, and in 2019, approved use among children aged 2-11 years by trained professionals. National guidelines for HIVST further allow caregiver-assisted testing; however, HIVST for all populations is limited. CHAI is supporting the Federal Ministry of Health (FMoH) to demonstrate effective HIVST delivery models and identify enablers for scale-up.
Methods: Between April- December 2021, CHAI and FMoH supported training and commodities for HIVST among children aged 2-11 of index clients via HIV testing services (HTS) officers at 9 facilities, adolescents/ young people (AYP) via adolescent champions at 9 Adolescent and Youth Friendly Centers (AYFC) and pregnant and breastfeeding women (PBFW) via 8 traditional birth attendants (TBAs) in Anambra and Akwa-Ibom states. Data collected included client demographics, testing history, HIVST mode, results, confirmatory testing and ART linkage from FMoH monthly summary forms and operational insights from CHAI-led learning sessions.
Results: Across models, 2,100 HIVST kits were distributed and 2,049 (98%) utilized. Thirty-eight (2%) clients self-reported reactive results, 32 (84%) received confirmatory testing and 32 (1.6%) were identified HIV-positive (Table). Yields were 0.9%, 2.9% and 1.8% in facility index testing, AYFC and TBA models respectively, and all were linked to ART. Overall, 95% of tests were for first-time testers and 94% were conducted with assistance by distributors.

Distribution Model	HIVST Kits Distributed	HIVST kits distributed for secondary use	HIVST kits distributed for First- Time Testers	HIVST Conducted	HIVST Assisted by Distributor	Results Reported	Reactive Results	Clients receiving Confirmatory Tests	Clients Identified HIV-Positive	Clients Linked to ART
Facility index testing for children aged 2-11	1,100 (52%)	n/a	1,100 (100%)	1,054 (96%)	1,054 (100%)	1,023 (97%)	10 (1%)	9 (90%)	9 (0.9%)	9 (100%)
AYFC for AYP and their peers	451 (21%)	152 (34%)	443 (98%)	446 (99%)	330 (74%)	443 (99%)	13 (3%)	13 (100%)	13 (2.9%)	13 (100%)
TBA for PBFW	549 (26%)	n/a	444 (81%)	549 (100%)	542 (99%)	549 (100%)	15 (3%)	10 (67%)	10 (1.8%)	10 (100%)
Total	2,100		1,987 (95%)	2,049 (98%)	1,926 (94%)	2,015 (98%)	38 (2%)	32 (84%)	32 (1.6%)	32 (100%)

EPC373 Table.

At AYFCs, 34% of HIVST kits were collected for secondary use. Distributors and target populations recommended community sensitization, incentives such as condoms, additional distribution points and resources for follow-up to improve uptake and confirmatory testing.

Conclusions: Decentralized, peer-driven models for HIVST can be effective for testing, including adolescent social network testing, and ART linkage; however, uptake was low and further research is needed on improving yields among children. To optimize impact, HIV programs should leverage existing venues and cadres serving target populations, prioritize demand generation and train distributors to provide support aligned with client preferences.

EPC374

Promoting HIV self-testing services among adolescents and young people using social marketing technologies: a case study of SMARTPack intervention in Lagos, Nigeria

I. Moses[1], O.C. Jennifer[1], O. Richard Atoreze[1], O. Ezechi[1], I. Juliet[2], J. Tuker[3], T. Gbajabiamila[1], C. Obiezu-Umeh[2], O. David[1], S. Muyideen[4], E. Shoyemi[5], A. Monsurat[6], O. Fisher[6], O. Moses[7], I. Ehimario[8], H. Aboki[9], V. Isiramen[10], M. Boladale[11]

[1]Nigeria Institute of Medical Research, Clinical Science, Lagos, Nigeria, [2]St. Louis University, Missouri, United States, [3]University of North Carolina at Chapel Hill, North Carolina, United States, [4]Society for Information and Human Advancement Initiative, Ajegunle-Apapa, Nigeria, [5]Population Council, Lagos, Nigeria, [6]Lagos State AIDS Control Agency, Lagos, Nigeria, [7]National Youth Network on HIV/AIDS, Population and Development, Abuja, Nigeria, [8]University of the Western Cape, Cape Town, South Africa, [9]National Agency for the Control of AIDS, Abuja, Nigeria, [10]UNICEF, Abuja, Nigeria, [11]Obafemi Awolowo University/ Teaching Hospitals, Mental Health, Ile-Ife, Nigeria

Background: Adolescents and Young People (AYP) are under-served by the convectional HIV Testing Services due to social stigma and inadequate youth-friendly services in Nigeria. Only 1 out of 5 AYP (15-24 years) know their HIV status; thus, the need for innovative testing strategies targeting AYP. HIV Self-Testing (HIVST) is a promising approach towards fast-tracking the 95-95-95 UNAIDS target by 2030. However, implementable and sustainable strategies of HIVST among AYP in Lagos, Nigeria are unknown. This study explored the use of SMARTPack intervention to increase uptake of HIV testing services among AYP.

Methods: The OraQuick HIVST kit was re-branded and repackaged as "SMARTPack" with value added commodities including: male and female condoms, lubricants, wrist band, Free STI services upon completion of user journey, coupon referrals to Youth Friendly Health Centers (YFC) to qualify for raffle draws for chances to win prizes and following a peer-led approach by AYP and for AYP. It was then marketed to AYP in Lagos State from August, 2019 to March, 2020. Data on socio-demographic, sexual history, and previous HIV testing were collected using structured questionnaires at baseline and after 6 months of follow-up. Information on SMARTPack perception in relation to affordability and stigma reduction were also collected. Descriptive statistics using mean, standard deviation and proportion were employed.

Results: A total of 114 AYP comprising 60 males (52.6%) with mean age 21.0±2.9years were reached. At follow-up, 91% had undertaken a second HIV self-test and 71% had been linked to YFC for confirmatory testing irrespective of their HIVST result, either reactive or non-reactive. Forty-six percent of AYP diagnosed with STI at the YFC received treatment including those confirmed HIV positive enrolled into care. Also, 85% agreed that SMARTPack reduced social stigma associated with HIV testing; 59% were willing to disclose their result to a caregiver. About half (52%) of AYP could afford SMARTPack every 6 months at a mean price of N1,225.35(USD3.22)±NGN803.86(USD2.11).

Conclusions: AYP in Lagos perceived SMARTPack as a discreet and affordable HIVST option which could improve testing rate and referrals. Scaling up strategies such as SMARTPack could accelerate efforts to achieve the 95-95-95 UNAIDS targets.

Uptake of free mail-home hiv self-tests among gay, bisexual, queer, and trans men and two-spirit and non-binary people across Canada: the Sex Now 2021 Test@Home Implementation Science Study

N. Lachowsky[1,2], C. Draenos[1], B. Klassen[1], S. Child[1], D. Purzycki[1], C. Babin[2], S. Arthur[2], A. Hu[2], A. Stark[2], K. Card[1,3], S. Rourke[4]

[1]Community Based Research Centre, Vancouver, Canada, [2]University of Victoria, Public Health & Social Policy, Victoria, Canada, [3]Simon Fraser University, Burnaby, Canada, [4]St. Michael's Hospital, MAP Centre for Urban Health Solutions and REACH Nexus, Toronto, Canada

Background: Canada approved its first HIV self-test in 2020. We developed a community-based implementation study that provided free mail-home HIV self-tests. We sought to examine which gay, bisexual, trans, and queer men as well as Indigenous Two-Spirit and non-binary people (GBTQ2) across Canada opted-in to participate.

Methods: Participants were recruited from 03/2021-09/2021 via an online community health survey that used advertisements on sociosexual websites/apps, and community-based organizations' social media and email lists. Eligible participants were at least 18 years old, lived in Canada, and either identified as non-heterosexual or reported recent sex with a man.

Women were ineligible. After completing a baseline questionnaire, participants could opt-into Test@Home and request up to 3 free HIV self-tests that were mailed within 36 hours to their chosen address, which could be used by the participant or distributed to others.

Participants completed a 2-week follow-up survey. Trained peer support was available via text, email, or toll-free telephone. Chi-square tests compared participants who opted into Test@Home versus not on demographic and sexual health indicators ($p<0.05$ significant).

Results: Of 6098 Sex Now participants, 2261 (37.1%) opted into Test@Home with 5395 self-tests distributed (mean=2.39/participant).

Test@Home participants were more likely to be aged <30 (33.1% versus 26.2%), born outside Canada (25.2% versus 19.6%), live in urban cores (32.4% versus 24.7%), experience financial strain ("cannot make ends meet": 10.3% versus 6.5%), be single (54.3% versus 43.5%), report a past-year STI diagnosis (22.7% versus 17.6%), have an HIV Incidence Risk Index-MSM score >10 (56.4% versus 40.6%), and to identify as a person of colour (20.2% versus 14.9%) and disabled (18.1% versus 13.3%). Test@Home participants were less likely to identify as bisexual (17.2% versus 31.0%), be first-time testers (9.2% versus 16.5%) and self-report living with HIV (3.9% versus 9.6%).

At follow-up, participant experiences with HIV self-tests were positive (e.g., 88.0% reported it was easy to use, 94.9% would recommend to others); the greatest benefits of Test@Home were convenience (80.9%), privacy (65.9%), and free-cost (50.7%).

Conclusions: Mail-home HIV self-tests reached several, but not all, key sub-populations of GBTQ2. Additional follow-up to 6-months will further understandings of HIV self-test use, distribution, and linkage to care.

EPC376

Expanding free HIV Self-Testing (HIVST) with community health-based follow-up in New York City

A. Mogili[1,2], O. Singh[1]

[1]GMHC, Testing Center, New York, United States, [2]Icahn School of Medicine at Mt. Sinai, New York, United States

Background: GMHC's Testing Center, located in New York City, provides free and confidential HIV testing and counseling, and linkage to medical and supportive services. The COVID-19 pandemic disrupted free HIV/STI testing services, thus free at-home HIV Testing (HIVST) was introduced, facilitated by the local health department (NYC DOHMH). GMHC distributed HIVST to community members and monitored testing outcomes.

Description: From April 2020 to December 2021 the HIVST program provided coupon codes for clients to order a free OraQuick In-Home HIV test. The NYC DOHMH program provided over 4,300 coupon codes to partners throughout New York; GMHC provided 549 codes to clients. The program was available to anyone who might need an HIV test, including both first-time testers and those who test regularly. Clients were mailed kits and then were contacted by a GMHC test counselor two weeks after.

Lessons learned: GMHC distributed HIVST to 510 clients and successfully followed up with 241(47.3%) clients. 219(90.9%) clients reported using their kits and 30 PrEP, 3 PEP, and 10 STI referrals were made. In comparison with those who chose to be tested in person, HIVST users were more likely to be women or heterosexuals. Most notably we saw an increase in first-time testers with 23.9% (n=221) HIVST users compared to 7.9% (n=4718) in-person testers.

Conclusions/Next steps: HIVST has been shown as an effective additional testing option. However, concerns have been cited with difficulty in result-reporting and providing appropriate medical follow-up. Patients have cited the price of HIVST as a barrier. Our program demonstrated high uptake of HIVST when the cost barrier was removed, particularly among first-time HIV testers. Counselors were able to successfully connect with clients to confirm kit arrival and us and to provide counseling, education, and medical referrals virtually.

The ability to provide accurate, safe and free at-home testing represents a pathway to provide testing to individuals who might not otherwise seek services. Programs such as the one described in this project, where public health departments partner with community-based organizations and primary care providers to establish a network of test distribution and follow-up, can be a powerful tool to engage more at-risk individuals in regular testing.

EPC377

Examining the use of HIV self-testing to support PrEP initiation and continuation: a systematic literature review

C. Kiptinness[1,2], A.P. Kuo[3], A.M. Reedy[4], C.C. Johnson[5], K. Ngure[6], A.D. Wagner[3], K.F. Ortblad[4]
[1]University of Nairobi, Nairobi, Kenya, [2]Partners in Health and Research Development, Thika, Kenya, [3]University of Washington, Seattle, United States, [4]Fred Hutchinson Cancer Research Center, Seattle, United States, [5]World Health Organization, Geneva, Switzerland, [6]Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya

Background: While HIV pre-exposure prophylaxis (PrEP) access has been expanding globally, initiation and continuation remain low and service delivery challenges persist. HIV self-testing (HIVST) has the potential to expand PrEP reach and access by simplifying delivery.

We conducted a systematic literature review to understand the evidence on HIVST use for PrEP initiation/continuation.

Methods: We searched electronic databases, clinical trial registries, and conference abstracts until 25 August 2021; our search strategy included terms to identify studies focused on HIVST use for PrEP initiation and/or continuation.

We included studies that measured: effectiveness (including comparative and case studies with no comparison), values and preferences (V&P), and economic outcomes.

Two authors identified studies for inclusion and extracted data; we reported outcomes descriptively and resolved any disagreements through consensus.

Results: After screening 1,053 records, we identified 18 relevant studies: 15 effectiveness (7 randomized trials, 8 case studies), 3 V&P, and 3 economic studies (3 studies were included in multiple categories).

Most studies occurred in sub-Saharan Africa (67%, 12/18) and included diverse populations. All studies (100%, 18/18) reported PrEP continuation and few (22%, 4/18) reported initiation.

Of the trials and case studies, 71% (5/7) and 38% (3/8 respectively were protocols with no reported outcomes.

One trial used HIVST to reduce the number of PrEP clinic visits in half with at-home interim testing, another trial used HIVST to provide supportive testing between quarterly clinic visits; both found either non-inferior or no statistically significant differences in refilling and/or adherence (i.e., continuation) compared to standard-of-care delivery.

In the case studies, HIVST helped optimize PrEP delivery and facilitate PrEP initiation/continuation in new settings (e.g., retail pharmacies) at levels similar to clinic-based delivery.

The V&P studies found that HIVST-supported models of PrEP delivery were preferred; the economic studies found that people were willing to pay for these models.

Conclusions: Our review found that HIVST use for PrEP initiation and continuation largely resulted in similar outcomes to standard-of-care PrEP delivery. HIVST-supported PrEP-delivery models were also found to be preferred by various populations. This review will inform the development of WHO guidelines. This remains an important area for further review following the completion of ongoing studies.

EPC378

The impact of the COVID-19 pandemic on profiles of STI testing and sexual behaviours among clients attending a STI self-testing clinic in Quebec: A Latent Class Analysis

K. Yokoji[1,2], M. Regimbal-Éthier[1], K. Benomar[1], S. Saeed[3]
[1]Prélib, Montreal, Canada, [2]McGill University, Department of Epidemiology, Biostatistics and Occupational Health, Montreal, Canada, [3]Washington University in St. Louis, Division of Infectious Diseases, St. Louis, United States

Background: Sexually transmitted infections (STI) self-testing clinics aim to reduce barriers and stigma experienced by clients and reach high-risk populations that may not be engaged in regular medical care. We examined how STI testing and sexual behaviours changed as a result of the COVID-19 pandemic.

Methods: Prélib is a STI self-screening clinic that combines an Internet-based consultation and self-screening in Quebec, Canada. Prospective data was collected from anonymous questionnaire on demographics and sexual risk between December 2018-2021.

We used a Latent Class Analysis to identify distinct phenotypes of client attending the clinic based on recent condomless sex, the number of sexual partners in the past 2 months, sex under the influence of drugs, STI testing habits, past diagnosis, and MSM (men who have sex with other men).

We then evaluated if phenotypes changed as a result of the pandemic. Logistic regression was used to estimate the association of testing positive to any STI and latent class membership.

Results: Of 22,927 participants included in the analysis, 6,633 attended the clinic pre-pandemic and 16,294 post-pandemic. Clients were on average 28 years old, 45% female, and 10% MSM. We identified 4 phenotypes (see Figure 1) that remained consistent over time: "Safe sex with stable partner" (pre-; vs post-pandemic: 20%,17%), "Recent condomless sex with occasional testing" (35%; 49%), "Casual sex partners with regular testing, MSM" (18%; 11%), and "First time testers" (28%; 23%).

Compared to "safe sex", other class membership was associated with odds of testing positive to at least one STI (Chlamydia, Gonorrhea, syphilis, HBV, HIV) (OR=2.7 [95% CI: 2.0-3.7]; 5.8 [4.2-8.1]; 3.3 [2.4-4.4], respectively).

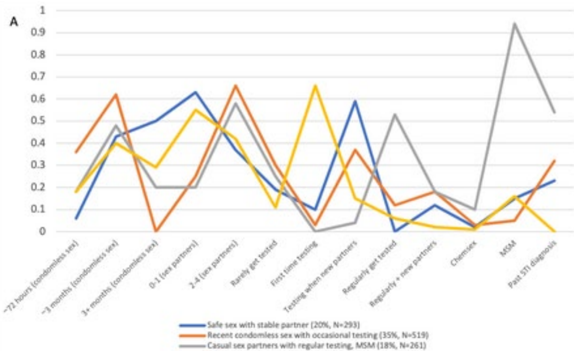
Late-breaker abstracts

Author Index



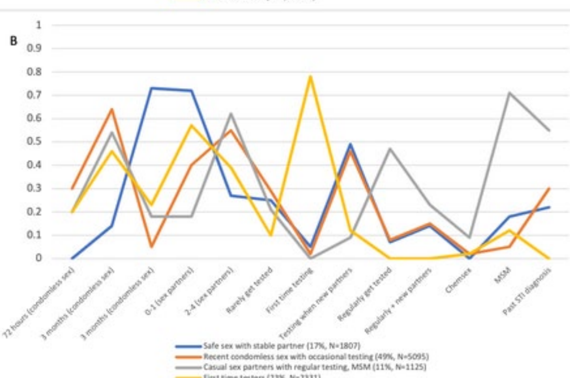


Figure 1. Sexual risk factor profile by latent class among individuals attending clinic A) before March 14, 2020, and; B) after May 14, 2020, based on predicted probability of class assignment.

Conclusions: The clinic was accessed by high-risk groups as well as first time testers. While testing increased post-pandemic, the characteristics of groups of clienteles attending the clinic remained constant, illustrating the resilience and importance of the self-testing clinics for sexual health.

Feasibility of using Motorcycle Riders to distribute HIV Self-testing kits to notified contacts of HIV positive Index patients in Kampala Uganda

E. Namulema[1], E. Mutambuze[1], R. Ankunda[2], M.T. Bafumba[3]
[1]*Mengo Hospital, HIV/AIDS, Mengo, Kampala, Uganda,* [2]*Mengo Hospital, HIV/AIDS, Kampala, Uganda,* [3]*Makerere University, School of Statistics and Planning, Kampala, Uganda*

Background: Despite a policy promoting HIV Self-test (HIVST) among contacts of HIV positive index patients, some notified clients fail to visit the health facility to take the test. We evaluated the impact of using motorcycle riders in the delivery and uptake of the oral HIVST among notified clients of HIV positive index patients.

Methods: From May 2019 to December 2021, we examined the feasibility of using motorcycle riders to deliver HIVST kits to notified contacts of HIV positive Index patients (IP). Participants were recruited through assisted partner notification (APN) and the Ante Natal clinics. We determined feasibility based on willingness of notified partners to give a trusted motorcycle rider the HIVST kit. Upon receipt of the kit, the contact was assisted on phone by the health provider to carry out the test in private. Results of the HIVST were shared with the provider on phone/via whatsapp and the used kits returned by the rider to the provider for accountability and verification.

Results: Half of the patients (55.55%) were male, average age 33 years. Approximately half (48.7%) preferred and used motorcycles suggesting that motorcycle delivery was acceptable. 147 (13.6%) tested positive, 933 (86.4%) tested negative. Positivity yield among motorcycle users was 83 % (122/147) compared to 17% (25/147) among facility mode. The motorcycle users were 7 times AOR more likely to test positive compared to those who use visited the facility 7.16 (4.26 – 12.03) (p-value 0.0000). Males were three times more likely to use the motorcycle compared to females (AOR 2.83 (2.11- 3.79), (p< 0.05). Age was positively associated with using a motorcycle. Men aged 30-49 were 8 more likely to use as a motorcycle times AOR 8.54 (2.28 – 31.10), p. Clients notified through APN were 67% less likely to come to the facility for testing AOR 32.81 (13.11 – 82.07) p<0.000.

Conclusions: Use of motorcycles is an effective strategy for notified clients of HIV positive index patients who are least likely to utilize the hospital for testing (particularly men). Using a motorcycle was associated with positive test, suggesting that we are capturing Individuals with an unknown HIV status, had they not accessed HIVST using motorcycles.

EPC380

Understanding the bottlenecks that affect the supply chain of HIV self testing; a qualitative study from key stakeholders' perspective

D. Ukaga[1], D. Aizobu[1], S. Malaba[2], G. Omoregie[1], O. Idogho[1], J. Anyanti[1], B. Adesina[1], P. Omodele[1], B. Abdullahi[1]
[1]*Society for Family Health, Abuja, Nigeria,* [2]*Population Services International, Nairobi, Kenya*

Background: HIV self-testing (HIVST) offers users an opportunity to check their HIV status in the comfort of their homes. However, there are key challenges with supply chain management that influence the availability and accessibility of HIVST in Nigeria. The study aimed to explore key stakeholders' perspectives on supply chain challenges affecting the availability and accessibility of HIV self-testing in Nigeria.

Methods: We conducted a qualitative descriptive study between July – August 2021 through semi-structured in-depth interviews with key supply chain stakeholders of HIVST kits in Nigeria. Data was uploaded, coded, and summarized using a qualitative software package, Nvivo. Data were transcribed verbatim and analyzed using thematic analysis and bottlenecks were identified.

Results: Our findings showed that manufacturers face challenges with forecasting and are often scared to manufacture enough HIV self test kits which leads to delays

and stock-outs. Disruptions of operations due to COVID-19 and poor insights into the number of kits per language to produce were additional bottlenecks identified by manufacturers.

Furthermore, distributors identified disruptions due to insecurity, storage issues due to Nigeria climate and potential profitability of HIV self testing as bottlenecks at each step in the supply chain. These bottlenecks had an impact on HIV self test kit supply and distribution in Nigeria, thus preventing potential users from accessing kits.

The manufacturers and distributors also stated they encountered difficulty when introducing new HIV self test products to the Nigerian market under local regulations especially with the high cost of clinical testing requirements mandated by regulators.

Conclusions: While there are various bottlenecks observed in impacting HIVST supply and distribution in Nigeria, utilizing existing data to improve forecasting, review of processes for new HIVST products and contingency planning can reduce the bottlenecks experienced in the supply chain thus improving the accessibility of HIVST by consumers.

EPC381

How much does HIV self-testing cost in low and middle income countries? A systematic review of evidence from economic studies

B. Empringham[1], A. Kashkary[2], A. Karellis[3], O. D'Silva[2], M. Fernandez Suarez[4], S. Carmona[4], N. Pai[3], A. Zwerling[2]

[1]Children's Hospital of Eastern Ontario, Pediatric Hematology-Oncology, Ottawa, Canada, [2]University of Ottawa, School of Epidemiology & Public Health, Ottawa, Canada, [3]McGill University, Division of Clinical Epidemiology & Experimental Medicine, Montreal, Canada, [4]Foundation for Innovative Novel Diagnostics, Geneva, Switzerland

Background: HIV self-testing (HIVST) has been proposed as an innovative strategy to diagnose human immunodeficiency virus (HIV). While HIVST offers the potential to broaden accessibility of early HIV diagnosis and treatment initiation, this testing strategy incurs additional cost and requires individuals with positive ST to follow up with confirmatory testing and treatment. We have conducted the first systematic review to date, summarizing the currently economic literature for HIVST in low and middle income countries (LMICs).

Methods: A search strategy was developed including key terms for HIV, self-testing and costs and was conducted in two databases. Studies published up until October 15, 2021 were included. Abstract and full text screening was conducted and a standardized data abstraction form was used for included studies.

Results: We identified 23 studies, that provided both cost and outcome data on HIVST. There was significant heterogeneity in the HIVST intervention, study population, costs included and outcomes reported among included studies. Cost per person tested ranged from $2-144 USD. Cost per case diagnosed ranged from $23-1249 USD. Cost-utility estimates ranged from cost-saving to $2000 USD per DALY averted. Higher cost-effectiveness estimates were associated with more expensive testing algorithms with increased support for linkage to care and post-test counseling.

Conclusions: All studies considered HIVST cost-effective although major drivers were identified included underlying HIV prevalence, testing cost and linkage to care. HIVST is likely to be cost-effective in a LMIC context, however policy makers should be aware of the drivers of cost-effectiveness when implementing HIVST programs as these underlying factors can impact the overall cost-effectiveness of HIVST.

EPC382

An Economic Model of HIV Self-Testing

B. Empringham[1], A. Karrelis[2], M. Fernandez Suarez[3], S. Carmona[3], N. Pai[2], A. Zwerling[4]

[1]Children's Hospital of Eastern Ontario, Pediatric Hematology-Oncology, Ottawa, Canada, [2]McGill University, Division of Clinical Epidemiology & Experimental Medicine, Montreal, Canada, [3]Foundation for Innovative Novel Diagnostics, Geneva, Switzerland, [4]University of Ottawa, School of Epidemiology & Public Health, Ottawa, Canada

Background: HIV self-testing (HIVST) is an innovative strategy that has been shown to increase the accessibility and uptake of HIV testing compared to conventional facility-based testing. It can be provided with digital or community based supports that help facilitate linkage to post-test counselling and confirmatory testing after a positive self-test.

Methods: We developed a cost-effectiveness model to predict the cost-utility of HIVST in addition to facility based testing alone among the general population (15-65 years of age). We included a base case estimate and several emblematic scenarios where HIVST scaleup may be considered. We parametrized a combined Markov and decision tree model using comprehensive literature reviews on the cost, effectiveness and epidemiological parameters associated with HIVST along with digital or community based supports.

Results: We found that HIVST is cost effective at a threshold of 3xGDP per capita in all scenarios tested. Our base case scenario predicted that HIVST would be highly cost effective and associated with a cost of $513 USD/DALY averted. Our model predicted that the cost/DALY averted through HIVST was lowest when modeled in Malawi (a low-income, high prevalence setting) and highest when modeled in Brazil (a middle-income, low prevalence setting). Implementing HIVST among high-risk subgroups, such as men who have sex with men (MSM), increased cost-effectiveness due to increased underlying prevalence of undiagnosed HIV.

Conclusions: Both digital and community based supports for HIVST were associated with increased cost, but similar cost utility due to improved uptake and linkage to care. The cost utility associated with HIVST varied between contexts and the drivers of cost utility should be carefully considered prior to implementation of HIV self-testing programs. Main drivers of cost utility included underlying HIV prevalence, testing & programmatic costs, linkage to care and antiretroviral (ART) initiation rates. On a policy level, these drivers should be considered prior to implementation of HIVST programs.

It is imperative to investigate the cost-effectiveness of screening programs, to advocate for the most efficient allocation of resources. Our model suggests that HIVST is cost-effective due to improved diagnosis, treatment and ultimately mitigation of the morbidity and mortality associated with HIV/AIDS.

EPC383

Why does secondary distribution happen? A social network modeling study in HIV self-testing among Chinese MSM

F. Jing[1], X. Yan[1], C. He[2], Y. Zhou[3], Q. Zhang[4], W. Tang[5]

[1]The University of North Carolina at Chapel Hill, UNC Project-China, UNC Global, UNC School of Medicine, Guangzhou, China, [2]Wuhan University, School of Information Management, Wuhan, China, [3]Zhuhai CDC, Zhuhai, China, [4]City University of Hong Kong, School of Data Science, Hong Kong SAR, China, [5]The University of North Carolina at Chapel Hill, Institute for Global Health and Infectious Diseases, Chapel Hill, United States

Background: Many innovative strategies for HIV self-testing (HIVST) promotion were developed, such as secondary distribution. In HIVST secondary distribution (HIVST-SD), individuals (defined as indexes) first apply for multiple HIVST kits and then distribute these HIVST kits to their social network neighbors in their social network (defined as alters). In this study, we aim to find reasons why secondary distribution happens in an HIVST-SD implementation program by understanding how an edge (between the index node and the alter node) comes into being among Chinese MSM.

Methods: There are two types of edges between the index node and the alter node: unidirectional edge and bidirectional edge. Through unidirectional edges, the index plans to distribute kits to his target alters according to the baseline survey completed by indexes. Through bidirectional edges, the index successfully distributed kits to alters as the testing result was returned and the testing survey was completed by the alter. Followed by descriptive analysis and ego-centric network analysis, multilevel models and exponential random graph models (ERGM) were used to interpret the formation of unidirectional edges and bidirectional edges (i.e., why secondary distribution happens in edges) respectively.

Results: There were 309 MSM indexes participating in our HIVST-SD program in Zhuhai, China. The multilevel modeling results showed that some factors (e.g., index-alter relationship) were significantly associated with secondary distribution choices of the indexes (i.e., distribution willing in unidirectional edges).

For instance, compared to other non-specified relationships, the index and the alter being lovers mostly increased the odds ratio of the index being willing to distribute kits (aOR=54.95, 95% CI=[3.21, 94.16], p<0.01).

ERGM also showed that some factors could lead to the real happening of secondary distribution (i.e., distribution behavior in bidirectional edge).

For example, if the absolute value of ages' difference between the index and the alter is smaller, then the secondary distribution is more likely to appear (Monte Caro MLE estimates=-0.068, Std.Error=0.014, p<0.001).

Conclusions: Our study discovered the endopathic factors (intrinsic dynamics) of secondary distribution happening instead of the exopathic factors (external interventions) in previous HIVST-SD studies (e.g., monetary incentives). This work can provide insights into guiding HIVST-SD implementation programs in the future.

EPC384

A pilot feasibility study of HIV self-testing with online supervision among MSM who attend sexualized drug parties in Thailand

T.E. Guadamuz[1], N. Samoh[1], S.H. Lim[2], K.J. Jonas[3]

[1]Mahidol University, Center of Excellence in Research on Gender, Sexuality and Health, Nakorn Pathom, Thailand, [2]University of Malaya, Faculty of Medicine, Kuala Lumpur, Malaysia, [3]Maastricht University, Faculty of Psychology and Neuroscience, Maastricht, Netherlands, the

Background: A volatile HIV epidemic is emerging among MSM in Asia, particularly among MSM who attend sexualized drug parties (SDP). While sustained HIV testing is an effective intervention tool, venue-based testing present numerous challenges. This study examines the feasibility of HIV self-testing with online supervision (STOS) among MSM who attend SDP.

Methods: Between September and December 2021, MSM age 18+ who reported HIV negative or unknown status, and had attended at least one SDP in the past 12 months were recruited with the assistance of community-based partners and social media platforms (e.g., private Line® chat groups, private Facebook® groups, and private Twitter® groups). STOS involves sending a 4th generation Alere Determine™ HIV-1/2 finger prick self-testing kit to the participant's home, coupled with support from a counselor via video conferencing.

Participants who tested positive confirmed results at our community-based clinic partner. Exit interviews with 10 MSM were conducted to assess intervention fidelity and acceptability.

Results: Of 508 MSM recruited, 303 were eligible and willing to conduct STOS. Of these, 267 successfully conducted STOS at baseline where 25.8% tested positive and 1.9% were inconclusive. At 3-month follow-up, 175 participants were sent test kits and 153 successfully conducted STOS where 100% tested negative. Participants preferred STOS, compared to venue-based testing. They also felt that STOS was more convenient, free from stigma and discrimination by health care providers, and the process was more confidential and their identity/personal information (e.g., HIV test results) was better protected. Participants who tested positive were quickly linked to HIV care, treatment and support (100% linkage).

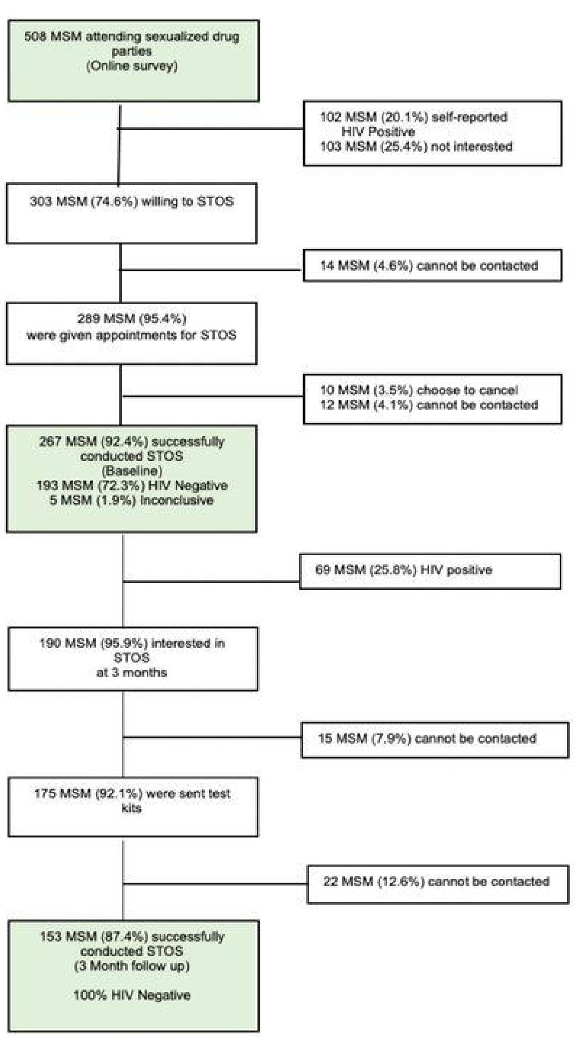

Figure 1. HIV self-testing with online supervision (STOS) among MSM attending sexualized drug parties.

Conclusions: STOS proved to be feasible and acceptable among MSM who attend SDP, particularly during the COVID-19 lockdowns where many HIV testing venues were closed. For a population where HIV prevalence is high, STOS may be a viable option for sustained testing.

EPC385

Peer-led community HIV self-testing (HIVST) distribution models improves access to HIV testing services (HTS) among key populations (KP) in Uganda

J. Tumusiime[1], E. Twesigye[1], G. Taasi[2], L. Hicks[3], I. Thiour[4], K. Green[5], D. Canagasabey[4]

[1]PATH, Uganda Country Program, Kampala, Uganda, [2]Minstry of Health, ACP/STD Control Unit, Kampala, Uganda, [3]PATH, Global TB/HIV Programs, Seattle, United States, [4]PATH, Global TB/HIV Programs, Washington DC, United States, [5]PATH, Primary Health Care (PHC), Veit Nam, Viet Nam

Background: Key populations (KP) in Uganda continue to be disproportionately affected by HIV, with a prevalence two-to five-times greater than the general population, driven by deep-rooted stigma and harsh cultural and legal environments. More targeted HIV case-finding strategies tailored to KP preferences are required to improve reach and access to HTS services.

Through the Unitaid/STAR-III project, PATH worked with Ministry of Health to introduce peer-delivered, community HIVST delivery models in three central Ugandan districts to strengthen HIV testing services for KPs.

Description: KP peer leaders provided community-based HIVST services through: household outreach, community outreach events, KP hotspots, and KP drop-in centers. Peer leaders were trained to deliver HTS counseling, and provide assisted and unassisted HIVST.

For KP opting for unassisted HIVST, peer leaders followed up by phone or WhatsApp to confirm HIVST result and provided escorted referrals for confirmatory diagnosis and treatment initiation. Peer leaders were given transportation and airtime to support follow-up and referrals.

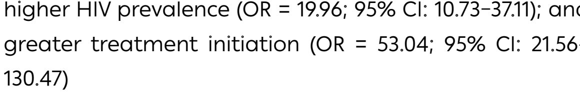
We analyzed program data from Wakiso, Kampala, and Mukono Districts from November 2020 to December 2021 to understand these models' contribution to KP HIVST uptake and linkage to treatment.

	HIVST distributed	HIVST results returned	Reactive HIVST results	Linkage to confirmatory diagnosis	Confirmed HIV-positive	Initiated on treatment
Community distribution	65,222	64,974	712	697	686	681 (99%)
Other distribution modalities	96,354	93,965	793	697	528	380 (71%)
Total	161,576	158,839	1,505	1,394	1,214	1,061

Table.

Lessons learned: As summarized in the table, 40.4% of all HIVST kits distributed during the implementation period was through peer-driven community.

Peer-led community distribution model led to higher percentage of HIVST results returned (odds ratio [OR]= 6.66; 95% confidence interval [CI]: 5.84–7.59); higher reactivity rate (OR = 1.31; 95% CI: 1.18–1.45); greater linkage to confirmatory diagnostic services (OR = 6.40; 95% CI: 3.67–11.13);



higher HIV prevalence (OR = 19.96; 95% CI: 10.73–37.11); and greater treatment initiation (OR = 53.04; 95% CI: 21.56–130.47)

Conclusions/Next steps: Our results highlight the feasibility, acceptability, and effectiveness of peer-led community HIVST distribution models to reach KPs with HTS and link clients to treatment services. Peer-led models that offer differentiated and decentralized HTS should be scaled up further to address KP barriers to testing and help Uganda reach epidemic control.

HIV testing algorithms

EPC386

Gap in diagnosis ofHIV exposed infantsin Cambodia Exposes theneedfor the integration ofpoint-of-care testingto achievethe elimination of mother-to-child transmission

V. Ouk[1], S. Hul[2], S. Samreth[1], R. Kim[3], K. Te[3], B. Ngauv[4], K. Chetra[4], S. Chhorn[3], C. Mom[4], B. Chamrouen[4], K. Yi[5], R. Cheu[6], D. Rathakrishnan[7], C. Amole[7]

[1]National Center for HIV/AIDS Dermatology and STDs, Ministry of Health, Phnom Penh, Cambodia, [2]Clinton Health Access Initiative, HIV and Viral Hep, Phnom Penh, Cambodia, [3]National Maternal and Child Health Center (NMCHC), Ministry of Health, Phnom Penh, Cambodia, [4]National Center for HIV/AIDS, Dermatology and STDs (NCHADS), Ministry of Health, Phnom Penh, Cambodia, [5]Clinton Health Access Initiative (CHAI), HIV/AIDS, Phnom Penh, Cambodia, [6]Clinton Health Access Initiative (CHAI), HIV, Phnom Penh, Cambodia, [7]Clinton Health Access Initiative (CHAI), Global HIV Access Program, Boston, United States

Background: Cambodia's progress in the elimination of mother-to-child transmission (eMTCT) achieved 95% antenatal care coverage, 90% HIV screening in ANC, and 86% antiretroviral coverage.

However, early infant diagnosis (EID) coverage is only 78% and the vertical transmission rate is high at 12%. Cambodia's HIV testing guidelines recommend DNA PCR tests for HIV exposed infants (HEI) at birth (PCR1), 6 weeks (PCR2), and 6 weeks post-breastfeeding (PCR3).

Description: To understand the gaps in adherence of the testing algorithm for HEI, NMCHC and NCHADS analyzed nationwide HEI testing data from 2020 to 2021 using the annual laboratory database maintained by the government. This analysis was based on an algorithm where 2020 and 2021 data, extracted from the national lab is used to reflect the gaps in the testing cascade and sample transportation, in the context of COVID-19 disruption. A total of 1,649 samples were analyzed over the 2-year period.

Lessons learned: Limited point-of-care testing and COVID-19 disruptions led to substantial turnaround time (TAT) and loss to follow up, with the number of samples reduced by 30% in 2021. Over 50% of patients experienced long TAT for test results, defined as >2 weeks from sample collection to lab result dispatch.

- Testing algorithm adherence was low in the 2020-2021 period due to COVID-19. In 2020, 64% received at-birth testing or a PCR1 test, 22% received a PCR2 test, and only 1.4% received a PCR3 test. In 2021, at-birth or PCR1 testing was at 40%, PCR2 testing was at 34%, and PCR3 testing was not observed. Substantial testing decline is rooted in high LTFU and limited monitoring.
- 43% of samples had TAT of <2 weeks in 2020, and this figure declined to 19% in 2021, illustrating a critical need for efficient sample transport.

Conclusions/Next steps: Limited EID access to reach 0-3 day TAT and low adherence to the testing algorithm are major barriers to achieving Cambodia's goal of eMTCT by 2025. Cambodia should explore point-of-care DNA-PCR testing (GeneXpert) to reduce TAT and improve adherence, thereby reducing LTFU for pregnant women and children. Strengthening breastfeeding data and testing to inform HIV vertical transmission estimates reduce vertical transmission via breastfeeding.

HIV testing to support prevention

EPC387

Exploring profiles of HIV and STI testing. A latent class analysis of men who have sex with men (MSM) in Sweden

T. Herder[1], N. Dennermalm[2], K. Ingemarsdotter Persson[3], F. Månsson[4], A. Agardh[1]

[1]Lund University, Social Medicine & Global Health, Department of Clinical Sciences, Malmö, Sweden, [2]Stockholm University, Department of Social Work, Stockholm, Sweden, [3]Karolinska Institutet, Department of Global Public Health, Stockholm, Sweden, [4]Lund University, Clinical Infection Medicine, Department of Translational Medicine, Malmö, Sweden

Background: Aggregated evidence on the effective antiretroviral therapies effects on HIV transmission contributes to further importance of differentiated HIV testing strategies, to shorten the time between infection and diagnosis. With substantial proportions of late presenters among men who have sex with men in Sweden and increases in STI incidence, there is a need for increased knowledge on testing behaviors to inform future HIV and STI testing strategies.

This study aimed to identify sub-groups of MSM based on HIV and STI testing behaviors and study associated factors.

Methods: Data were collected through a cross-sectional survey at six HIV testing venues in Sweden, three community-based and three within the public health care system in Sweden. Inclusion criteria were identifying as a man,

≥18 years, having had sex with a man during the preceding 12 months, and not reporting an HIV diagnosis, which resulted in a sample of 669 MSM. Heterogeneity of testing profiles in the sample was analyzed through latent class analysis (LCA), and associated factors examined through multinomial logistic regressions.

Results: Based on model fit and interpretability,a five-class model was deemed optimal, identifying five distinct sub-groups of MSM; Class 1 "Seldom community testers", Class 2 "Routine community testers", Class 3 "Seldom health care testers", Class 4 "Frequent health care testers", and Class 5 "Medically motivated testers". Multinomial logistic regression showed associations between HIV-risk related covariates and class membership, in comparison to class 1, with larger effect sizes in classes 4 and 5, predominantly testing within the health care system.

Conclusions: Groups with MSM who predominantly got tested within the health care system had higher probabilities of risk-associated behaviors and bacterial STI infections. Groups predominantly getting tested at community-based venues would likely benefit from improved STI testing frequencies.

EPC388

Low uptake of exposure-influenced HIV testing among a sample of pre/post-exposure prophylaxis (PrEP/PEP) naïve young men who have sex with men in two U.S. cities: implication for targeted interventions

Y. Liu[1], J. Mitchell[2], C. Zhang[3]

[1]*University of Rochester Medical Center, Public Health Sciences, Rochester, United States,* [2]*Florida International University, Miami, United States,* [3]*University of Rochester School of Nursing, Rochester, United States*

Background: Numerous studies have documented the prevalence and predictor of HIV testing uptake among YMSM in the US. However, these findings can be confounded by failing to disentangle the contexts in which HIV testing is initiated. For instance, whether HIV testing is self-initiated due to perceived heightened HIV risk after recent sexual exposure to HIV (i.e., exposure-influenced HIV testing) or triggered by scenarios such as research participation, PrEP candidacy evaluation, or HIV testing for financial incentives (i.e., passive HIV testing). As exposure-influenced HIV testing represents a crucial HIV testing mechanism to detect individuals with the highest probabilities of HIV seroconversion, we conducted the present study to pinpoint its prevalence and correlates.

Methods: A cross-sectional study was conducted in Nashville, TN, and Buffalo, NY, among YMSM self-reported as PrEP/PEP-naïve and having engaged in various risky sexual behaviors (e.g., condomless anal sex, substance use before sex, and/or group sex) in the past 24 months before the study participation. Data were collected using a self-administered questionnaire survey on various demographics, psychosocial factors, substance use, risky sexual behaviors, HIV prevention indicators, and frequency of exposure-influenced HIV testing (*never/rarely vs. mostly/always*). We used multivariable log-linked Poisson regression models to assess the significant correlates of seeking exposure-influenced HIV testing.

Results: Of the 261 eligible YMSM, only 26.5% reported *mostly/always seeking* exposure-influenced HIV testing in the past 24 months. Multivariable analyses showed that younger age, sexual orientation non-disclosure, perceived HIV stigma, internalized homophobia, lower general resilience, and lower perceived social support were associated with a lower likelihood of mostly/always seeking exposure-influenced HIV testing.

YMSM who *never/rarely* sought exposure-influenced HIV testing were more likely to use recreational drugs before sex, binge drinking alcohol, have group sex; while less likely to be aware of PrEP, test for sexually transmitted infections, and demonstrated condom use self-efficacy compared to those *mostly/always seeking*exposure-influenced HIV testing.

Conclusions: Exposure-influenced HIV testing is suboptimal among YMSM at high HIV risk (i.e., non-PrEP/PEP using YMSM who frequently engage in risky sexual behaviors). Findings from our study may help inform the design of future targeted interventions to promote exposure-influenced HIV testing among high-risk YMSM in the US.

EPC389

Experiences implementing partner notification in the private sector in Jamaica

G.J. Barrow[1], P. Prince[2], A. Gordon[2], S. Brissett[2], W. Githens Benzerga[3], A. Brooks-Hanson[3], S. Lebert[2], O. Williams[2], R. Hewitt[2], D. Allen[2], T. Beckford[2], A. Symonds[4], N. Persaud[5], M. Thame[1]

[1]*The University of the West Indies, Mona, Faculty of Medical Sciences, Kingston, Jamaica,* [2]*Health Connect Jamaica, Kingston, Jamaica,* [3]*United States Agency for International Development, Jamaica Office, Health Team, Kingston, Jamaica,* [4]*FHI360, Kingston, Jamaica,* [5]*FHI360, Washington DC, United States*

Background: The USAID/PEPFAR funded Health Connect Jamaica (HCJ) project aims to expand access to high-quality HIV-services in the private health sector for prevention, testing, treatment, and viral suppression. Services are provided through a network of private clinicians and laboratories across the entire country.

Description: All HIV positive persons accessing services within the network are offered partner notification services (PNS). Those who accept are linked to trained contact investigators who use the Partner Notification Register to collect information on is used to collect socio-demographic, sexual history, and medical information on reported contacts. Contacts are then contacted directly or using the Online Reservation Application (ORA) that sends anonymous messages to contacts who are difficult to locate, suggesting that they should go and do a HIV test.

Late-breaker abstracts

Author Index

Lessons learned: During a 15-month period (October 2020 to December 2021), 199 persons were offered PNS and 80.4% (160/199) accepted; 74 (37.1%) were ART Naïve/Newly Diagnosed with HIV and 125 (62.8%) were ART Experienced. A greater proportion of males (87% [72/84]) than females (75.5% [88/115]) accepted PNS (p<0.05).

Provider referral (32%) was the most common requested method for contacting partners followed by contractual referral (11%) while 56% did not have a preference.

Of the 280 contacts, 126 (45%) were tested for HIV and 13 (10.3%) were HIV positive; while 50 (29 males and 21 females) contacts were known HIV positive cases; 35 (12.5%) refused testing while 69 (24.6%) were not found due to incomplete, incorrect, or missing contact information. Uptake for testing was significantly higher (p<0.01) among males (69.4%, [86/210]) than females (57.1%, [40/70]).

The average age of an index case that accepted partner notification was 36 years, while the average age of a contact elicited was 34 years. Lack of perceived confidentiality was the most common reason cited by index cases who refused to participate in the PNS. Many index cases who did not provide contacts on first request did so during follow up visits.

Conclusions/Next steps: There is a high uptake of PNS among HIV-positive persons accessing services in the private sector. Further investigation will be required to develop a comprehensive understanding of PNS among this population.

HIV testing to support identification of new cases of people living with HIV

EPC390

Predicting HIV testing outcome among vulnerable children and adolescents: analysis from a large PEPFAR program in Nigeria

M. Katbi[1], A. Adedoyin[2], A. Ukaere[3], A. Adegboye[1], L. Lee[4], H. Meri[5], A. Onovo[1], R. Goldstein[1]

[1]United States Agency for International Development, HIV and TB, Abuja, Nigeria, [2]USAID MELSA Project, Abuja, Nigeria, [3]Society for Family Health, KP-CARE2 Project, Abuja, Nigeria, [4]United States Agency for International Development, OHA, Washington DC, United States, [5]United States Agency for International Development, Abuja, Nigeria

Background: Out of the 191,395 children and adolescents estimated to be living with HIV (CALHIV) in Nigeria in 2020, only 46,461 (24%) are on treatment. Children and adolescents are being left behind in the fight against HIV.

The Pediatric ART Saturation Strategy (PASS) is an integrated pediatric case-finding model implemented across PEPFAR/USAID-funded states in Nigeria which leverages community-based OVC case managers to close gaps across the pediatric clinical cascade for CALHIV. We examined HIV testing from the PASS.

Methods: Trained OVC community case managers conducted HIV testing among CALHIV in areas with high HIV prevalence in three states from May-July 2021. Inclusion criteria were being a biological child of PLHIV, children living with positive caregivers, and survivors of gender-based violence.

Associations between the client's gender and HIV status were assessed using chi-square tests. ANOVA was used to determine associations of HIV positivity by age band (0-4, 5-9, 10-15, and 16-19) and by state. We conducted a linear regression analysis to predict any relationship between age and HIV positivity.

Results: Number of tests, N=18076 (Male – 8126, Female – 9950), positives= 94 (Male – 50, Female – 44), Positivity rate, 0.5% (Male– 0.6%, Female – 0.4%). Testing for the different age bands: 1-4 (tested n=2169, pos n=14), 5-9 (tested n=4497, pos n=22), 10-14 (tested n =5514, pos n =22) and 15 -19 (tested n=5896, pos n =36).

There is no significant association between gender and HIV positivity yield -$\chi^2(1)$, p=0.119. No significant difference in HIV test and positivity yield across the different age bands by state -Tested: F (4, 69) = 0.898, p =0.471: Positive F (4, 69) = 0.898, p=0.471).

A linear regression analysis predicted that testing children aged 15-19 could significantly increase HIV positivity yield -F (1, 13) =13.31, p= 0.00332.

Conclusions: Testing adolescents (15-19) gives higher testing positivity yield compared to other age bands. A focus on this age group is essential towards ensuring HIV epidemic control among children and adolescents.

The low testing positivity yield among children <15 could be due to a significant reduction in vertical transmission of HIV from mother to child over the years. Further studies will be required to ascertain this finding.

EPC391

Prison-based assisted partner notification (APN) services to increase HIV testing among sex and drug-injecting partners of HIV-positive incarcerated men in Indonesia

G. Culbert[1], A. Waluyo[2], J. Levy[3], V. Earnshaw[4], A. Steffen[1], A. Rahadi[5]

[1]University of Illinois Chicago, Population Health Nursing Science, Chicago, United States, [2]Universitas Indonesia, Faculty of Nursing, Depok, Indonesia, [3]University of Illinois Chicago, Health Policy and Administration, Chicago, United States, [4]University of Delaware, Human Development and Family Sciences, Newark, United States, [5]Atma Jaya Catholic University, AIDS Research Center, Jakarta, Indonesia

Background: With assisted partner notification (APN), trained health care workers assist people diagnosed with HIV to voluntarily identify their at-risk sex and/or drug-injecting partners and to inform these partners of possible HIV exposure along with offering access to voluntary HIV testing. Despite numerous studies demonstrating APN's

efficacy, little is known of its success when used with prison populations. To help address this gap, we describe pilot findings from a randomized trial in Indonesia to evaluate the effects of APN on increasing HIV testing among sex and/or needle-sharing partners of HIV-positive men incarcerated in Indonesia.

Methods: We recruited 55 HIV-positive inmates from 5 all-male correctional facilities in Jakarta as index participants for a pilot, 2-group randomized trial comparing the effects of APN versus self-tell partner notification (NCT04155320).

Participants voluntarily provided names and contact information for partners with whom they possibly had shared an HIV sex and/or drug-injecting exposure immediately before incarceration.

Men randomized to a self-tell condition were encouraged and coached to notify their partners by phone or in person within 6 weeks.

Men randomized to APN could choose to self-tell or have a nurse or peer counselor notify their partner(s) anonymously. Logistic regression using robust standard errors to account for clustering due to index participants with multiple partners examined group differences in partner outcomes.

Results: Overall, index participants (n=55) named 117 partners (70% female, 30% male). Compared to self-tell notification, APN resulted in nearly a 6-fold increase (uOR=5.9, 95%CI: 2.5, 13.6,*p*<0.001) in the odds of named partners being notified of exposure (56.8% of partners, 29/51, were notified in the APN group versus 18%, 12/66, in the self-tell notification group.

Moreover, about half of notified partners in the APN group (51.7%, 15/29) completed HIV testing, compared to no partners in the self-tell notification group. One third of APN partners who completed HIV testing (33%, 5/15) were newly HIV-diagnosed.

Conclusions: APN shows promise to increase HIV testing and diagnosis among sex and drug-injecting partners of incarcerated men with HIV and should be considered for implementation in jails and prisons in Indonesia and elsewhere.

EPC392

Index partner testing among recency testing clients in BMA health facilities in Bangkok, Thailand, 2020 - 2021

K. Lerdtriphop[1], P. Visavakum[2], S. Tanpradech[2], A. Kanphukiew[2], P. Chaiphosri[1], C. Kittinunvorakoon[2], T. Palakawong Na Ayuthaya[1], C. Brukesawan[1], N. Thanasit[1], C. Manopaiboon[2], S. Northbrook[2]

[1]Bangkok Metropolitan Administration, Department of Heath, Bangkok, Thailand, [2]U.S. Centers for Disease Control and Prevention, Division of Global HIV and TB, Nonthaburi, Thailand

Background: Bangkok Metropolitan Administration (BMA) started index partner testing services in December 2019 and recency testing in October 2020. We describe index partner testing among newly-diagnosed HIV-infected persons who accepted recency testing in health facilities during October 2020 – September 2021.

Methods: Newly diagnosed PLHIV at least 13 years of age receiving HIV services at 15 BMA sites were offered the Asante Rapid Test for Recent Infection (RTRI), followed by viral load test (Recent Infection Testing Algorithm, RITA) to confirm recent infection status. Index testing services were offered to all HIV-infected clients during the initial visit. Exposed contacts of index clients (i.e., sexual partners and drug injecting partners within the past year, biological children, or biological parents if child was the index client) were elicited and offered HIV testing services. Recency and index testing results were reported in separate databases and linked with an Application Programming Interface. Descriptive statistics and Fisher's exact test summarized results of index partner testing among HIV recent and long-term infection (LT) clients.

Results: Of 492 eligible newly diagnosed cases consenting for RITA, 295 (60%) were offered index testing services and 150/295 (51%) provided contact information. Of 43 recent index cases, 9 (21%) accepted index testing with an elicitation ratio of 1:1.1. Of the 6 partners successfully contacted, 1 was already aware of HIV-positive status and 1/5 (20%) tested HIV-positive. Of 449 LT index cases, 141 (31%) accepted index testing with an elicitation ratio of 1:1. Of the 102 partners successfully contacted, 16 were already aware of HIV-positive status and 26/86 (30%) tested HIV-positive. Partner HIV-positivity did not differ by recency status (p>.05) and 25/27 (93%) HIV-positive partners initiated antiretroviral treatment (ART) within 7 days. No locatable information was mainly cited by recent and LT index cases whose contacts could not be elicited (55% and 44%, respectively).

Conclusions: Integrating recency and index testing services is feasible. Index partner testing identified high HIV-positivity yield among partners of recent and LT index cases. Increased coverage of index testing will generate a more robust effort to improve partner solicitation and testing to help Thailand end AIDS by 2030.

Identifying population-specific HIV diagnosis gaps in Western Africa and assessing their impact on new infections: a modelling analysis for Côte d'Ivoire, Mali and Senegal

R. Silhol[1], M. Maheu-Giroux[2], N. Soni[1], A. Simo Fotso[3], N. Rouveau[3], A. Vautier[4], C. Doumenc-Aïdara[4], K.N. N'Guessan[5], C. Mukandavire[6], P. Vickerman[7], A. Keita[8], C.T. Ndour[9], J. Larmarange[3], M.-C. Boily[1], ATLAS Team
[1]*Imperial College London, MRC Centre for Global Infectious Disease Analysis, School of Public Health, London, United Kingdom,* [2]*McGill University, Department of Epidemiology and Biostatistics, School of Population and Global Health, Faculty of Medicine and Health Sciences, Montréal, Canada,* [3]*Université de Paris, Ceped (Centre Population & Développement UMR 196), Paris, France,* [4]*Solthis, Dakar, Senegal,* [5]*Solthis, Abidjan, Cote D'Ivoire,* [6]*London School of Hygiene & Tropical Medicine, Faculty of Epidemiology and Population Health, London, United Kingdom,* [7]*University of Bristol, Population Health Sciences, Bristol Medical School, Bristol, United Kingdom,* [8]*Institut National de Recherche en Santé Publique (INRSP), Bamako, Mali,* [9]*Ministère de la Santé et de l'Action Sociale Institut d'Hygiène Sociale, Division de Lutte contre le Sida et les IST, Dakar, Senegal*

Background: Progress towards HIV elimination in Western Africa may be hindered by diagnosis gaps among people living with HIV (PLHIV), especially among key populations (KP) such as female sex workers (FSW), their clients, and men who have sex with men (MSM).
We aimed to identify largest gaps in diagnosis by risk group in Mali, Côte d'Ivoire, and Senegal, and project their contribution to new HIV infections.
Methods: Deterministic models of HIV transmission/diagnosis/treatment that incorporate HIV transmission among KP were parameterized following comprehensive country-specific reviews of demographic, behavioural, HIV and intervention data.
The model was calibrated to country- and group-specific empirical outcomes such as HIV incidence/prevalence, the fractions of PLHIV ever tested, diagnosed, and on treatment.
We estimated the distribution of undiagnosed PLHIV by risk group in 2020 and the population-attributable-fractions (tPAFs) (i.e. fraction of new primary and secondary HIV infections 2020-2029 originating from risk groups of undiagnosed PLHIV).
Results: From 46% (95% UI: 38-58) to 69% (59-79) of undiagnosed PLHIV in 2020 were males, with the lowest proportion in Mali and the highest proportion in Senegal, where 41% (28-59) of undiagnosed PLHIV were MSM. Undiagnosed men are estimated to contribute most new HIV infections occurring over 2020-2029 (Table).
Undiagnosed FSW and their clients contribute substantial proportions of new HIV infections in Mali, with tPAF=20% (10-36) and tPAF=43% (26-56), respectively, while undiagnosed MSM in Senegal are estimated to contribute half of new infections. A lower proportion of new HIV infections are transmitted by undiagnosed KP in Côte d'Ivoire (tPAF=21%(10-38)).

	Mali	Côte d'Ivoire	Senegal
All women	43% (35-54)	35% (29-42)	16% (9-22)
All men	67% (59-73)	56% (48-65)	72% (60-80)
FSW	20% (10-36)	6% (2-14)	8% (3-17)
Clients of FSW	43% (26-56)	16% (7-33)	15% (6-24)
MSM	5% (2-10)	2% (1-5)	51% (37-68)
KPs combined	53% (35-67)	21% (10-38)	68% (54-79)
Non-KPs women	25% (18-32)	30% (23-37)	7% (4-13)
Non-KPs men	21% (8-36)	39% (22-50)	6% (2-13)

Table. Estimated fraction of all new primary and secondary HIV infections over 2020-2029 originating from undiagnosed PLHIV from risk groups (tPAF: median and 95% uncertainty interval). The sum of the tPAFs over mutually exclusive groups exceeds the tPAF of their combined group as it accounts for secondary transmissions that may overlap for different groups.

Conclusions: Current HIV testing services and approaches are leaving members of KP behind. Increasing the availability of confidential HIV testing modalities in addition to traditional tests may substantially reduce gaps in HIV diagnosis and accelerate the decrease of new HIV infections in Western Africa since half of them could be transmitted by undiagnosed KP.

EPC394

The feasibility and acceptability of prison-based voluntary assisted partner notification among incarcerated men with HIV and their community partners

A. Rahadi[1], J. Levy[2], A. Waluyo[3], V. Earnshaw[4], A. Steffen[5], G. Culbert[5]
[1]*Atma Jaya Catholic University, AIDS Research Center, Jakarta, Indonesia,* [2]*University of Illinois Chicago, Health Policy and Administration, Chicago, United States,* [3]*Universitas Indonesia, Faculty of Nursing, Depok, Indonesia,* [4]*University of Delaware, Human Development and Family Sciences, Newark, United States,* [5]*University of Illinois Chicago, Population Health Nursing Science, Chicago, United States*

Background: Assisted partner notification (APN) safely and effectively increases HIV testing, but it has not been well-studied for implementation in correctional settings. We report findings from a 2-group randomized trial examining the acceptability and feasibility of prison-based APN among incarcerated men with HIV and their sex and needle-sharing partners in Indonesia (NCT04155320).
Methods: We recruited 55 male prison inmates with HIV who consented to voluntarily name and notify partners with whom they had shared a sex and/or drug-related exposure immediately before incarceration. Participants were randomly assigned initially to either a self-tell condition or an APN option that allowed them to choose between sell-tell or having a trained nurse or counselor

notify their partner(s). After 6 weeks, APN services were offered to participants in both groups to inform sell-tell partners whom they had failed to notify themselves. We examined APN's uptake, number of partners notified, and inmate/partner satisfaction with APN when offered in a prison setting.

Results: Participants (n=55) named 117 partners for notification with whom they had shared a possible HIV exposure before incarceration. Including selection at 6-weeks, APN was the preferred notification method for 70% of partners (82/117) whom index participants chose to notify.

Overall, nearly half of partners selected for APN (49.4%) were successfully notified. Successful notification did not differ statistically by partners age or gender. Neither did notification rates vary statistically among main sex partners (58%), drug-injecting partners (52%), and casual or regular sex partners (41%, *p*=0.366).

At follow-up, index participants indicated mostly favorable attitudes toward APN with few regrets about notifying partners. Follow-up interviews with partners (n=28) indicated that APN was favorably received, with most partners (75%) concluding they were better off having been notified.

Conclusions: Prison-based APN appears a feasible and acceptable service to implement among incarcerated men with HIV who otherwise have limited means to notify their at-risk partners in the community.

EPC395

Confidentiality counts: HIV testing among U.S. adolescents more likely in states with laws protecting the confidentiality of minors insured as dependents

C. Aivadyan[1], E. Wu[1]

[1]*Columbia School of Social Work, New York, United States*

Background: In the United States, adolescents are the age group least likely to be aware of their HIV infection, contributing to disproportionately low rates of viral suppression and increased risk of transmitting HIV to others. Confidentiality concerns are a major barrier to health care for adolescents, suggesting that state laws related to confidentiality in sexual health services may influence their HIV testing practices.

This study tested the hypothesis that state laws protecting the confidentiality of minors insured as dependents (e.g., to prevent parental disclosure through a health insurance explanation of benefits statement) would be significantly associated with lifetime HIV testing among a large, representative sample of sexually active U.S. high school students.

Methods: Data were aggregated from 27 states that participated in the 2019 state-level Youth Risk Behavior Surveillance System (N=26,754). We utilized multilevel logistic regression to evaluate the relationship between state laws protecting the confidentiality of insured dependents and lifetime HIV testing, adjusting for individual- (i.e., sex, grade, race/ethnicity, sexual risk behavior) and state-level covariates (i.e., estimated population, median household income, percentage of the population that graduated high school, percentage of the population that is non-Hispanic white, percentage of the population without health insurance, lifetime HIV testing among adults).

Results: Of the full sample, approximately 48% were male, 50% were white, 39% were in the 12th grade, 69% reported sexual risk behavior, and 19% reported lifetime HIV testing.

Consistent with our hypothesis, state laws protecting the confidentiality of insured dependents were significantly associated with lifetime HIV testing (AOR: 1.39, CI: 1.35-1.43, *p*<.001).

When results were disaggregated by sex, state laws protecting the confidentiality of insured dependents were associated with lifetime HIV testing for male adolescents only (AOR: 2.37, CI: 2.21-2.53, *p*<.001).

Conclusions: This study provides initial evidence of an association between state laws protecting the confidentiality of minors insured as dependents and lifetime HIV testing among sexually active U.S. high school students – particularly males.

Findings underscore the need to address confidentiality-related barriers to HIV testing in order to improve health outcomes among the age group least likely to be aware of their HIV infection.

EPC396

Expanding index testing to social networks among female sex workers in Burundi

T. Lillie[1], D. Boyee[2], T. Niyongabo[3], G. Kamariza[3], A. Nkunzimana[3], D. Gashobtse[3]

[1]*Family Health International (FHI) 360, District of Columbia, United States,* [2]*Family Health International (FHI) 360, Dar es Salaam, Tanzania, The United Republic of,* [3]*Family Health International (FHI) 360, Bujumbura, Burundi*

Background: The PEPFAR- and USAID-funded Meeting Targets and Maintaining Epidemic Control (EpiC) project implemented an HIV prevention and treatment program for key populations (KPs) in Burundi.

The purpose of the program was to reach KP to support them to access HIV and other health services to reduce HIV acquisition and transmission, and work toward achieving the UNAIDS 95-95-95 goals.

Description: From April to September 2021, risk network referral (RNR) was implemented among newly diagnosed FSWs to improve the reach and delivery of HIV testing to members of their social networks who were at risk of HIV but had not yet tested. RNR was offered during index testing and was the fifth referral option after the traditional four options (passive, dual, contract, provider) recommended by the World Health Organization. An index case was offered coupons to distribute to members of their sexual, social, and risk networks to encourage them to get tested for HIV.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Lessons learned: RNR was an effective HIV testing strategy among FSWs compared to other testing options. For RNR, a total of 414 coupons were distributed and 352 (85%) were returned. Most individuals (87%) who returned the coupons reported being friends with the person who gave them it, and most agreed to get tested (345/352, 98%). About 75% of those who tested HIV positive were ages 25-39 years. Those who had been tested within the last six to 12 months had an HIV case-finding rate of 25%.
Overall case finding among FSWs through all testing modalities was 6.6% compared to 17% among RNR contacts. Using the Pearson Chi^2 test, these results were found to be statistically significant, as the RNR outcome had a higher positivity rate than standard testing (p-value = <0.001).
Conclusions/Next steps: Effective and efficient testing modalities are necessary to reach the first 95 UNAIDS goal. RNR was successful in identifying a higher number of newly diagnosed individuals who were social contacts of FSW compared to other testing modalities. RNR should be scaled among social networks, but also among individuals in their sexual networks as contact information among paid and occasional partners may be limited.

EPC397

Earlier HIV diagnosis of clients at higher CD4 counts: effectiveness of community-led HIV testing sites within key populations in Thailand

T. Wansom[1], K. Sirisup[1], J. Macom[2], S Sittikarn[3], P Chanlearn[4], S. Janyam[5], T Chaisalee[6], S Teeratakulpisarn[7], M. Avery[1], S. Mills[1]
[1]FHI 360, Asia-Pacific Regional Office, Bangkok, Thailand, [2]FHI 360, Phnom Penh, Cambodia, [3]Caremat, Chiang Mai, Thailand, [4]Mplus Foundation, Chiang Mai, Thailand, [5]Service Workers In Group (SWING) Foundation, Bangkok, Thailand, [6]Rainbow Sky Association of Thailand, Bangkok, Thailand, [7]Thai Red Cross HIV/AIDS Research Centre, Bangkok, Thailand

Background: Late HIV diagnosis and delayed antiretroviral therapy (ART) initiation can significantly increase mortality among people living with HIV. In a study using the national AIDS database within eight provinces in Thailand, the median CD4 count at diagnosis for those initiating ART at public hospitals from 2014 through 2018 was 162 (IQR 44-353 cells/mm3). Those with CD4 counts below 200 were four times as likely to die within five years.
Methods: The USAID/PEPFAR-support EpiC project supports key population (KP), community-led HIV testing and treatment for men who have sex with men (MSM), transgender women, and sex workers (SWs) at 13 sites in provinces with high HIV prevalence. HIV counseling and testing are conducted according to national guidelines, and point-of-care CD4 testing is conducted after HIV diagnosis is confirmed. We evaluated CD4 at the time of diagnosis and factors significantly associated with being diagnosed at higher CD4 counts. CD4 was treated as a categorical variable, and Pearson chi-squared tests were conducted to explore factors associated with being diagnosed at CD4 ≥ 200.
Results: From October 2016 through September 2021, 6,119 clients were diagnosed with HIV. A total of 6,077 received CD4 testing, 98% (n=5,955) of whom were male at birth. Mean CD4 at time of diagnosis was 397.1 with a standard deviation of 226.4. CD4 was ≥200 among 81.9% (n=4,796).
Factors significantly associated with higher CD4 at diagnosis included younger age, method of being reached for HIV testing, and KP group. Walk-in clients had lowest percentage of high CD4 at HIV diagnosis [78.9%] compared to clients reached via peer referral [85.7%] or trained community outreach workers [86.6%] [X^2=39.42, p<0.0001. All SWs [87.3%] and MSM [81.5%] more likely to have higher CD4 compared to transgender women [79.6%] and non-KPs [73.2%], [X^2=19.63, p<0.0001]).
Conclusions: Community-led HIV testing diagnosed clients earlier than testing at public hospitals. Those reached by trained community outreach workers or peer referral were more likely to be diagnosed at a higher CD4 count than walk-in clients; however, all HIV testing at community-led health services diagnosed clients at higher CD4 counts. National programs should support expansion of community-led HIV testing.

EPC398

Improving HIV partner notification in the Netherlands: a qualitative study from the perspective of index patients, notified partners, and community actors

A. Watzeels[1,2], E. Op de Coul[3], H. Götz[1,3]
[1]Municipal Public Health Service Rotterdam-Rijnmond, Department of Infectious Disease Control, Rotterdam, Netherlands, the, [2]Municipality of Rotterdam, Department Research and Business Intelligence, Rotterdam, Netherlands, the, [3]National Institute for Public Health and the Environment (RIVM), Centre for Infectious Disease Control, Bilthoven, Netherlands, the

Background: A (cost-)effective approach to earlier detect HIV is to test partners of newly diagnosed individuals. This study explored barriers for partner notification (PN) and options to improve PN, by interviewing index patients, notified partners, and community actors.
Methods: Semi-structured interviews with 18 index patients (14 MSM, 2 bisexual men, 1 transwoman, 1 heterosexual woman) and 10 notified partners (by telephone), and 10 key actors (face-to-face) from community organizations. Focus group discussions were held with peers: 5 HIV+ MSM and 5 HIV+ migrant women. Interviews were recorded, transcribed, and thematically analyzed.
Results: *Index patients* expressed a need to first process the diagnosis before being able to notify partners. Barriers to PN were providing openness about numbers of sex-partners, lacking contact information of sex-partners, fear for negative reactions, and unwanted disclosure.

Notified partners preferred face-to-face notification or by telephone. For most the notification was a surprise; half were never tested or >10 years ago, and most were unfamiliar with PrEP.

Community actors emphasized the importance of professional- (or peer-) assisted tailored PN when index patients feel ready. Suggestions to improve testing for notified partners include facilitating home-sampling kits for partners, delivered by index patients or via the PN-tool (partnerwaarschuwing.nl).

Advantages of home-sampling kits for partners, addressed by community actors, were quick results, and testing at your own time and place. Possible disadvantages included index patients who feel responsible for partner testing while still processing their diagnosis, reliability of test results, and the impact of a positive result (e.g. fear of partner violence, lack of professional support). Bringing partners to test at sexual health centers (SHCs) or HIV clinics was acceptable for most interviewees.

Most preferred PN via the SHC (professional & reliable), but some favored a choice between home testing for partners and/or through the SHC, depending on type of partner and the need for a quick result.

Conclusions: There is no single solution for overcoming barriers to PN for HIV. Tailored PN is essential. Expansion of the current test offer by delivering home-sample kits to index patients for partners or through the online PN-tool should be further explored.

EPC399

Comparative analysis of facility and community-based implementation models for index testing services in Akwa Ibom State: a non-inferiority study

C. Nwangeneh[1], U. Akpan[1], I. Elechi[1], E. Nwanja[1], O. Toyo[1], J. Onu[1], C. Charles[1], P. Otu[1], P. Nwaokoro[2], T. Badru[3], A. Idemudia[4], O. Sanwo[3], H. Khamofu[3], S.R. Pandey[3], M. Bateganya[3]

[1]Achieving Health Nigeria Initiative, Uyo, Nigeria, [2]Family Health International 360, Uyo, Nigeria, [3]Family Health International 360, Abuja, Nigeria, [4]Achieving Health Nigeria Initiative, Abuja, Nigeria

Background: HIV index case testing (ICT) has been heralded as an efficient testing strategy. To sustain the gains from ICT in identifying people at high risk of HIV, the Meeting Targets and Maintaining Epidemic Control (EpiC) project in Akwa Ibom State, Nigeria, scaled-up provision of safe and ethical ICT services using a community-service model. We compare outcomes across the service cascade for the facility- and community-based models (FBMs, CBMs) and hypothesize their noninferiority.

Methods: We reviewed data collected during ICT in facilities and the community from April 2020 through September 2021. As part of routine ICT, newly identified HIV-positive adults and those with unsuppressed viral load and no history of intimate partner violence were prioritized for HIV ICT counselling and asked to refer their sexual partners and biological children (<14 years) for HIV testing. The FBM used health care providers, while CBM used trained lay providers (i.e., community index tracers/testers) to follow clients across the ICT cascade of services.

We compared acceptance rates (proportion of index that accepts ICT services), elicitation rates (ratio of the index to contacts elicited), testing rates (proportion of elicited contacts with known HIV status), and linkage rate (proportion of identified HIV-positive individuals linked to antiretroviral therapy [ART]) for both models using Mann Whitney U test in SPSS v26 at 0.05 significance level.

Results: A total of 119,650 records were reviewed: 25,807 in the FBM, 93,843 in the CBM. Overall, 119,220 (99.6%) were ages 15 years and older, while 67,696 (76.8%) were females. ICT acceptance, elicitation, testing, positivity, and linkage rates were 91.24% (23,546/25,807), 1:1.7 (40,719/23,546), 77.8% (31,678/40,719), 10.3% (2,769/26,842), and 85.1%, respectively in the FBM, vs. 77.8% (73,041/93,843), 1:1.6 (116,736/73,041), 86.5% (100,954/116,736), 27.1% (26,953/99,578), and 99.03%, respectively, in the CBM.

In comparative analysis, the CBM had significantly higher testing (U;1,398, 95% CI: 0.064-0.123, p<0.01), and partners linked to ART (U;789, 95% CI: 0.110-0.162, p<0.01) than FBM. There was no difference in partner elicitation (U;3,403, 95% CI: 0.129 -0.030, p=0.201).

Conclusions: The CBM expanded the reach of ICT and could be an add-on strategy for reaching last-mile clients.

ing quality HIV testing services (HTS) to military personnel, their dependents, and civilian communities. Despite progress toward epidemic control, HIV testing remains the major challenge to achieving UNAIDS' 95-95-95 goal.

Description: PEPFAR programmatic data from 18 African countries spanning October 2018-September 2021 were used to assess HIV testing uptake among military personnel, their families, and surrounding communities. Data was analyzed by five testing strategies: provider-initiated testing and counseling (PITC), index case testing (ICT), voluntary counseling and testing (VCT), mobile testing and voluntary medical male circumcision (VMMC) testing. Descriptive analysis included standardized indicators: number of HIV tests performed, number of HIV-positive test results, and positivity yield.

Lessons learned: From October 2018-September 2021, 1,683,762 tests were administered, yielding 97,831 newly identified positives (6%, range: 0.2%-Ethiopia to 12%-Eswatini). More males (887,865) tested than females (795,897) but females had higher yield (7%) than males (5%). Across 17 countries (excluding Ethiopia due to limited data), PITC accounted for 53% of all testing and 44% of all new diagnoses. Mobile testing and VCT yields were higher among females (8%; 7%, respectively) than males (4%; 5%, respectively). ICT had the highest yield in all countries and for both sexes, except for females in Eswatini, where VCT had the highest yield, while VMMC yielded the lowest percentage of positives in each country.

Conclusions/Next steps: In military settings, similar to the general population, ICT is the most efficient testing approach, with the highest positivity rates, while PITC identifies the largest volume of clients but much lower positivity rate. The data reflect high positivity in military settings and indicate the need for enhanced context-specific, tailored testing strategies at military sites. Programs should continue to scale up the implementation of state-of-the art combination prevention interventions including HTS and pre-exposure prophylaxis adapted to military settings to identify and prevent new HIV infections.

Mother-Baby Pairs: a way to establish reliable national Early Infant Diagnosis (EID) coverage

O. Phuthego[1], G. Gokatweng[1], C. Baumhart[2], N. Blanco Herrera[2], R. Marima[1]

[1]Botswana-University of Maryland School of Medicine Health Initiative (Bummhi), Gaborone, Botswana, [2]Center for International Health, Education, and Biosecurity (Ciheb), University of Maryland School of Medicine, Baltimore, United States

Background: In 2015, Botswana University of Maryland School of Medicine Health Initiative (Bummhi) implemented the prevention of mother-to-child transmission program through a 5-year project. With 70-80% early infant diagnosis (EID) coverage in 2019, Bummhi faced challenges in establishing reliable coverage measurements using PEPFAR's proxy EID calculation. To establish a more accurate reflection of EID coverage in Botswana, Bummhi paired mothers and babies. We describe the methodology used and benefits for reporting.

Methods: Bummhi piloted the mother-baby pair (MBP) methodology in two districts (Serowe, Palapye) starting August 2019. The program was scaled up to 13 Bummhi-supported districts in October 2019. The methodology prospectively tracked pregnant women from initial antenatal care (ANC) registration through labor and delivery. Tracking continued for the exposed infant's first HIV test through their final outcome test at 18-24 months. Data were collected from ANC and baby testing registers and captured into the Health Information System (DHIS2); pairing was done using mothers' IDs and other identifiers. Data were triangulated with electronic medical record data to verify babies not found in manual registers. The MBP data were then compared to the PEPFAR proxy EID which was calculated as the number of babies tested in a given period divided by the number of HIV-positive women during the same period.

Results: Implementing the MBP methodology showed overall quarterly EID coverage between 91% and 95% compared to proxy EID calculation between 77% to 87% (Figure 1). Of the 13 Bummhi-supported districts, only 2 were under 90% coverage (Gaborone [83%] and Francistown [89%]), with 6 districts over 95% EID coverage.

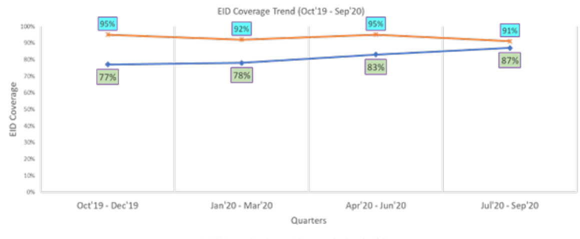

Figure 1.

Conclusions: The implementation of the MBP methodology provided Bummhi a more reliable EID coverage than the proxy calculation. This pairing methodology was scaled-up to remaining Bummhi-supported districts. The next step is to complete linking of mothers and babies prospectively at the time of data collection.

EPC402

HIV rapid testing to support identification of new cases among partners of HIV-positive clients at healthcare facilities of Leningrad region of Russian Federation: 2019-2021 results

S. Semikova[1], P. Supronenko[2], V. Stanilevskiy[2], O. Gorodkov[2], A. Merzlyakova[3], Y. Godunova[4], A. Kovelenov[1], A. Chuykov[2], N. Mironova[2], A. Żakowicz[5]

[1]Leningrad Region's AIDS Center, St. Petersburg, Russian Federation, [2]AHF Russia, St. Petersburg, Russian Federation, [3]Diakonia Foundation, St. Petersburg, Russian Federation, [4]EVA Association, St. Petersburg, Russian Federation, [5]Żakowicz, Amsterdam, Netherlands, the

Background: WHO recommendations outline the need of testing of partners of people who live with HIV; however, this approach is not systematically implemented in Russia. Rapid HIV testing in 6 districts of Leningrad region started in 2013. The project is implemented at government healthcare facilities by Regional AIDS center in cooperation with Russian NGOs and with the support of AIDS Healthcare Foundation (AHF Russia). Testing partners is one of the main foci of this activity.

Description: Anonymous free rapid HIV testing and consulting is performed by medical staff. Client receives pre- and post-test consultations and provides information about age, risk behavior, belonging to risk groups, previous testing experiences, etc. The procedure lasts for 15-30 minutes; in the end client gets prevention materials and condoms. To attract more partners of HIV-positive people, AIDS center staff is actively encouraging their patients to bring partners to test.

Lessons learned: From January 1, 2019 to December 31, 2021, overall 31,820 clients were tested with 1,633 (5,1%) positive results. Among these, 5,825 IDUs were tested with 528 (9,1%) positive results, 2,964 partners of HIV+ people with 273 (14,8%) positive, 3,667 partners of people with risk behavior with 320 (8,7%) positive, 19,364 other groups with 345 (1,8%) positive results.

The highest positivity rate was found among partners of HIV-positive people. Among 1,490 males tested there were 238 positive results (16% positivity); among 1,474 females - 202 positive results (13,7%). 45% of all tested partners were 30-39 years old, 28% 40-49 years old. There are no statistically significant differences in the positivity level between different age groups. Linkage to care in this group was 88%, with upward trend over the past 3 years, which is the same high value as in general group.

Conclusions/Next steps: The results confirm the need to work with the partners of HIV-positive clients. Rapid HIV testing at healthcare facilities has proven its effectiveness and has several advantages including easiness of bringing partners of HIV-positive people to test and almost immediate linkage to care. It is necessary to study behavioral traits, including additional risk factors of clients from this group.

EPC403

Late HIV diagnosis among patients with newly diagnosed HIV/AIDS in Kazan, Russia: a cross-sectional study

S. Agliullina[1], L. Kryukova[1], G. Gil'mutdinova[2], G. Khasanova[1,3]

[1]Kazan State Medical University, Epidemiology and Evidence-Based Medicine, Kazan, Russian Federation, [2]Hygiene and Epidemiology Center in Tatarstan, Epidemiological Surveillance, Kazan, Russian Federation, [3]Tatarstan Republican Center for the Prevention and Control of AIDS and Infectious Diseases, Kazan, Russian Federation

Background: The effectiveness of prevention measures is limited in part by the long period of asymptomatic HIV infection, which affects the timeliness of HIV detection and helps to sustain the epidemic process of HIV infection. Late HIV diagnosis contributes to its spread and is an obstacle to achieving the early treatment goal. The present study aimed to specify factors associated with the late HIV diagnosis.

Methods: The study included data from 348 adult patients, permanently residing in Kazan, who were diagnosed with HIV infection for the first time in 2019. The proportion of patients with late HIV diagnosis was determined. The criteria for late HIV diagnosis were the presence of stage 3 – Acquired Immunodeficiency Syndrome (AIDS) and/or the CD4+ cell level of less than 200 cells/mm3 at the time of diagnosis.

The assessment of the influence of probable factors on the timeliness of diagnosis was carried out using binary logistic regression. The regression model included data from 307 people; others were excluded due to the lack of data on the HIV stage and/or CD4+ cell levels within 3 months after HIV detection. The adjusted odds ratios (aOR) and their 95% confidence intervals (95% CI) for each factor are calculated.

Results: Late HIV diagnosis was noted in 32.6% of cases of HIV infection. Examination for clinical indications was associated with late diagnosis in comparison with examination for preventive purposes (aOR 2.427, 95% CI 1.184 – 4.973).

The age of 50 years and older was associated with late HIV diagnosis in comparison with persons 30-49 years old (aOR 3.348, 95% CI 1.542 – 7.265). The odds of late HIV diagnosis under the age of 30 years are 5 times lower than in the group of 30-49 years (aOR 0.200, 95% CI 0.072 – 0.556).

The odds of late HIV diagnosis are significantly higher among people infected with injecting drug use compared to those infected heterosexually (aOR 2.012, 95% CI 1.042–3.885).

Conclusions: To control the spread of HIV infection in the population, it is necessary to increase the HIV screening testing coverage for all population groups, especially older people and injecting drug users.

EPC404
Characteristics and clinical outcomes of patients receiving HIV diagnoses in emergency departments in Philadelphia, 2014-2019

N. Aitcheson[1], T. Nassau[2], G. Choi[3], K. Brady[4], F. Momplaisir[1]
[1]University of Pennsylvania, Perelman School of Medicine, Infectious Diseases, Philadelphia, United States, [2]Philadelphia Department of Public Health, Philadelphia, United States, [3]University of Pennsylvania, Perelman School of Medicine, Infectious Diseases, Shaw Lab, Philadelphia, United States, [4]Philadelphia Department of Public Health, AIDS Activity Coordinating Office, Philadelphia, United States

Background: Decreasing new HIV infections requires reaching populations that are at increased risk of acquiring HIV but do not access regular testing. Acute care, comprised of emergency department (ED) visits and associated hospitalizations, serve as the only healthcare many individuals at increased risk of HIV receive.
We describe the population of Philadelphians who received their HIV diagnoses in EDs and compare their clinical outcomes with those who received their diagnosis in community-based settings.
Methods: A population-based surveillance analysis of new HIV diagnoses from 2014-2019 in Philadelphia compared demographic and clinical characteristics and HIV care continuum outcomes of those diagnosed in the ED (and hospital) to those diagnosed in community-based settings (outpatient medical settings, correctional systems, STI/HIV testing sites.)
Characteristics included year, age, sex at birth, race/ethnicity, transmission risk categorized as men who have sex with men (MSM), heterosexual sex, people who inject drugs (PWID), and no identified risk factors (NIR), concurrent AIDS at diagnosis, and insurance type (public, private, none, other/unknown).
Chi-square tests and multivariable logistic regressions evaluated the association between diagnosis location and patient characteristics, linkage to care within 30 days, receipt of any care, and retention in care and viral suppression one year after diagnosis.
Results: Between 2014-2019, 2,968 individuals were diagnosed with HIV in Philadelphia, including 323 (10.9%) in EDs. 29.7% were diagnosed with concurrent AIDS. Age over 50, non-MSM transmission risk, concurrent AIDS diagnosis, and having no insurance were significantly associated with diagnosis in EDs compared to community-based settings ($p<0.05$). Linkage to HIV care was similar for both groups, however, the odds of being retained in care (aOR 0.65, 95% CI 0.50, 0.85) and virally suppressed (aOR 0.69, 95% CI 0.541, 0.875) one year after diagnosis were significantly lower among those diagnosed in an ED/hospital compared to community-based settings.
Conclusions: About 1 in 10 HIV diagnoses were made in an ED visit; almost 1 in 3 of those individuals were diagnosed with AIDS at the same time.
Patients diagnosed in the ED experienced poorer care continuum outcomes compared to those diagnosed in the community. New strategies for routine testing and linkage to care for patients diagnosed in EDs are needed.

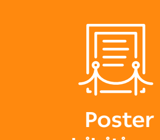
Optimizing HIV case finding through Screening and testing non-patients at outpatient department (OPD): A pilot case from Kombewa County referral hospital (KCRH) in Kisumu, Kenya

D. Ogola[1], O. Nzoutchoum[2,3], S. Anangwe[1], C. Oduor[1], J. Owuoth[4], D. Okeyo[5], E. Nyamusi[6], S. Oyule[7], P. Ocholla[6], N. Pule[6], E. Ogwang[5], E. Akom[2,3]
[1]HJF Medical Research International (HJFMRI), Prevention, Kisumu, Kenya, [2]U.S. Military HIV Research Program (MHRP), Walter Reed Army Institute of Research, Department of International HIV Prevention and Treatment (IHPT), Silver Spring, United States, [3]Henry M. Jackson Foundation for the Advancement of Military Medicine, Department of International HIV Prevention and Treatment (IHPT), Bethesda, United States, [4]HJF Medical Research International (HJFMRI), Program Management/Clinical Research, Kisumu, Kenya, [5]Kombewa County Referral Hospital, Medical Services, Kisumu, Kenya, [6]Ministry of Health, Public Health Sciences, Kisumu, Kenya, [7]HJF Medical Research International (HJFMRI), Clinical Care, Kisumu, Kenya

Background: The 2018 Kenya Population-based HIV Impact Assessment estimates Kisumu county's HIV prevalence in western Kenya at 17.5%, while the national prevalence is 4.9%. Recently, Kenya has adopted innovative testing strategies, including targeted provider-initiated counseling and testing (PITC); yet over 20% of Kenyans are unaware of their HIV-positive status.
Convenient and people-centered approaches are needed to facilitate greater uptake of HIV testing services (HTS) and enhance case identification.
Methods: Trained expert clients at OPD waiting areas in Kombewa County Referral Hospital (KCRH) in Kisumu County conducted short HIV educational sessions to encourage relatives and friends accompanying patients (referred to as non-patients) to test for HIV.
Consenting non-patients were escorted to a private room for eligibility screening. If eligible, an HTS provider conducted the test using the national HIV diagnosis algorithm and connected those tested to either prevention or treatment services, depending on their result.
Results: Between October 2020 to September 2021, 1,699 non-patients screened for HTS, including 397 males and 1,302 females, and 256 (15%) were eligible for testing (90 males, 166 females). The majority of non-patients (245) consented and were tested resulting in the identification of 25 new positive cases (9 males, 16 females), representing a 10% yield. Testing of non-patients accounted for 33% of total newly identified positives at KCRH by PITC and 15% of total positives diagnosed through all testing modali-



ties. Linkage to treatment was 88% (8 males and 14 females), and providers are now following up on the three unlinked individuals. All those who tested HIV-negative were offered prevention services.

Conclusions: Screening and testing non-patients at health facilities is an additional opportunity to identify people living with HIV (PLHIV) unaware of their status, particularly those who might not seek health services otherwise. The intervention was highly acceptable at KCRH, and Kisumu County is planning expansion to other facilities in the region.

HIV programs should consider offering HIV testing to non-patients, particularly in areas with high numbers of undiagnosed PLHIV. This approach can be further refined to target subpopulations of interest, such as men or young adults, more likely to be undiagnosed.

EPC406

The use of a customized Electronic National App to improve ICT(Index-Contacts-Testing) performance and the identification of new cases of HIV: ISPD/BRIDGE experience and implications for the Haitian Ministry of Health

M.L. Excellent[1,2], E. Michel[1], M. Laguerre[1], E. Emmanuel[1], G. Galbaud[1], B. Neptune[1], S.T. Oméro[1], A. Apply[1], D. Lauture[1], J.W. Domercant[1]

[1]Institut pour la Santé, la Population et le Développement (ISPD), Pétion-Ville, Haiti, [2]University of North Carolina at Chapel Hill, Chapel Hill, North Carolina, United States

Background: To achieve the first 95 of the UNAIDS goals, the Ministry of Health (MoH) implemented index-contacts testing (ICT) according to WHO guidelines in 2020 with limited results. In response, MoH collaborated with key partners to develop an electronic Application to monitor ICT, aimed at improving HIV-testing services (HTS) process for indexes' partners. BRIDGE project implemented the ICT-App at its affiliated health facilities.

We present here the results of our interventions combined with the ICT-App that help increase the proportion of contacts accessing HTS.

Description: For the project first semester, two sites were using ICT paper-based forms. During the second semester, providers and community health workers (CHWs) received ICT-App training followed by weekly mentoring. We ensured availability of high-speed internet and tablets/computers/smartphones. We monitored closely the data collected daily on the ICT-App, compared them with HTS/Laboratory registers and prompt feedback for timely mitigation. Two other sites started implementing ICT in the third semester and three others the fourth semesters. The app was introduced right away for the new sites.

Lessons learned: From January to June 2020,from the 203 contacts identified by 106 index-patients, only 37% (N=75/203) knew their HIV status including 60 who were newly tested from whom 15% (N=9/60) were HIV-positive and linked to care.

Following adoption of ICT-App in July 2020, an improvement was reported for the following semester (July-December 2020), showing 247 contacts tested out of the 400 listed (62%) including 230 newly tested for HIV with a seropositivity yield of 23% (N=53/230).

The use of national ICT-App by trained/mentored providers led to substantially improve contacts' access to HTS (75_607) and identify new HIV cases (9_253) while protecting confidentiality.

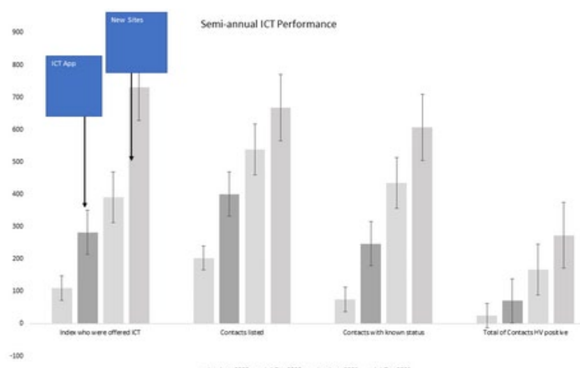


Figure.

Conclusions/Next steps: ICT-App implementation led to increase the proportion of contacts identified and newly diagnosed with HIV without stigma. We recommend wider use of ICT-App to help achieve the first 95 of UNAIDS goals.

Integration of HIV testing with other services

EPC407

Integrating routine antenatal testing for curable, asymptomatic STIs in a high HIV prevalence setting, Botswana

A. Mussa[1,2], A. Wynn[3], R. Ryan[1], S. Simon[1], C. Babalola[4], E. Hansman[5], J.D. Klausner[4], C. Morroni[6,1]

[1]Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana, [2]Usher Institute, University of Edinburgh, Edinburgh, United Kingdom, [3]University of California, San Diego, Division of Infectious Diseases and Global Public Health, San Diego, United States, [4]University of Southern California, California, United States, [5]University of California, Los Angeles, Los Angeles, United States, [6]University of Edinburgh, MRC Centre for Reproductive Health, Edinburgh, United Kingdom

Background: Routine, rapid antenatal HIV testing has expanded ART coverage and reduced vertical transmission of HIV throughout Sub-Saharan Africa. However, testing for other STIs, including *Chlamydia trachomatis* (CT) and *Neisseria gonorrhoeae* (NG), is not routine in most countries and asymptomatic infections are likely missed.

This study assessed the integration of STI testing into antenatal care and prevalence of asymptomatic infections among pregnant women in a high HIV prevalence setting, Botswana.

Methods: The Maduo ("results"in Setswana) Study is an ongoing prospective, cluster-controlled trial in Gaborone, Botswana to compare a diagnostic CT/NG testing and treatment intervention among asymptomatic pregnant women with the standard of care (syndromic management based on symptoms). Using baseline data (February 2021-January 2022), we assessed the integration of STI testing, including uptake of testing, receipt of results and treatment, and the prevalence and correlates of CT/NG infections. Correlates were evaluated using a multivariable logistic regression.

Results: Among 427 eligible women, 406 (95%) enrolled, 188 were assigned to the "standard of care" arm, and 218 to the "STI testing" arm at their baseline visit. The HIV prevalence was 18% (72/406); 10 of 72 women were newly diagnosed with HIV. In the testing group, 23% (51/218) tested positive for CT or NG, 49 with CT and 2 with CT and NG. Among women living with HIV infection in the testing arm, 23% (11/48) had CT and/or NG. All women testing positive for CT/NG were treated; those with a test of cure (n=40) were all negative.

In regression analyses, older age was associated with lower odds (OR: 0.91; 95% OR: 0.84-0.98) and harmful alcohol use during pregnancy was associated with increased odds (OR: 6.81; 95% CI: 1.24-37.41) of testing positive for CT/NG, after controlling for marital status, nationality, education, income, primigravida, and depression risk.

Conclusions: Integrating routine STI screening in antenatal care was highly acceptable and feasible. We found a high frequency of curable asymptomatic infections, known to be associated with adverse pregnancy and birth outcomes, including vertical transmission of HIV. Antenatal STI testing has the potential to decrease morbidity among pregnant women and infants.

EPC408

Provision of HIV testing services to pregnant women in Nigeria: HIV/AIDS Indicator and Impact Survey (NAIIS), 2018

B. Ibrahim[1], O. Alo[1], A. Ehoche[1], I. El-Imam[1], E. Iwara[1], O. Adedokun[1], S. Adebajo[1], L. Taylor[2], A. Whittington[2], K. Stafford[2], M. Alagi[3], O. Asaolu[3], I. Dalhatu[3], M. Bronson[4], S. Greby[4], A. Ikpeazu[5], G. Aliyu[6]

[1]Maryland Global Initiative Corporation Nigeria, affiliate of the University of Maryland, Baltimore, Epid. & Surveillance, Abuja, Nigeria, [2]University of Maryland, Baltimore, Institute of Human Virology, Center for International Health, Education and Biosecurity, Baltimore, United States, [3]Centers for Disease Control and Prevention, Epidemiology and Surveillance, Abuja, Nigeria, [4]Centers for Disease Control and Prevention, Atlanta, United States, [5]Federal Ministry of Health, National AIDS and STDs Control Programme, Abuja, Nigeria, [6]Federal Ministry of Health, National Agency for the Control of AIDS, Abuja, Nigeria

Background: Mother-to-child transmission remains a significant contributor to HIV burden in Nigeria. In 2018, Nigeria conducted the HIV/AIDS Indicator and Impact Survey (NAIIS 2018), a population-based household survey.

This study assessed the provision of HIV testing services during pregnancy and at delivery among Nigerian women.

Methods: We analyzed data from NAIIS 2018, a two-stage cluster sampled nationally representative survey. We extracted data of women aged 15-49 years who reported deliveries within three years prior to the survey. Bivariable analyses and multiple logistic regression were used to estimate associations between socio-demographic, health seeking variables and the offering of HIV testing services during antenatal care (ANC). We presented weighted results using STATA 16.

Results: Of the 88,593 women aged 15-49 years interviewed, 23,612 (25.7%) had delivered within three years prior to the survey. About 47.2% of these women were between 25-34 years (median: 28.8years). Most (76.3%) reported attending ANC during their last pregnancy, and 61.8% and 12.2% of these women were offered HIV testing during pregnancy and at delivery respectively. Women residing in the southeast, southsouth, and southwest zones had significantly higher chances of being offered HIV test at ANC, 74.7%, 71.1% and 68.8% respectively, when compared to those residing in northcentral, northeast, and northwest zones with 62.6%, 50.6% and 48.7% respectively.

In adjusted analyses, women who attended ANC facilities in urban communities had higher odds of being offered HIV testing compared to women who attended ANC facilities in rural areas [aOR=2.1, 95%CI:1.8–2.5]. Women who reported being able to make their own healthcare decision were more likely to be offered HIV testing compared to women who rely on others to make such decision for them [aOR=1.9, 95%CI:1.1–3.5].

Also, women with tertiary level of education were more likely to be offered HIV testing at ANC, compared to women with no formal education [aOR=5.6, 95%CI:4.5-6.9].
Conclusions: While about 3-in-4 women attended ANC, offering of HIV testing services to pregnant women at ANC was low, which significantly affects uptake of HIV testing among the women. To enhance uptake, HIV programs can focus on improving routine HIV services at ANC especially across northern regions of Nigeria.

EPC409

Missed opportunities for HIV testing among those tested for sexually transmitted infections: a systematic review and meta-analysis

K. Saleem[1,2], A. J. W. Loh[1], E.L. Ting[1], R.C. Baggaley[3], C.C. Johnson[3], M. Brito de Mello[3], E. P. F. Chow[1,2,4], J. J. Ong[1,2,5,4]
[1]Monash University, Central Clinical School, Melbourne, Australia, [2]Alfred Health, Melbourne Sexual Health Centre, Carlton, Australia, [3]World Health Organization, Geneva, Switzerland, [4]University of Melbourne, Melbourne School of Population and Global Health, Melbourne, Australia, [5]London School of Hygiene and Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, United Kingdom

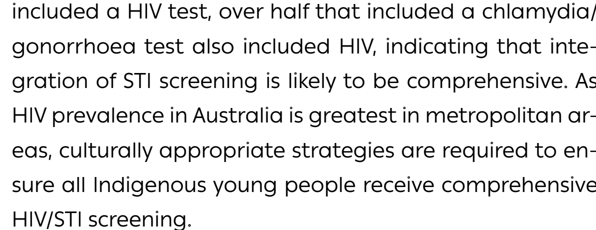
Background: Of 37.7 million people living with HIV in 2020, 6.1 million still do not know their HIV status. There may be opportunities to reduce this gap if HIV testing was routinely implemented among those attending a sexually transmitted infection (STI) service, tested for other STIs or diagnosed with STIs.
We aimed to synthesize the evidence for the proportion of people receiving HIV testing in the above scenarios and their HIV test positivity.
Methods: We conducted a systematic review (Prospero: CRD42021231321) using five databases (Ovid MEDLINE, Ovid Embase, Ovid Global Health, EBSCO CINAHL Plus and Web of Science Core Collection), and clinical trial registries (clinicaltrials.gov, WHO international clinical trials registry platform). We included publications between 2010 and May 2021 that documented primary data on concurrent HIV testing uptake among people receiving STI services. We conducted a random-effects meta-analysis to report a pooled proportion who were tested for HIV.
Results: Of 7582 articles, 612 full texts were examined and 96 included in our final analysis. Most (73%) studies were from high-income countries, with a third from general populations (36%) and sexual minorities (30%).
Eighteen studies provided estimates for the meta-analysis for the proportion of people tested for HIV who attended an STI service, 15 studies for those tested for STIs, and 13 studies for those diagnosed with STI.
The pooled percentage of people tested for HIV who attended an STI service was 71.0% [95% confidence intervals: 61.0-80.1, I^2=99.9%], people tested for HIV among those who were tested for STIs was 61.3% [53.9-68.4, I^2=99.9%], people tested for HIV among those who were diagnosed with an STI was 35.3% [27.1-43.9, I^2=99.9%]. Only three studies provided estimates for HIV testing among patients presenting with STI symptoms, with pooled percentage of 27.1% [20.5-34.3].
Conclusions: There is an urgent need for better integration of HIV and STI services where there may be opportunities for greater synergies to improve prevention, testing, early diagnosis, and linkage to care for people living with HIV.

EPC410

Key population led primary care services integrates HIV and STI testing into comprehensive annual preventive health assessments

H. McCormack[1,2], H. Wand[1], C. Bourne[1,2,3], R. Guy[1]
[1]UNSW, Kirby Institute, Sydney, Australia, [2]NSW Ministry of Health, NSW STI Programs Unit, St Leonards, Australia, [3]Sydney Sexual Health Centre, Sydney, Australia

Background: The World Health Organisation recommends comprehensive health assessments inclusive of HIV and STI testing for key populations. Annual health assessments for Indigenous people in Australia are delivered in primary care and reimbursed by the universal health insurance program, through Medicare Benefits Schedule (MBS) Item 715.
We examined for the first time inclusion and completeness of testing for HIV and STIs within annual health assessments for Indigenous young people aged 16 – 29 years in Aboriginal Community Controlled Health Services.
Methods: Using routinely collected electronic medical record data from a national sentinel surveillance system (ATLAS), we performed a cross-sectional analysis on tests for HIV, chlamydia, gonorrhoea and syphilis completed within one day of the MBS 715 health assessment.
We used logistic regression to assess correlations between test completion and age, sex, area of residence and year of consultation.
Results: Of 13,892 health assessments conducted between 2018 - 2020, 11.5% included tests for all four STIs and 23.9% included a test for any STI. Of health assessments that included a chlamydia/gonorrhoea test, 59% also included HIV and 57% also included both syphilis and HIV.
In the multivariate model, inclusion of HIV test was associated with patient aged 20 – 24 (OR 1.40, 95% CI 1.23 to 1.58)) and 25 – 29 (OR 1.33, 95% CI 1.18 to 1.51)) compared to 16 – 19, patient being male (OR 1.15, 95% CI 1.04 to 1.26) compared to female, and patient residing in very remote (OR 3.47 (95% CI 2.95 to 4.08)), remote (OR 1.87 (95% CI 1.57 to 2.23)) and regional areas (OR 2.30 (95% CI 2.01 to 2.64)) compared to metropolitan. Similar correlates were observed for other STIs.
Conclusions: Integration of HIV and STI was higher in remote areas where disease burden from STIs is greatest. While only a small proportion of total health assessments



included a HIV test, over half that included a chlamydia/gonorrhoea test also included HIV, indicating that integration of STI screening is likely to be comprehensive. As HIV prevalence in Australia is greatest in metropolitan areas, culturally appropriate strategies are required to ensure all Indigenous young people receive comprehensive HIV/STI screening.

Strategies to improve HIV linkage and ART initiation

EPC411
The disruption of COVID-19 pandemic on individual level HIV care continuum

X. Yang[1], J. Zhang[2], S. Chen[2], B. Olatosi[3], S. Weissman[4], X. Li[1]
[1]University of South Carolina, Department of Health Promotion, Education and Behavior, Columbia, United States, [2]University of South Carolina, Department of Epidemiology and Biostatistics, Columbia, United States, [3]University of South Carolina, Health Services Policy and Management, Columbia, United States, [4]University of South Carolina, School of Medicine, Columbia, United States

Background: The COVID-19 pandemic is likely to disrupt global HIV care continuum services and impede ending the HIV epidemic. However, limited real-world data has supported such a hypothesis. Using state-wide data, this study compared the HIV care continuum outcomes before and during the COVID-19 outbreak.

Methods: Extractedthrough an electronic reporting system in South Carolina, the study population was people living with HIV (PWH) diagnosed between January 2000 and December 2020 and followed up until June 2021. Linkage to care was measured as having at least one CD4 or viral load (VL) test within 30 days after initial HIV diagnosis. Using the sub-population who had at least one year of follow-up information, retained in care was measured as the percentage of persons with diagnosed HIV who had two or more CD4 or VL tests, performed at least 3 months apart.

Similarly, time to first viral suppression was the time interval from initial HIV diagnosis to the first time of VL test result of <200 copies/ml. The timepoint of March, 2020 was used to differ pre- and post-COVID-19 status. Logistic regression and Cox proportional hazards models were employed for these analyses.

Results: Among a total of 12,999 people with HIV (PWH), PWH who were diagnosed after the COVID-19 pandemic were less likely to be linked to care (OR: 0.60, 95%CI: 0.48, 0.75). While PWH had a lower likelihood of being retained in care during the COVID-19 pandemic than before (OR: 0.55, 95%CI: 0.52, 0.59), non-significant differences were observed regarding time to first viral suppression before and during the pandemic (HR: 1.09, 95%CI: 0.98, 1.22). Blacks, Hispanics, or younger individuals were less likely to be either linked to care or retain in care (all p-values<0.05) yet men who have sex with men were more likely to achieve the initial viral suppression during the pandemic than their counterparts (HR: 1.21, 95%CI: 1.04, 1.41).

Conclusions: The COVID-19 pandemic has a generally negative impact on HIV care continuum outcomes, particularly for vulnerable populations. Resources should be directed to ensuring sustainable HIV care (e.g., home-based testing, and telemedicine) to mitigate any adverse effects of COVID-19 related disruption on HIV care.

EPC412
Extended working hours increase linkage to ART services among key populations in Kilimanjaro region

A. John[1], B. Minja[2], B. Ogwang[1], M. Sanze[1], J. Ng'weshemi[1], G. Nkya[1], W. Shing'wenda[2], N. Njuguna[3], D. Itemba[2], J. Maina[2], U. Kategile[4]
[1]Family Health International 360, HIV Programs (EpiC Project), Dar es salaam, Tanzania, The United Republic of, [2]Tanzania Women Research Foundation, Kilimanjaro, Tanzania, The United Republic of, [3]Family Health International 360, HIV Programs (LINKAGES), Nairobi, Kenya, [4]United States Agency for International Development, Dar es Salaam, Tanzania, The United Republic of

Background: Tanzania's linkage to antiretroviral therapy (ART) services remains low among men who have sex with men (MSM) and female sex workers (FSWs). MSM and FSWs feel insecure about accessing highly visible ART clinics and find standard facility hours inconvenient. Health care workers (HCWs) are perceived as unaccepting, and criminalization of MSM and FSWs in the community leads to low use of traditional facilities.

Traditional approaches to enhance service quality, including HCW counseling, peer navigation, and escorted referrals, have not been successful. The Meeting Targets and Maintaining Epidemic Control (EpiC) project introduced HCW engagement and extended working hours to complement linkage to ART services among key populations.

Description: Through routine client feedback, extended clinic hours were identified as a way to better meet the needs of FSWs and MSM. An assessment was conducted in 14 care and treatment center (CTC) sites in Kilimanjaro to determine feasibility of extending opening hours to improve linkage to ART services. EpiC began an incentive system offering CTC nurses transport reimbursement for working during extended hours (before 7 a.m. or after 3 p.m. on weekdays, or on a weekend). EpiC trained 19 HCWs from 19 health facilities on key-population-friendly services during extended working hours.

Lessons learned: Linkage rates increased from 82% to 99% among FSWs and MSM after the introduction of extended working hours and HCW training on the provision

of key-population-friendly services. Extended working hours may better meet the needs of key populations and enhance linkage rates among populations that are traditionally difficult to reach.

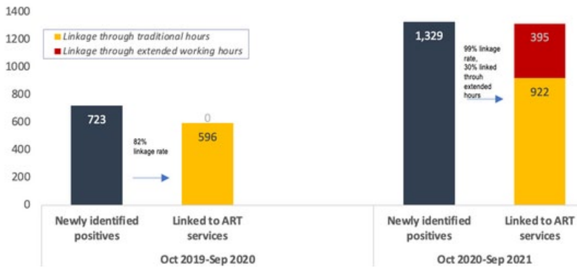


Figure. Rates of ART linkage before and after introduction of extended working hours.

Conclusions/Next steps: There should be a scale-up of key-population-friendly services during extended clinic hours to all EpiC regions to increase linkage among FSWs and MSM. These interventions are simple to implement and could be tested among other populations to accelerate progress toward the Joint United Nations Programme on HIV/AIDS (UNAIDS) 95-95-95 goals.

EPC413

Characterizing the impact of the Key Populations Investment Fund (KPIF) on HIV prevention and treatment programs for key populations in Malawi

C. McGuire[1], L.M. Banda[2], K. Willis[1], C. Akolo[3], A. Zakaliya[2], D. Chilongozi[3], N. Persaud[3], A. Gottlieb[3], M. Ruberintwari[2], K. Rucinski[4], S. Baral[1]

[1]Johns Hopkins Bloomberg School of Public Health, Department of Epidemiology, Baltimore, United States, [2]FHI 360/LINKAGES, Lilongwe, Malawi, [3]FHI 360/LINKAGES, Washington DC, United States, [4]Johns Hopkins Bloomberg School of Public Health, Social and Behavioral Interventions Program, Department of International Health, Baltimore, United States

Background: In 2021, there remain gaps in HIV prevention and treatment programs for key populations (KP) in Malawi. To address these gaps, the Key Populations Investment Fund (KPIF), implemented through the Meeting Targets and Maintaining Epidemic Control (EpiC) project, augmented and expanded existing differentiated services for KP beginning in January 2020. We examined the impact of this program on HIV case finding and antiretroviral therapy (ART) initiation among female sex workers (FSW), men who have sex with men (MSM), and transgender persons (TG).

Methods: Routinely collected individual-level program data were collected through implementing partners across six Malawi administrative districts from October 2018–April 2021. Data were assembled across multiple forms to construct an analytic cohort. HIV testing outcomes and subsequent dates of ART initiation were used to generate monthly estimates of 30-day ART initiation. We utilized a single group interrupted time series analysis with unadjusted segmented Poisson regression models to assess the impact of the KPIF intervention on HIV testing and ART initiation outcomes.

Results: 7,176 tests HIV tests were reported from Oct 2018–April 2021, yielding 1,235 positive tests (FSW 304/2,100; MSM 382/3,121; TG 291/1,154), with 1,114 (90.2%) of those testing positive through EpiC initiating ART within 30 days (FSW 242/304; MSM 351/382; TG 276/291). KPIF implementation (January 2020) resulted in an immediate increase in HIV test positivity (IRR: 1.44, 95% CI 1.01–2.06) and 30-day ART initiation (IRR: 1.26, 95% CI 1.07–1.47), and trends were sustained over the following year (*Figure*).

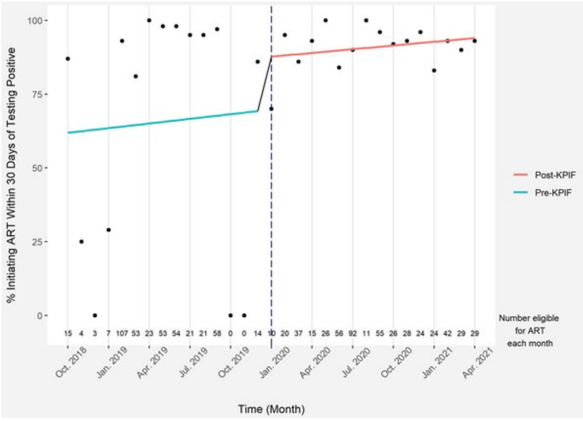

Figure. Estimated 30 day ART initiation after testing positive through program.

Conclusions: The expansion of differentiated HIV services through KPIF implementation was associated with a rapid and sustained increase in HIV case finding and ART initiation for KP.

These findings highlight the potential impact of scaling investments in dedicated programs for KP in Malawi as central to addressing unmet individual and community needs and overall efforts at achieving HIV epidemic control.

Identifying HIV-infected patients at high risk of defaulting treatment

I. Dieye[1], H. Wong[1], M. McNairy[2], H. Iyer[3], G. Tshabalala[4], J. Bor[5], S. Koenig[1], P. Cremieux[1], K. Otwombe[6], I. Katz[7]
[1]Analysis Group, Boston, United States, [2]Centre for Global Health, Weill Cornell Medicine, Division of General Internal Medicine, Ithaca, United States, [3]Dana-Farber Cancer Institute, Division of Population Sciences, Boston, United States, [4]University of the Witwatersrand, Perinatal HIV Research Unit, Faculty of Health Sciences, Johannesburg, South Africa, [5]Boston University, Department of Global Health and Epidemiology, School of Public Health, Boston, United States, [6]University of the Witwatersrand, School of Public Health, Faculty of Health Sciences, Johannesburg, South Africa, [7]Brigham and Women's Hospital, Department of Medicine, Boston, United States

Background: There is a significant gap in South Africa between HIV diagnosis and antiretroviral therapy (ART) initiation. The objective of this study was to develop a simple risk assessment tool to identify patients at highest risk for ART non-initiation.

Methods: A prediction model was developed in a primary cohort that consisted of 498 patients with HIV in South Africa, and data was gathered from June 2014 to June 2015. Risk factors for treatment non-initiation included demographics, clinical measures, indicators of religiosity, mental health, perceived stress and social support. The least absolute shrinkage and selection operator (LASSO) regression analysis was used to optimize variable selection. Multivariable logistic regression analysis was applied to build a predicting model based on the predictors selected from the LASSO analysis using 80% of the primary cohort as a training dataset. The model was validated using the remaining 20% of the primary cohort (hold-out sample) and an independent cohort of 96 patients (external cohort). Model calibration and discrimination were assessed by the Hosmer-Lemeshow goodness of fit (GOF) test and C-statistic, respectively. A point-based risk score was developed.

Results: Of 498 participants with mean age 35.7, 38% were treatment non-initiators. Specific predictors (Age, recruitment from Soweto, feeling abandoned by God, coping with alcohol/drugs, not having concentration problems, and not feeling overwhelmed by difficulties) were selected by LASSO (Table 1).

The logistic model had a good fit (GOF p=0.89) and C-statistic values of 0.74 and 0.60 in the hold-out sample and the external test sample, respectively. Total points associated with different risk levels ranged from -4 to 14, corresponding to a 3% and 86% default risk, respectively.

Conclusions: A simple risk score using patient characteristics and including behavioral factors at ART screening may predict ART non-initiation in newly diagnosed HIV+ patients in South Africa. It may help a priori identify patients less likely to initiate treatment and focus individualized counselling and risk assessment.

Intercept and variables	Coefficients	P-values	Odds ratios	Confidence intervals
Intercept	-1.571	<0.05	0.208	(0.054, 0.730)
Age	-0.029	<0.05	0.971	(0.948, 0.994)
Lives in Soweto	0.419	0.087	1.520	(0.940, 2.457)
Feels abandoned by God	0.507	0.072	1.660	(0.956, 2.888)
Copes using drugs	1.023	<0.05	2.782	(1.326, 6.043)

Impact of Linkages Case Management (LCM) in improving ART initiation and early retention amongst PLHIV in Eswatini

H. Mamba[1], S. Gulwako[2]
[1]Ministry of Health-Eswatini National AIDS Program, HIV Linkages, Mbabane, Eswatini, [2]Ministry of Health - Eswatini National AIDS Program, Monitoring & Evaluation, Mbabane, Eswatini

Background: Although the initiation of Anti-Retroviral Treatment (ART) was decentralized in Eswatini, many People Living with HIV (PLHIV) were reluctant with test and treat initiative following Human Immunodeficiency Virus (HIV) diagnosis. This resulted with the country having slow increase in ART initiation among newly diagnose PLHIV, as in 2018 it was still below 90%.

Some barriers to early ART initiation included long waiting time/ queues, fear of stigma and disclosure, denial, feeling healthy and fear of medications side-effects. Therefore, the LCM initiative was introduced to assist and support with bridging these barriers identified.

Description: LCM was implemented as of May 2019 in the four regions of Eswatini. Newly initiated PLHIV are voluntarily enrolled into LCM during health facility visits and are paired with an Expert Client (EC) for a period of 3 months. On the day of HIV diagnosis clients are escorted for ART initiation and informed about the facility layout to reduce waiting time.

The EC routinely review the chronic care file to identify issues to be deliberated with the client before calling the client. During the three months, the EC provides four telephone calls to provide support on how clients are coping with treatment and to remind them of their next appointment.

For clients delaying ART, follow up calls are made to offer counselling until they are ready for initiation. Three face-to-face counselling sessions are also provided to offer ongoing support on disclosure, index testing and adherence counselling.

Lessons learned: According to Eswatini HIV annual reports (2018 - 2020) and routine program data, the introduction of LCM increased ART initiations from16,755/26131 (64.1%) in 2018 to 22,104/23,970 (92.2%) in 2019 and 10,350/11,138

(92.9%) in 2020. Retention at six months increased from 78% in 2018 to 89% in 2019 and 99% in 2020. This is in alignment with the decline of lost-to follow ups from 7,880 in 2018 dropping to 6,974 in 2019.

Conclusions/Next steps: Providing targeted psychosocial support, relevant educational information and motivational counselling on the benefits of early enrolment and disclosure improved ART initiation, retention, and viral suppression. We recommend implementation of LCM for priority populations that seem to be lagging behind.

EPC416

Associations between alcohol use and antiretroviral therapy uptake among people living with HIV in Central Uganda

A. Wynn[1], K. Sileo[2], K. Schmarje Crockett[3,4], R. Naigino[3,4,5], M. Ediau[4,6,3], R.K. Wanyenze[5,3], N.K. Martin[1], S.M. Kiene[3,5]
[1]University of California, San Diego, Division of Infectious Diseases and Global Public Health, La Jolla, United States, [2]The University of Texas at San Antonio, Department of Public Health, San Antonio, United States, [3]San Diego State University, Division of Epidemiology and Biostatistics, San Diego, United States, [4]University of California, San Diego, Herbert Wertheim School of Public Health and Human Longevity Science, La Jolla, United States, [5]Makerere University, Department of Disease Control and Environmental Health, Kampala, Uganda, [6]Makerere University, Department of Policy, Planning and Management, Kampala, Uganda

Background: Alcohol use among people living with HIV (PLHIV) is common and associated with negative impacts on the HIV care cascade. In 2017, Uganda implemented the universal test-and-treat (UTT) strategy, which expanded access to antiretroviral therapy (ART) to all PLHIV. However, gaps in ART coverage persist in certain populations.

We evaluated the relationship between alcohol use and ART uptake among PLHIV and linked to care in Uganda. We also assessed ART adherence among a sub-sample of participants.

Methods: PATH/Ekkubo was a cluster-randomized trial that evaluated a linkage to HIV care intervention in four districts of Central Ugandan, Nov 2015-Sept 2021.

Our sample included: 1) baseline data from individuals not enrolled in the trial (previously diagnosed HIV+ and linked to care); and 12-month follow-up data from those enrolled in the control group (previously diagnosed, but not linked to care, or newly diagnosed HIV+ at enrollment). Alcohol use was measured as any current (AUDIT-C>0), harmful (AUDIT-C women ≥3, men 4≥), and binge use (≥6 drinks on one occasion).

ART use was assessed with, "Are you taking ARVs?" ART and alcohol use were examined using logistic regressions adjusting for age, gender, marriage, education, religion, wealth, depression, and baseline or control group.

We assessed ART adherence among the control group, dichotomized as any versus no missed doses in the past four days.

Results: Among 931 HIV+ adults, 40% reported current (32% of women, 61% of men); 21% reported harmful (19% of women, 28% of men); and 18% reported binge alcohol use (14% of women, 29% of men).

In multivariable models, those with current (adjusted Odds Ratio [aOR] 0.46; 95% CI: 0.30-0.72), harmful (aOR 0.32; 95% CI: 0.20-0.51), and binge use (aOR 0.32; 95% CI: 0.19-0.51) were significantly less likely to be on ART. In the sub-analysis, current (aOR 5.25; 95% CI: 1.69-16.33) and binge use (aOR 5.16; 95% CI: 1.45-18.35) were associated with increased odds of missed ART doses.

Conclusions: Any current, harmful, and binge alcohol use were associated with lower uptake of ART and adherence. Tailored interventions for individuals who use alcohol may be needed to optimize the benefits of the UTT strategy.

EPC417

95,95,95 – an analysis of linkage and retention of newly identified HIV positive key and priority populations at AIDS Information Centre (AIC) Kampala, Uganda

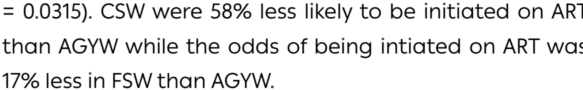
H. Kizito[1], J. Nalweyiso[2], H. Sairo[2]
[1]AIDS Information Centre, Programs and Planning, Kampala, Uganda, [2]AIDS Information Centre, Monitoring and Evaluation, Kampala, Uganda

Background: The 95, 95, 95 strategy aims to accelerate HIV epidemic control and end AIDS by 2030. Targeted testing for key and priority populations (KP/ PPs) contributes to the first 95 however without linkage to and retention in care, new infections will remain unchecked.

AIC provides integrated HIV prevention and treatment services for KP/ PPs and endeavors to link and retain all new positives in care. As part of continuous improvement activities, analysis of linkage and retention are periodically conducted to address implementation gaps and inform strategies for improvement.

Description: An analysis of linkage and retention was conducted for 117 newly diagnosed HIV positive KP/PPs between January – December 2021 by AIC Kampala. Data was extracted from the Uganda National KP Tracker (online database) and analyzed using descriptive statistics, logistic regression and multivariate analysis. KP/PPs were classified into pre-defined groups such as Female sex workers (FSW), Adolescent Girls and Young Women (AGYW), Clients of sex workers (CSW), discordant couples (DC) among others.

Lessons learned: Of the 117 KP/PPs, 95 (81%) were successfully linked to care (84%male, 80%Female) with FSW achieving 88% linkage and CSW the least (50%); AGYW and DC achieved linkage rates of 75.8% and 100% respectively. Using logistic regression, there was a significant relationship between classification and initiation on ART (p



= 0.0315). CSW were 58% less likely to be initiated on ART than AGYW while the odds of being intiated on ART was 17% less in FSW than AGYW.
No significant relationship was found between gender and ART initiation (p= 0.8684) although the odds of males being initiated on ART was 8% less than females.
A multivariate analysis demonstrated that classification and age had a significant association with ART initiation (p= 0.02).
Despite 88% linkage, only 50% of FSW remained in care by 6 months and 30% at 12 months while CSW had 100% retention at 12 months. Overall males had a higher retention (100%) at 12 months than females (71%). All KP/PPs retained in care were virally suppressed.
Conclusions/Next steps: Targeted innovative strategies are required to secure linkage of particularly young people and men to care and retain FSW in HIV care.

EPC418
Antiretroviral therapy initiation at entry into HIV care, Croatia, 2015-2020

J. Begovac[1,2], N. Bogdanić[2], L. Močibob[2], D. Lukas[2,1], Š. Zekan[1,2]
[1]*University of Zagreb, School of Medicine, Zagreb, Croatia,* [2]*University Hospital for Infectious Diseases, Zagreb, Croatia*

Background: In Croatia, persons living with HIV (PLWH) are treated and supplied with antiretroviral therapy (ART) only at the University Hospital for Infectious Diseases, Zagreb. Since about 55% of PLWH are not from Zagreb, we introduced ART on the first day of entry into care. We examined the frequency, virologic outcome, and factors related to same-day ART initiation from 2015-2020.
Methods: Included were Croatian citizens/permanent residents ≥16 years old. Same-day ART was defined as ART initiation at the date of entry into care or the next day (Days 0 & 1). Multivariable logistic regression was done to assess factors related to same-day ART. We measured time from ART initiation to HIV-1 RNA < 50 copies/ml by Kaplan- Meier estimates.
Results: Of 540 persons who entered HIV care, 530 started ART. Same-day ART was present in 348/530 (65.7%)(Table). Median time to ART initiation from HIV diagnosis was 8.0 days, rapid ART (within 7-days of HIV diagnosis) was initiated in 264/530 (48.9%). Of 348 same-day ART starters, 211 (60.6%) initiated ART within 7-days of HIV diagnosis. Same-day and rapid ART initiation was more frequent in 2018-2020 vs. 2015-2017 and increased from 2015 to 2020 (Figure-A&B). Persons with no clinical AIDS were more likely to start same-day ART vs. those with clinical AIDS as were those living outside Zagreb (Figure-C). Same-day ART resulted in earlier viral suppression (Figure-D).

Characteristics	Total N=530 (%)	Same-day ART initiation N=348 (%)	Not same-day ART initiation N=182 (%)	P-value
Males	507 (95.7)	331 (95.1)	176 (96.7)	0.394
Age, median (Q1-Q3)	36.2 (28.7-44.3)	35.1 (27.8-42.6)	37.7 (30.4-47.2)	0.008
MSM	470 (88.7)	305 (87.6)	165 (90.7)	0.298
CD4+ cell count**per µL, median (Q1-Q3)	315.0 (139.5-486.0)	338.0 (193.0-486.0)	244.0 (45.0-475.0)	<0.001
CD4+ <200 per µL**	169 (32.5)	91 (26.8)	78 (43.1)	<0.001
HIV RNA >100 000 copies/ml	245 (46.2)	140 (40.2)	105 (57.7)	<0.001
Had clinical AIDS	93 (17.5)	30 (8.6)	63 (34.6)	<0.001

ART, antiretroviral therapy. MSM, men who have sex with men. Q1-Q3, first and third quartile.
*At entry into care (Days 0 & 1) **Based on 520 persons, 10 did not have an CD4 cell count measurement.

Table. Comparison of major HIV characteristics of persons who initiated same-day antiretroviral therapy versus those who did not in Croatia from 2015 to 2020.*

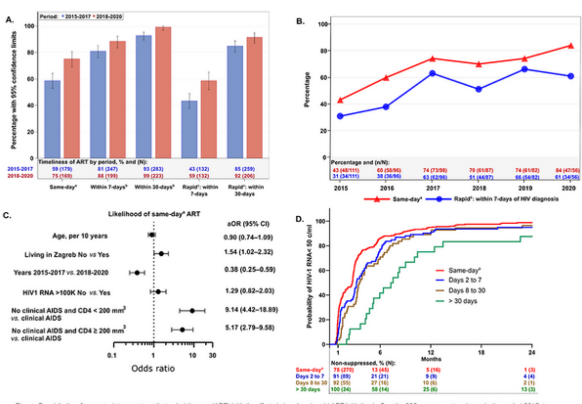


Figure.

Conclusions: Same-day ART became more frequent in recent years, it was associated with not having clinical AIDS and living outside Zagreb, and had a favorable virologic outcome.

EPC419
MenConnect: engaging men living with HIV through an mHealth platform

K. Lemon[1], M. Khan[2], L. Lunika[2], C. Aigbe[1], N. Mabhena[2], S. Johnson[2]
[1]*Praekelt, Johannesburg, South Africa,* [2]*Genesis Analytics, Johannesburg, South Africa*

Background: Despite modern advances in the treatment, management and spread of HIV, many men who become HIV positive still feel shame and self-stigmatisation. This limits men seeking medical advice in public spaces like local clinics. Since adequate treatment is a means of near-halting transmission, this poses a health risk both to men living with HIV (MLHIV) and the general spread of the virus.
Description: MenConnect is an innovative mHealth chatline for MLHIV in South Africa delivered via WhatsApp and SMS/USSD. It was developed in partnership with the Men-

Star Coalition program led by PEPFAR. Men who register are segmented through a psychographic assessment to receive a personalised messaging regime navigating the realities and responsibilities of living with HIV. These messages provide medical and mental support, with the aim of improving antiretroviral initiation and adherence, and improving mens' sense of self-worth. A qualified HelpDesk also fields any personal questions men have beyond the existing content.

Lessons learned: While recruitment has been slow due to the COVID-19 pandemic, 2766 men have registered between July 2020 - Feb 2022, those who join appear highly engaged with the platform, receiving over 293'000 reliable content messages across them (avg. messages per man > 100). Of these, 747 men (27%) have sent in over 1800 questions to the helpdesk, with emerging themes including understanding HIV testing, treatment access and prevention of mother-to-child transmission (PMTCT).

Conclusions/Next steps: While self-report tests indicate reduced self-stigmatisation of users across their journey, this is also met with declining treatment knowledge over time. A comparative impact assessment is still needed to know what effects exist outside of men's normal progression with the disease.

Despite this, MenConnect has clearly provided helpful and seemingly valued information to thousands of MLHIV. This has been shown by mens' engagement with the platform and men being able to ask questions they may not otherwise not have been able to.

EPC420

Awareness of current ART benefits and policies is associated with treatment acceptance and successful outcomes among people who inject drugs in Ukraine

Y. Sazonova[1], R. Kulchynska[1], N. Podolchak[1], R. Keating[1], M. Azarskova[1], I. Doan[1], I. Titar[2], S. Salnikov[2], E. Barzilay[1]
[1]*CDC-Ukraine, Overseas Strategy and Management Branch, Division of Global HIV & TB, U.S. Centers for Disease Control and Prevention, Kyiv, Ukraine,* [2]*Center of Public Health of the Ministry of Health of Ukraine, Kyiv, Ukraine*

Background: In 2015, Ukraine adopted a new HIV treatment protocol that emphasized the importance of immediate antiretroviral therapy (ART) for newly diagnosed individuals. People who inject drugs (PWID) in Ukraine have a disproportionately high risk of infection and have the lowest ART coverage compared to the general and other key populations.

This study investigates whether higher awareness of ART benefits is associated with greater prevalence of ART enrollment among PWID.

Methods: We performed analysis of cross-sectional Bio-Behavioral Surveillance (BBS) data collected in 12 cities in 2020 using Respondent-Driven Sampling (RDS). A standardized, interviewer-administered questionnaire collected socio-demographic characteristics, behavioral risks, knowledge about HIV treatment approaches, and ART use. We restricted multivariate regression analyses to known HIV-positive respondents (n=784) to identify co-variates associated with greater ART engagement.

Results: Almost half of the HIV-positive PWID (n=576, 46%) were not on ART and the majority (n=669, 51.3%) were unaware that sexual transmission is zero if the person living with HIV (PLHIV) has an undetectable viral load (VL).

Almost 25% (n=303) of PWID did not realize that PLHIV should start ART immediately after an HIV diagnosis, and 35% (n=432) thought ART could be delayed if a PLHIV "felt healthy". The adjusted analysis controlled for age and use of other HIV-related services, such as harm reduction and opioid agonist therapy was done to estimate the independent association between knowledge and ART use. PWID who correctly reported that sexual HIV transmission can be prevented when VL is undetectable had 1.9 higher odds to be on ART (95% CI: 1.27-2.94).

Those who reported that ART should be started immediately after diagnosis had 1.74 higher odds of being on ART (95%CI: 1.08-2.82). PWID who knew that ART should be started even if a person feels healthy had 3.59 higher odds to be on ART (95% CI: 2.32-5.55).

Conclusions: This investigation demonstrates a lack of awareness among HIV-positive PWID about the benefits of early ART initiation and the effect of ART on secondary sexual prevention. Given that better knowledge of HIV correlates with improved access to treatment services, more efforts might be taken to educate PWID on current ART benefits and policies.

EPC421

The effect of opioid agonist therapy on HIV care cascade among PWID in Ukraine

K. Dumchev[1], M. Goncharova[2], H. Manoilenko[2], M. Filippovych[3], I. Ivanchuk[2]
[1]*Ukrainian Institute on Public Health Policy, Kyiv, Ukraine,* [2]*Public Health Center of the Ministry of Health of Ukraine, Kyiv, Ukraine,* [3]*European Institute of Public Health Policy, Kyiv, Ukraine*

Background: People who inject drugs (PWID) constitute more than 50% of all people living with HIV in Ukraine, and most of them were using opioids. Opioid agonist therapy (OAT) is known to reduce risks associated with injecting drug use, improve access to ART and adherence. OAT in Ukraine is expanding gradually, currently reaching >17,000 patients. In this study we assessed the effect of OAT on HIV care cascade outcomes.

Methods: A cross-sectional survey was conducted in 6 regions of Ukraine in 2021, with half of participants recruited using simple random sampling among OAT patients and another half using respondent driven sampling among out-of-treatment PWID. PWID seeds were selected from clients of harm reduction programs. The survey questionnaire administered anonymously, and included questions

on HIV and OAT treatment history, adherence, barriers to care, and mental health. HIV care cascade outcomes were compared using Chi-square tests.

Results: The survey recruited 652 OAT patients (17% women) and 650 PWID (25% women). Ever tested for HIV were 632 (96.9%) among OAT patients and 516 (79.4%) among PWID (p<0.001). Of those tested, 217 (35.2%) of OAT patients and 84 (17.2%) of PWID disclosed their HIV positive status. HIV care cascade for two groups is presented in Figure 1.

All indicators, including having confirmatory testing and being registered in HIV care, being prescribed ART, currently taking ART, and ART adherence were significantly higher in the OAT group (p=0.002, p=0.007, p<0.001, p<0.001, respectively).

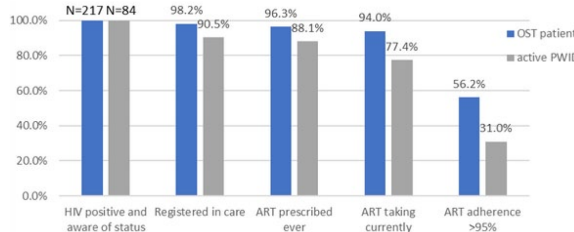

Figure. HIV care cascade among OAT patients and PWID in Ukraine

Conclusions: ART uptake was relatively high in OAT patients and out-of-treatment PWID in Ukraine. Despite the limitations of cross-sectional design, the study confirmed the significant positive effect of OAT on HIV treatment engagement and adherence. ART adherence remains suboptimal in both groups.

Further analysis will identify factors associated with OAT engagement and adherence to ART to inform strategies to reach 95-95-95 goals in this population.

Strategies to improve early retention in care (first year on ART)

EPC422

The HIV care cascade among transgender women living with HIV

M. Bertolini[1], N. D'Amico[1], M. De Ilzarbe[1], M.V. Tomaino[1], M. Jaume[1], D. Bruno[1], C. Frola[1], J.Á.E. Barletta[1], M.J. Rolón[1]

[1]*Hospital Juan A. Fernández, Infectious Diseases Division, CABA, Argentina*

Background: The prevalence of HIV among transgender women (TGW) in Argentina is estimated at 34%, as compared to 0.4% in the general population. Stigma and discrimination are barriers to healthcare, but information about HIV care cascade and clinical outcomes among TGW living with HIV (TGWLHIV) is limited.

Methods: This is a retrospective cohort study conducted between February-2011 and August-2020; TGWLHIV aged ≥18 years linked to care in an HIV clinic in Buenos Aires, Argentina, were included. Demographic, clinical variables and other care cascade associated factors were analyzed at baseline and during the first 12 months of follow-up.

Results: A total of 220 TGWLHIV were included, with a median age of 31 years (IQR 26-35). Median baseline CD4 count was 360 cells/uL (IQR 140-659); 51.8% had low level of education (<10 years) and 141 (64.1%) were sex workers. At the time of enrollment, 67 (30.5%) had an AIDS-defining illness, being tuberculosis the most frequent (n=24).

At the end of the year of follow-up, 9 (4.1%) patients had died and 30 (13.6%) were transferred to a different center. Of the remaining 181 TGWLHIV, 120 (66.3%) were retained in HIV care. Among those retained, 101 (84.2%) were on ART. Of those on ART, 69 (68.3%) achieved virological suppression (viral load <40 copies/mL) after one year.

AIDS-defining illness at baseline and low educational level were associated with lower ART use (OR: 0.2, 95% CI: 0.07-0.61, p<0.01 and OR: 0.34, 95% CI: 0.12-0.93, p=0.031), but without significant association with retention in HIV care (OR: 0.77, 95% CI: 0.39-1.52, p=0.45 and OR: 0.87, 95% CI: 0.47-1.62, p=0.66) and virological suppression at 12 months within patients who were on ART (OR: 1.63, 95% CI: 0.54-4.93, p=0.38 and OR: 0.53, 95% CI: 0.22-1.25, p=0.15).

Conclusions: Additional efforts are necessary to address structural barriers and to achieve UNAIDS 95-95-95 targets in this population. More studies that compare the HIV care cascade in different populations and scenarios are necessary for a better understanding of the current situation of TGWLHIV worldwide.

EPC423

Factors associated with timing of HIV diagnosis and antiretroviral therapy and its impact on mortality among newly reported people living with HIV in Guangdong Province, China: a prospective cohort study

K. Lin[1], J. Liu[2], Y. Yan[1], X. Fu[2], Z. Tan[1], Q. Liu[3], J. Li[3], L. Wang[4], Y. Zhou[5], C. Ye[6], M. Cen[7], X. Liao[7], L. Xu[8], C. Zhang[8], Y. Yan[9], L. Huang[9], F. Yang[2], Y. Yang[1], Y. Li[2], H. Jiang[1]

[1]*Guangdong Pharmaceutical University, Department of Epidemiology and Biostatistics, Guangzhou, China,* [2]*Guangdong Provincial Center for Disease Control and Prevention, Guangzhou, China,* [3]*Guangzhou Eighth People's Hospital, Guangzhou, China,* [4]*Jiangmen Center for Disease Control and Prevention, Jiangmen, China,* [5]*Zhuhai Center for Disease Control and Prevention, Zhuhai, China,* [6]*Yangjiang Center for Disease Control and Prevention, Yangjiang, China,* [7]*Yunfu Center for Disease Control and Prevention, Yunfu, China,* [8]*Shantou Center for Disease Control and Prevention, Shantou, China,* [9]*Huizhou Center for Disease Control and Prevention, Huizhou, China*

Background: Earlier HIV diagnosis and antiretroviral therapy (ART) are essential for better disease progression among people living with HIV (PLHIV).

In this study, we explored factors associated with timing of HIV diagnosis and ART and its impact on mortality among newly reported PLHIV in Guangdong Province, China.

Methods: A prospective cohort study was conducted to recruit newly diagnosed PLHIV from six cities in Guangdong Province from May 2018 to June 2019. Participants were followed up till August, 2020. Data were collected from a questionnaire and the national HIV surveillance system. Multinomial logistic regression was conducted to explore factors associated with timing of HIV diagnosis and ART. Propensity Score Matching (PSM) and Cox proportional hazard regression model were used to explore the impact of timing of diagnosis and treatment on mortality.

Results: Among the 1018 participants, 920 (90.37%) were on ART and 106 (10.41%) died during the study period. Compared to the early diagnosis with early ART group, personal monthly income <3000 yuan (a*OR*=0.20, 95%*CI*: 0.05~0.87) was negatively related to early diagnosis with late ART.

Sample source of voluntary counseling and testing (VCT) clinics (a*OR*=0.64, 95%*CI*: 0.45~0.91), previous willingness of HIV testing (a*OR*=0.67, 95%*CI*: 0.45~0.99), high level of social support (a*OR*=0.65, 95%*CI*: 0.48~0.89) were negatively related to late diagnosis with late ART.

Age of 30 to 49 years (a*OR*=1.79, 95%*CI*: 1.12~2.86), age over 50 years old (a*OR*=1.97, 95%*CI*: 1.09~3.56), having HIV-related symptoms in the past year (a*OR*=2.23, 95%*CI*: 1.65~3.01), and having not used HIV self-testing kits (a*OR*=2.31, 95%*CI*: 1.29~4.13) were positively related to late diagnosis with late ART.

After weighted by PSM, the Cox regression results showed that the risk of death for late diagnosis with delayed treatment group and untreated group were 5.53 times (95%*CI*: 3.05~10.03, *P*<0.001) and 10.29 times (95%*CI*: 5.19~20.41, *P*<0.001) compared to that of early diagnoses with early treatment group, respectively (*P*<0.001).

Conclusions: Timing of HIV diagnosis and ART among newly reported PLHIV in Guangdong Province was relatively late and resulted in higher risk of mortality. Targeted interventions should be tailored to facilitate early HIV diagnosis and ART, ultimately to reduce the risk of mortality among PLHIV.

EPC424

Implementation of a hub-and-spoke telemedicine model to deliver HIV care and treatment services in Zambia: Lessons learned for program expansion and replication

M. Kawayo[1], B. Siangonya[1], G. Mukanga[1], B. McKinnon[1], J. Daka[1], E. Mulenga[1], W. Mbewe[1], N. Toppin Dera[1], D. Mack[1]
[1]*Morehouse School of Medicine, National Center for Primary Care, Atlanta, United States*

Background: The Morehouse School of Medicine Zambia Program implements activities aimed at improving antiretroviral treatment (ART) treatment initiation, patient retention, viral load testing and reporting, and viral load suppression for people living with HIV (PLHIV).

The rapid spread of the SARS-CoV-2 pandemic has presented challenges in delivering HIV care and treatment services in high-density clinic settings in Zambia and globally.

Description: To ensure continuity of care for adult PLHIV on ART during the COVID-19 pandemic, we worked with the Ministry of Health (MOH) and implemented a telemedicine program using a hub-and-spoke model in Lusaka, Zambia. The program has been operational since June 2021 in one tertiary hospital, four secondary hospitals serving as hubs, and nine primary health clinics serving as spokes. From June 2021 to January 2022, we have provided 855 women, 563 men and 3 adolescent girls and young women on ART with enhanced adherence counseling, tuberculosis preventive therapy, treatment post-initiation reviews, abnormal vital sign reviews, and mental health services via the telemedicine program. The telemedicine program aligns with the MOH's eHealth goal of developing and implementing efficient e-Health solutions for quality health service delivery.

Lessons learned: Successful implementation of telemedicine services in Zambia requires significant initial investment in information technology and regulatory support. With the appropriate investment in technology, human resource training and regulatory support, telemedicine can complement health service delivery for PLHIV.

Community health workers (CHWs) have demonstrated effectively persuading HIV clients to receive care via telemedicine.

We learned that switching clients from in-person HIV-related visits to virtual visits requires CHWs trusted by clients to make the transition. By working with CHWs, we reduced missed appointment ratesfor those newly initiated on ARTfrom 18% in October 2021 to 3% in December 2021.

Conclusions/Next steps: More research is needed to understand the challenges and enabling factors for telemedicine service uptake. There is need to continuously assess the virologic suppression rates of individuals receiving care via telemedicine.

Furthermore, more work is needed to plan for the delivery of HIV care in Zambia using telemedicine beyond the COVID-19 pandemic and to ensure a positive telemedicine experience for clients.

Strategies to improve retention in care beyond the first year on ART

EPC425

Predictive modeling for retention in care using electronic healthcare records from multiple healthcare systems in Chicago

J. Mason[1], E. Friedman[1], J. Schneider[2], J. Ridgway[2]
[1]The University of Chicago, Biological Sciences Division, Chicago, United States, [2]The University of Chicago, Biological Sciences Division/Department of Medicine, Chicago, United States

Background: Improving retention in care for People Living with HIV (PLWH) is critical to ending the HIV epidemic. Predictive modeling can identify healthcare factors that affect retention in care. We used a large, multi-site, non-curated database of electronic healthcare records (EHR) to build predictive models of retention in care.
Methods: We used data from 2011-2019 from the Chicago Area Patient-Centered Outcomes Research Network (CAPriCORN), a database that includes a majority of PLWH in Chicago. CAPriCORN uses a hash-based data deduplication method to follow people across multiple Chicago healthcare systems with different EHRs, providing a unique city-wide view on retention in care for PLWH.
From the database, we utilized diagnosis codes, medications, laboratory tests, demographics, and encounter information to build predictive models. We included PLWH with at least two HIV care encounters in the database, resulting in 17,169 PLWH with a total of 192,562 encounters.
Our primary outcome was retention in care, which we defined as having no more than 12 months between subsequent HIV care encounters.
We built logistic regression, random forest, and elastic net logistic regression models using all factors, and compared their performance to a baseline logistic regression model containing only demographics and retention history.
Results: All models outperformed the baseline logistic regression model, with the most improvement from the elastic net logistic regression model (AUC 0.752 [0.744-0.760] vs 0.676 [0.667-0.682], p <0.001). Top predictors included retention history, being seen by an Infectious Disease provider (vs. primary care provider), site of care, and laboratory testing for Gonorrhea, Chlamydia, and TB.
The random forest model (AUC 0.744 [0.735-752]) revealed age, insurance type, and chronic comorbidities such as hypertension as important in predicting retention in care.
Conclusions: We used a real-world approach to leverage the full scope of data available in modern EHRs to predict retention in care.
Our findings reinforce previously known factors, such as retention history, while also showing the importance of laboratory testing, chronic comorbidities, and individual clinic-specific factors for predicting retention in care for PLWH in Chicago.
This work provides a framework allowing others to use data from multiple healthcare systems to examine retention in care using EHR.

EPC426

Medication-hiding behaviors and antiretroviral treatment adherence among people living with HIV: early findings from the Florida Cohort Study

C. Parisi[1], R. Fisk-Hoffman[1], N. Siuluta[2], M. Widmeyer[3], C. Somboonwit[4], R.L. Cook[1]
[1]University of Florida, Epidemiology, Gainesville, United States, [2]Kitwe District Health Office, Ministry of Health, Kitwe, Zambia, [3]Project Response, Inc., Melbourne, United States, [4]University of South Florida, Morsani College of Medicine, Tampa, United States

Background: Antiretroviral therapy (ART) access is critical to ending the HIV epidemic. It is unknown whether medication-hiding behaviors to prevent others from discovering one's HIV status influence ART adherence. The purpose of this study is to describe medication-hiding behaviors and factors associated with these behaviors among a cohort of people living with HIV (PLWH) and to assess whether medication hiding is associated with ART adherence or running out of medication.
Methods: The ongoing Florida Cohort Study has been enrolling local adult PLWH since October 2020. In this analysis, participants (n=309, mean age 50, 56% male, 44% Non-Hispanic Black, 16% Hispanic) were asked about having at least 90% ART adherence in the preceding 30 days and running out of ART medications for more than 24 hours in the past year. Participants were also asked if they engaged in at least one of five medication-hiding behaviors to prevent others from finding out their HIV status in the past year.
Results: Thirty percent of the sample had less than 90% ART adherence and 14% ran out of their medication. Many (44%) reported engaging in at least one behavior to hide their ART medications. The most common medication-hiding behaviors were hiding medication bottles (35%), removing prescription labels (25%), moving medications to another bottle (16%), changing where they got their medications (6%), and traveling at least 30 miles to obtain medications (4%). PLWH who were under 50 years old had greater odds of engaging in medication-hiding behaviors (OR=2.47, 95% CI=1.54-3.97, p=0.002).There was no association between medication-hiding behavior and running out of medication. However, PLWH who engaged in medication-hiding behaviors were more likely to have less than 90% ART adherence (OR=3.10, 95% CI=1.41-6.79, p=0.006)
Conclusions: Taking action to conceal HIV medications to hide one's HIV status was common. PLWH under 50 were more likely to engage in medication-hiding behaviors. Medication-hiding behaviors were associated with less than 90% ART adherence. These findings suggest that

PLWH may want to receive ART medications in ways that ensure privacy. Further research is necessary to determine the impact of other behaviors to hide one's HIV status on ART adherence and health outcomes.

EPC427
Developing theory-driven Treatment-as-Prevention and U=U communication materials for persons living with HIV and health workers in South Africa

D. Onoya[1], T. Sineke[1], R. King[2], L. Hansrod[3], I. Mokhele[1], R. Inglis[3], B. Richman[4], C. Kinker[4], M. Dukashe[5], J. Blandford[6], D. Bokaba[7], J. Bor[8,1]
[1]*University of the Witwatersrand, Department of Internal Medicine, Health Economics & Epidemiology Research Office, Johannesburg, South Africa,* [2]*University of California, Institute for Global Health Sciences, San Francisco, United States,* [3]*Jive Media Africa, Pietermaritzburg, South Africa,* [4]*Prevention Access Campaign, New York, United States,* [5]*HIV Survivors and Partners Network, Tshwane, South Africa,* [6]*Centers for Disease Control and Prevention, Global Health, Tshwane, South Africa,* [7]*Gauteng Department of Health, Tshwane District Health Services, Tshwane, South Africa,* [8]*Boston University School of Public Health, Department of Global Health, Boston, United States*

Background: Messages on HIV treatment-as-prevention (TasP) and undetectable=untransmittable (U=U) have not historically been emphasized during HIV counselling in South Africa.
We sought to develop video-based communication materials to support HIV counsellors and persons living with HIV (PLHIV) in confidently sharing accurate information on TasP.
Methods: We followed the Intervention Mapping protocol, including consultations with a stakeholder planning group, formative research consisting of five focus group discussions (FGDs, N=47) with healthcare workers, three FGDs (N=27) with PLHIV from civil society organisations, and 27 in-depth interviews with PLHIV at primary healthcare clinics. Data were analysed thematically.
We adapted the Information Motivation and Behaviour (IMB) skills model, refined strategies to enhance the intervention's acceptability, and developed storyboards and scripts for the videos.
Results: Our formative research revealed that:
a. Counsellors and PLHIV had doubts that TasP worked and needed support to improve their confidence in sharing TasP information;
b. They felt it essential to promote TasP alongside standard condom use as prevention strategies;
c. PLHIV were motivated to achieve viral suppression but needed counselling to improve their viral load literacy;
d. PLHIV worried a lot about transmitting HIV to others and felt that TasP promoted self-acceptance and peace of mind.
Following this evidence, we will develop a series of short videos featuring PLHIV's testimonials of experience with TasP. The videos will be embedded in a tablet-based mobile application and presented in local languages.
The video themes – quotes from the participants – are:
1. "My treatment boosts how I look at myself. I am a full human again.";
2. "HIV does not control me. I control it and I keep my partner safe.";
3. "My child is my testimony. U = U really works";
4. "Now that I am virally suppressed, I can talk about HIV without feeling like I'm the victim or a villain";
5. "We have been practising U=U for years now. She is positive and I'm still negative."
Conclusions: Our engagement with healthcare providers and PLHIV as well as advocates of U=U informed the development of a theory and contextually grounded communication intervention to support counselling on HIV TasP.

EPC428
Scale-up of enhanced adherence counseling through targeted mentorship and telemedicine: lessons from a general hospital in Lusaka, Zambia

P. Daka[1], E. Titima[1], E. Mulenga[1]
[1]*Morehouse School of Medicine, National Center for Primary Care, Atlanta, United States*

Background: Enhanced adherence counseling (EAC) uptake at Matero General Hospital (GH) in Lusaka, Zambia has historically been low for persons living with HIV (PLHIV) due to transport costs, waiting times, and limited staff capacity. In June 2021, Morehouse School of Medicine implemented a hub and spoke telemedicine program model at Matero GH, which serves as a hub with nine peripheral and primary care health centers serving as spokes. One of the goals of this model is reduce SARS-CoV-2 transmission in antiretroviral treatment (ART) clinics at GHs.
We also provided targeted mentorship on EAC service delivery to 16 out of 18 clinicians at Matero GH. We hypothesized that telemedicine services and EAC mentorship at Matero GH and its two associated peripheral health centers contributed to increased uptake and completion of EAC sessions.
Description: We analyzed EAC enrollment and completion rates between February 2021 and December 2021. We conducted a cross-sectional study to assess EAC completion rates among adult PLHIV on ART at Matero GH. We compared EAC enrollment and completion rates between individuals receiving HIV care between February 2021 and June 2021 and those receiving HIV care July 2021 and December 2021. We collected data from the national electronic medical record system and facility's high viral load register to identify unsuppressed adult PLHIV needed to be enrolled in EAC. We conducted descriptive statistics on the collected data.

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Lessons learned: Only 218 out of 363 clients (60%) with high viral load test results were enrolled for enhanced adherence counselling at Matero GH in the period between February and June 2021, leaving a deficit of 145 (40%) clients required to be enrolled for EAC. By December 2021, all 363 ART clients had enrolled into EAC in-person or via telemedicine. A total of 355 clients (98%) had completed EAC and 344 (97%) had achieved viral load suppression.

Conclusions/Next steps: Targeted EAC mentorship for clinicians serving PLHIV coupled with telemedicine services during and beyond the COVID-19 pandemic has the potential significantly improve EAC uptake and health outcomes for PLHIV. There is need to provide continued mentorships to clinicians serving PLHIV to ensure that gains from these investments are not lost.

EPC429

Telemedicine results in shorter clinical visit turnaround time for adult recipients of care in Lusaka, Zambia: implications for treatment initiation and adherence

E. Mulenga[1], M. Chabala[1], C. Mutale[1]

[1]*Morehouse School of Medicine, National Center for Primary Care, Atlanta, United States*

Background: The amount of time it takes for Recipients of Care (RoC) to receive healthcare services is a significant contributor to adherence to their HIV treatment and viral load suppression. RoC must visit health facilities regularly to maintain their wellbeing, receive medications, and check viral load. The length of their visits often determines their willingness to keep future appointments based on other responsibilities competing for their time.

The Morehouse School of Medicine in Zambia is implementing a telemedicine program to improve care for people living with HIV (PLHIV) and to compare the turnaround time (TAT) for RoC utilizing the telemedicine platform with in-person visits at government clinics.

Description: We collected patient TAT data in Ministry of Health (MOH) ART clinics from April 2021 to September 2021 from four Morehouse School of Medicine-supported health facilities in Zambia: Chawama, Chilenje Kanyama, and Matero General Hospital. Patient TAT for telemedicine services was collected from July 2021 to September 2021. We worked with the MOH and the Lusaka Provincial Health Office to assess the amount of time the RoC spent waiting to receive a health service.

We utilized a quantitative data collection tool to capture time in and time out and compared the waiting time and duration of visits between the telemedicine platform and in-person visits.

Lessons learned: The mean length of waiting time for the in-person facility visit against the telemedicine platform improved from 45 minutes to 15 minutes for tuberculosis preventive therapy, from 52 minutes to 23 minutes for enhanced adherence counseling, and from 45 minutes to 21 minutes for new treatment post-initiation review.

Conclusions/Next steps: We have demonstrated that telemedicine significantly reduces clinical visit turnaround times for RoC. Expansion of telemedicine services to more RoC has the potential to contribute to improving clinical appointment adherence and treatment out comes by reducing length of appointments.

Strategies to improve re-engagement

EPC430

Change in HIV clinical characteristics from time of loss to follow-up to return to care

L.E. Browne[1], D.M. Agil[1], T. Davy-Mendez[1], C. Farel[1], A. Durr[1], H. Henderson[1], K.-P. Li[1], J.J. Eron[1], S. Napravnik[1]

[1]*University of North Carolina at Chapel Hill, School of Medicine, Chapel Hill, United States*

Background: Consistent contact with HIV care improves outcomes among persons with HIV (PWH); however, many PWH have gaps in care.

In this study, we evaluated loss to follow-up (LTFU) and patient characteristics between LTFU and return to care (RTC).

Methods: Among PWH initiating HIV care (≥2 HIV clinic visits in 12 months) from 1996-2019 in the UNC CFAR HIV Clinical Cohort, we estimated

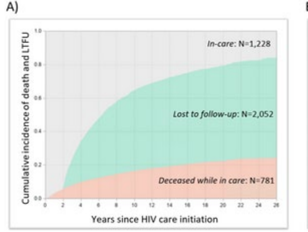
(1) time from first visit to LTFU (24 months alive without a visit) and

(2) time from LTFU to RTC (first subsequent visit), censoring PWH on 12/31/2021 and accounting for competing risk of death (from health records and death registries).

For PWH returning to care, we compared CD4 counts and virological suppression (HIV RNA <400 copies/mL) at LTFU and RTC.

Results: The median age at first visit among 4,061 PWH was 38 years (IQR: 30-46), and 28% were women, 60% Black, 29% White, and 7% Hispanic. During a median follow-up time of 6.2 years (IQR 3.2-11.2), 781 (19%) had a documented death and 2,052 (51%) were LTFU.

LTFU was highest during the first few years of HIV care (Fig. A). Among patients with LTFU, 27% (N=561) returned to care, and 16% (N=331) died without RTC (Fig. B).



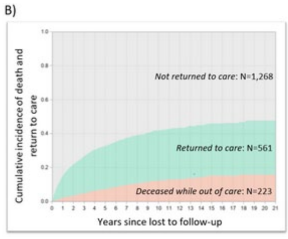


Figure. Stacked cumulative incidence of (A) loss to follow-up (LTFU) and (B) return to care (RTC). Deaths treated as a competing event.

Among patients who RTC (N=561), the median gap in care was 3.1 years (IQR: 2.4-4.9). Upon RTC, CD4 cell counts decreased, stayed the same, and increased among 50, 17, and 32% of patients respectively; 45% had undetectable HIV RNA levels at LTFU, versus 33% at RTC.
Conclusions: In this large HIV clinic population over 1996-2021, >50% of patients experienced gaps in care, with <10% returning to care with evidence of receiving effective HIV therapy elsewhere. Further work is ongoing to assess LTFU patients who died or RTC with low CD4s to inform clinic-based interventions for re-engagement.

EPC431

Loss to follow-up in HIV care: Issues in retention and re-engagement among People Living with HIV (PLHIV) in 13 African countries

V.O. Popoola[1], L. Buzaalirwa[2], E. Ijezie[3], T. Popoola[4], E. Nwabueze[3], P. Iutung[5]
[1]AIDS Healthcare Foundation, Training and Quality Services, Abuja, Nigeria, [2]AIDS Healthcare Foundation, Quality Services, Kampala, Uganda, [3]AIDS Healthcare Foundation, Abuja, Nigeria, [4]Victoria University of Wellington, School of Nursing, Midwifery and Health Practice, Wellington, New Zealand, [5]AIDS Healthcare Foundation, Kampala, Uganda

Background: Retention of People Living with HIV (PLHIV) in care is critical to attaining favorable treatment outcomes and the overall achievement of the 90-90-90 objectives. However, despite the importance of retention in HIV care, LFTU continues to pose serious challenges to effective HIV antiretroviral therapy.
Given the above, this study aims to identify factors contributing to disengagement from HIV care and the factors contributing to retention among previous LFTU clients in 13 African Countries.
Methods: This study was a descriptive cross-sectional study among PLHIV who have ever disengaged from care between January 2019 and December 2020 in 13 African AHF-supported countries. Based on individual preferences (face-to-face or telephone), survey responses were collected from 430 participants. The participating countries include Uganda, South Africa, Nigeria, Ethiopia, Rwanda, Zambia, Eswatini, Lesotho, Kenya, Malawi, Mozambique, Zimbabwe, and Sierra Leone. Data was aggregated using google forms and analyzed using Statistical Package for Social Sciences Version 20.0.
Results: The average age of the participants was 34 years, and most were females (62.3%). Uganda accounts for the highest (19.8%) number of participants. 40% of the participants were currently receiving treatment in another facility, and the primary reason (89.8%) for going to another facility is distance.
Factors leading to exiting the clinic include personal challenges (75%), health facility-related issues (10%), treatment fatigue (5%), spiritual beliefs (3%), and others (7%) which include stigma, medication side effects, and work. About half (48.6%) had experienced symptoms of mental illness in the last year. Most of the respondents (72.9%) who are currently not receiving treatment are willing to return to care, and about 15% returned within one month after the survey.
Predictors of poor retention in care were low socio-economic status, poor adherence, not being a support group member, previous history of mental illness, stigma, and non-disclosure to partners.
Conclusions: Understanding clients' present status and their reasons for disengagement are helpful in designing appropriate strategies necessary for minimizing LFTU and improving retention/re-engagement.
Attention needs to be paid to the client's mental health status and participation in support group activities. Also, scheduled follow-up might be useful in client re-engagement even after a client has been declared LFTU.

EPC432

Substance use and psychosocial factors limit inpatient to outpatient transition of HIV care

L. Hill[1], C. Thompson[1], A. Karim[1], T.C. Martin[1], M.Y. Karris[1], S. Balcombe[1], L. Bamford[1], R. Deiss[1]
[1]University of California, San Diego, United States

Background: For patients hospitalized with HIV-related illness, timely outpatient follow-up serves the dual role of engagement (or re-engagement) in care and prevention of disease complications. Despite significant efforts to improve linkage and retention in care, hospital follow-up outcomes remain understudied in HIV treatment settings. We sought to characterize factors associated with missed follow-up appointments and hospital readmission.
Methods: The Owen Clinic is an HIV primary care center affiliated with a tertiary-care university hospital in San Diego, California. An inpatient transitions-of-care team assesses all hospitalized patients with HIV and schedules outpatient follow-up appointments within 14 days as appropriate.
We retrospectively analyzed data from 114 patients who were referred for an early hospital follow up appointment (EHFUA) between June, 2020 – November, 2021.
Multivariate logistic regression was used to determine factors associated with attendance at the EHFUA, attendance at a discharge visit within 30 days of hospitalization, and hospital readmissions within 45 days of discharge.
Results: 70.7% (80/114) of patients attended their scheduled EHFUA and 79.9% (91/114) attended a visit within 30 days of discharge (Table 1). In multivariate analysis, active substance use disorder (SUD) was associated with lack of EHFUA attendance (OR 0.33; 95% CI [0.14-0.82] and the presence of the composite of SUD, mental health disorder (MHD), and unstable housing was associated with lack of attendance to a discharge visit within 30 days (OR 0.23

Oral abstracts

Author Index

95% CI [0.08-0.65]). Additionally, 19.3% (22/114) experienced hospital readmission within 45 days. Having the composite of SUD, MHD and unstable housing was associated with hospital readmission (p=0.004, OR 4.48 (1.63-12.28), while follow-up appointment attendance was not.

Patient Characteristics	Total (n=114)	Attended visit (n=80)	Missed visit (n=34)	Unadjusted P-value
Median Age (IQR)	51 (40-60)	51 (39-61)	51 (43-60)	0.46
Sex assigned at birth (%) Female	15 (13.2)	11 (13.8)	4 (11.8)	1.00
Race (%) White Black Asian Other/Mixed Race Unknown	 63 (55.3) 20 (17.5) 4 (3.5) 25 (21.9) 2 (1.8)	 42 (52.5) 11 (13.8) 4 (5.0) 22 (27.5) 1 (1.3)	 21 (61.8) 9 (26.5) 0 (0) 3 (8.8) 1 (2.9)	0.08
Undetectable HIV viral load (%)	42 (36.8)	34 (42.5)	8 (23.5)	0.06
Diagnosed with Substance Use Disorder (SUD) (%)	63 (55.3)	38 (47.5)	25 (73.5)	**0.01**
Diagnosed with a mental health disorder (MHD) (%)	72 (63.2)	46 (57.5)	26 (76.5)	0.06
Homeless or have unstable housing (%)	50 (43.9)	30 (37.5)	20 (58.8)	**0.04**
Presence of SUD, MHD and unstable housing (%)	37 (32.5)	21 (26.3)	16 (47.1)	**0.048**
Have insurance-related barrier to care (%)	28 (24.6)	16 (20.0)	12 (35.3)	0.10

Table.

Conclusions: Despite high rates of hospital follow-up, challenges remain in re-engaging patients with certain psychosocial barriers, particularly SUDs and unstable housing. Prompt identification of these barriers and inpatient treatment of SUDs with appropriate follow-up may further improve outpatient participation in HIV care.

EPC433

Data linkages, resource sharing, and collaboration: optimizing HIV Out-of-Care Re-engagement between siloed public health entities in Florida, USA

K. Denny[1], A.M. Stringer[1], K. Poschman[2], C. Cohen[2], C. Angell[1]

[1]*Georgetown University, Center for Global Health Practice and Impact, Washington, United States,* [2]*Florida Department of Health, HIV/AIDS Surveillance Program, Tallahassee, United States*

Background: Florida - the third most populated US state - had the third highest HIV incidence rate in 2019 (23.9/100,000). In 2020, 20% of people with HIV (PWH) were presumed out-of-care (OOC). The Florida Department of Health (FDOH) utilizes HIV surveillance data to identify cases for targeted re-engagement throughout the state. Highly prioritized OOC PWH are assigned to case managers at county health departments (CHDs). Current FDOH re-engagement efforts reach a fraction of the OOC population.

The US government funds six high-incidence regions in Florida via Ryan White Part A (RWPA), to improve HIV care provision. Florida's RWPA programs are governed at the county level - meaning the state cannot share person-identifiable data with these programs. This results in inefficient/duplicative re-engagement efforts and underutilized RWPA funding, limiting efficacy of efforts to end the HIV epidemic.

Description: Georgetown University (GU) is funded by the Health Resources and Services Administration to assist with data integration for improved HIV care outcomes. GU supports FDOH in designing an optimized HIV care re-engagement program. FDOH receives data from the six RWPAs, matches these data to state systems, and returns updated data to the RWPAs for OOC re-engagement. FDOH will simultaneously send expanded OOC lists for re-engagement to the CHDs, utilizing RWPA funded staff. This circumvents privacy regulations that prevent data sharing of non-clients with the RWPA programs.

Lessons learned: Communication and collaboration between agencies and their data systems is crucial in optimizing high-quality data use for widespread OOC re-engagement. In one RWPA, 494 clients presumed OOC reduced to 189 after an FDOH match. This initiated re-engagement for a subset of the initial client list, reducing time spent on individuals who were deceased or already receiving care.

Conclusions/Next steps: Resource sharing and collaborative planning between various arms of the public health sector can allow for drastic increases in the number of OOC clients who are receiving re-engagement services – improving prospects for re-engagement into HIV care.

Further analysis of the implications of expanding the CHD OOC re-engagement effort due to resource sharing by the RWPA is needed, and the impact of routine data sharing will be evaluated as this program grows.

Epidemiology of COVID-19

EPC434

The impact of COVID-19 on a health workforce providing HIV services in South Africa

K. Rees[1,2], J. Dunlop[1], C. O'Connor[1]

[1]*Anova Health Institute, Johannesburg, South Africa,* [2]*University of Witwatersrand, Department of Community Health, Johannesburg, South Africa*

Background: The COVID-19 pandemic has decreased access to HIV services, in part due to impacts on the health workforce. There is limited evidence about how COVID-19 has affected HIV-service providers.

Methods: Anova Health Institute is a PEPFAR partner supporting five districts in South Africa. All COVID-19 cases and exposures in health care workers (HCW) employed by Anova were reported from Apr2020-Dec2021. Anova supported testing for symptomatic and exposed HCWs and maintained a database of cases.

We report monthly incidence and factors associated with COVID-19 diagnosis in each wave using logistic regression.

Results: 5653 individual HCW were employed at any time during the study period. 1529 (27%) were diagnosed with COVID-19, 130 (8%) had multiple episodes. Monthly incidence was 7% in the Alpha wave (July 2020), 4% in Beta and Delta (January and July 2021) and 13% in Omicron (December 2021).

The highest proportion of HCW off work was in Alpha and Omicron waves. During the peak week of Alpha, 540 HCW (14%) were off (331 quarantined; 209 cases). During the peak week of Omicron, 500 HCW (16%) were off (225 in quarantine; 275 cases). There was at least one HCW off work due to COVID-19 every week during the study period (91 weeks), and only 14 weeks when there were fewer than 10 HCWs off work.

In the Omicron wave, COVID-19 infection was less likely among HCW in allied roles (OR=0.45, 95%CI 0.24; 0.85), more likely among those who had COVID-19 in the first wave (OR=1.67, 95%CI 1.17;2.38) and less likely among those who had COVID-19 in the third wave (OR=0.58, 95%CI 0.34;0.98). Associations varied in each wave.

In November 2021, 67% of HCW reported being vaccinated, which increased to 81% by the end of the Omicron wave. 85% of cases in the fourth wave were vaccinated.

Conclusions: This primary care-based HIV workforce was heavily impacted by COVID-19. Although the number of HCW quarantined due to exposure decreased, it was still substantial by December 2021.

To ensure continuity of services, there is an urgent need to update South African COVID-19 quarantine and isolation guidelines to account for higher levels of natural and vaccine-related immunity.

EPC435

Preliminary estimate of SARS-CoV-2 vaccine effectiveness among healthcare workers – Zambia, 2021

J. Simwanza[1], O. Mweso[1], J.Z. Hines[2], W. Malambo[2], N. Sinyange[3]

[1]Zambia National Public Health Institute/Zambia Field Epidemiology Training Program, Surviellance, Lusaka, Zambia, [2]Centers for Disease Control and Prevention Zambia, Lusaka, Zambia, [3]Zambia National Public Health Institute, Workforce Development, Lusaka, Zambia

Background: During the COVID-19 pandemic, healthcare workers (HCWs) have been at a higher risk of infection because of frequent patient interactions. Deployment of SARS-CoV-2 vaccines, which have demonstrated remarkable vaccine effectiveness (VE), is key to protecting the health workforce.

However, VE data from countries in Africa are limited. We evaluated SARS-CoV-2 VE in preventing symptomatic COVID-19 among Zambian HCWs.

Methods: A test-negative case-control study among HCWs with COVID-like illness (CLI) was initiated in June 2021 and this preliminary analysis presents data through 30th November 2021 (the period before the Omicron variant was detected in Zambia). Cases had confirmed COVID-19 and controls tested COVID-19 negative.

A standardized questionnaire was administered that included information on demographics, medical history, and COVID-19 testing. COVID-19 testing was done with either PCR or RDTs.

The odds of symptomatic COVID-19 by vaccination status were assessed using mixed-effects logistic regression, adjusting for age, comorbidities, test week, and province (random-effects term). VE was calculated as 1 minus the adjusted odd ratios of vaccination times 100.

Results: Among 549 HCWs (348 cases and 201 controls) with CLI, 256 (46.6%) had received ≥1 vaccine dose, with 104 (18.9%) being vaccinated with their first dose ≥14 days before testing, but only 14 (2.6%) having completed their primary series. Of the 104 HCWs, 100 (96.2%) received AstraZeneca and four (3.8%) received Janssen. Having received ≥1 vaccine dose ≥14 days before COVID-19 testing was associated with a VE against symptomatic COVID-19 of 40.4% (95% confidence interval [CI]: 1.7–63.7).

Conclusions: Covid-19 vaccines were effective at reducing symptomatic COVID-19 among HCWs in Zambia. The VE point estimate is consistent with studies from other countries where persons were partially vaccinated and the Delta variant was the dominant strain, as in Zambia during the study period. Many Zambian HCWs recruited were unvaccinated, signaling a high-risk group in which to rapidly scale-up vaccination.

EPC436

SARS-CoV-2 antibodies prevalence among sexual and gender minorities youth in Brazil

L. Magno[1,2], C. Carvalho dos Santos[3], F. W. Mendonça-Lima[3], D. Ferraz[4,5], A. Grangeiro[6], M. Préau[7], I. Dourado[2]

[1]Universidade do Estado da Bahia, Departamento de Ciências da Vida, Salvador, Brazil, [2]Universidade Federal da Bahia, Instituto de Saúde Coletiva, Salvador, Brazil, [3]Universidade Federal da Bahia, Faculdade de Farmácia, Salvador, Brazil, [4]Fundação Oswaldo Cruz, Escola FIOCRUZ de Governo, Brasília, Brazil, [5]Université Lyon 2, UMR 1296 Radiations - Défense, Santé, Environnement, Bron, France, [6]Universidade de São Paulo, Faculdade de Medicina Preventiva, São Paulo, Brazil, [7]Université Lumière Lyon, Bron, France

Background: Brazil was strongly affected by the COVID-19 and it is still unknown how it affected sexual and gender minorities' youth in the country during its burdensome first wave. The aim was to estimate the seroprevalence of antibodies to SARS-CoV-2, and analyze factors associated with the infection among young men who have sex with men (yMSM) and transgender women (yTGW).

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

Methods: A cross-sectional survey nested in PrEP1519, a cohort that investigates the effectiveness of PrEP, and monitors sexual practices among yMSM and yTGW in Salvador, Northeast of Brazil. Serum samples were collected from yMSM and yTGW aged 15-22 years between June-October/2020. IgG and IgM anti-SARS-CoV-2 were detected by chemiluminescence, and data were collected through a socio-behavioral questionnaire.

Descriptive, bivariate, and multivariate analyzes with estimated adjusted odds ratios (aOR) and 95% confidence intervals(95%CI) were carried out.

Results: Among the 137-youth participants, the joint prevalence of IgM and IgG was 20.4% (95%CI:14.4- 28.1), and separately: 11.7% (95%CI: 7.2-18.3) for IgM and 16.8% (95%CI:11.3-24.1) for IgG. The rate of self-reporting COVID-19 infection based on symptoms but without tests was 7.6% and based on tests was 5.3%. Most remained sexually active during quarantine measures reporting sex with steady and/or casual partners(67.2%); 19.1% reported never wearing a mask in public venues, and 23.9% believed they could easily recover from COVID-19.

Among the participants with positive SARS-CoV-2 antibodies, most remained sexually active during quarantine measures reporting sex with steady and/or casual partners (66.6%); little more than a third reported not wearing a mask in public venues (36%), and believed they could easily recover from COVID-19 (34.4%).

The multivariate analysis estimated a statistically significant association between SARS- CoV-2 infection and reports of no use of masks in public venues (aOR=3.11; 95%CI:1.02-9.42), and among those who believed that they could easily recover from COVID-19 (aOR=2.68; 95%CI:1.03-6.95).

Conclusions: The prevalence of SARS-CoV-2 antibodies among yMSM and yTGW was higher than that estimated in seroprevalence surveys conducted in 2020 in the general population of Salvador, indicating a low perception of risk and low adherence to quarantine measures among yMSM and yTGW during the first wave, and likely underreporting of official seroprevalence data for Salvador.

EPC437

Knowledge, attitudes, practices and perceptions of the populations of the Koulikoro region (Mali) on the COVID-19 pandemic

F.d.S. Keita[1], F. Sidibe[1], A.S. Sidibe[1], E. Diabs[1], M.B. Traore[2], H. Konare[1], O. Sidibe[1]

[1]ONG SOUTOURA, Bamako, Mali, [2]CDC, Bamako, Mali

Background: Given the seriousness of the COVID-19 pandemic, with 16,294 confirmed cases including 574 deaths, a case fatality rate of 3.51% as of November 5, 2021, its impact on the global economy and, by extension, on Mali (growth forecasts for the year 2020 have dropped from 5% to 0, 9%), the NGO SOUTOURA, with financial support from CDC Atlanta, conducted a CAP research project aimed at collecting the knowledge, attitudes, and practices of the populations of the Koulikoro region on the COVID-19 pandemic.

Translated with www.DeepL.com/Translator (free version)

Methods: Analytical cross-sectional study conducted from November 1 to 30, 2021. A two-stage cluster search was conducted in the health districts. Univariate and multivariate analyses were performed using SPSS 25 software.

Results: One thousand (1000) people were interviewed in the Koulikoro region. The respondents (94.7%) knew about preventive measures. In fact, the majority of respondents (93%) do not see the need for vaccination in adulthood, except in the case of international travel and, more widely, vaccination against tetanus in the event of accidents.

Notwithstanding those in favor of vaccinating family members against COVID-19, a significant proportion of respondents said "I don't trust the COVID-19 vaccine" (14.6%) to indicate their lack of support for vaccination against COVID-19. The majority of respondents feel that they alone are in control of their decision to be vaccinated against COVID-19 Me (44.8%), followed by those who leave it to My spouse/partner (28.2%) and My father (19.7%).

Inevitably, the population as a whole has not been happy with the arrival of COVID-19 in their daily lives, with its attendant inconveniences due to the many upheavals in their daily routine

Translated with www.DeepL.com/Translator (free version)

Conclusions: In practice, however, certain ambiguities remain to be resolved in order to achieve the objectives of the fight against COVID-19 in terms of collective immunity.

Epidemiology of COVID-19 among persons living with HIV and / or including tuberculosis

EPC438

HIV infection and risk of COVID-19 death in sub-Saharan Africa. A meta-analysis

B. Bepouka[1], M. Mandina[1], M. Longokolo[1], N. Mayasi[1], O. Odio[1], M. Mbula[1], J.R. Makulo[1], J.M. Kayembe[1], H. Situakibanza[1]

[1]University of Kinshasa, Internal Medicine, Kinshasa, Congo, Democratic Republic of the

Background: Little is known about COVID-19 outcomes among People living with HIV in sub-Saharan Africa. The goal of this meta-analysis was to determine the relationship between HIV infection and the risk of coronavirus disease 2019 (COVID-19) mortality in Sub-Saharan African countries.

Methods: From December 1, 2019 to December 31, 2021, we systematically retrieved papers from PubMed, Google Scholar, Europe PMC, and EMBase. Studies from Niger, the Democratic Republic of the Congo, Uganda, Kenya, and South Africa are all represented in this meta-analysis.

The quality of the included studies was assessed using the Newcastle–Ottawa Scale (NOS). To quantify heterogeneity, the Cochran Q test and I2 statistics were used.

The odds ratio (OR) and 95% confidence intervals (CI) were calculated and plotted as forest plots. The Egger test and the funnel plot were used to look for potential publication bias. The review manager version 5.4 was utilized to analyze all the statistical data.

Results: Through computerized searches, a total of 560 records were found. Six papers were finally included in this review. In total, 7208 COVID-19 patients with HIV infection and 53073 COVID-19 patients without HIV infection were included. Among COVID-19 patients with HIV, the mortality rate was 10.90% (786/7208).

According to one study, those living with HIV have a greater risk of COVID-19 death than those who do not have HIV. According to five studies, there was no link between HIV infection and COVID-19 mortality risk. The OR effect size ranged from 0.03 to 10.27 in the various investigations. There was no substantial heterogeneity among the six studies (Q=2.92, p 0.71; I2=0%).

In this meta-analysis, the overall effect size (OR) was 1.13 (95% CI 1.04–1.23). The funnel plot analysis revealed symmetry among the research considered. The Egger test revealed that there was no publication bias (t = 0.56, P =0.586).

Conclusions: This meta-analysis found a link between HIV infection and the probability of death from the COVID-19. Those with HIV co-infection should be treated as a priority group during COVID-19 clinical treatment to reduce death risk.

EPC439

SARS-CoV-2 seroprevalence in children born to women living with HIV on life-long antiretroviral therapy (ART) in Zimbabwe: PEPFAR-PROMOTE study

T.A. Matubu[1], N. Dhibi[1], T. Chidemo[1], K. Nyarota[1], T. Nematadzira[2], J. Gumbo[2], T. Chipato[1], S. Dadabhai[3], J. Aizire[3], R.E. Fernandez[4], T.E. Taha[3], M.G. Fowler[5], L. Stranix-Chibanda, for PROMOTE study team[2,6]

[1]University of Zimbabwe-Clinical Trials Research Centre, Faculty of Medicine and Health Sciences, Unit of Obstetrics and Gynaecology, Harare, Zimbabwe, [2]University of Zimbabwe-Clinical Trials Research Centre, Harare, Zimbabwe, [3]Johns Hopkins Bloomberg School of Medicine, Department of Epidemiology, Baltimore, United States, [4]Johns Hopkins School of Medicine, Department of Medicine, Baltimore, United States, [5]Johns Hopkins University School of Medicine, Department of Pathology, Baltimore, United States, [6]University of Zimbabwe, Child and Adolescent Health Unit, Faculty of Medicine and Health Sciences, Harare, Zimbabwe

Background: There is paucity of data on seroprevalence of SARS-CoV-2 infection in children, especially in children born to women living with HIV (WLHIV) who may be at higher risk of severe disease and mortality due to immune compromise.

We retrospectively estimated SARS-CoV-2 antibody prevalence within the PEPFAR-PROMOTE observational cohort between July and October 2021 in Zimbabwe.

Methods: Children were enrolled in 2016 in the PEPFAR-PROMOTE longitudinal cohort to study long-term effects of perinatal exposure to maternal HIV and ART. Blood was collected six-monthly at scheduled visits during the 5-year study and stored in -70C conditions. Stored plasma samples from children who attended study visits during the study period and for whom consent was available were tested using 2021 EUROIMMUN qualitative antibody assay for IgG antibodies to SARS-CoV-2 spike protein. Point prevalence estimates and 95% confidence intervals (CI) were calculated by age group and sex.

Results: Plasma samples from 578 children born to 386 WLHIV were tested, of which 270 (46.7%) were male and 7 (1.2%) were living with HIV. Children were aged <2 years (predominantly being breastfed; n=74, 12.8%); 2-5 years (pre-school, n=134, 23.2%); and >5 years (mostly school-going; n=370, 64%).

Almost all participants resided in high-density urban areas of Harare and Chitungwiza, Zimbabwe. The overall SARS-CoV-2 IgG seroprevalence was 47% (43–51%). Seroprevalence estimates by category were 45% (34-56%) for 0-2 years, 43% (35-52%) for 2-5 years49% (44-54%) for >5 years, 41% (35 – 47%) for males and 51% (46 – 57%) for females.

No association with age band was evident (p=0.36) in this cohort, however, seropositivity was more common among female children (p=0.03).

Conclusions: Prevalence of SARS-CoV-2 antibodies was high in this population of HIV/ART exposed urban children during the third COVID-19 wave. Further analysis is required to assess sero-concordance within mothers and siblings and to assess associations with clinical symptom, Innovative prevention strategies are required to avoid spread of the virus in children within families and communities taking into account prevailing cultural and living conditions. The long-term consequences of these infections remain to be elucidated.

EPC440

Social vulnerability and COVID-19 vaccination rates among people living with HIV in Michigan

C. Convery[1], J. Diesel[2], J. Miller[3], S. Karram[3], A. Brantley[3]
[1]Michigan Department of Health and Human Services, Division of HIV/STI Programs, Detroit, United States, [2]Centers for Disease Control and Prevention, Detroit, United States, [3]Michigan Department of Health and Human Services, Detroit, United States

Background: People living with HIV (PLWH) are a priority population for COVID-19 vaccination due to potential for immunodeficiency if not virally suppressed. They are also more likely to reside in socially vulnerable census tracts.

Methods: HIV surveillance data was matched with immunizations records to ascertain the COVID-19 vaccination status of people living with HIV in Michigan as of July 30, 2021.

Results: As of July 30, 2021, 59% of PLWH had initiated a COVID-19 vaccine. People in the most vulnerable 25% of census tracts were less likely to initiate vaccination (OR [95% CI]: 1.9 [1.7-2.1]), as were younger PLWH, Black PLWH, and women. People who were virally suppressed and people who had received a Ryan White (RW) service in the past year were significantly more likely to have initiated vaccination.

Social Vulnerability	Vaccine Initiation	
	OR	95% CI
1 (Least Vulnerable)	1.903	(1.712,2.115)
2	1.68	(1.527,1.848)
3	1.34	(1.234,1.454)
4 (Most Vulnerable)	(reference)	

Table. Association Between SVI Theme Quartile And Vaccine Initiation In People Living With HIV, Michigan, July 30, 2021

Conclusions: Living in a socially vulnerable census tract was associated with lower vaccination likelihood for people living with HIV, indicating a need for targeted approaches to vaccination campaigns based on SVI components of socio-economic status; household composition and disability; racial/ethnic minority status and language; and housing type and transportation.

EPC441

COVID-19 outcomes and vaccination coverage among migrants living with HIV in Catalonia, Spain: a propensity score-adjusted analysis using the prospective PISCIS cohort

D.K. Nomah[1], A. Bruguera[1], Y. Diaz[1], S. Moreno[1], J. Aceiton[1], J.M. Llibre[2], V. Falcó[3], A. Imaz[4], F.J. Fanjul[5], J. Peraire[6], E. Deig[7], P. Domingo[8], J.M. Miro[9], J. Casabona[1], PISCIS Study Group
[1]Centre for Epidemiological Studies of Sexually Transmitted Disease and HIV/AIDS in Catalonia (CEEISCAT), Badalona, Spain, [2]Hospital Universitari Germans Trias i Pujol, Badalona, Spain, [3]Hospital Universitari Vall d'Hebron, Vall d'Hebron Research Institute (VHIR), Barcelona, Spain, [4]Hospital Universitari de Bellvitge, Bellvitge Biomedical Research Institute (IDIBELL), University of Barcelona, L'Hospitalet de Llobregat, Spain, [5]Hospital Son Espases, Palma de Mallorca, Spain, [6]Hospital Joan XXIII, Tarragona, Spain, [7]Hospital General de Granollers, Granollers, Spain, [8]Hospital de la Santa Creu i Sant Pau, Barcelona, Spain, [9]Hospital Clínic-Institut d'Investigacions Biomèdiques August Pi i Sunyer, University of Barcelona, Barcelona, Spain

Background: Migrants are disproportionally impacted by some transmissible infections affect because of the social and structural determinants affecting this group.
We performed a retrospective propensity-score matched cohort study to assess COVID-19 outcomes and SARS-CoV-2 vaccination coverage among migrants and natives living with HIV.

Methods: Leveraging data from the PISCIS cohort of people living with HIV (PLWH) in Catalonia, Spain between March 1, 2020, and July 18, 2021, we matched 4770 migrants with 4770 Spanish PLWH using a greedy nearest-neighbor algorithm. Patients were matched by age, sex, socioeconomic deprivation, HIV acquisition risk group, latest CD4 count, latest plasma HIV-RNA, number of comorbidities, and backbone antiretroviral therapy (ART).
We compared COVID-19 testing, test positivity, hospitalization, intensive care unit (ICU) admission, associated mortality, and vaccination coverage between the two groups.

Results: There were 14939 PLWH in our overall cohort (males: 82%; median age: 46.4 years) of which 8808 were Spanish and 6131 migrants. After propensity score matching, all variables were adequately matched (standardized mean differences [SMD] <0.10 were achieved on all covariates). After matching, 82.8% and 82.4% of Spanish-born PLWH and migrants respectively were males (SMD=0.011) with a median age of 44.8 years.
More than half (58.2%) of participants were men who have sex with men (MSM). The median CD4 count was 681 cells/mm3, and 89.2% and 88.9% of natives and migrants respectively had undetectable HIV viraemia (SMD=0.011). COVID-19 testing was significantly lower among migrants (56.3% vs 59.2%, P=0.004) but test positivity was higher (14.0% vs 11.5%, P<0.00001).

Among positive cases, we found no significant differences between the two groups in terms of hospitalization (P=0.43), ICU admission (P=0.87), and mortality (P=0.99). Regarding vaccination, coverage was higher among Spanish PLWH than migrants (70.4% vs 60.8%, P<0.00001).

Conclusions: Migrants living with HIV tested lower for SARS-COV-2, had higher test positivity, and lower vaccination coverage compared to their native counterparts. Country of origin does not significantly impact COVID-19 clinical outcomes among PLWH, including hospitalization, ICU admission or mortality.

These results reinforce the importance of identifying and addressing the structural determinants that are currently acting as barriers to health services among migrant populations in our settings.

EPC442

Safety and immunogenicity of SARS-CoV-2 vaccines among a marginalized urban population of people living with HIV

H. Reddon[1], B. Barker[2], K. DeBeck[3], K. Hayashi[3], A.C. Marquez[4], I. Sekirov[5], M. Morshed[5], A. Jassem[5], M.E. Socias[5], S. Bartlett[4], M-J Milloy[5]

[1]University of British Columbia, Medicine, Vancouver, Canada, [2]BC Centre on Substance Use, Vancouver, Canada, [3]Simon Fraser University, Vancouver, Canada, [4]BC Centre for Disease Control, Vancouver, Canada, [5]University of British Columbia, Vancouver, Canada

Background: We sought to evaluate the uptake, safety and immunogenicity of SARS-CoV-2 vaccines among structurally-marginalized people living with HIV who use drugs.

Methods: Study participants completed an interviewer-administered questionnaire and provided a dried blood spot sample (DBS) between June-September 2021 in Vancouver, Canada. DBS samples were tested on the V-PLEX COVID-19 Coronavirus Panel 2 (IgG) by Meso Scale Discovery (MSD).

Mixed-effects models were used to identify baseline correlates of SARS-CoV-2 vaccine uptake, adverse events, and SARS-CoV-2 IgG antibody response.

Results: We enrolled 97 participants living with HIV, of whom 56 (57.7) reported receipt of two SARS-CoV-2 vaccine doses, and 17 (17.5%) reported being unvaccinated. Self-reported COVID-19 infection was associated with a lower odds of vaccination (Odds Ratio [OR]=0.28, 95% confidence interval: 0.08-0.92, P=0.036).

Among those who were unvaccinated, the anti–SARS-CoV-2 Spike antibody geometric mean titre (GMT) was 34.1 AU/mL. Among people who had received two SARS-CoV-2 vaccine doses, the anti–SARS-CoV-2 Spike antibody GMT was 1,088.7, 2,213.8, 2,357.2 and 1,595.8 AU/mL among those receiving their second vaccination within 0-30, 31-60, 61-90 and 91-120 days of DBS collection, respectively (trend P=0.679).

We did not observe any significant associations between sociodemographic factors, substance use or clinical conditions and adverse events or vaccine immunogenicity (P>0.05). No serious adverse events were reported, and the most common adverse events included pain at injection site (n=23, 23.7%) and fatigue (n=13, 13.4%).

Conclusions: The observed vaccination uptake among this marginalized urban population (57.7% with two doses) was below the rate (75.0%) reported in the provincial population at the time data were collected. Anti-SARS-CoV-2 Spike antibody responses appeared to wane among participants after 90 days following vaccination although this trend was not statistically significant.

Adverse events and vaccine immunogenicity did not appear to vary across sociodemographic, substance use or clinical subgroups.

Given that suspected prior COVID-19 infection was associated with lower odds of vaccine uptake, education efforts focused on the benefits of vaccination among those with previous COVID-19 exposure may be worthwhile among marginalized populations with high rates of COVID-19 infection.

EPC443

Characterizing COVID-19 outcomes among PLHIV in India: findings from community-based national survey

R. Pollard[1], M. Pardeshi[2], A. Baidya[3], D. Patel[4], N. Yadaw[4], M. Balani[4], J. Bell[1], S. Solomon[1], S. Mehta[3]

[1]The Johns Hopkins University School of Medicine, Baltimore, United States, [2]TAAL+ Integrated Health Center and Community Pharmacy, Pune, India, [3]The Johns Hopkins Bloomberg School of Public Health, Baltimore, United States, [4]National Coalition of People Living with HIV in India, Delhi, India

Background: Most data on COVID-19 impact among people living with HIV (PLHIV) derive from clinic-based samples.In India, over 490,000 people have died from SARS-CoV-2 infection, yet not much is known about the COVID-19 burden and impact among the estimated 2.3 million PLHIV.

Methods: We conducted an online survey in January 2022 (self-administered online or conducted over the phone in local languages). Community-based organizations facilitated recruitment. Eligible participants were living with HIV and ≥18 years. The survey included questions related to COVID-19 symptoms, testing, and treatment history and COVID-19 risk behaviors. Multivariable logistic regression was used to assess factors associated with a positive COVID-19 diagnosis and hospitalization.

Results: 1,749 PLHIV responded to the survey across 36 Indian states/union territories (32.8% central, 2.6% north, 27.6% east, 27.8% west, 7.8% south, and 1.5% northeast regions). Mean age was 34 years; 41% self-identified as male, 58% female and 1% transgender or gender diverse.

About half (51.3%) reported experiencing COVID-19 symptoms in the past year. Of the 934 (53.4%) who had ever been tested for COVID-19, 349 received a positive result. 78 (22.3% of people with COVID-19) were hospitalized, of whom 40 (51.2% of hospitalized) were put on a ventilator. There were no observable differences between men and women; transgender/gender diverse people (n=18) demonstrated higher disease burden and severity (Figure).

Key correlates associated with a positive COVID-19 test were working in-person during lockdown (aOR=2.0, 95%CI: 1.6-2.5) and any household member testing positive for COVID-19 (aOR=8.0, 95%CI: 5.1-12.2). Those who reported missing taking ART for at least one week or longer in the past year were 10 times more likely to report hospitalization (aOR=10.0, 95%CI: 4.5-22.0).

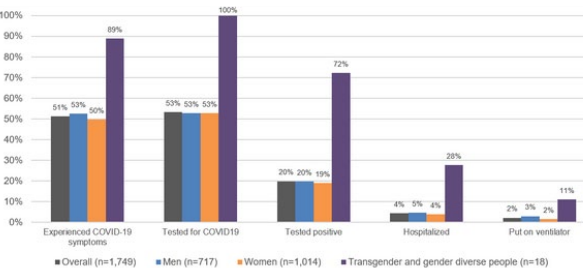

Figure. COVID-19 outcomes among 1,749 PLHIV in India stratified by gender.

Note: Percentages are relative to total population size per gender category.

Conclusions: These findings suggest substantial COVID-19 burden among PLHIV, particularly among transgender and gender diverse PLHIV. It is critical that HIV programs integrate access to non-pharmaceutical interventions and vaccines to address this burden.

Effects of the COVID-19 on HIV epidemiology and prevention

EPC444

HIV mortality among adult PLHIV in PEPFAR-supported programs - 12 countries, October 2019 - September 2021

D. Fernandez[1], K.A. Fisher[2], I. Oboho[2], N. Shah[3], S. Hackett[2], I. Faturiyele[4], E. Agyemang[2], H. Chun[2], M. Letebele[5], N. Wadonda-Kabondo[6], A. Maida[6], D. Morof[7], P. Nguyen[8], H.B.T. Minh[8], P. Nyika[9], G. Siberry[4], H. Ali[2], C. Godfrey[10]

[1]U.S. Centers for Disease Control and Prevention, Center for Global Health, Division of Global HIV and Tuberculosis, Atlanta, United States, [2]U.S. Centers for Disease Control and Prevention, Atlanta, United States, [3]U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Springs, United States, [4]United States Agency for International Development, Washington, D.C., United States, [5]Centers for Disease Control and Prevention (CDC) Botswana, Gaborone, Botswana, [6]Centers for Disease Control and Prevention (CDC) Malawi, Lilongwe, Malawi, [7]Centers for Disease Control and Prevention (CDC) South Africa, Pretoria, South Africa, [8]Centers for Disease Control and Prevention (CDC) Vietnam, Hanoi, Viet Nam, [9]Centers for Disease Control and Prevention (CDC) Zimbabwe, Harare, Zimbabwe, [10]Office of the Global AIDS Coordinator, U.S. Department of State, Washington, D.C., United States

Background: In 2019, the United States President's Emergency Plan for AIDS Relief (PEPFAR) began collecting interruption in treatment (IIT) and mortality data among people living with HIV (PLHIV) receiving antiretroviral treatment (ART) in PEPFAR-supported programs. The COVID-19 pandemic disrupted HIV service delivery worldwide and COVID-19 has disproportionately impacted older populations. We reviewed mortality over time to assess if mortality increased among older adult (50+) PLHIV on ART during the COVID-19 pandemic.

Methods: PEPFAR-supported programs submit aggregate data quarterly using standardized indicators disaggregated by age and sex. Relevant indicators, including TX_ML, which captures information on IIT and mortality, were reviewed to assess deaths reported for adult PLHIV (15–49 and 50+) on ART from October 2019–September 2021 for countries with at least 80% TX_ML reporting completeness (n=12). The proportion died was calculated quarterly as number of reported deaths in the current reporting quarter divided by the sum of the number of PLHIV on ART in the previous quarter and the number of PLHIV newly initiated on ART in the current quarter.

Results: The proportion died ranged quarterly across countries from 0.12%–0.50% and was higher in the 50+ age group and among men (Figure). Increases in proportion died were observed only in the 50+ group with increases of 0.11% (men) and 0.09% (women) compared to a 0.02% decrease (men) and no change (women) in the 15–49 group over time. In the 50+ group, proportion died

ranged between 0.24%–0.50% and was higher among men than women (range: 0.38%–0.50% (men) versus 0.24%–0.34% (women)).

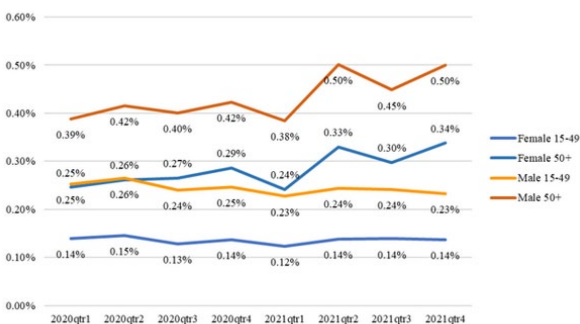

*Figure. Mortality proportion among adult persons living with HIV (PLHIV) on antiretroviral treatment (ART) by sex, age group and reporting quarter — 12 PEPFAR-supported countries, October 2019-September 2021**

** Countries included inthe analysis were Angola, Cameroon, Dominican Republic, Eswatini, Lesotho, Malawi, Nigeria, Rwanda, South Africa, Tanzania, Uganda and Vietnam.*

Conclusions: During the COVID-19 pandemic, HIV mortality increased among PLHIV 50+ in PEPFAR-supported countries with more complete data reporting. To better understand the impact of COVID-19 on HIV mortality, future studies could examine the roles of higher risk of severe COVID-19 in older populations, HIV IIT, and comorbid conditions.

EPC445

Examining the impacts of the COVID-19 pandemic on syndemic conditions and PrEP use among HIV among gay, bisexual and other men who have sex with men in Vancouver, Canada

J. Sang[1], D. Moore[1,2], L. Wang[1], J. Chia[1], J. Toy[1], J. Montaner[1,2], S. Skakoon-Sparling[3], J. Cox[4,5], G. Lambert[5,6], D. Grace[7], T. Hart[3,7], A. Lal[1], J. Jollimore[8], N. Lachowsky[8,9]

[1]BC Centre for Excellence in HIV/AIDS, Vancouver, Canada, [2]University of British Columbia, Vancouver, Canada, [3]Ryerson University, Toronto, Canada, [4]McGill University, Montreal, Canada, [5]Direction Régionale de Santé Publique -Montréal, Montreal, Canada, [6]Institut National de Santé Publique du Québec, Montreal, Canada, [7]University of Toronto, Toronto, Canada, [8]Community-Based Research Centre, Vancouver, Canada, [9]University of Victoria, Victoria, Canada

Background: The secondary impacts of the COVID-19 pandemic may disproportionately affect the health and wellbeing of gay, bisexual and other men who have sex with men (GBM), particularly related to HIV. We assessed trends of syndemic production and trends and correlates of pre-exposure prophylaxis (PrEP) interruptions among HIV-negative/unknown GBM in Vancouver.

Methods: Sexually-active GBM, aged ≥16 years, were recruited through respondent-driven sampling (RDS) from February 2017 to August 2019. Participants completed a Computer-Assisted Self-Interview every 6 months and data were linked to BC HIV Drug Treatment Program to assess PrEP uptake and continuation. We used univariable generalized-linear mixed models to examine:

1. Trends in syndemic conditions (i.e. anxiety, depression, interpersonal violence, polysubstance use, alcohol use) and;
2. Trends in PrEP interruptions (6-month periods) among HIV-negative/unknown GBM.

We also applied 3-level mixed-effects logistic regression with RDS clustering to examine the individual additive and interaction effects of syndemics among GBM reporting PrEP use before study visit and factors associated with PrEP use interruptions. Follow-up analyses includes data from before and during the COVID-19 pandemic (March 2018-April 2021).

Results: Our study included 760 participants/data on 2339 visits, from March 2018-April 2021. Depressive symptoms increased over the study period (OR=1.33, 95%CI=1.14-1.54) with an increase after the onset of COVID-19 pandemic in Canada. We also found an increasing trend of GBM reporting PrEP interruptions over time (aOR=2.59, 95%CI=1.96, 3.42). The time-period after the onset of COVID-19 (Sept 2020-April 2021) had greater odds of PrEP interruptions (aOR=16.33, 95%CI=4.73, 56.44) compared to the March 2018-March 2020 time-period. The only associated syndemic condition was depression (aOR=7.22, 95%CI=1.12,46.47). We did not find interactions with other syndemic conditions. Assessing HIV risk, GBM who met clinical eligibility for PrEP were less likely to report PrEP interruptions than GBM who were not PrEP eligible (aOR=0.15, 95%CI=0.04-0.53).

Conclusions: We found increased depressive scores and PrEP interruptions among HIV-negative/unknown GBM since the onset of the COVID-19 pandemic. However, those most at risk for HIV were less likely to have PrEP interruptions. Additional mental health services and targeted follow-up for assessment for PrEP continuation may be needed to mitigate the impacts of the pandemic on GBM.

EPC446

The treatment cascade and continuum care of pregnant women living with HIV in Brazil: were there impacts due to COVID-19 pandemics?

L. Neves da Silveira[1], C. Silvia Bruniera Domingues[1], R. Elisa G. Gonçalves Pinho[1], A. Monica Brandão Beber[1], A. Sampaio Diniz Guarabyra[1], P. Cristina Gaspar[1], M. Gonçalves Aragón[1], L. Henriette de Lannoy[1], G. Fernando Mendes Pereira[1], A. Espinosa Barbosa Miranda[1], A.R. Pati Pascom[1]

[1]Brazilian Ministry of Health, Chronic Conditions and Sexually Transmited Diseases Department, Brasília, Brazil

Background: The elimination of HIV mother-to-child transmission(HIV-MTCT) as a public health problem is a national priority. For an adequate policy planning, it is fundamental to analyze the treatment cascade and continuum care and of pregnant women living with HIV (PW-

HIV). It is more important since the COVID-19 pandemic has affected the care of all people living with HIV. The aim was to show trends in the cascade of PW-HIV from 2018-2020, in Brazil, and identify possible impacts of COVID-19.

Methods: We estimated a comprehensive cascade of care for PW-HIV, using national programmatic data related to laboratory exams and antiretroviral therapy (ART) from 2018-2020. PW-HIV using ART are those identified in the ART system, including both who became pregnant on ART or started during pregnancy. Women undetectable at delivery are those on ART whose HIV viral load exam was ≤50 copies/mL 180 before or 15 days after delivery. We defined late presenters as PW-HIV with a TCD4+ lymphocyte count≤350cells/mm^3.

Results: The number of PW-HIV identified dropped 22.3% (from 10,055 in 2018 to 7,979 in 2020). PW-HIV on ART and undetectable at delivery remained around 95% and 75% during the analyzed period, respectively. However, late presentation increased from 23% in 2018 to 26% in 2020 among those women.

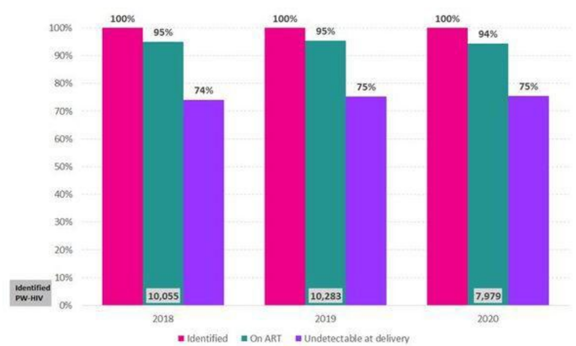

Figure 1. Continuum of care cascade of pregnant women living with HIV - Brazil 2018-2020

Identified: all PW-HIV identified in the laboratory and/or ART systems; On ART: PW-HIV that were on ART in any moment of pregnancy; Undetectable at delivery: PW-HIV who present HIV-VL <50 copies/mL between 180 days before or 15 days after delivery.

Conclusions: There was a decrease in the overall number of PW-HIV identified in 2020, possibly as an impact of COVID-19 pandemic on birth rate and on access to antenatal care (ANC). However, for PW-HIV who accessed health system, we observed a maintenance on the cascade steps before and during the pandemic. It may suggest that adjustments recommended by Ministry of Health to reorganize HIV services and prioritize ANC for PW-HIV was worthy, and contributed to the HIV-MTCT prevention. The challenge remains to improve diagnosis and linkage to diminish PW-HIV presenting late to ANC.

EPC447

When pandemics collide: impact of the COVID-19 pandemic on HIV and STI testing, treatment and PrEP use in a Boston community health center

K. Mayer[1,2], S. Gitin[1], D. Krakower[2,1], C. Grasso[1], K. Biello[3,1]

[1]Fenway Health, The Fenway Institute, Boston, United States, [2]Harvard Medical School/Beth Israel Deaconess Medical Center, Medicine, Boston, United States, [3]Brown University School of Public Health, Social and Behavioral Sciences, Providence, United States

Background: The COVID-19 pandemic disrupted care for many HIV-positive and at risk people. Trends in HIV/STI testing and PrEP at a Boston health center specializing in HIV care were analyzed throughout the pandemic.

Methods: The analyses divided the pandemic temporally (Pre-pandemic: 12/2019-2/2020; Early pandemic: 3/2020-5/2020; Delta surge: 6/2021-8/21; Post-Delta: 9/2021-11/2021; plus Omicron month: 12/1-31/2021), to compare the prevalence of HIV and STI tests performed, test positivity, new HIV diagnoses and PrEP starts. Comparisons were made using Student's t tests for means and chi-square tests for proportions.

Results: The monthly average of HIV tests decreased from 1685 pre-pandemic to 575 in the early pandemic (p=.017), but rebounded and remained stable during subsequent periods (NS). Although monthly average of new HIV diagnoses declined from 7 pre-pandemic to 3.7 during the early pandemic (p=.206), it increased significantly after Delta, averaging 17 new diagnoses a month (p=0.02).

Monthly plasma HIV RNA tests dropped significantly from 336 to 145 between the pre-pandemic and first surge period (p=0.007), and has not returned to pre-pandemic levels, though virologic suppression rates remained over 90% throughout the pandemic. PrEP starts and restarts dropped between the pre-pandemic and first wave periods (p=0.014 and 0.071 respectively), but restarts increased significantly through the post-Delta period (p=0.049). New PrEP starts remained lower at each period of the pandemic compared to pre-pandemic. The mean number of syphilis, gonorrhea (GC) and chlamydia (CT) tests performed monthly decreased during the early pandemic compared to pre-pandemic (p=0.012 and 0.01 respectively) with a rebound approaching, and then reaching, pre-pandemic levels during Delta and Omicron surges. GC/CT test positivity increased significantly during the early pandemic ($p<0.0001$), but returned to pre-pandemic levels by the Delta surge (p=0.478). Syphilis test positivity remained at 1.8-2% until 12/2021, but then increased to 2.8%.

Conclusions: The COVID-19 pandemic initially led to major decreases in HIV/STI testing and services in a Boston clinic. Monthly HIV RNA tests declined throughout the pandemic, but viral suppression rates remained high, raising questions whether some patients disengaged from care. HIV/STI screening, STI test positivity, and PrEP start/restart trends suggest a progressive increase in sexual risk and the use of sexual health services.

EPC448

Retention on treatment and mortality of methadone maintenance therapy patients before and after take-home dosing policy change during COVID-19 pandemic in Ukraine

R. Ivasiy[1], S. Galvez de Leon[1], M. Polonsky[1], L. Madden[2], S. Farnum[2], A. Mateliuk[3], I. Pykalo[4], Z. Islam[3], S. Dvoriak[4]
[1]Yale University, School of Medicine, New Haven, United States, [2]APT Foundation, New Haven, United States, [3]ICF Alliance for Public Health, Kyiv, Ukraine, [4]Ukrainian Institute on Public Health Policy, Kyiv, Ukraine

Background: The aim of this research is to assess the effect of the expansion of methadone maintenance treatment (MMT) take-home dosing, a drug dispensing policy relaxation implemented due to the COVID-19 pandemic, on retention and mortality of patients who inject drugs (PWID) in Ukraine.

Methods: A prospective quasi-experimental Kaplan-Meier survival analysis was applied to compare MMT retention and mortality between OUD patients enrolled in treatment during the year before the take-home dosing regulation update (03/18/2020), induced by COVID-19 restrictions, and those enrolled during the year following the policy change. Age, sex, HIV status, methadone dosing, take-home dispensing, and previous MMT experience were assessed for their effect on treatment retention and death using Cox multivariate regression models.

Results: Among the pre-(N=3,350) and post-(N=3,775) COVID policy change cohorts, 26% and 55% of patients were transferred to take-home dosing within 365 days, respectively. Patients enrolled in treatment post-COVID had significantly (p<0.0001) higher retention at 1(98%vs.96%) and 12(82%vs.78%) months (Fig.1); and higher (p<0.0001) survival probability at 1(99.6% vs. 99.2%) and 12(97.9%vs.95.1%) months (Fig.2).

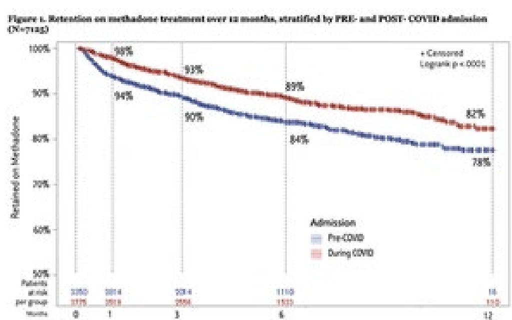

Figure .1

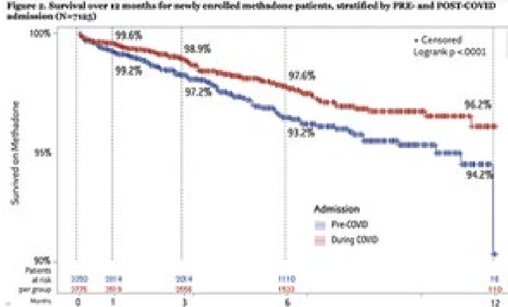

Figure. 2

Patients enrolled post-COVID had 29%(p<0.0001) lower risk for dropout and 30%(p=0.03) lower risk of death at 12 months controlling for methadone dose, HIV-status. MMT retention and patient mortality didn't differ after controlling for take-home dosing, indicating that take-home dosing is significantly associated with higher treatment retention and survival in a post-COVID group (Table 1).

	Crude			Adjusted for dose and HIV status			Adjusted for dose, HIV-status, and Take-Home Dosing		
	cHR	95% CL	p-val.	aHR	95% CL	p-val.	aHR	95% CL	p-val.
Risk of Drop-Out in the Pre-COVID Cohort Compared to the Post-COVID Cohort									
12 months	0.64	0.56-0.73	<.0001	0.70	0.61-0.80	<.0001	0.90	0.83-1.25	0.158
Risk of Death in the Pre-COVID Cohort Compared to the Post-COVID Cohort									
12 months	0.72	0.49-0.91	0.01	0.70	0.52-0.96	0.03	0.80	0.60-1.1	0.168
Legend: cHR: crude hazard ratio; aHR: adjusted hazard ratio; CL: confidence limits;									

Table 1. Cox regression model of factors associated dropout and death on opioid agonist therapy, N = 7,125

Conclusions: The proportion of patients transferred to take-home dosing during the post-COVID period was more than double compared to pre-COVID period. Take-home dosing contributed to higher retention and survival in the post-COVID group, presenting further opportunity for the treatment scale-up as cost-effective HIV-prevention strategy in Ukraine.

EPC449

Interpreting trends in new HIV diagnoses in England in the COVID-19 era

A. Brown[1], V. Martin[1], A. Shah[1], N. McKay[1], H. Mohammed[1], N. Connor[1], V. Delpech[1]
[1]UK Health Security Agency, London, United Kingdom

Background: England has set an ambition to end HIV transmission by 2030. While the number of new HIV diagnoses fell between 2019 and 2020, the COVID-19 pandemic affected social mixing, sexual behaviour and access to HIV testing.This combined with a reduction in data reporting (COVID-19 staff redeployment) resulted in challenges in data interpretation. We described our approach in the COVID-19 era to understand recent trends in new HIV diagnoses.

Description: The Health Security Agency analyses reports of people newly diagnosed with HIV in England collected through the HIV and AIDS Reporting System (HARS). These were compared to the number having an HIV test in specialist sexual health services (SHS) reported to GUMCAD STI surveillance. New diagnoses were ascertained through multiple sources, and monthly data quality checks were undertaken to mitigate against underreporting.

Lessons learned: After adjustment for missing exposure, among gay/bisexual men, diagnoses fell by 41% from 1,500 in 2019 to 890 in 2020, and the number testing for HIV at SHS decreased by 7% from 157,710 in 2019 to 146,900 in

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

2020. This compares with the 132,770 men tested in 2018. The high and sustained number of gay/bisexual men having an HIV test in 2020 combined with continuing provision of PrEP indicates the fall in HIV diagnoses reflects reduced HIV transmission.
Among heterosexual adults, HIV diagnoses fell by 23% from 1,320 In 2019 to 1,010 in 2020, and the number tested fell by 33%, from 1,142,950 to 760,260 respectively.The number of tests fell by 41% and 29% among men and women respectively (coverage in specialised SHS reduced from 77% to 57%, and 56% to 38% among men and women respectively).Among heterosexual adults, the reduced number testing for HIV is likely the main contributor to fewer HIV diagnoses. Missed testing opportunities in 2020 may mean late diagnoses rise in future years.
Conclusions/Next steps: In the era of ending HIV transmission, and in the context of COVID-19 causing under-reporting, multiple source cross-checks are needed to mitigate against undercounting diagnoses. Trends in new diagnoses must be analysed by exposure group and interpreted in the context of testing activity.

EPC450
Impact of the COVID-19 pandemic on time to HIV viral suppression in the U.S. Deep South

J.R. Bassler[1], E.B. Levitan[2], A.F. Nassel[3], L. Ostrenga[4], I. Cagle[5], S. Preg[5], M. Bender[6], X. Wang[6], E.S. Kay[7], M. Parman[8], M.J. Mugavero[8], D.S. Batey[7], A. Rana[8]
[1]*University of Alabama at Birmingham, Department of Biostatistics, Birmingham`, United States,* [2]*University of Alabama at Birmingham, Department of Epidemiology, Birmingham, United States,* [3]*University of Alabama at Birmingham, Birmingham, United States,* [4]*Louisiana Department of Health, New Orleans, United States,* [5]*Alabama Department of Public Health, Montgomery, United States,* [6]*Mississippi State Department of Health, Jackson, United States,* [7]*University of Alabama at Birmingham, Department of Social Work, Birmingham, United States,* [8]*University of Alabama at Birmingham, Department of Medicine, Birmingham, United States*

Background: Between 2012 and 2018, states in the United States (US) Deep South, the epicenter of the US HIV epidemic, achieved year-over-year reductions in time to viral suppression (VS) following HIV diagnosis, critical to improving outcomes and reducing transmission. However, the COVID-19 pandemic disrupted HIV services and may have reduced previous gains.
Methods: We conducted a retrospective, population-based cohort study of all persons ≥ 13 years with newly diagnosed HIV from 2018-2020 in Alabama (AL), Louisiana (LA), and Mississippi (MS), using data collected in the Enhanced HIV/AIDS Reporting System (eHARS), a standardized HIV surveillance system maintained in each state. We used the Kaplan-Meier method to describe time in days to VS by year of diagnosis.

Results: In AL (n=570) and LA (n=703), median time to VS in 2020 increased 21 and 16 days, respectively, while MS (n=412) improved by 4 days compared to 2019, reversing prior trends in rates of improvement from 2018 (Figure 1).
Compared with 2019, there was an increase in proportion of new HIV diagnosis with Stage 3 presentations in AL (23.7% vs 22.3%) and LA (23.3% vs 22.3%), and a higher proportion of missing data in HIV method of transmission in all 3 states (AL=70.9% vs 46.5%, MS= 46.4% vs 45.1%, LA=25.5% vs 17%) in 2020. The proportion achieving VS at 180 days also decreased in 2020 compared with 2019 (AL: 64.1% vs 64.9%, MS: 57.7% vs 59.1%, LA: 66.9% vs 68.3%).

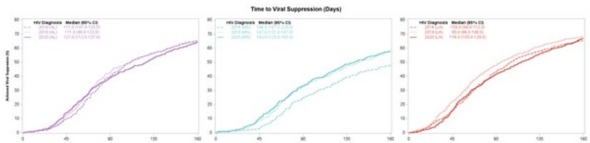

Figure 1.

Conclusions: The COVID-19 pandemic within the HIV epidemic has complicated efforts in ending HIV in the US South. Prior to COVID-19, consistent improvements in median time to VS were seen in AL, LA, and MS.
This positive trend has been stunted with HIV treatment and prevention impacts including later stage presentations and challenges to public health agencies' ability to collect information critical to informing targeted HIV prevention programming.

EPC451
How did use of HIV prevention methods change during the COVID-19 pandemic in Manicaland, Zimbabwe?

R. Morris[1], R. Maswera[2], L. Moorhouse[1], P. Mandizvidza[2], T. Dadirai[2], C. Nyamukapa[1,2], S. Gregson[1,2]
[1]*Imperial College London, Department of Infectious Disease Epidemiology, London, United Kingdom,*
[2]*Biomedical Research and Training Institute, Harare, Zimbabwe*

Background: The Covid-19 pandemic, it's associated lockdowns and reallocation of healthcare resources has the potential to disrupt HIV prevention efforts globally.
This study aims to assess the impact of Covid-19 on uptake of HIV prevention methods among HIV negative adults reporting sexual risk behaviours in eastern Zimbabwe.
Methods: Data were taken from two rounds of a general population open-cohort survey in Manicaland, Zimbabwe shortly prior to (July 2018 to December 2019) and a year following the outbreak of Covid-19 (February to July 2021). Descriptive statistics and logistic regression were used to assess changes in sexual risk behaviours (multiple partners in the past year, transactional sex, concurrent partners, and (for women) age-disparate relationships); and in use of HIV prevention methods among HIV-negative adults aged 15-54 years.

		Males 15-54yrs reporting sex in past year				Females 15-54yrs reporting sex in past year			
Risk Group	Reported prevention method(s)	Pre-Covid-19 % (95%CI)	During Covid-19 % (95%CI)	Adjusted Odds Ratio AOR(95%CI)	p value	Pre-Covid-19 % (95%CI)	During Covid-19 % (95%CI)	Adjusted Odds Ratio AOR(95%CI)	p value

EPC451 Table 1.

Results: During Covid-19 more men reported sex in the past year compared to the pre-Covid period (92.9% vs. 88.5%; AOR 1.72, 95%CI 1.37-2.16); and more of these men reported ≥1 sexual risk behaviours (40.1% vs. 34.0%; 1.33,1.16-1.54). No differences in these indicators were found for women (p>0.05); and no changes in sexual risk behaviours in the past 1-3 months were found for either sex.

Amongst people with ≥1 sexual risk behaviours, more men reported sexual abstinence and faithfulness to one partner during Covid-19 than before Covid-19 and more women reported using abstinence, male condoms, and PrEP for HIV prevention (Table 1).

Amongst people with sexual risk behaviours in the past 1-3 months, more men reported periodic abstinence during Covid-19 and more women reported using PrEP (7.74% vs. 0.89%; 7.08, 1.46-34.3).

Conclusions: Despite the impacts of Covid-19, our study population continued to report high levels of sexual risk behaviours for HIV acquisition. Overall, we found no significant disruption to uptake of HIV prevention methods during the Covid-19 pandemic and promising increases in women's use of PrEP were reported.

EPC452

Impact of COVID on PrEP use and HIV/STI testing: a community based survey of MSM, San Francisco

M. Tate[1], G. Baguso[1], C. Turner[1], K. D. Taylor[2], D. Trujillo[1], J. Quintana[1], S. Sicro[1], K. McNaughton[1], S. Arayasirikul[2], W. McFarland[1], E. Wilson[1]

[1]San Francisco Department of Public Health, San Francisco, United States, [2]University of California, San Francisco, United States

Background: Before COVID-19, San Francisco was on track to achieve zero HIV infections by 2030. New diagnoses dropped 65% from 2012 to 2019. However, the COVID-19 pandemic threatens access to two successful pillars for ending the epidemic: HIV testing and PrEP. In a community-based survey among men who have sex with men (MSM) in San Francisco in 2021, we assessed barriers in obtaining PrEP, HIV testing, and STI testing as a result of the COVID-19 pandemic.

Methods: Data are from the National HIV Behavioral Surveillance survey, which are cross-sectional surveys led by the CDC in 23 US cities. The MSM survey uses venue-based sampling/recruitment. Due to COVID-19, the sampling method changed to online venue recruitment. Participants were approached on MSM-oriented dating apps and social media groups on random days-time periods. A structured interview was conducted virtually; participants were mailed HIV and STI home tests. Eligibility criteria were adult men (18+) who had sex with men, English-or Spanish-speaking, and San Francisco resident. Interviews collected demographics, risk behaviors, and use of preventive services.

Results: Of 505 MSM enrolled, 99 (19.6%) were HIV-positive. The majority was white (74.3%); the average age was 43 years. Of 406 HIV-negative MSM, 267 (65.8%) sought PrEP during the COVID-19 epidemic, with 25 (9.4%) reporting difficulties in obtaining PrEP due to COVID-19. Difficulties in getting HIV testing were reported by 151 (37.2%).

Among HIV-positive and negative MSM, 193 (38.2%) reported difficulties in getting STI testing. Younger respondents were more likely to report barriers to obtaining PrEP, HIV testing, and STI testing (p<0.001, differences in mean ages). No racial/ethnic differences were noted in attempting or obtaining PrEP, HIV testing, or STI testing.

Conclusions: Delivery of healthcare including HIV prevention have been challenged by the COVID-19 pandemic. We corroborate substantial barriers to HIV testing among MSM during the COVID-19 epidemic, as noted by a 44% drop in monthly tests performed at community testing sites compared to 2019. Under10% of MSM reported barriers to obtaining PrEP. Programs to increase home HIV and STI testing, and longer-acting PrEP, may help meet HIV prevention needs during the current and future pandemics.

The impact of the COVID-19 pandemic on sexual behavior and HIV prevention and treatment services among US MSM in the post-lockdown era: a comparison of two studies

L.M. Mann[1], T. Sanchez[1], R. Stephenson[2], P.S. Sullivan[1], S.M. Jenness[1]
[1]Emory University, Department of Epidemiology, Atlanta, United States, [2]University of Michigan, Department of Systems, Populations, and Leadership, Ann Arbor, United States

Background: Early in the COVID-19 pandemic, disruptions to sexual health services and changes to sexual behavior due to the first COVID-19 lockdowns were common among gay and other men who have sex with men (MSM) globally. Less is known about the persistence of these changes after this initial lockdown period.

Methods: Data from two independent longitudinal studies of US MSM surveying participants at multiple timepoints in 2020 through January 2021 were used to assess changes in sexual behavior and service access attributed to the COVID-19 pandemic. We classified the post-lockdown period as June 2020 to present.

Results: A total of 1,694 MSM comprised the two study samples, which both demographically and geographically approximated the US MSM population. Though one study observed reduced sexual behavior impacts later in the pandemic, nearly half of participants continued to report reduced sexual partners throughout 2020. For MSM not living with HIV, initial disruptions to HIV testing and preexposure prophylaxis prescriptions continued in late 2020 for 15% and 7% of participants, respectively.

For MSM living with HIV, care access was reduced throughout 2020; in late 2020, approximately 19% of participants reported a decrease in HIV medical care visits, down from 28% in April 2020. Few participants in either study reported disruptions in their access to antiretroviral therapy.

Conclusions: COVID-related disruptions to HIV prevention and treatment services continued into January 2021. Although sexual behavior also did not return to pre-pandemic levels in the post-lockdown period, the reduced access to HIV prevention, testing, and treatment services during this period could result in an overall increased HIV transmission rate.

Ongoing assessment of pandemic-related disruptions are needed as the COVID-19 pandemic and associated lockdown policies continue to evolve.

	American Men's Internet Survey COVID Impact Survey (AMIS-COVID) April 2020 (n=1,051) n (%)	AMIS-COVID July 2020[1] (n=572) n (%)	AMIS-COVID September 2020[1] (n=373) n (%)	Love & Sex in the Time of COVID Study (LS-COVID) April - May 2020 (n=643) n (%)	LS-COVID November 2020 - January 2021[1] (n=180) n (%)
Reported a Decrease in Number of Sexual Partners[2]	542 (51.5)	320 (58.4)	189 (53.5)	356 (58.2)	84 (49.4)

Analysis of HIV case finding and continuity on treatment strategies and outcomes before and during the COVID-19 pandemic: The RISE Nigeria experience

Y. Ogundare[1], O. Benjamin[1], B. Dare[1], A. Adetosoye[1], P. Anyanwu[2], A. Ogundipe[3,2], E. Atuma[1], I. Iyortim[4], K. Curran[5], C. Laube[5], M. Strachan[5]

[1]Jhpiego, Abuja, Nigeria, [2]ICAP, Abuja, Nigeria, [3]National Agency for the Control of AIDS, Abuja, Nigeria, [4]USAID, Abuja, Nigeria, [5]Jhpiego, Baltimore, United States

Background: The COVID-19 pandemic has posed challenges in ensuring continued access to HIV services globally. The Reaching Impact Saturation and Epidemic control (RISE) project, with funding from PEPFAR through USAID and in partnership with the government of Nigeria, implemented HIV case finding, treatment initiation and continuity of treatment strategies to maintain services during the COVID-19 lockdown in four Nigerian states: Akwa Ibom, Cross River, Adamawa and Niger.

Methods: Two six-month aggregate datasets were compared to analyze testing and treatment volume and outcomes in the six months prior to COVID-19 (Period A) and during the first six months of the COVID-19 pandemic (Period B).

Chi-square tests were used to determine the association between testing and treatment outcomes in community and facility settings before period A (October 2019 - March 2020) and during period B (April - September 2020) respectively, at p-value of 0.05.

Results: The total number of clients that were counselled, tested and received results during the two time periods (A and B) were 236,049 and 302,100 respectively. HIV positivity during these two periods were 4.5 and 4.7% respectively. The number of clients supported on ART increased from 47,482 to 62,763 (period A and B). Program growth increased from 25.8% from 31.6% in period A and B, respectively.

The proportion of clients tested in the community in period A and during period B period differ significantly ($p < .001$) with increased of 29% in period B, likewise, clients tested in the facilities during the period A as compared to period B differ significantly ($p < .001$) with increased of 29% in period B.

In addition, index client tested in the community increased by 67% and index client tested in the facility increased by 55% during periods A and B with differ significant difference of ($p < .001$) respectively.

Conclusions: The early COVID-19 pandemic period did not have a negative impact on HIV testing and treatment services provided by the RISE project in Nigeria. Strategies utilized by RISE improved HIV program outcomes and sustained growth in the size of the treatment cohort during the initial COVID-19 pandemic period, April to September 2020.

EPC455

The effects of COVID- 19 on HIV detection in Mexico

A. Villafuerte García[1], C.L. Magis Rodríguez[1]

[1]National Autonomous University of Mexico, Public Health, Mexico City, Mexico

Background: COVID-19 has had a negative impact on the HIV response, with effects on late diagnosis, morbidity, mortality, and increase of new infections. In Mexico, HIV detection in the first half of 2020 fell 59%, compared to 2019. The objective of this study was to describe the behavior of HIV detection in terms of new diagnoses and late diagnoses.

[i] National Center for the Prevention and Control of HIV and AIDS. World AIDS Day 2020 Bulletin. December 2020. Available at: https://www.gob.mx/censida/documentos/boletin-dia-mundial-del-sida-2020

Methods: Cross-sectional descriptive study that included HIV detections carried out during 2019 and 2020, as well as new cases reported, and late diagnoses admitted to care at the Ministry of Health (CD4+ <200 cells/ml). Data from the Health Information System, the National Registry of HIV/AIDS Cases (national), and reports from the bulletins published by the Ministry of Health were used. For the analysis, the data was disaggregated by state.

Results: HIV detections in men who have sex with men (MSM) decreased more than 50% between 2019 and 2020 (75,496 and 36,373, respectively). The three states with the highest number of accumulated HIV and AIDS cases reported a decrease in detection around 25 and 46% in this period (Mexico City 25%, State of Mexico 42%, Veracruz 46%). Mexico City reported 71% less cases in 2020 compared to 2019, State of Mexico 52%, and Veracruz 94%. Late diagnoses increased, Mexico City went from 29% to 45% of late diagnoses, State of Mexico, 42% to 58%, and Veracruz, from 49% to 52% (Figure 1).

Figure 1. HIV detections carried out in the Mexico Ministry of Health in three states, 2019-2020.

Conclusions: The response to HIV and AIDS is facing old and new challenges in the context of the health emergency. Implementing effective strategies, based on scientific evidence (such as HIV self-testing), as well as maintaining partnerships with civil society, is essential to successfully reach key populations and achieve the 2030 diagnostic goals.

EPC456

Viral sequence-based near real-time cluster monitoring of HIV-1 reveals the impact of the COVID-19 Pandemic on HIV testing in Japan

T. Shiino[1], M. Otani[2], T. Kikuchi[2], K. Yoshimura[3], W. Sugiura[1], Japanese HIV Drug Resistance Surveillance Network
[1]National Center for Global Health and Medicine, Center for Clinical Sciences, Shinjuku-ku, Japan, [2]National Institute of Infectious Diseases, AIDS Research Center, Shinjuku-ku, Japan, [3]Tokyo Metropolitan Institute of Public Health, Shinjuku-ku, Japan

Background: Pathogen genomic sequencing is essential for understanding their epidemics. To assess the regional trends of HIV-1 transmission networks in near real-time settings, we developed a search program for HIV nationwide clusters by sequence (SPHNCS). SPHNCS enables identification of domestically transmitted clusters (dTCs) and their network structures based on HIV sequences of newly diagnosed HIV/AIDS cases collected through the Japanese HIV Drug Resistance Surveillance Network. Using SPHNCS, we compared the transmission dynamics of HIV-1 before (2018–2019) and during the COVID-19 pandemic (2020–2021).

Methods: Protease-reverse transcriptase sequences of 1,836 newly diagnosed cases in 2021–2022 were recruited from our surveillance network. Using SPHNCS, dTCs of 1,460 subtype B and 232 CRF01_AE cases reported in 2018–2021 were identified. The number of outbreak events, and newly identified cases in dTCs, involving late diagnosis or rare detection by the SPHNCS reporting and alerting system were investigated. dTCs reported in < 3 cases over the last three years were considered rare. Time-based phylogenetic trees of some dTCs with outbreaks or late diagnoses were inferred using BEAST1.

Results: In 2020–2021, 693 newly diagnosed cases were registered in our surveillance, whereas 1,143 were registered in 2018–2019. Ten of the top 20 identified dTCs in 2019 were not detected during the pandemic; instead, ten less reported dTCs were ranked. The number of outbreak cases (n = 23) also decreased by two-thirds of those in 2018–2019 (n = 34), and more newly diagnosed cases (n = 52) were found in rarely detected dTCs (OR = 0.61, p = 0.043).

Thus, the number of dTC-affiliated cases remained constant. The proportion of acute cases in 6/10 newly ranked dTCs increased from 0 to > 0.3 during the pandemic.

Conclusions: Monitoring with SPHNCS indicated a pattern shift to detection of rarer HIV-1 transmission cases during the COVID-19 pandemic. Reduction in both the recruited cases and outbreaks demonstrated a negative impact of the pandemic on HIV testing and prevention in Japan. Increased acute cases in some dTCs suggests that the high sensitivity of the healthcare system to acute febrile illnesses might result in episodic improvement.

EPC457

The COVID-19 pandemic affects immune status of new HIV clients enrolled in two Brazilian reference services

R. Chuster H. Humar[1], M. Borges L. Cordeiro[2], A. C. de Araújo[3], K. Azevedo N. Almahnoud[4], M. Vinítius de F. Guerra[5], A. P. da Silva[6], R. da C. Menezes[7], C. de F. Dantas[8], F. S. Cruz[9], R. de Jesus[10], F. F. Fonseca[11]
[1]AIDS Healthcare Foundation - Brazil, Quality and Data, São Paulo, Brazil, [2]Aids Healthcare Foundation, Project Coordinator, Manaus, Brazil, [3]Aids Healthcare Foundation, Project Coordinator, Recife, Brazil, [4]Aids Healthcare Foundation, Quality Data Assistant, Recife, Brazil, [5]Fundação de Medicina Tropical Heitor Vieira Dourado - FMT HVD, President, Manaus, Brazil, [6]Hospital Correia Picanço - HCP, SAE - IST/HIV/AIDS, Recife, Brazil, [7]Hospital Correia Picanço - HCP, Director, Recife, Brazil, [8]Secretaria de Estado da Saúde de Pernambuco - SES PE, Coordinator - IST/HIV/AIDS, Recife, Brazil, [9]Aids Healthcare Foundation, M&E, Rio de Janeiro, Brazil, [10]Aids Healthcare Foundation, Country Program, São Paulo, Brazil, [11]Aids Healthcare Foundation, Global Medical, Salvador, Brazil

Background: HIV care and treatment services (HIV-C&T) under the Tropical Medicine Foundation (FMT) of Manaus/Amazonas, and Correia Picanço Hospital (HCP) of Recife/Pernambuco, function as principal HIV-C&T reference centers in Brazil. Since 2017, Aids Healthcare Foundation (AHF-Brazil) works on projects in partnership with these centers, aiming to improve quality of care.

The objective of this study was to evaluate how the pandemic affected access to HIV-C&T by monitoring the HIV immune status of new clients enrolled.

Methods: This is an observational study using retrospective data from the AHF-Brazil monitoring tool. All new clients with no documented previous ART use and with baseline-CD4 count (b-CD4) enrolled in these 2 services from January 2019 to September 2021, were included.

Considering that the 1st official case of COVID-19 in Brazil was identified in February 2020, our analysis will separate and compare the b-CD4 profile of clients in two groups; group 1 with clients enrolled from January 2019 to March 2020, and group 2 with clients enrolled from April 2020 to September 2021.

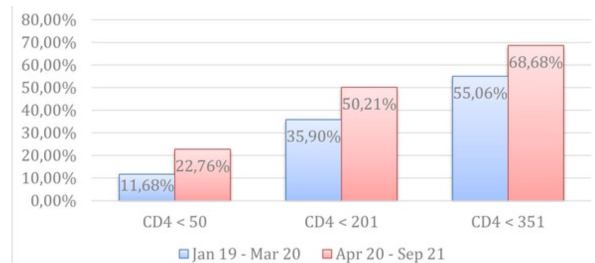

Figure. Baseline CD4 - new enrolles clients without previous use of ART at FMT and HCP

Results: From the 2,242 new clients enrolled, 1,284 were from group 1 and 958 group 2. In group one 55% (N=707) clients had a b-CD4 <351 cells/mm³, 35% (N=461) <201 cells/mm³. Group 2 had 69% (N=658) clients with b-CD4 <351 cells/mm³, 50% (N=481) <201 cells/mm³, evidencing 13% increase in the number of late presenters, and an 14% increase in people presenting at HIV-C&T with advanced aids.

Conclusions: The onset of the COVID-19 pandemic has shown an increase in the number of late presenters in HIV-C&T in Brazil. Both the FMT and the HCP are central hospitals in their states for HIV care and the arrival of a greater proportion of late presenters may be associated with obstacles in the HIV diagnosis networks, affecting timely access to HIV diagnosis. New arrangements in HIV-C&T, adapting to this new scenario are required.

EPC458

Impact of the COVID-19-related economic crisis and the mitigation effects of social protection on HIV/AIDS and Tuberculosis: an integrated economic, mathematical and epidemiological study

F. Rubio[1], A. Amad[2], E. Moya[1], R. de Oliveira[1], T. Aransiola[1], R. Anderle[1], A. Sironi[1], J. Ordoñez[1], M. Sanchez[3], L. de Souza[1], I. Dourado[1], J. Macinko[4], D. Rasella[5], DSAIDS

[1]Institute of Collective Health/Federal University of Bahia, Salvador, Brazil, [2]Swansea University, College of Engineering, Swansea, United Kingdom, [3]University of Brasilia, Department of Public Health, Brasilia, Brazil, [4]University of California, Department of Health Policy and Management, California, United States, [5]Instituto de Salud Global, Barcelona, Spain

Background: The COVID-19 pandemic will have impactful long-term effects on the global growth of poverty and social inequalities. Morbidity and mortality from poverty-related infectious disease will increase and the current trends will compromise the achievement of the health-related Sustainable Development Goals. To face these trends, the implementation of large-scale social protection policies is paramount to mitigate these adverse effects of the global economic crisis. We aimed to evaluate the impact of the sudden increase in poverty rates on HIV/AIDS and Tuberculosis (TB) incidence and mortality, and the mitigation effects of social protection in one of the world's largest Low- and Middle-Income Countries (LMIC): Brazil.

Methods: We integrated economic, mathematical, and epidemiological models to forecast the trends of HIV/AIDS and TB according to possible economic crisis scenarios and their alternative poverty-reduction policies response up to 2030. Two mathematical models of infectious diseases composed of nonlinear ordinary differential equations to model HIV/AIDS and TB transmission dynamics were proposed. As a novel approach, we forecast poverty trends, which were calculated by autoregressive and deterministic approaches, and inserted in the model parameters. The HIV/AIDS and TB models were calibrated considering a multiobjective genetic algorithm to fit the AIDS and TB incidence and mortality rates.

Results: These models showed that the implementation of poverty-reduction policies could mitigate the potential large and long-lasting rise in poverty over the next few years, avoiding an increase of 41% and 50% of HIV/AIDS incidence and mortality respectively, and of 32% and 53% for TB incidence and mortality. Overall, more than 250 thousand new cases and 43 thousand HIV/AIDS and TB deaths could be averted up to 2030.

Conclusions: Our effort to understand and model complex phenomena - such as the COVID-19-pandemic effects on poverty rates and population health - required the integration of methodologies from different areas such as economics, mathematics, and epidemiology. Using a comprehensive approach, it was possible to show the importance of large-scale social protection interventions to avert dramatic increases, during the future post-pandemic period, in morbidity and mortality from poverty-related diseases such as HIV/AIDS and Tuberculosis.

EPC459

Impact of the Covid-19 pandemic on HIV testing in a global HIV/AIDS support program

F. Fernandes Fonseca[1], W. Odoke[1], J. van den Hombergh[1], E. Waweru[1], B. Biwot[1], J. Nakhumwa[1], A. Benzaken[1]

[1]AIDS Healthcare Foundation (AHF), Global Quality Team, Los Angeles, United States

Background: The COVID-19 pandemic is associated with severe disruptions in health care services and nonpharmacological measures such as social distancing and restrictions had an impact on access to HIV-tests at facilities and outreach activities. The impact of the pandemic on the HIV testing program of AIDS Healthcare Foundation (AHF) was assessed by comparing monthly test activity and outcomes for 2019 (pre-pandemic) and 2020-2021.

Methods: Observational study using retrospective data from the AHF Global Quality Program, including HIV testing data from 44 countries in Asia, Latin America and the Caribbean, Europe and Africa. Information on HIV testing numbers and proportion of positive results were compared, from 1 January 2019 to 31 December 2021.

Results: Over 1,000,000 people were tested in the last trimester of 2019. In the first trimester of 2020, the number of HIV-tests reduced for the first time (N=883,928), and the lowest performance coincided with Covid-19 pandemic waves, from April-June 2020 (N=545,501). The number of HIV-tests ranged from 811,201-917,526, not achieving the performance of 2019.

In 2019, 4,311,168 people were tested, 3.2%(N=138,421) positivity ratio. In 2020 this number decreased to 3,127,408 with an increased positivity ratio of 3.5% (N=109,685). 3,448,939 people were tested in 2021, 3.3% positivity ratio (N=117,119).

Author Index

The number of people tested for HIV reduced 27% and 20%, and identification of new HIV cases reduced 21% and 15%, respectively, in 2020 and 2021, compared to 2019.

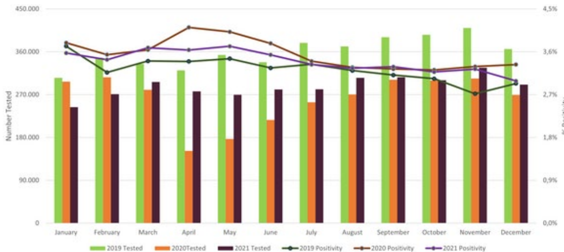

Figure. Number of persons tested for HIV and average positivity rate (2019 to 2021) by Month

Conclusions: Despite inter-country heterogeneity, COVID-19 appeared to be associated with a significant reduction in the number of people tested for HIV, probably related to less access to HIV testing at health facilities, due to restrictions and lockdowns. The slight increase in the percentage of positive tests might be related to the programmatic decision to intensify testing of sexual partners of PLHIV in health services and because of a major shift towards health facility based testing.

[1]*Clinton Health Access Initiative, COVID-19 Emergency Response, Pretoria, South Africa,* [2]*Clinton Health Access Initiative, HIV Prevention, Pretoria, South Africa,* [3]*National Department of Health, Hiv Prevention and Testing, Pretoria, South Africa*

Background: The COVID-19 pandemic overwhelmed health services and critically disrupted the routine provision of essential health services globally. When the World Health Organization declared COVID19 a public health emergency, the South African government in response to an increase in cases and to mitigate the spread of COVID19 implemented several measures to limit the spread of COVID-19, which unfortunately reduced the use of health services and affected continuity of care for people with TB, HIV and other chronic diseases like diabetes and hypertension.

This study seeks to assess the effect of COVID-19 on HIV prevention and treatment programs as well as on mortality.

Methods: A retrospective mortality line-list review was conducted on COVID-19 deaths from 27th March to 28th February 2021 from all nine provinces in South Africa. Descriptive statistics were used to summarise mortality data reports from provinces. In addition, retrospective HIV testing and ART initiation data were extracted from the District Health Information System (DHIS) for the 2019-2021 period.

Results: A review of DHIS data indicated a 1,1% decline of HIV tests done in 2020 compared with 2019. In 2021, there was a further decline in HIV testing of 35.4% compared to 2020. In 2019, 81.8% of those who tested positive were initiated on ART; however, the figure declined to 71,6% in 2020, rising marginally to 74,7% in 2021.

COVID-19 mortality data shows that of the total 50 148 deaths reported during the review period, 4% were HIV positive patients and 58% were female. TB-HIV co-infection was reported in 13% of the HIV deaths, diabetes was reported in 24.2% of the HIV positive deaths, whilst a combination of HIV, diabetes and hypertension was reported in 13% of the deaths.

Conclusions: Lockdown measures impacted an already fragmented health system, including HIV testing and treatment services. Management of COVID-19 for patients with HIV is further complicated by co-morbidities such as hypertension and diabetes.

Preparing for pandemics and having a resilient health system (especially the primary health care system) is vital to ensure continuity of care. In addition, the importance of designing health systems to treat patients with multi-morbidities should be prioritised.

EPC461

Lower CD4 count in new clients enrolled during Covid-19 pandemic in a global HIV program

F. Fernandes Fonseca[1], J. van den Hombergh[1], W. Odoke[1], E. Waweru[1], B. Biwot[1], J. Nakhumwa[1], A. Benzaken[1]

[1]*AIDS Healthcare Foundation (AHF), Global Quality Team, Los Angeles, United States*

Background: Late presenters are priority for HIV programs. Baseline CD4 cell count (CD4) is essential as the best predictor of disease status and risk of death and identifies those with advanced HIV disease. This study evaluates how the pandemic affected access to HIV care by monitoring CD4 of newly enrolled clients.

Methods: Analysis of retrospective CD4 data from the AHF Global Program (32 countries in Asia, Latin America and the Caribbean, India, and Africa), from 1 January 2019 to 31 December 2021.

Results: Comparing 2019, 2020 and 2021, the number of new people enrolled into care declined (N=95,131 in 2019, N=91,536 in 2020, and N=70,000 in 2021). In the same period, the CD4 coverage (proportion of clients who had a CD4 at baseline) ranged from 58% to 62%, with a marked reduction in total clients who had a CD4 (N=55,518 in 2019, N=54,032 in 2020, and N=43,275 in 2021).

The number and the proportion of clients enrolled with CD4≤350 cells/mm^{3}is increasing over the years (N=27,854, 50% in 2019; N=31,491, 58% in 2020, and N=23,992, 55% in 2021) whereas the proportion of those presenting with advanced AIDS (CD4<200cell/mm^3) ranged from 27% (N=14,963) in 2019 to 35% (N=18,700) in 2020 and 31% (N=13,386) in 2021.

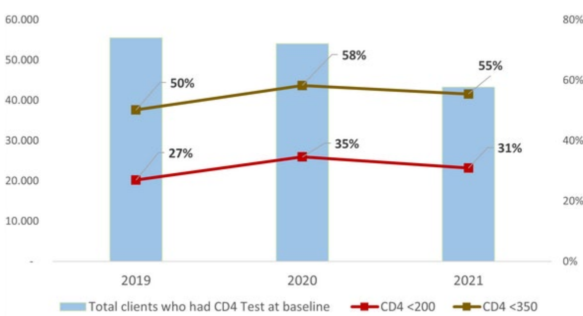

Figure. 2019-2021 Trend late presenters (CD4 <200 or CD4 <350) as proportion of clients with a baseline CD4 result.

Conclusions: The Covid-19 pandemic negatively impacted health services. The first 2 years of the Covid-19 pandemic saw an increase of people living with HIV presenting late to care with 1/3 of all having a CD4 presenting with advanced AIDS. Low CD4 at enrolment is associated with high co-morbidity, early mortality, higher direct health-care costs and poor retention in care.
Healthcare teams must be trained to manage complex patients including prophylaxis and treatment of OIs, and adopt a fast-track approach for clients with advanced AIDS, avoiding that Covid-19 takes the control over the HIV pandemic.

EPC462

Determinants of psychological distress and perceived changes in associated HIV/HCV risks during the COVID-19 pandemic among people who use drugs in Montreal, Canada

I. Makarenko[1,2], N. Minoyan[3,2], S. Larney[2,4], S. Hoj[2], S. Udhesister[2], J. Bruneau[2,4]
[1]McGill University, Family Medicine, Montreal, Canada, [2]Centre de Recherche du Centre Hospitalier de l'Université de Montréal (CR-CHUM), Montreal, Canada, [3]School of Public Health, Université de Montréal, Department of Social and Preventive Medicine, Montreal, Canada, [4]Université de Montréal, Department of Family Medicine and Emergency Medicine, Montreal, Canada

Background: Psychological impacts of the COVID-19 pandemic have been widely reported, however data is limited among people who use drugs (PWUD). This study aimed to determine HIV/HCV risks prevalence and correlates of psychological distress among PWUD during the pandemic period, and assess whether these differ between certain sub-groups of people who use different types of drugs.
Methods: We conducted a rapid assessment study from May-December 2020 among participants recruited in HEPCO, a community-based cohort of people who inject drugs (PWID) in Montreal (N=127), and community organizations serving people who use illicit drugs (N=99).
Among individuals reported past 6-months drug use, we collected and analyzed data on socio-demographics and drug use, including perceived changes in drug use behaviours and survival needs since COVID-19 was declared a public health emergency. Past-month psychological distress was assessed with the Kessler K6 scale. Multivariable logistic regression was conducted to examine correlates of high psychological distress (score ≥13) stratified by recent drug injection (past 6 months, yes/no).
Results: Of 226 survey participants (mean age 48 years old, 22% female, 42% recent drug injection), one quarter (n=56) screened positive for severe past-month psychological distress.
In multivariable analysis among participants with recent drug injection (42%), higher distress was associated with perceived increases in food insecurity (adjusted odds ratio = 6.16 [95% confidence interval: 1.71, 22.20]), non-injection drug use (8.15 [1.22,11.21]), and non-fatal overdose frequency (9.43 [1.39,64.19]) since declaration of the health emergency.
Among those recently using non-injection drugs only (58%), variables associated with high distress included younger age (per year of increment: 0.94 [0.91, 0.97]), any past 6-month alcohol use (5.67 [1.55, 20.77]), and perceived increase in food insecurity (2.64 [1.04, 6.72]).
Conclusions: This study documented a high prevalence of psychological distress among PWUD during the COVID-19 pandemic. Psychological distress was associated with increased food insecurity in both sub-groups of PWUD. Increased overall non-injection drug use in addition to drug injecting and self-reported overdoses were associated with high psychological distress among PWID, while alcohol use and younger age were significant determinants of high distress among those who used non-injection drugs. Ongoing monitoring of distress and tailored interventions are urgently needed to mitigate negative impacts of the pandemic in this vulnerable population.

EPC463

Effect of COVID-19 on HIV prevention among the LGBTQ+ population in New York City (NYC)

J. Platt[1], C. Wright[1], C. Chang[1], E. Romero[1], W. El-Sadr[1], A. Low[1]
[1]ICAP at Columbia University, New York, United States

Background: The COVID-19 pandemic has caused widespread disruptions to HIV services worldwide. Although a number of innovative mitigation strategies have been employed, a significant reduction in HIV prevention services has been noted. Key populations and communities disproportionately impacted by HIV, including LGBTQ+ individuals, are particularly vulnerable to these disruptions. To better understand the effects on this population, we examined PrEP access and use of HIV and STI testing among LGBTQ+ individuals in New York City during the COVID-19 pandemic.
Methods: Self-reported LGBTQ+ adults living in New York City (N=1,038) were recruited from June to December 2021 to participate in an online survey. The survey included questions related to their sociodemographic characteristics, COVID-19 burden, practices, and impact, vaccination

willingness and uptake, and access to health care and HIV prevention services. Descriptive statistics and multivariable analysis were conducted.

Results: Most participants (67%) reported that the pandemic had not affected their ability to access STI or HIV testing services. However, 20% indicated that they had not tried to access those testing services since the pandemic began. Of all participants, 27% reported that their last HIV or STI test was over a year prior to the survey, 22% 6-12 months ago, and 46% within the last 6 months. Of HIV-negative participants assigned male at birth who reported casual sexual partners in the past three months, 44% had not been tested for HIV in the past 6 months, and 19% said that the pandemic had made testing harder. For participants currently taking PrEP (n=190), 27% said the pandemic had affected their ability to access PrEP.

Conclusions: The findings suggest that the pandemic had a moderate impact on the ability to access PrEP and HIV and STI testing services among this group. Over half of participants, including those assigned male at birth who had recent casual sexual partners, had not been tested in the past 6 months suggesting the need for intensive educational outreach and efforts to make testing more accessible.

COVID-19 testing

SARS CoV-2 seroprevalence in a cohort of people living with HIV before COVID-19 vaccination, Rio de Janeiro, Brazil

G. Calvet[1], S. Cardoso[1], L. Freitas[1], M.S. Pereira[1], F. Victoriano[1], R. Moreira[1], I. Georg[1], S. Nazer[1], S. Silva[1], V. Veloso[1], B. Grinsztejn[1]

[1]*Evandro Chagas National Institute of Infectious Diseases, Oswaldo Cruz Foundation, Rio de Janeiro, Brazil*

Background: The study aimed to determine the seroprevalence of SARS-CoV-2 infection from a single referral center for people living with HIV (PLWH) before the COVID-19 vaccination.In Brazil, the initial dose of COVID-19 vaccination was available by the end of April 2021 for this population.

Methods: Participants from the Evandro Chagas National Institute of Infectious Diseases cohort of PLWH in Rio de Janeiro, Brazil, with available leftover sera samples from routine outpatient CD4/CD8 cell counts and or viral load testing between November 26th, 2019, and May 5th, 2021, were included in this cross-sectional study. SARS-CoV2 IgG and IgM anti S were measured using the Abbott SARS-CoV-2 IgG II Quant and the Abbott Architect SARS-CoV-2 IgM chemiluminescent microparticle immunoassays. Both Architect IgM and IgG results were interpreted together. Any reactive IgG and IgM result was considered positive for COVID-19 infection.

Results: Overall, 11,423 serological assays were performed in 3,964 participants (68.8% male), median age 44.5 (IQR: 35.6-54.4), median CD4 cell count 676 cell/µL (IQR:443-913], 85.9% with viral suppression, 98.5% on antiretroviral therapy. The overall seroprevalence for SARS-CoV-2 was 23.2% (1989/8559, 95% CI 22.3-24.1), increasing from 1.62% in the first three months [(November 2019-January 2020 (17/1051, 95% CI 1.39-1.83)] to 42.18% (577/1368, 95% CI 39.56-44.80) in March-May 2021 (figure).

During the study period, 33 (0.83%) participants died, eight (24.2%) with suspected/confirmed COVID-19, and 25 (75.8%) with other causes. All patients who died with COVID-19 had negative serology for SARS-CoV-2. The median time from negative serology for SARS-CoV-2 to death in these participants was 139 days (IQR: 51-180.8).

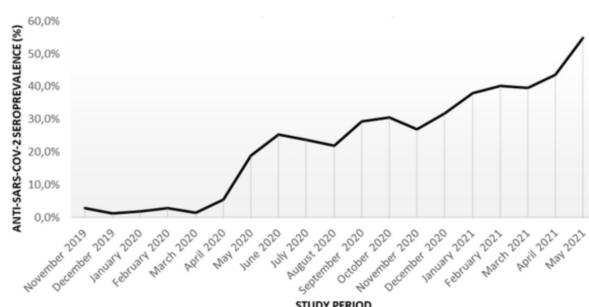

Figure. Month by month anti-SARS-CoV-2 seroprevalence, Evandro Chagas National Institute of Infectious Diseases HIV cohort, Rio de Janeiro, Brazil.

Conclusions: SARS-CoV-2 antibodies were detected before the first reported COVID-19 cases in Rio de Janeiro, Brazil. A high SARS-CoV-2 seroprevalence was observed in PLWH before the launch of COVID-19 vaccination for this population, and overall death related to COVID-19 was low in this setting.

Lopinavir/Ritonavir post-exposure prophylaxis did not protect against Covid-19

D. Tan[1], A. Chan[2], A. Qamar[1], C. Cooper[3], S. Currier[4], M. Lafrenier-Roula[4], K. Thorpe[5], T. Mazzulli[6], S. Walmsley[7], N. Press[8], R. Somayaji[9], P. Juni[4], S. Daneman[2], A. McGeer[6]
[1]St. Michael's Hospital, Division of Infectious Diseases, Toronto, Canada, [2]Sunnybrook Hospital, Division of Infectious Diseases, Toronto, Canada, [3]The Ottawa Hospital, Division of Infectious Diseases, Ottawa, Canada, [4]St. Michael's Hospital, Applied Health Research Centre, Toronto, Canada, [5]University of Toronto, Dalla Lana School of Public Health, Toronto, Canada, [6]Mount Sinai Hospital, Department of Microbiology, Toronto, Canada, [7]Toronto General Hospital, Division of Infectious Diseases, Toronto, Canada, [8]St. Paul's Hospital, Division of Infectious Diseases, Vancouver, Canada, [9]University of Calgary, Division of Infectious Diseases, Calgary, Canada

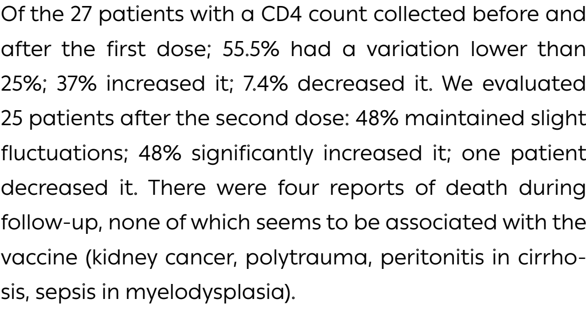
Background: Early in the Covid-19 pandemic, the HIV protease inhibitor lopinavir/ritonavir (LPV/r) was hypothesized to have antiviral activity against SARS-CoV-2.
Methods: We conducted an open-label cluster-randomized controlled trial of LPV/r as COVID-19 PEP at 6 sites in Canada.'Rings' of individuals in close contact with a case of SARS-CoV-2 infection within the preceding seven days were randomized to receive LPV/r 800/200mg twice daily for 14 days, or no intervention, if they could be contacted within 48 hours. Participants self-collected throat/nasal swabs on days 1, 7 and 14, plus a saliva specimen on day 14, for SARS-CoV-2 PCR testing.
The primary outcome was SARS-CoV-2 infection by day 14 among those testing negative at baseline. We estimated PEP efficacy using a generalized estimating equation with exchangeable correlation structure to account for clustering of participants in rings.
Secondary outcomes included safety, symptomatic disease, hospitalization, respiratory failure, and mortality. Widespread availability of COVID-19 vaccines in Spring 2021 rendered recruitment of participants impractical and the trial was formally terminated in 09/2021.
Results: Of 1634 referred patients with SARS-CoV-2 infection, 1104 were reached to ask about close contacts; 671 close contacts underwent screening and 123 were enrolled, representing 84 rings.Mean (SD) participant age was 31.7 (16.5) years, 64.2% were female, 43.3% were White, and 43.9% were born outside Canada. Most (94.3%) were exposed in the community and time since last contact with the case was 5.3 (3.4) days. Of the 94 participants with negative or indeterminate baseline SARS-CoV-2 tests, 46 (48.9%) received LPV/r.
The primary outcome was reached in 12/46 and 3/48 of intervention and control participants, respectively (OR=4.5, 95%CI=1.1,18.4). Symptomatic SARS-CoV-2 occurred in 9/46 and 3/48 respectively (OR=3.52, 95%CI=0.84,14.7). The proportion of LPV/r participants with an adverse event at least possibly related to study drug was 30.4% (14/46), primarily gastrointestinal and dermatologic (9/14 or 64.3% and 3/14 or 21.4% of events, respectively). We observed no COVID-related hospitalizations, respiratory failure or deaths in either arm.
Conclusions: We observed no signal that LPV/r has efficacy as SARS-CoV-2 PEP in this prematurely terminated trial. Possible reasons for the unexpected direction of the final results include small sample size and changes in behaviour in this unblinded trial.

EPC466

Coronavirus vaccine safety in people living with HIV/AIDS

S. De Sousa dos Santos[1], C. Martins Ruggiero[2], D.M. Falcão de Oliveira[2], S. Saad Guarda[1], M. Martins de Andrade[1], C. Toniolo Zenatti[2], C.A. Antonio Mestre[3]
[1]Universidade Federal de São Carlos, Department of Medicine, São Carlos, Brazil, [2]São Carlos Municipal Health Department, São Carlos Chronic Infection Care Center, São Carlos, Brazil, [3]São Carlos Municipal Health Department, Department of Health Surveillance, São Carlos, Brazil

Background: Current evidence points against an increased risk of severe COVID-19 in PLWHA. Nevertheless, little is known about the effects of the immune response, either to the virus or the vaccines, in immunological and virological parameters. This study aims to evaluate the safety of COVID-19 vaccines in PLWHA.
Methods: Retrospective cohort of 470 HIV/AIDS adults who received the first dose of COVID-19 vaccine at the São Carlos Chronic Infection Care Center, SP, Brazil, from 05/13/2021 to 07/16/2021. We assessed the Ministry of Health report system for therapeutic history, CD4 counts and HIV viral load, and the "Vacivida" system for vaccine information.
Results: 68.1% of patients were male, mean age 41.8 years. All patients were on antiretroviral treatment; 42.8% were on tenofovir, lamivudine and dolutegravir. 156 of the patients had a CD4 count within six months before vaccination (median 644.5; IQR 394-932). 59.1% patients had a viral load within six months before vaccination; 84.9% had undetectable viral load (UVL) (< 40 cp/mL).469 patients received ChAdOx-1 vaccine; 448 had both doses from this immunogen.
After the first dose, 89.4% had UVL; 88.9% after the second dose. Assessment of viral load variation after the first dose was possible in 67 patients: 73.1% maintained an UVL; 13.4% undetected a previously detectable viral load (DVL); 10.5% maintained a DVL; 3% had a detection after a previously UVL. 90 patients were compared between pre-vaccination and after the second dose; 82% maintained an UVL; 10.1% undetected a previous DVL; 3% maintained a DVL; 4% had a detection after a previous UVL.



Of the 27 patients with a CD4 count collected before and after the first dose; 55.5% had a variation lower than 25%; 37% increased it; 7.4% decreased it. We evaluated 25 patients after the second dose: 48% maintained slight fluctuations; 48% significantly increased it; one patient decreased it. There were four reports of death during follow-up, none of which seems to be associated with the vaccine (kidney cancer, polytrauma, peritonitis in cirrhosis, sepsis in myelodysplasia).

Conclusions: Apparently, COVID-19 vaccination has no impact on virological and immunological response of PLWH. However, the epidemic may have impacted healthcare of these patients.

EPC467

Omicron: infection rate and clinical outcomes in Johannesburg, South Africa

S. Sokhela[1], B. Bosch[1], A. Hill[2], B. Simmons[3], J. Woods[1], H. Johnstone[4], S. Madhi[1], A. Qavi[5], L. Ellis[5], G. Akpomiemie[1], E. Bhaskar[1], J. Levi[6], J. Falconer[7], M. Mirchandani[5], C. Perez Casas[8], K. Moller[1], V. Pilkington[9], T. Pepperrell[10], F. Venter[1]

[1]University of the Witwatersrand, Johannesburg, South Africa, [2]University of Liverpool, Liverpool, United Kingdom, [3]London School of Economics and Political Science, London, United Kingdom, [4]HJ-Clinical Trial Consultancy, George, South Africa, [5]Imperial College London, London, United Kingdom, [6]Kings College Hospital, London, United Kingdom, [7]Barts Health NHS Trust, London, United Kingdom, [8]Unitaid, 1218 Le Grand-Saconnex, Switzerland, [9]Oxford University, Oxford, United Kingdom, [10]University of Edinburgh, Edinburgh, United Kingdom

Background: The Omicron SARS-CoV-2 variant spread globally from November 2021. We compared infection rates and clinical data from a prospective cohort of healthcare workers and others at high risk of infection, throughout Delta and Omicron waves in Johannesburg, South Africa, where the Omicron epidemic first emerged.

Methods: This investigator-led study evaluated repurposed drugs as pre-exposure prophylaxis for 24 weeks for participants at risk for SARS CoV-2 infection. Participants were evaluated every 4 weeks, or if symptomatic, for new infections.All participants were tested for PCR and/or antibodies at each study visit.The cumulative incidence of infections was compared between the Delta and Omicron waves using Kaplan-Meier analysis.

Results: We enrolled 828 participants from December 2020 to December 2021 (561 participants prior to/during the Delta wave, 397 during the Omicron wave). Overall, 50% were women, 99% Black, with mean age 24 years. Risk factors included obesity (21%) and elevated blood pressure (8%); 20% received at least one vaccine dose during follow up. Of the 561 participants evaluated during the Delta wave, 125 (22%) were infected, with 43 (33%) symptomatic infections. Of the 397 participants evaluated in the six weeks from start November 2021 (Omicron wave), 188 (47%) were infected by 18 December 2021, with 46 (24%) symptomatic infections. Infection rates were significantly higher for the Omicron wave ($p<0.001$).

In each wave, antibody testing identified more infections versus PCR testing alone (Figure 1a-1b). There was one COVID-19-related death and one hospitalization during Delta, with none in the Omicron wave. Clinical symptoms were otherwise mild.

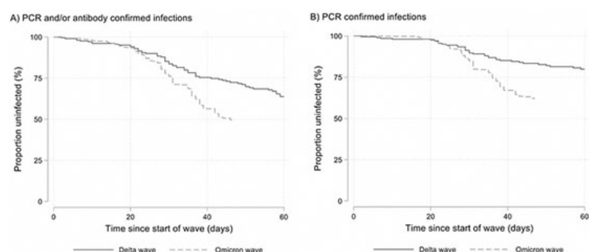


Figure 1a & 1b

Conclusions: During the Omicron wave, 47% of participants were infected in 6 weeks, 76% asymptomatically. This analysis suggests that PCR testing alone could underestimate the incidence of new omicron infections.

If the intervals between PCR tests are too wide, short intervals of viraemia may be missed and infections only detected after the subsequent emergence of antibodies.

EPC468

Nitazoxanide as post exposure prophylaxis (PEP) of COVID-19 household contacts (FH-53 PENTZ)

H. Ludvik[1,2], E. Ludvik[3], L. Tejeiro[3], J. Sameghini[4], M. Lopez[4], M. Portela[4], N. Mendez[1], J. Garcia[1], C. Biscayart[4], P. Sujansky[4], F. Gadea[1], P. Angeleri[4], L. Cahn[1], V. Fink[1], M.I. Figueroa[1], Z. Ortiz[1], P. Cahn[1], O. Sued[1,5]

[1]Fundación Huésped, Clinical Research, Buenos Aires, Argentina, [2]Hospital Juan A. Fernandez, Infectious Diseases Unit, Buenos Aires, Argentina, [3]Hospital Juan A. Fernandez, Neurology Unit, Buenos Aires, Argentina, [4]Ministry of Health, Epidemiology Area, Buenos Aires, Argentina, [5]Pan American Health Organization, Washington, United States

Background: PEP could have a potential role in the management of COVID-19, in particular among unvaccinated or immunocompromised individuals. Nitazoxanide (NTZ) has shown in vitro activity against SARS-CoV-2 and is currently being studied in several clinical trials to control viral infections.

Methods: We conducted a pilot, cluster-randomized, double-blind, placebo-controlled trial in Buenos Aires to evaluate the efficacy and safety of nitazoxanide as PEP (NCT04788407). Household contacts of COVID-19 confirmed cases were offered to participate. After consenting, a salival sample for SARS-CoV-2 PCR was obtained from asymptomatic unvaccinated individuals with negative COVID-19 IgM/IgG rapid test. Patients were randomly assigned by household 1:1 to receive a 7-day course of ni-

tazoxanide (500 mg) three times daily or placebo (PBO). Our primary endpoint was confirmed SARS-CoV-2 infection (PCR+ at day 14 or IgM/IgG+ at day 28) in participants who were randomized and had a baseline PCR negative. Secondary outcomes included safety and treatment adherence.

Efficacy analysis in the modified intent-to-treat population was performed using a mixed-effects model. Other comparisons were carried out using T-test and Chi-square.

Results: We enrolled 221 participants between December/2020 and August/2021: (NTZ:110, PBO:111). Mean age was 38.5 (SD 13.0), 18% had baseline PCR+ (NTZ:16, PBO:27), and 6.7% (NTZ:4, PBO:8) discontinued due to loss to follow-up or consent withdrawal.

During a 28-day follow-up, 23 participants (13%) developed a SARS-CoV-2 confirmed infection, without statistical significance between arms: mITT=[PBO:16.7% vs NTZ:22.3% OR: 2.08 (95%CI:0.06-99.0); p:0.67]. Adverse events were more frequent with NTZ vs PBO (66.3 % vs 23.4%, respectively; p<0.001), most commonly reported mild gastrointestinal upset.

Overall adherence was 82% (NTZ:76.6%-PBO:85.7%). A dramatic reduction of cases in the study period and the broad expansion of the national vaccination program prevented the completion of the planned recruitment.

Conclusions: Nitazoxanide did not show efficacy as PEP among household contacts of COVID-19 cases in the studied sample. Safety was comparable to previous studies, and adherence was acceptable. More studies are needed to understand the potential role of NTZ in preventing COVID-19, including vaccinated and post COVID populations.

EPC469
Anti-SARS-CoV-2 antibodies after vaccination in people living with and without HIV

S. Noe[1], C. Wiese[1], F. Schabaz[1], A. von Krosigk[1], S. Heldwein[1], R. Rasshofer[1], E. Wolf[2], C. Jonsson-Oldenbuettel[1], ArcHIV-Study Group
[1]*MVZ München am Goetheplatz, Munich, Germany,* [2]*MUC Research, Munich, Germany*

Background: COVID-19 vaccines have become the mainstay in the management of the global SARS-CoV-2 pandemic. However, while vaccines have proved a high degree of protection from SARS-CoV-2 infection and a severe course of COVID-19, comparative data from people living without (PLw/oH) or with HIV (PLWH) are scarce.

This study aimed to compare the humoral response to standard vaccinations against SARS-CoV-2 in PLw/oH and PLWH.

Methods: Retrospective single center case-control study, comparing anti-SARS-CoV-2-antibodies after a COVID-19 standard vaccination in PLw/oH with PLWH with a CD4 cell count > 450 cells/µL after matching 1:2 for age, sex, time between vaccination and measurement of anti-SARS-CoV-2-antibodies, and standard vaccination scheme (mRNA-containing yes/no). Groups were compared using Wilcoxon-Mann-Whitney test for continuous and chi-square tests for binary outcome variables.

Results: Overall, 86 people living without HIV were matched to 172 people living with HIV, resulting in an overall sample size of 258 subjects (median age: 43 [IQR 36; 52] years; 185 [71.7(%)] men). Among people living with HIV, median CD4 cell count was 804 (IQR 649; 971) and 162 (94.2 %) had a HIV-PCR < 50 copies/mL. Median anti-SARS-CoV-2 antibody concentrations were 1425 (IQR 794; 2248) and 1055 (IQR 516; 1770) for people living with and without HIV, respectively (p=0.007).

	PLWH	PLw/oH	p-value
Age, median [years] IQR	43 (36;52)	44 (36;53)	0.520
Male sex, n (%)	123 (71.5)	62 (72.1)	1.000
mRNA-containing scheme, n (%)	151 (87.8)	70 (81.4)	0.233
Time from last vaccine dose, median [days] IQR	54 (40;75)	56 (43;84	0.113
Antibody concentration, median [BAU/mL] IQR	1425 (794;2248)	1055 (516;1770)	0.007

Table.

Conclusions: In our study, people living with HIV with at least 450 CD4 cells/µL demonstrated higher concentrations of anti-SARS-CoV-2 antibodies after a standard vaccination when compared to matched, uninfected controls. It is unclear if this translates into an overall better protective effect in people living with HIV and warrants further investigation.

EPC470
"Why do you want to kill me again? Isn't HIV enough?" Acceptability and factors influencing uptake of COVID-19 vaccines among persons living with HIV in three districts in Uganda

M. Lekuru Aketoko[1], A. Onzia[1], P. Ajeru[2]
[1]*Infectious Diseases Institute, Research, Kampala, Uganda,* [2]*Kampala International University, Medicine, Bushenyi, Uganda*

Background: Since 2019 when COVID-19 was declared a pandemic,various control measures have been instituted globally including vaccination.However vaccine hesitancy remains a big challenge in many communities in Uganda with only 4.2% of the population fully vaccinated.

This study aimed to understand acceptability of COVID-19 vaccines and evaluate factors influencing vaccine uptake and acceptance among persons living with HIV who are among the vulnerable populations.

Methods: Following ethical approval,we conducted a mixed methods study among persons attending rural and urban HIV clinics in the three districts of Kampala, Wakiso and Mpigi with the highest prevalence of COVID-19 in Uganda. Interviewer administered face-to-face

questionnaires, focus group discussions and in depth interviews were used to collect data. Quantitative data was cleaned and analysed using STATA version 15 and qualitative data was coded and analysed using emerging themes.

Results: 282 participants were enrolled in the quantitative study and 24 in the qualitative. Majority (118) were aged 25-40 years, 97.9 % were Ugandans and 59.6% females in monogamous relationships. 66% had some level of formal education, 63.9% were employed and majority (97%) had heard about COVID-19 and its prevention methods. 81.1% of the participants had not received any COVID-19 vaccine and of these the majority (67.6%) were not willing to receive the vaccine if offered to them.

Reasons cited were fear of side effects of the vaccine, myths and misconceptions, lack of trust in government programs and fear of co-infection of HIV and COVID-19 through vaccination.

Multivariate analysis showed that marital status, education level, employment status, awareness of signs and symptoms of COVID-19, prior history of COVID-19 diagnosis and treatment for friends and relatives, source of information about COVID-19 and self-perceived risk for the disease were significantly associated (p value < 0.001) with vaccine uptake.

Qualitative study identified lack of vaccine knowledge, lack of transparency and trust in government programs, myths and misconceptions, side effects,religious and cultural beliefs (herbs) and no history of infection as factors hindering vaccine uptake.

Conclusions: Findings demonstrate the importance of social demographic characteristics, adequate awareness and risk communication, engagement of all stake holders with transparency in government programs in attempt to increase vaccination uptake among persons living with HIV in Uganda.

Safety and immunogenicity of Sputnik-V, AstraZeneca and Sinopharm vaccines against SARS-CoV-2 in people living with HIV

R. Mauas[1], A. Urueña[1], D. Cecchini[1], D. Pinto[1], L. Teston[1], M.L. Strada[2], S. Arietti[2], F. Rombini[1], P. Rodriguez lantorno[1], E. Bottaro[1], I. Cassetti[1]

[1]Helios Salud, Ciudad Autónoma de Buenos Aires, Argentina, [2]Laboratorio Stamboulian, Ciudad Autónoma de Buenos Aires, Argentina

Background: Information about safety and immunogenicity of Sputnik-V, AstraZeneca and Sinopharm SARS-CoV-2 vaccines in people living with HIV (PLWH) remains limited. We aimed to describe such outcomes in PLWH in Argentina.

Methods: Prospective, observational, descriptive study in PLWH assisted in an HIV ambulatory care center (March-December 2021), and who received at least one dose of SARS-CoV-2 vaccination. Participants completed an online questionnaire. Clinical-epidemiological data, variables linked to vaccination and local or systemic adverse events probably related to vaccination and immunization (AEFIs) were collected and classified according to WHO guidelines.

Detection of S1-RBD IgG antibodies was performed between days 28-60 after the second dose in a subgroup of individuals (ADVIA Centaur® SARS-CoV-2 IgG chemiluminescent immunoassay, Siemens).

A multivariate analysis was applied to evaluate the relationship between AEFIs with age, sex, viral load (VL), immunological status (according to CD4+ T cell count) and type of vaccine received. A linear regression analysis was performed to evaluate correlation between antibody titers and CD4+ T cell count.

Results: 867 PLWH completed the survey. Median age: 45 years (18-84); male: 69.5%. VL <20 HIV RNA copies/mL: 92.9%; Median CD4+ count: 682.7 (492.5-841) cells/mm^3. Of the 867 doses applied, 36.7% were Sputnik-V; 46.3% AstraZeneca; 13.3% Sinopharm and 3.59% other vaccines. 311 AEFIs (35.8%) were reported: 99.7% non-severe vaccine product-related reactions and one severe coincident event. Prevalence of AEFIs was higher with AstraZeneca (60.4%) and Sputnik-V (29.5%) than with Sinopharm (5.4%) (OR=1.4, p=0.005, 95%CI=1.42-1.52).

On multivariate analysis, AEFIs were associated with viral vector vaccines (OR=1.7, p=0.032, 95%CI=1.5-1.8). 97/100 of the individuals assessed (97%) reached S1-RBD IgG antibody titers ≥1 U/mL (positive); median titer was 44 U/mL. Higher antibody titers correlated with higher CD4+ T-cell counts (p=0.011).

Conclusions: In PLWH, Sputnik-V, AstraZeneca and Sinopharm vaccines showed a safety profile comparable to clinical trials in general population. Higher frequency of AEFIs was observed with viral vector vaccines.

Vast majority of patients developed adequate humoral response with a positive correlation between antibody titers and CD4+ T-cell count.

EPC472

Early receipt of COVID-19 vaccines among people living with HIV: age, knowledge, and trust as determinants

R. Fisk-Hoffman[1], C. Parisi[1], P. Manavalan[2], B. Isma[3], M. Widmeyer[4], R.L. Cook[1]

[1]University of Florida, Epidemiology, Gainesville, United States, [2]University of Florida, College of Medicine, Division of Infectious Diseases and Global Medicine, Gainesville, United States, [3]Florida International University, Epidemiology, Miami, United States, [4]Project Response, Inc., Melbourne, United States

Background: Race/ethnicity and trust have been associated with the uptake of voluntary vaccinations, including COVID-19 vaccines. It is unclear whether:

1. Race/ethnicity and trust in the medical system affected early vaccination in people living with HIV (PLWH), and;
2. Which organizations involved in vaccine rollout are most trusted by PLWH.

Methods: The Florida Cohort Study is a National Institute of Health-funded study enrolling adult PLWH from 7 clinical and community-based sites. Participants who enrolled between March 2021 and October 2021 and self-reported their COVID-19 vaccination status were included in this analysis (n=146, 63% male, 34% non-Hispanic Black, 22% Hispanic, average age 52 years).

Early vaccination was defined as receiving the first vaccine before the end of April 2021.Survey questions included COVID-19 knowledge and trust in 5 organizations involved in vaccine development and promotion. A cumulative trust score was calculated based on previous research on influenza vaccination, with values ranging from 5 to 25 (Cronbach's alpha= 0.91). COVID-19 knowledge was measured as the number of correct responses to 5 questions about transmission and risk groups.

We assessed whether demographics (race/ethnicity, age, gender, and education), trust, and knowledge were associated with early vaccination using simple and multivariable logistic regressions.

Results: Overall, 51% reported early COVID-19 vaccination, 45% answered all knowledge questions correctly, and trust scores were relatively high (median 19, IQR 16-23). Healthcare providers were the most trusted (79% endorsing "agree" or "strongly agree"), followed by the Centers for Disease Control and Prevention (77%), the Food and Drug Administration (64%), the World Health Organization (51%), and pharmaceutical companies (46%).

Early vaccination was associated with higher trust scores (aOR 1.2, 95% CI 1.07-1.31), older age (aOR 1.1 95% CI 1.05-1.21), and higher COVID-19 knowledge (aOR 1.6 95% CI 1.10-2.37). Early vaccination did not differ significantly by race/ethnicity (51% in non-Hispanic Whites, 55% in non-Hispanic Blacks, and 47% in Hispanics, p=0.76).

Conclusions: There were no disparities by race/ethnicity in early vaccination. Greater trust in organizations involved in vaccine rollout was associated with increased early acceptance independent of other factors. Efforts to increase trust within this community may help improve vaccine acceptance.

EPC473

Multiple strategies are needed for enrolling individuals in randomized COVID-19 trials. Lessons learned from a home base postexposure trial in Argentina

A. De Luca[1], D. Farran[1], P. Copello[1], E. Ludvik[2], J. Sameghin[3], M. Lopez[4,5], M. Portela[6], L. Tejeiro[2], N. Mendez[1], J. Garcia[1], P. Sujansky[7], C. Biscayart[7], F. Gadea[8], P. Angeleri[9], I. Aristegui[1], O. Sued[10], P. Cahn[1,11], H.K. Ludvik[11,1]

Fernández, Infectious Diseases Unit, Buenos Aires, Argentina*

Background:
Post-exposure studies require immediate access to exposed candidates. This work presents a home recruitment strategy for post-exposure COVID-19 household contacts in Argentina (NCT04788407).

Description: This study enrolled participants between December 2020 to July 2021. Recruiting strategies were: Strategy 1 (S1) Public Health Emergency Operations Center (EOC) offered index cases to invite their household contacts; if interested, EOC referred the list of individuals to be contacted.Due to the difficulty of enrolling on time, we included: Strategy 2 (S2) Self-referrals through a mass media communication campaign inviting household contacts to fill an online form to be contacted, Strategy 3 (S3) Direct referral of providers who cared for index cases. All potential candidates were interviewed by phone and the eligible ones were scheduled for a home visits.

S1 required official clearance, was more complex to navigate, needed to coordinate with multiple individuals, and proved less sensitive, as clinical research was not its primary objective.

S2 required both financial investment and attractive marketing to generate interest, and the public reacted in waves. However, its implementation resulted in a 61% increase in the study admissions.

S3 had a limited scope due to few providers being aware or interested in the study.

At the end of the enrollment period, 2972 potential candidates were identified, 2421 were interviewed by phone, and 231 were randomized, mostly reached by S1 (S1:67%, S2:25%, S3:8%). However, when we analyze effectiveness (randomized/interviewed per strategy), the relationship was inverse (S1:7%, S2:19%, S3:59%).

Oral abstracts

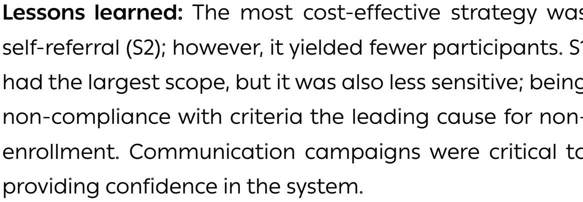
E-posters

Late-breaker abstracts

Author Index



Lessons learned: The most cost-effective strategy was self-referral (S2); however, it yielded fewer participants. S1 had the largest scope, but it was also less sensitive; being non-compliance with criteria the leading cause for non-enrollment. Communication campaigns were critical to providing confidence in the system.

The main challenge was reaching individuals on time. A large and motivated team of interviewers trained in the research study to provide information and support was critical.

Telephonic enrollment and home visits represented additional challenges (i.e. mistrust or fear of participants and safety concerns in some neighborhoods). The ability to introduce team members via social media enhanced trust and confidence.

Conclusions/Next steps: Innovation and adaptation is critical for ensuring enrollment during pandemics.

EPC474

COVID-19 vaccination intention among people who use drugs in France in 2021: results of the international community-based research program EPIC

C. Lacoux[1,2], V. Villes[2], R. Diagne[2], S. Coulmain[1], A. Negaret[1], R. Delabre[2], L. Riegel[2], P. Roux[3], D. Michels[1,2], D. Rojas Castro[2,3]

[1]AIDES, Pantin, France, [2]Coalition PLUS, Community-Based Research Laboratory, Pantin, France, [3]Aix Marseille University, Inserm, IRD, SESSTIM, Sciences Economiques & Sociales de la Santé & Traitement de l'Information Médicale, ISSPAM, Marseille, France

Background: Covid-19 vaccination is one of the key ways to fight the pandemic. People who use drugs (PWUD), often experiencing barriers to healthcare access, are a priority population for vaccination in France, due to their precarious living conditions and potential comorbidities (co-infection HIV-HCV). However, data on Covid-19 vaccination intention among this group is limited. This study aims to identify factors associated with Covid-19 vaccination intention among PWUD.

Methods: The survey was carried out as part of the international community-based research program EPIC, coordinated by Coalition PLUS. This program aims to document the impact of Covid-19 health crisis among key populations and community health workers. In France, it was rolled out among PWUD from May to October 2021. A paper questionnaire was available in the 28 low-threshold drug user centers of the French AIDES organization. A multivariate logistic regression was conducted to identify factors associated with a moderate/low intention to get vaccinated ("Yes, probably"; "Maybe"; "Probably not"; "Not at all" vs. "Yes, absolutely").

Results: Among the 211 PWUD respondents, 166 were unvaccinated (79%). The majority of them were men (n=138, 83%) with a median age of 40 [34-47]. Around 80% had a lower education level (high school education or less) and 26% were in unstable housing. When asked about their intention to be vaccinated against Covid-19, 32 (19%) answered "Yes, absolutely" and 134 (81%) answered "Yes, probably" (n=9), "Maybe" (n=41), "Probably not" (n=25) or "Not at all" (n=59).

Main reported barriers to vaccination were lack of confidence (46%) and fear of risks and side effects (34%). Being younger (aOR=1.11 [1.05.-1.17]), having a lower education level (2.71 [0.97-7.61]) and unstable housing (5.47 [1.35-37.77]) were independently associated with a moderate/low vaccination intention.

Conclusions: These results show that few PWUD have a high intention to get vaccinated against Covid-19. Younger PWUD and those who have precarious living conditions are most likely to have moderate/low intention.

Strategies that target PWUD through reinforcing their confidence, giving information about collective and individual benefits of vaccination and offering vaccinations in low-threshold drug user centers seem important to implement to increase vaccine uptake.

Medical and demographic factors associated with COVID-19 vaccination among people living with HIV (PLWH) in an urban United Kingdom clinic

I. Maan[1,2], R. Owen[1,2], M. Kohli[1,2], C. Mullender[1,2], R. Gilson[1,2], A. Teague[2], L. Waters[2], S. Pett[1]

[1]University College London, Institute for Global Health, London, United Kingdom, [2]Central and North West London NHS Trust, HIV Medicine, London, United Kingdom

Background: The December 2021 UK COVID-19 vaccine guidance for people living with HIV (PLWH) is 2-vaccine schedule plus booster, or 3-vaccine schedule plus booster in those with CD4+ T-cells <200cells/mm^3. COVID-19 vaccine hesitancy has been described among PLWH in the UK and other countries. We aimed to describe the COVID-19 vaccinated and unvaccinated population of PLWH in an HIV-specialist clinic in London.

Methods: Data was extracted in November 2021 from electronic health records of all PLWH who had attended our service since December 2020, when COVID-19 vaccination began in the UK. Demographics and clinical characteristics were compared based on vaccination status using chi-squared tests.

Multivariate logistic regression models were used to calculate adjusted odds ratios of the association between vaccination, and age, gender and ethnicity; with *p*-values calculated using likelihood ratio tests.

Results: Of 4,594 PLWH included, 58.0% were White and 81.8% were male, with a median age of 50 (IQR 41-57). 67.4% had received ≥1 COVID-19 vaccines but coverage was significantly lower amongst people of Black and Mixed ethnicities, adjusted for age and gender (Table). Male gender and increasing age were associated with higher vaccination coverage in the multivariate model. No asso-

ciation was found between vaccination status and CD4+ T-cell count <200cells/mm^3[vaccinated 2.7% vs unvaccinated 3.7%, χ^2p=0.097], diabetes mellitus (HbA1c>48mmol/mol)[4.5% vs 4.8%, χ^2p=0.595] or chronic kidney diseases (eGFR<60ml/min/1.73m^2)[7.6% vs 7.2%, χ^2p=0.682], however these three factors were all more prevalent in people of Black ethnicity (χ^2p=<0.001).

Demographic Factors	Total number of PLWH (%)	Number vaccinated with 1 or more COVID-19 vaccines (%)	Number unvaccinated for COVID-19 (%)	Adjusted Odds Ratio	95% Confidence Interval	P -value
Ethnicity						
White	2666 (58.0)	1960 (73.5)	706 (26.5)	1	1	<0.001
Black	1033 (22.5)	601 (58.2)	432 (41.8)	0.60	0.50 – 0.72	
Asian	146 (3.2)	99 (67.3)	47 (32.7)	0.91	0.63 – 1.31	
Mixed	204 (4.4)	118 (57.8)	86 (42.2)	0.63	0.47 – 0.85	
Other	145 (3.2)	99 (68.3)	46 (31.7)	0.83	0.58 – 1.21	
Not Stated	400 (8.7)	218 (54.5)	182 (45.5)	0.55	0.44 – 0.69	
Gender						
Male	3756 (81.8)	2617 (69.7)	1139 (30.3)	1.26	1.06 – 1.53	0.011
Female	838 (18.2)	478 (57.0)	360 (43.0)	1	1	
Age						
18-29	239 (5.2)	104 (43.5)	135 (56.5)	1	1	<0.001
30-39	735 (16.0)	435 (59.2)	300 (40.8)	1.59	1.18 – 2.15	
40-49	1234 (26.9)	809 (65.6)	425 (34.4)	2.02	1.51 – 2.70	
50-59	1578 (34.4)	1138 (72.1)	440 (27.9)	2.73	2.05 – 3.64	
60-69	658 (14.3)	484 (73.6)	174 (26.4)	2.84	2.07 – 3.91	
70 +	150 (3.2)	125 (83.3)	25 (16.7)	4.60	2.77 – 7.66	

Table: COVID-19 vaccination coverage and adjusted odds ratios from multivariate logistic regression model for association between demographic factors and vaccination (n=4,594)

Conclusions: COVID-19 vaccine uptake in this clinic in London, despite freely available vaccines throughout 2021, varied significantly by ethnicity and age. Co-morbidities were not associated with vaccination status, however Black ethnicity patients had higher rates of co-morbidities which would place them at risk of more severe COVID-19 disease. Strategies to overcome barriers to COVID-19 vaccine uptake in PLWH remains an urgent health priority.

Randomized clinical trial of nitazoxanide or sofosbuvir/daclatasvir for the prevention of SAS CoV-2 infection

S. Sokhela[1], B. Bosch[1], A. Hill[2], B. Simmons[3], J. Woods[1], H. Johnstone[4], S. Madhi[1], A. Qavi[5], L. Ellis[5], G. Akpomiemie[1], E. Bhaskar[1], J. Levi[6], J. Falconer[7], M. Mirchandani[5], C. Perez Casas[8], K. Moller[1], V. Pilkington[9], T. Pepperrell[10], F. Venter[1]

[1]University of the Witwatersrand, Johannesburg, South Africa, [2]University of Liverpool, Liverpool, United Kingdom, [3]London School of Economics and Political Science, London, United Kingdom, [4]HJ-Clinical Trial Consultancy, George, South Africa, [5]Imperial College London, London, United Kingdom, [6]Royal Free Hospital, London, United Kingdom, [7]Royal Brompton Hospital, London, United Kingdom, [8]Unitaid, 1218 Le Grand-Saconnex, Switzerland, [9]Oxford University, Oxford, United Kingdom, [10]University of Edinburgh, Edinburgh, United Kingdom

Background: The COVER trial was set up in April 2020, to evaluate whether nitazoxanide or sofosbuvir/daclatasvir could lower the risk of SARS-CoV-2 infection in healthcare workers and others at high risk of infection. Nitazoxanide was selected given favourable pharmacokinetics and in vitro antiviral effects against SARS-CoV-2. Sofosbuvir/daclatasvir, normally used to treat Hepatitis C infection, had shown favourable results in early clinical trials.

Methods: In this clinical trial in Johannesburg, South Africa, healthcare workers and others at high risk infection were randomized to 24 weeks of either nitazoxanide, sofosbuvir/daclatasvir or standard of care as prevention. Subjects were evaluated every 4 weeks, with symptom evaluation, antibody testing and PCR.

The primary endpoint was confirmed SARS-CoV-2 infection, defined as either positive PCR or serology after baseline, regardless of symptoms. A Poisson regression model was used to estimate the incidence-rate ratios (IRR) of the incidence of confirmed SARS-CoV-2 between each experimental arm and control.

	Arm A: no pharmacological intervention	Arm B: NTZ	Arm C: SOF/DCV
Primary analysis			
n/N (%)	96/261 (37)	88/235 (37)	77/213 (36)
Person-years (person-days)	56.0 (20,455)	41.7 (15,219)	37.4 (13,670)
Incidence rate per 1,000 Person-years (95%CI)	1714 (1403-2094)	2112 (1714-2603)	2057 (1646-2572)
Comparison against control			
Incidence rate ratio (95%CI)*	[reference]	1.23 (0.92-1.65)	1.20 (0.89-1.62)
p-value		0.157	0.233
Relative risk ratio (95%CI)*	[reference]	1.02 (0.81-1.28)	0.98 (0.77-1.25)
p-value		0.878	0.887

Table. COVER trial, Primary efficacy analysis

Results: Between April 2020 and December 2021, confirmed infections were detected for 88/235 for nitazoxanide (37%), 77/213 for sofosbuvir (36%) and 96/261 for standard of care (37%).

There was no significant difference in the primary endpoint between the treatment arms and the results met the criteria for futility. In the safety analysis, 59 patients discontinued nitazoxanide for adverse events, and 56 discontinued sofosbuvir/daclatasvir.

Conclusions: In this randomised trial, nitazoxanide and sofosbuvir/daclatasvir had no significant preventative effect on infection with SARS-CoV-2, among healthcare workers and others at high risk of infection.

EPC477

COVID-19 vaccination rates and correlates associated with nonvaccination among the LGBTQ+ population in New York City

C. Wright[1], J. Platt[1], C. Chang[1], E. Romero[1], W. El-Sadr[1], A. Low[1]

[1]*ICAP at Columbia University, New York, United States*

Background: LGBTQ+ populations disproportionately have higher prevalences of health conditions associated with severe COVID-19 illness. Additionally, this population has historically experienced challenges trusting health care providers and is not routinely captured in SARS-CoV-2 vaccination data.

We examined the prevalence of vaccination among New York City's LGBTQ+ population and the association of nonvaccination to sociodemographic and behavioral correlates.

Methods: LGBTQ+ adults living in New York City were recruited for an online survey using social media and direct marketing from June to December 2021. The survey included questions on sociodemographic characteristics, including sexual orientation and gender identity, history of testing for and diagnosis of COVID-19, receipt of at least one dose of a COVID-19 vaccine, and vaccine intentions. Logistic regression analysis was conducted to determine correlates of being unvaccinated.

Results: Of the 1038 recruited participants, 61% were assigned male at birth, and 89% were under 40 (mean age 29 years). Most identified as gay or lesbian (56%), cisgender (64%), and being non-Hispanic White (49%).

Most participants (81%) had received at least one dose of a COVID-19 vaccine. Vaccination uptake was highest among Asian participants (97%) and lowest among non-Hispanic Black participants (73%).

In multivariable analysis, factors associated with being unvaccinated were being 30-39 years of age (adjusted odds ratio (aOR) 1.55, 95% CI 1.06-2.28), being bisexual (aOR 2.15, 95% CI 1.45-3.18), having a lower household income (<$50,000 per year, aOR 1.92, 95% CI 1.24-2.95), not having a college degree (aOR 1.49, 95% CI 1.00-2.23), and not being anxious (aOR 1.94, 95% CI 1.36-2.78).

The strongest predictor of nonvaccination was not having health insurance, with a more than 3-fold increase in the odds of being unvaccinated (aOR 3.07, 95% 2.11-4.48). The reasons selected for not wanting to ever get vaccinated (n=85) were that COVID-19 vaccines weren't safe (45%), they might have long-term side effects (40%), they don't work (27%), or that they were developed too quickly (16%).

Conclusions: These findings indicate high vaccination uptake by LGBTQ+ population. However, certain sociodemographic characteristics, mental health issues and insurance status were associated with nonvaccination. The findings highlight a need for continued targeted efforts to enhance vaccination uptake.

EPC478

Mistrust and COVID-19 vaccine acceptability among sexual and gender minority youth

A. Alvarenga-Arteaga[1], M. Niguse[2], Y. Yang[1], A. Schlupp[3], A. Lopez[3], N. Galai[4], M. Castillo[3], D. Celentano[4], R. Arrington-Sanders[4]

[1]*Johns Hopkins School of Medicine, Baltimore, United States,* [2]*University of Virginia, Charlottesville, United States,* [3]*Children's Hospital of Philadelphia, Philadelphia, United States,* [4]*Johns Hopkins Bloomberg School of Public Health, Baltimore, United States*

Background: Youth have the highest COVID-19 incidence rates in the United States, yet have low vaccination rates. Prior research with adolescents suggests that vaccine concerns about safety, educational level and migrant status were associated with lower vaccine uptake. Mistrust has been associated with vaccine hesitancy among adult Americans living with HIV.

There have been few studies that examined vaccine acceptability in Young Black and Latinx Sexual Minority Men (YBLSMM) and Transgender Women (TGW). This study aims to examine factors, including HIV status, associated with being vaccinated in a sample of YBLSMM/TGW.

Methods: YBLSMM/TGW (n=84), aged 15-24, were recruited June 2021 - November 2021 across four major metropolitan areas (Baltimore, MD; Washington D.C.; Philadelphia, PA; St Petersburg/Tampa, FL) to complete an online COVID-19 survey. Chi-squared and Fisher's exact tests were used for bivariate associations and multivariate Poisson regression was used to assess factors associated with COVID-19 vaccination.

Results: The mean age was 21.3 (SD 2.38). Most (57%) identified as gay and 22.3% identified as transgender/gender diverse. Over half (56%) of youth reported being vaccinated. Reasons for vaccination included: protecting themselves (83%), protecting family (79%), protecting community (72%), feeling safe around others (60%), not wanting to get sick from COVID-19 (57%), believing that the pandemic will not end until most people are vaccinated (57%), being recommended by a doctor (21%) and reporting a chronic health condition (15%). Individuals with a bisexual or "other" sexual orientation were 12% more likely to report vaccine receipt (p=0.012), while youth with vaccine mistrust were 37% less likely (p<0.001). HIV status was not associated with vaccination. In the adjusted model,

controlling for history of COVID-19, sexual orientation, and HIV status, participants with vaccine mistrust were 39% less likely to receive a COVID-19 vaccine (p<0.001).
Conclusions: Vaccine mistrust is still a challenge. To address vaccine acceptability in YBLSMM/TGW, programs should focus on linking vaccinations to personal values of protecting oneself and their families.

EPC479

Factors associated with COVID-19 vaccine receipt among adults in Malawi

L. Makonokaya[1], L. Kapanda[1], T. Maphosa[1], H. Nkhoma[1], R. Kanyenda[1], L. Kalitera[1], G. Woelk[2]
[1]*Elizabeth Glaser Pediatric AIDS Foundation, Lilongwe, Malawi,* [2]*Elizabeth Glaser Pediatric AIDS Foundation, Washington DC, United States*

Background: Malawi implemented a COVID-19 vaccine campaign for adults, 18 years+ in March 2021. We assessed factors associated with planned receipt of COVID-19 vaccine in Malawi as part of a telephone-based syndromic surveillance survey.
Methods: We conducted telephone-based syndromic surveillance surveys among adults (≥18 years old) with verbal consent to be interviewed from March to December 2021; random digit dialing was used to randomly select mobile phone numbers, and electronic data collection forms using secure tablets were used.
Survey questions included whether the respondent had received at least one dose of COVID-19 vaccine. We used multivariable analysis to identify factors associated with intention to receive COVID-19 vaccine.
Results: A total of 7,740 respondents reported they had received the vaccine; 67.5% were male. Females were more likely to receive vaccination compared to males [Adjusted Odds Ratio (AOR) 1.17 95% confidence interval (CI) 1.1-1.24].
Compared to the Northern region, respondents who resided in the Central or Southern regions were less likely to vaccinate: (AOR 0.84 CI 0.77-0.92, and AOR 0.58 CI 0.53-0.63), respectively. Older age was associated with increased vaccine receipt compared to those age 18-24 years: 35-44 years (AOR1.9 CI 1.69-2.07), 45-54 years (AOR 3.0 95% CI 2.67-3.35), 55-64 years (AOR 3.7 95% CI 3.19-4.28) and 65 years+ (AOR 4.31 95% CI 3.55-5.22).
Respondents with no formal education were less likely to receive vaccination compared to those with primary (AOR 1.45 95% CI 1.17 – 1.81), secondary (AOR 2.35 95% CI 1.89 – 2.93) and tertiary (AOR 5.25 95% CI 4.19– 6.59) education.
Respondents who received vaccine information from health workers or through social media were more likely to vaccinate: (AOR: 1.39 CI 1.30-1.48, and 1.58 CI 1.07-1.26), respectively. Those who were a little or not at all concerned about getting COVID-19 disease had reduced odds of receiving the vaccine: AORs 0.7 (95% CI 0.61 – 0.8) and 0.92 (95% CI 0.84- 1.01), respectively, compared to those who were very concerned.
Conclusions: COVID-19 vaccination is associated with residence, age, education and source of information. Targeted vaccination messages by these factors will be critical for the success of the vaccination programme.

EPC480

HIV viral load and CD4+ count are not associated with experiencing COVID-19 vaccine adverse events: case-control study

E. Perez Barragan[1], J.A. Mata Marin[2], J. Mancilla Galindo[3], A. Kammar Garcia[4]
[1]*Hospital General de Zona 48, Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico,* [2]*Hospital de Infectologia, Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico,* [3]*Universidad Nacional Utonoma de México, División de Posgrado Facultad de Medicina, Ciudad de Mexico, Mexico,* [4]*Instituto Nacional de Geriatria, Dirección de Investigación, Ciudad de Mexico, Mexico*

Background: COVID-19 vaccines under development or approved by regulators are believed to be safe for most people, including people living with HIV (PLH). CD4+ cells count lower than 200 cells per µL has been associated with more vaccine adverse events (VAE). The aim of this study was to evaluate the safety of COVID-19 vaccine in PLH in Mexico.
Methods: We conducted a case-control study in PLH attending at an HIV clinic in Mexico City who had received the COVID-19 vaccine up to 31 December 2021. Cases were defined as those who reported at least one VAE, whereas controls did not experience any VAE. Descriptive quantitative results are presented as mean with standard deviation (SD) or median with interquartile range (IQR). Qualitative results, as frequency and percentage. Factors associated with VAE was evaluated with a Chi-squared test. A logistic regression model was applied and adjusted for age and comorbidities to determine the association of experiencing any VAE according to latest HIV-1 RNA and $CD4^+$ cells count.
Results: We included 253 patients living with HIV, with a mean age of 37.2 years (±SD: 10.8). Most of them were men 244 (96.4%) and had HIV RNA-1 <40 copies/mL [228 (90.1%)] and median CD4+ cells count of 609 (IQR:414-840.5). Comorbidities of PLH were overweight (30.4%) dyslipidemia (24.5%), obesity (14.2%), polypharmacy (11.9%), hypertension (7.5%), psychiatric disorders (7.5%), type 2 diabetes (4.3%), chronic kidney disease (1.6%), and heart disease (0.4%). A total of 61 (24.1%) had been diagnosed with COVID-19 before vaccination. The frequency of VAE was in 135 (53%), all of them mild. There were no associations with VAE according to an undetectable HIV-1 RNA (1.34, 95%CI:0.57-3.13, p=0.5) or CD4+ cells count (OR=0.99, 95%CI:0.97-1.01, p=0.4).
Conclusions: VAE occurred in 53% of patients living with HIV, all of which were mild. The latest viral load and CD4+ count were not associated with VAE.

EPC482

Attitudes of PLHIV in Greece towards COVID-19 vaccination

K. Protopapas[1], K. Thomas[1], C.D. Moschopoulos[1], I. Grigoropoulos[1], D. Kavatha[1], K. Androulakis[1], A. Anastopoulos[1], A. Papadopoulos[1], A. Antoniadou[1]
[1]*National Kapodistrian University of Athens, Fourth Department of Internal Medicine, ATTIKON University Hospital, Athens, Greece*

Background: People living with HIV (PLHIV) are considered a high-risk group for severe COVID-19 infection. Therefore, according to the Greek vaccination program, they were included in the vulnerable groups and given priority for COVID-19 vaccination. Nevertheless, a portion of the population appears to hesitate to receive the vaccine. The aim of this study was to investigate the acceptance of COVID-19 vaccine among greek PLHIV.

Methods: Single-center, cross-sectional study conducted in October 2021. Patients followed in the HIV-outpatient clinic were asked to fill-in an anonymous questionnaire that included epidemiological data, data on HIV infection as well as data related to vaccination against COVID-19.

Results: 327 PLHIV were included in the analysis (male: 90%, mean age: 44.1 years, working: 64%, tertiary education: 55%). 278 (85%) were vaccinated at the time of the survey and 82% of those, completed the two-dose vaccination schedule between May and August 2021.

Compared to non-vaccinated PLHIV, those vaccinated were more likely to be employed (67% vs 47%, p=0.02) and have tertiary education (60% vs 26%, p<0.001), while no differences were found regarding mean age, gender and place of residency. Both employment (OR: 2.0, 95% CI: 1.007-4.17) and tertiary education (OR: 3.80, 95% CI: 1.82-7.92) remained statistically significant after adjustment for age and gender.

The main reasons for vaccination were self-protection (91%), protection of vulnerable family members (50%), social responsibility against the pandemic (50%) and to avoid obstacles with their work or daily activities (35%). 25% reported adverse events after vaccination, with fever (35%), fatigue (19%) and pain at the site of injection (16%) being the most frequently reported.

Among the 49 (15%) non-vaccinated PLHIV, the main reasons for hesitancy were that vaccines "are not enough tested" (39%), fear of side effects (49%), the perception that they were "not at risk" (12%) and an overall attitude against vaccines (10%).

Conclusions: The majority of PLHIV monitored in our clinic were fully vaccinated against COVID-19. Vaccine awareness strategies could lead to even higher vaccine coverage through the targeting of those populations more reluctant to receive vaccination.

EPC483

Uptake and barriers to COVID-19 vaccination in Thane, India: findings from a Community-Based Survey

S. Kapoor[1], A. Vankara[1], D. Raj[1], P. Agrawal[1], D. Subramaniam[2], S. Kapoor[3], G. Agrawal[4], A.K. Srikrishnan[5], C.K. Vasudevan[5], K.J. Zook[6], S.S. Solomon[6], S.H. Mehta[6]
[1]*Johns Hopkins University School of Medicine, Baltimore, United States,* [2]*Southern Illinois University of Edwardsville, Edwardsville, United States,* [3]*BASIS Independent Silicon Valley, San Jose, United States,* [4]*Silver Creek High School, San Jose, United States,* [5]*YRGCARE, Chennai, India,* [6]*Johns Hopkins Bloomberg School of Public Health, Baltimore, United States*

Background: Vaccine hesitancy continues to hamper global COVID-19 vaccination efforts. Yet, limited community-based data on vaccine uptake and barriers especially from low and middle-income countries (LMICs) exist. We examined COVID-19 vaccination uptake, hesitancy, and associated factors in a community-based sample of residents in Thane district, Maharashtra – an Indian district with one of the highest reported COVID-19 burden during the Delta wave in India.

Methods: An at-home COVID-19 rapid antigen testing program was implemented in Thane district (mean income: USD 2300/year) from August 2021 - present.

Field workers went door-to-door in high COVID burden areas identified by the Thane Municipal corporation offering Rapid SARS-CoV-2 antigen testing and administered a survey collecting demographic and socioeconomic information, COVID-19 symptoms/exposure history, vaccine uptake, barriers, and preferences.

COVID-19 vaccines (non-mRNA) became available free-of-charge to in India January 2021; at the time of this survey, all adults (18 years of age and older) were eligible for vaccine. Logistic regression was used to identify correlates of vaccine uptake.

Results: The median age of the 11,568 residents sampled was 31.2 years; about half (48.7%) were female. Overall, 4415 (38.0%) respondents self-reported receiving at least one dose of a COVID-19 vaccine: CoviShield (Serum Institute India) = 92.3%; Covaxin (Bharat Biotech) = 6.0% and Sputnik V = 1.7%.

Of vaccinated individuals, less than a third (32.1%) had received their second dose. Factors independently associated with being fully or partially vaccinated included older age (OR:1.05 per year of age), going to work in-person (OR:1.48), and education completed (OR: 3.88 for bachelor's degree vs. ≤8 years of schooling; p<0.05 for all).

Of those who had not received a vaccine, 64%reported interest in receiving the vaccine if offered and 36% were hesitant. The primary reason for deferring vaccination was wanting to wait until a better vaccine was available (36%) followed by concerns about vaccine efficacy (20%).

Conclusions: Despite high interest in COVID-19 vaccination, over two-thirds of this community-based sample was not fully vaccinated. It is critical that vaccine programs integrate vaccine literacy and demand generation programs with mass vaccination programs to ensure optimal timely uptake.

Visual access to create greater comprehension: Incorporating the visual arts into a representational analysis of HIV community dialogue on living with HIV and a quality of life

D. Cordner[1], B. Allan[2], D. Reeders[3], F. Drummond[4], A. Maccarrone[4]

[1]Daniel Cordner Designs, Principle, Melbourne, Australia, [2]Qthink Consulting, Malmsbury, Australia, [3]National Association of People Living with HIV Australia, Sydney, Australia, [4]ViiV Healthcare Australia, Melbourne, Australia

Background: Over the course of 2021, the National Association of People Living with HIV Australia (NAPWHA) set out to discover what constitutes a quality of life (QoL) for people living with HIV (PLHIV) in Australia.

As part of this project, they engaged an artist living with HIV to sit in on the webinars, debates, discussions and briefings with the explicit intention of capturing the key messages that came out of the project.

Five unique pieces of art have been created to compliment a narrative position describing what a QoL means to PLHIV in Australia.

Description: With the support of ViiV Healthcare and utilising the ViiV Positive Perspectives 2 Manifesto as the catalyst for discussions, NAPWHA held a number of events (n=8) over 12 months which interrogated issues such as polypharmacy, intersectionality, healthcare and patient relationships, health literacy and quality of life through a variety of online formats.

NAPWHA recruited an artist living with HIV to sit in and take part in these sessions with the explicit instruction to capture essence and key aspects of these sessions. In the end five pieces of artwork have been developed which have reflected the issues and discussions.

Lessons learned: Examples of the co-creation of art within the HIV academic, research and service provision spheres are rare. Co-creative activities are an integral part of artistic experiences, as participants in collaborative learning engage and are engaged in cognitive, emotional, and imaginal practices to appropriate and make sense of lived experiences. A visual response creates a wider engagementthan words may do by themselves.

Conclusions/Next steps: The artworks created through this project will be integrated as visual elements of a final report on the activities. They will speak to the discussions that were had and draw attention to the elements that were seen at the different activities for those who could not be present.

EPD002

Using a three-layered approach to understand the needs for effective community engagement in HIV biomedical research in India – Perspectives from community representatives, implementing researchers and domain experts

J. Mukherjee[1], P. Saha[1], N. Khan[1], D.L. Bose[1], S. ul Hadi[1], V. Loganathan[2], V. Chakrapani[2], T. Aurora[3], J. Narayan[3], C. Dewan[3]

[1]IAVI, New Delhi, India, [2]Centre for Sexuality and Health Research and Policy (C-SHaRP), Chennai, India, [3]Quicksand Design Studio, Goa, India

Background: The success of any HIV biomedical research is primarily pillared on end-user communities' acceptance and support. However, the contours of community-research intersections are predominantly shaped by understanding and willingness of researchers and sponsors. Creating a paradigm shift requires recognition of the perspectives of key stakeholders (community, researchers, others including policymakers, bioethicists, regulators, product experts) to understand the challenges and identify opportunities. Thus, IAVI facilitated diverse discussions with an aim to capture the dynamic relationship and triangulate all views for the most impactful insights on community engagement.

Description: Between January and October 2021, fourteen virtual consultations were conducted in India with community representatives (N= 53); HIV researchers

(N=10); national HIV domain experts and advisors (N=10) to understand the current practices and identify needs to make community engagement robust, equitable, ethical and effective. Data were analyzed using constant comparison method to identify themes. Source triangulation strengthened the validity of findings.

Lessons learned: *Understanding common grounds*

All the groups highlighted the need for:

a. Increased and innovative efforts to strengthen science communication and augment research literacy to enable community ownership;

b. Understanding the role of connectors (who are closely knitted with the communities like community-based organisations) in bolstering trust and becoming advocates for research;

c. Leveraging digital media to facilitate better outreach, awareness and retention.

Highlighting gaps through unique lenses

- Community representatives highlighted:

a. Engagement of communities are primarily at the time of recruitment; there is a need for their early and sustained engagement throughout the research

b. Lack of sensitivity towards community cultures, lived experiences, power dynamics, gender norms and not enough transparent communication.

- Researchers stated:

a. Limited funding for community engagement

b. Low priority for people-centered engagement skills among researchers as other aspects of instrumental goals have precedence.

- Domain Experts opined on

a. Limited researcher capacities in simplifying science communication and sustaining engagement beyond study period

b. Limited focus on accountability mapping and need for competency assessment frameworks for both researchers and communities.

Conclusions/Next steps: The insights highlight the criticality of meaningfully engaging diverse stakeholders to co-design multi-dimensional engagement strategies and operational tool-kit to address these needs for most effective community engagement in HIV research.

EPD003

Community dialogue: lessons learnt from results dissemination to the community about adolescent sexual activity. Experience from CHAPS Study

A. Sango[1], L. Mungate[1], T.G. Nematadzira[1], C. Chasakara[1], M. Mazipetele[2], A. Soza[2], G. Rewu[2], J. Seeley[3], J. Fox[4], L. Stranix-Chibanda[1]

[1]*University of Zimbabwe-Clinical Trials Research Centre, Harare, Zimbabwe,* [2]*University of Zimbabwe-Clinical Trials Research Centre, Youth Community Advisory Board, Harare, Zimbabwe,* [3]*Medical Research Council/ Uganda Virus Research Institute and London School of Hygiene & Tropical Medicine Uganda Research Unit, Entebbe,, Uganda,* [4]*Guys and St Thomas' NHS Trust/Kings College London, London, United Kingdom*

Background: CHAPS, a cross-sectional mixed methodology study, explored perceptions of event-driven oral PrEP in young people aged 13-24 years in South Africa, Uganda and Zimbabwe and collected data on sexual activity. We report proceedings of the facilitated discussion which followed results dissemination with the Youth Community Advisory Board (YCAB) in Zimbabwe.

Description: YCAB members are aged 16-25 years and drawn from research clinic catchment areas to represent young people in their community. During dissemination of study results, the YCAB discuss study findings with researchers to offer insight and contribute to results interpretation.

We used the ORID framework (Objective, Reflective, Interpretive, Decisional) to explore CHAPS results, focusing on sexual activity, to find out what findings they considered most striking, the emotions elicited, their insights into the causes of the behaviors, and suggested activities in response.

Lessons learned: CHAPS data aligned with YCAB's personal experiences and knowledge. The YCAB were disturbed by the early age of sexual debut. They feared that, when adolescents engage in unprotected sex, they might threaten their futures by taking risks. YCAB interpreted the reasons driving adolescents to engage in sexual activities to be peer pressure, experimentation, naivety, substance/ alcohol use and transactional sex. They suggested interventions to transform current Sexual Reproductive Health (SRH) programs:

1. Include both adolescents and their parents/guardians;
2. Youth experts should lead SRH programs in educational settings;
3. Provide free WIFI zones to access trusted online SRH information;
4. Use social media influencers to educate adolescents on SRH; and
5. Health facilities need non-judgmental youth zones for adolescents to access PrEP without fear.

At the societal level, YCAB proposed focusing on vocational training to reduce poverty in school leavers. They encouraged multi-generational dialogue on how to sup-

Oral abstracts

Poster exhibition

E-posters

Late-breaker abstracts

Author Index

port adolescents develop self-discipline and a healthy attitude towards sex, while preserving traditional values and respect for elders. YCAB highlighted how parents also need help navigating the shifting dynamics of the modern-day family.

Conclusions/Next steps: YCAB involvement in results dissemination is not only good participatory practice, but it also brings important insights to data interpretation and generates ideas for implementing study findings.

EPD004
Utilizing standardized metrics to track recruitment strategies in a global preventive HIV vaccine study during the COVID-19 pandemic

R. Gonzalez[1], L. Kamel[1], P.M. Segura Marquez[1], G.M. Corbelli[1], G.B. Broder[1], S. Wallace[1]
[1]*Fred Hutchinson Cancer Research Center, Social Behavioral Science and Community Engagement Unit, Seattle, United States*

Background: Though Good Participatory Practice (GPP) are implemented globally, there are no standardized metrics to evaluate or refine its application. Utilizing an approach developed by the HIV Vaccine Trials(HVTN)and HIV Prevention Trials Networks (HPTN), we sought to describe, monitor, and evaluate the recruitment practices of the Mosaico study (HVTN706/HPX3002), a phase 3 HIV vaccine clinical trial conducted among cisgender men and transgender people who have sex with cisgender men and/or transgender people from communities in the United States, Latin America and Europe. Recruitment and enrollment for Mosaico occurred during evolving local and national COVID-19 mitigation efforts, which varied by country.

Methods: Recruitment strategy descriptors were used in the study based on knowledge of site practices to characterize responses to "How did you hear about the Mosaico Study?" These descriptors were vetted and edited by Community Working.

Groups of prior HIV prevention trials of the HVTN and HPTN and were not modified in the Mosaico study. Definitions were established and timepoints selected to allow comparisons across sites. Clinical Research Sites (CRSs) were required to develop recruitment plans and reports in REDCap, a web-based application to capture data for clinical research, using specific measurable objectives. Data were collected by48 global CRSs from June 2020 – August 2021.

Results: All 47 sites utilized multiple recruitment strategies successfully. Globally, internet use resulted in the most screens (5059 of 8121, 62%) and enrollments (2404 of 3806, 63%) while in-person outreach was most efficient (screening: enrollment ratio of1.5:1in Europe and South America and 5.6:1 in the United States). In the United States, referrals were most efficient (4.8:1). In Europe and South America, referrals were also efficient (3.3:1 and 2:1respectively) whereas print materials were the least efficient recruitment strategy (24.8:1 and 5.3:1respectively).

Conclusions: While CRSs had to adapt their recruitment plans due to COVID-19, the recruitment practices were broad enough that they did not require changes. Implementing a system to monitor screening-to-enrollment ratios reveals effective use of outreach staff time and available resources. Although Internet use, such as social media advertising, was predominant due to the COVID-19 global pandemic, in person outreach was still the most efficient strategy to achieve enrollment goals.

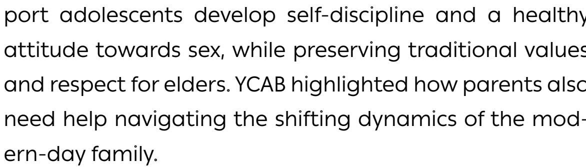
EPD005
Engaging youth to conduct research among peers: lessons from a PrEP study in Siaya County, Kenya

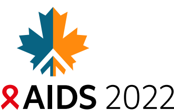
S. Otticha[1], S. Roberts[2], M. Hartmann[3], T. Marton[2], L. Nyblade[4], C. Bann[5], K. Agot[1], Akwede ok Bwoga (AOB) Study Group
[1]*Impact Research and Development Organization, Kisumu, Kenya,* [2]*Women's Global Health Imperative, RTI International, Berkeley, United States,* [3]*Women's Global Health Imperative, RTI International, Berkely, United States,* [4]*Global Health Division, International Development Group, RTI International, Washington, DC, United States,* [5]*Division of Statistical and Data Sciences, RTI International, NC, United States*

Background: In Kenya, adolescent girls and young women (AGYW) make up 30% of 53,000 HIV infections annually. Pre- exposure prophylaxis (PrEP) is effective in preventing HIV, but use among AGYW is sub-optimal. Youth engagement in the design and implementation of research is critical to address complex issues that affect their health, like PrEP use, in the context of stigma.

Description: We identified an eight-member youth research team (YRT) through competitive recruitment through Ministry of Health facilities and DREAMS safe spaces. Those eligible (age 18-24 years, knowledge of PrEP, completed secondary school, computer literate, proficient in English and the local language) were trained on the study protocol, PrEP stigma, human subject protection, research methods. YRT initially conducted study activities with mentorship from experienced research assistants. Once YRT were confirmed competent, they performed tasks independently. YRT participated in: i) co-facilitating focus group discussion (FGD) and transcribing audio-recordings; ii) concept mapping of debriefing reports; iii) translating cognitive interview tool and surveys; iv) reviewing participants' suggestions on question relevance and comprehension during cognitive interview process; v) administering consent and surveys; vii) coding and analysing qualitative data.

Lessons learned: YRT engagement improved the research conduct in multiple ways. In the concept mapping activity, they brought youth perspectives to identify drivers, facilitators, manifestations, outcomes, intersecting stigmas, health and social impacts of PrEP stigma, which contributed to the development of a quantitative scale





to measure PrEP stigma among AGYW who use PrEP. The YRT's involvement in translations led to better understanding of questions by study participants who are YRT peers. YRT participation in cognitive interview reviews allowed modification of the cognitive interview guide. Survey quality reviews found minimal error rate (per question 0.0002%, per page 0.18%) and high-quality data from FGDs, which were similar between YRT and experienced research assistants.

Conclusions/Next steps: Engagement of the YRT resulted in high quality data, insightful interpretation of findings, and identification of pertinent themes to research questions throughout the study. Our results confirm that youth with basic education can be mentored to successfully perform important research roles. Researchers should consider engaging youth throughout the research process to achieve study objectives.

EPD006

Maintaining long term and meaningful community and research partnerships by responding to and leveraging system-level enablers, barriers and benefits

G. Brown[1], P. Hilton[2], J. Rule[3], C. Howard[4], J. Costello[5], R. Keane[6], S. Crawford[7], J. Kim[8], H. Paynter[9], J. Docker[10], C. Henderson[11], A. Corey[12], C. Batrouney[13]

[1]University of New South Wales, Centre for Social Impact, Sydney, Australia, [2]La Trobe University, Australian Research Centre in Sex, Health and Society, Melbourne, Australia, [3]National Association of People Living with HIV Australia, Sydney, Australia, [4]Queensland Positive People, Brisbane, Australia, [5]Positive Life New South Wales, Sydney, Australia, [6]Living Positive Victoria, Melbourne, Australia, [7]Harm Reduction Victoria, Melbourne, Australia, [8]Scarlet Alliance, Australian Sex Worker Association, Sydney, Australia, [9]Australian Federation of AIDS Organisations, Sydney, Australia, [10]Australian Injecting and Illicit Drug Users League, Canberra, Australia, [11]New South Wales Users and AIDS Association, Sydney, Australia, [12]Peer Based Harm Reduction Western Australia, Perth, Australia, [13]Thorne Harbour Health, Melbourne, Australia

Background: The greater and meaningful involvement of people with HIV/AIDS (GIPA), communities affected by HIV, and their peer organisations are a foundation of the global HIV response. However, peer involvement in research is often limited to consultation for individual projects, rather than long term priority setting and conduct of research. The depth and value of peer organizations' insights for the entire research process are often underutilised. Strategies for meaningful participation are often focused on methodology rather than recognising system level factors and how to overcome them.

Description: For 10 years, and through the COVID19 pandemic, the What Works and Why (W3) Project has sustained a partnership across Australia of 12 peer led organisations and research. The W3 Project partnership co-designed, trialled, refined, and applied a systems framework and tools to demonstrate the role and impact of peer organisations within an overall HIV response, and built a consensus model of practical evaluation indicators. W3 Project required peer staff and researchers to undertake the simultaneous role of drivers, participants, and analysts in the research. To identify learnings for maintaining long term meaningful partnership with peer organisations in research, we drew together the documented insights and experiences of peer staff and researchers throughout the study.

Lessons learned: Research and peer organisations capacity to maintain meaningful participation can be restricted or enhanced by the systems in which they are embedded. While a strength of peer organisations is their relationships within their communities, this relationship means peer staff are also navigating pressure from marginalization, discrimination, criminalization, and more recently COVID19.

We identified strategies that reduced the influence of these system-level barriers and strengthened enablers to maintain meaningful participation and leadership from peer organisations.

Adapting research methodology to maintain active partnership ensured the research rigour was combined with practical and conceptual considerations, and high community engagement.

Example enablers to overcome systemic barriers included strengthening and demonstrating two-way trust and commitment; sustaining flexibility in research resources and management; and demonstrating the impact of peer leadership to counter system-level stigma.

Conclusions/Next steps: Maintaining meaningful collaboration with peer organisations requires looking beyond good practice methods to responding to and leveraging system-level enablers, barriers, and benefits.

EPD007

Leveraging technology to assess pharmacy professionals' knowledge, attitudes, and practices related to HIV/STIs and potential to improve coverage of key populations in Southeast Asia

C. Taguibao[1], J. Neukom[2], J.M. Lailo[1]

[1]mClinica Pharmacy Solutions, Public Sector, Taguig City, Philippines, the, [2]mClinica Pharmacy Solutions, Public Sector, Ho Chi Minh City, Viet Nam

Background: Innovative approaches to improve coverage for key populations are needed to support goals to eliminate HIV by 2030 in Southeast Asia. In Vietnam and Thailand, pharmacies are preferred sources of care for key populations, however, data regarding pharmacy professionals' knowledge, attitudes and practices related to HIV and other sexually transmitted infections (HIV/STIs) is time consuming and costly to collect at scale given fragmentation of the pharmacy channel.

Methods: With support from USAID-funded Linkages and SHIFT programs, researchers leveraged the SwipeRx mobile app to conduct cross-sectional, digital surveys among pharmacy professionals in Vietnam and Thailand in 2020, to understand their HIV/STI knowledge, attitudes, and practices. Using convenience sampling, digital methods were used to recruit 268 pharmacy professionals using SwipeRx in Thailand between June-July and 282 respondents from Vietnam between August-September. Descriptive analysis was conducted to assess survey data.
Results: Across both samples, the median age of respondents was 30 years. Most respondents identified as women (59% Vietnam, 69% Thailand). Sampled pharmacy professionals in Vietnam reported serving 19 clients who purchase condoms, 13 clients who purchase STI medication, and 10 clients perceived to identify as men who have sex with men, gay, or transgender (out of 139 total clients on average, each day). Only 18% in Thailand and 32% in Vietnam were aware of saliva-based HIV rapid testing and roughly half could identify benefits of pre-exposure prophylaxis (PrEP) (56% Vietnam, 49% Thailand). Twenty-nine percent in Vietnam and 12% in Thailand agreed or strongly agreed that "people with HIV brought it on themselves", indicating the influence of HIV-related stigma on attitudes. Roughly 8 in 10 reported willingness to provide HIV rapid-tests (83% Vietnam, 80% Thailand) and PrEP (85% Vietnam) at their pharmacies. Eighty-one percent in Vietnam reported interest in digitally referring clients to HIV/STI diagnostic and treatment services.
